A Companion for General Physics

Study Guide for General Physics

Also known as: some physics I would have liked to know when I was a student.

Alessandro Petrolini

Always Student; Sometimes Teacher.

In memory of my friend, Prof. ***Maurizio Lo Vetere****,*
with whom I have discussed so long about many of the things written in these notes,
... although I know that not everything I wrote he would agree on ...

Always work in progress ...

Everything should be made as simple as possible, but not simpler. Albert Einstein.

First Law of Progress in Theoretical Physics: You will get nowhere by crunching equations. Stephen Weinberg.

Strive for progress, not for perfection. Richard Feynman.

You cannot get educated by this self-propagating system in which people study to pass exams, and teach others to pass exams, but nobody knows anything. You learn something by doing it yourself, by asking questions, by thinking, and by experimenting. Richard Feynman.

The first principle is that you must not fool yourself - and you are the easiest person to fool. Richard Feynman

Idiocy is when you think you know everything, without questioning; Intelligence is when you question everything you think you know.

When you can measure what you are speaking about, and express it in numbers, you know something about it; but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre and unsatisfactory kind: it may be the beginning of knowledge, but you have scarcely, in your thoughts, advanced to the stage of science, whatever the matter may be. Lord Kelvin, often quoted as "If you cannot measure it, then it is not science."

> *A theorist excitedly runs into an experimentalist's office one day, exclaiming that not only has the theorist uncovered an elegant model that solves the biggest outstanding questions in particle physics, but that it makes a robust experimental prediction. The excitement is contagious, and the experimentalist applies for grants, hires postdocs, builds new laboratory equipment, and starts to take data. Many years after the initial encounter, the experimentalist's entire research group—now exclusively focused on proving this one, elegant model—is ready to unblind its data. That afternoon, the experimentalist sulks despondently into the theorist's office. "Prof. Theorist? I'm really sorry to break this to you, but the data rules out the model." The theorist looks up at the experimentalist, considers the streaks of white hair and their many years of collaboration on this project, and finally says, "What a shame! Did you know that I spent two whole weeks of my life developing that model?"*
>
> - Professor Tim M.P. Tait. From Just a Taste: Lectures on Flavor Physics

The history of physics is interesting but this notes will not follow the historical development. I will try to present things in a logical and coherent scheme. Many of the details will be left to the students as exercises, because this is a part of their learning process. Sometimes there will be some leaps, but I try to point the reader to the appropriate references to fill the gaps.

Much of the content of these notes is acknowledged to come from the various sources cited. **The author thinks to have fulfilled all due credits to the authors mentioned**. If you find this is not the case, please inform me, so I will take the appropriate actions.

DRAFT-IN-PROGRESS

CHAPTER 11

Introduction

11.01 Usage Notes 1002
11.02 Notations and Conventions 1003
11.03 Nomenclature 1004
11.04 Physical Constants 1005
11.05 Quantity of Matter 1017
11.06 Mathematical Pre-Requisites 1018

DRAFT-IN-PROGRESS

11.01 Usage Notes

- There are plenty of beautiful books about physics (but also many others are not so good...). Therefore I feel useless to try to re-write myself what is already very well presented in the literature; of course, all according to my ideas.
- I think to have properly acknowledged all the quotations. In case of any failure to do so, I apologize in advance.
- Whenever a quote is present without any explicit citation, it is implied that it refers to the unique reference at the beginning of that particular section.
- One main emphasis is on providing reference to more advanced treatments, to stimulate curiosity and further study.

DRAFT-IN-PROGRESS

11.02 Notations and Conventions

- Le definizioni sono indicate con il simbolo: $\equiv$.
- Gli angoli piani si intendono sempre misurati in radianti, ove non specificato altrimenti.
- Solid angles are always measured in steradians
- Whenever not specified otherwise, all physical quantities are assumed to be measured in units of the **International System** of units, **SI**; read § B.
- Si intende: $\Delta \equiv$ Variazione $\equiv$ Valore della grandezza (dopo) $-$ Valore della grandezza (prima).
- La derivazione rispetto al tempo viene talvolta indicata con un punto

$$\dot{x} \equiv \frac{\mathrm{d}x}{\mathrm{d}t} \quad ,$$
$$\ddot{x} \equiv \frac{d^2x}{\mathrm{d}t^2} \quad .$$

- In termodinamica le variabili intensive sono di solito indicate con un simbolo minuscolo mentre la variabili estensive con un simbolo maiuscolo. Le variabili intensive corrispondenti sono indicate con la corrispondente lettera minuscola.
- Si assume implicitamente che tutte le funzioni siano, quando necessario, differenziabili/integrabili tante volte quanto richiesto e/o sviluppabili in serie di Taylor/Fourier convergente quanto basta. That is, if any formula contains derivatives of some functions, then the functions are assumed to be differentiable as much as required; if any formula contains definite integrals, then the integrals are supposed to be convergent.
- Unless specified otherwise when dealing with tensors one always refers to three components tensors under the rotation group in euclidean three-space, for classical physics, and to four components tensors under the Lorentz group in Minkowski space, for relativistic physics.

DRAFT-IN-PROGRESS

11.03 Nomenclature

Beware that the names below, as often in science, are not necessarily universally used in the literature: whenever reading any publication one has, unfortunately, to check always definitions and conventions at the start.

- Uniform/Homogeneous: independent from position.
- Constant: independent from time.
- Fixed: fixed quantity; it is considered to be independent from time, position and independent from anything, within the specified context.
- Stationary: everything independent from time (stationary charge, target, particle, thermodynamic state,...); but steady wave (or stationary wave) (the wave is not moving).
- Steady: something is moving, but motion is time-independent (steady current, motion, flow,...); in a steady wave (or stationary wave) there is a steady motion of something.
- Rate:= something per unit time.
- Density:= something per unit length/area/volume; that is: linear density, surface density, volume density; density alone means volume density.
- **(Volume) Flux**:= something per unit perpendicular area and per unit time; on a 3D volume.
- **Surface Flux**:= something per unit perpendicular length and per unit time; on a 2D surface.
- **Flux of a vector field** := this is the usual definition of flux of a vector field (either 2D or 3D), as from sections § 16.05.02 and § 16.06.02, whose physical dimensions are not, in general, something per unit area-time, but depend on the dimensions of the vector fields.
- **(Volume) Fluence**:= something per unit perpendicular area; that is, a flux integrated over a specified period of time, on a 3D volume.
- **Surface Fluence**:= something per unit perpendicular length; that is, a surface flux integrated over a specified period of time, on a 2D surface.
- Production Rate density: something per unit volume and per unit time.
- Sinusoidal, Cosinusoidal and Harmonic are treated as exactly synonyms.
- Vibration = Oscillation.
- Reference Frame is a concept different from Coordinate System: in any chosen Reference Frame you can define infinitely many Coordinate System.
- Numeric: one single real or complex quantity.

When dealing with the modeling of physical problems one should never forget that a model is no better than the approximations (explicit and|or implicit) made when deriving it. It is never a question of just solving the equations, forgetting what is behind them.

UNDER THE PROGRESS

11.04 Physical Constants

GO TO AFTER included File

CODATA RECOMMENDED VALUES OF THE FUNDAMENTAL PHYSICAL CONSTANTS: 2018

NIST SP 961 (May 2019)

An extensive list of constants is available on the NIST Physics Laboratory Web site physics.nist.gov/constants. For numerical values a number in parentheses, if present, is the one-standard-deviation uncertainty in the last two digits. For units with square brackets the full descriptions of m^{-1} and m are cycles per meter and meter per cycle, respectively. For the first radiation constant the full description of m^2 is m^{-2} (m/cycle)^4.

Quantity	Symbol	Numerical value	Unit
speed of light in vacuum	c	299 792 458 (exact)	m s^{-1}
Newtonian constant of gravitation	G	$6.674\,30(15) \times 10^{-11}$	m^3 kg^{-1} s^{-2}
Planck constant	h	$6.626\,070\,15 \times 10^{-34}$ (exact)	J Hz^{-1}
in eV s		$4.135\,667\,696\ldots \times 10^{-15}$	eV Hz^{-1}
	$\hbar$	$1.054\,571\,817\ldots \times 10^{-34}$	J s
in eV s		$6.582\,119\,569\ldots \times 10^{-16}$	eV s
elementary charge	e	$1.602\,176\,634 \times 10^{-19}$ (exact)	C
vacuum magnetic permeability $4\pi\alpha\hbar/e^2c$	μ_0	$1.256\,637\,062\,12(19) \times 10^{-6}$	N A^{-2}
$\mu_0/(4\pi \times 10^{-7})$		1.000 000 000 55(15)	N A^{-2}
vacuum electric permittivity $1/\mu_0 c^2$	ϵ_0	$8.854\,187\,8128(13) \times 10^{-12}$	F m^{-1}
Josephson constant $2e/h$	K_J	$483\,597.848\,4\ldots \times 10^9$	Hz V^{-1}
von Klitzing constant $\mu_0 c/2\alpha = 2\pi\hbar/e^2$	R_K	25 812.807 45 . . .	Ω
magnetic flux quantum $2\pi\hbar/(2e)$	Φ_0	$2.067\,833\,848\ldots \times 10^{-15}$	Wb
Bohr magneton $e\hbar/2m_e$	μ_B	$9.274\,010\,0783(28) \times 10^{-24}$	J T^{-1}
in eV T^{-1}		$5.788\,381\,8060(17) \times 10^{-5}$	eV T^{-1}
nuclear magneton $e\hbar/2m_p$	μ_N	$5.050\,783\,7461(15) \times 10^{-27}$	J T^{-1}
in eV T^{-1}		$3.152\,451\,258\,44(96) \times 10^{-8}$	eV T^{-1}
fine-structure constant $e^2/4\pi\epsilon_0\hbar c$	α	$7.297\,352\,5693(11) \times 10^{-3}$

* The energy of a photon with frequency ν expressed in unit Hz is $E = h\nu$ in J. Unitary time evolution of the state of this photon is given by $\exp(-iEt/\hbar)|\varphi\rangle$, where $|\varphi\rangle$ is the photon state at time $t = 0$ and time is expressed in unit s. The ratio $Et/\hbar$ is a phase.

* The energy of a photon with frequency ν expressed in unit Hz is $E = h\nu$ in J. Unitary time evolution of the state of this photon is given by $\exp(-iEt/\hbar)|\varphi\rangle$, where $|\varphi\rangle$ is the photon state at time $t = 0$ and time is expressed in unit s. The ratio $Et/\hbar$ is a phase.

† The full description of m^{-1} is cycles or periods per meter and that of m is meter per cycle (m/cycle). The scientific community is aware of the implied use of these units. It traces back to the conventions for phase and angle and the use of unit Hz versus cycles/s. No solution has been agreed upon.

‡ Value recommended by the Particle Data Group (Tanabashi, *et al.*, 2018).

§ Based on the ratio of the masses of the W and Z bosons m_W/m_Z recommended by the Particle Data Group (Tanabashi, *et al.*, 2018). The value for $\sin^2\theta_W$ they recommend, which is based on a variant of the modified minimal subtraction ($\overline{\mathrm{MS}}$) scheme, is $\sin^2\hat{\theta}_W(M_Z) = 0.231\,22(4)$.

¶ This and other constants involving m_τ are based on $m_\tau c^2$ in MeV recommended by the Particle Data Group (Tanabashi, *et al.*, 2018).

$^{\|}$ The relative atomic mass $A_r(X)$ of particle X with mass $m(X)$ is defined by $A_r(X) = m(X)/m_u$, where $m_u = m(^{12}C)/12 = 1$ u is the atomic mass constant and u is the unified atomic mass unit. Moreover, the mass of particle X is $m(X) = A_r(X)$ u and the molar mass of X is $M(X) = A_r(X)M_u$, where $M_u = N_A$ u is the molar mass constant and N_A is the Avogadro constant.

** The entropy of an ideal monoatomic gas of relative atomic mass A_r is given by $S = S_0 + \frac{3}{2}R\ln A_r - R\ln(p/p_0) + \frac{5}{2}R\ln(T/\mathrm{K})$.

†† The full description of m^2 is $\mathrm{m}^{-2} \times (\mathrm{m/cycle})^4$. See also footnote for m^{-1}.

11.05 Quantity of Matter

L'unità di misura della quantità di materia è la mole (mol) definita come la quantità di materia che contiene tante entità elementari (atomi, molecole, particelle, ioni, etc.) quante sono contenute in 12 g dell'isotopo 12 del carbonio ($^{12}_{6}C$), pari al numero di Avogadro.

È quindi un'unità di misura di numero, per numeri molto grandi.

DRAFT-IN-PROGRESS

12.01.01 Some key points - unsorted

12.01.01.01 Physics Experiment Mathematics

- **In physics, one can only understands what one can measure. Beware: the fact that you can measure something, does not men you understand it**...
- **Physics is an experimental science.** The fundamental principle of science, the definition almost, is this: the sole test of the validity of any idea is experiment. R.P.Feynman.
- Any **scientific theory** must be always compared to experiments. Experimental verification is an attempt of **falsification** of the **scientific theory**. No **scientific theory** can be verified; any **scientific theory** can be falsified by a disagreement with physical reality. Any **"theory"** must be falsifiable to be a **scientific theory**.
- Any **scientific theory** must be able to make predictions (which can be falsified). A **scientific theory** with no predictive power is nothing.
- **It doesn't matter how beautiful your theory is, it doesn't matter how smart you are. If it doesn't agree with experiment, it's wrong. In that simple statement is the key to science**. (R.P.Feynman - Cornell University Lecture, 1964).
- Whenever there is any disagreement between a theory and an experiment, that is the moment when we learn something new. On. Margaret Thatcher: "What do you do? John Ellis: "Think of things for the experiments to look for, and hope they find something different. "On. Margaret Thatcher: "Wouldn't it be better if they found what you predicted?" John Ellis: "Then we would not learn how to go further!". (John Ellis and on. Margaret Thatcher at CERN).
- **Mathematics is the language of the Universe.**
- Mathematics is the fundamental language of physics; it must be perfectly known to be able to do physics, but it is not the physics, is a prerequisite. After understanding the purely mathematical aspects, Physics hasn't even begun: one has to look at an equation and figure out what it is saying; one has to be able to translate equations into concepts and conversely.
- In physics, emphasis on physics, but the mathematical language must be perfectly known, to concentrate on physics.
- **Physics is not mathematics: usually there is no neat theorem.**
- **Lagrangian and Hamiltonian is not a starting point for physics, it is an arrival point.**

12.01.01.02 Some R.P.Feynman quotes

- Some R.P.Feynman quotes.
  - See failure as a beginning.
  - Never stop learning.
  - Assume nothing, question everything.
  - Teach others what you know.
  - Analyze objectively.
  - Practice humility.
  - Respect constructive criticism.
  - Take initiative.
  - Give credit where it's due.
  - Love what you do.
  - Don't just teach your students to read.
    - Teach them to question what they read, what they study.
    - Teach them to doubt.
    - Teach them to think.
    - Teach them to make mistakes and learn from them.
    - Teach them how to understand something.
    - Teach them how to teach others.
  - **You don't really know something until you can rebuild it yourself from basic principles!** It's a good approach - learn everything and keep that child - like curiosity, question everything... and be humble enough to admit things that you don't know (R.P.Feynman).

12.01.01.03 Scientific Authority

- Science recognizes no authority: scientific claims are not valid for having been supported by some authority: influencer, web, social network, scientific, intellectual, religious, political, television, ...
- Science is not democratic: scientific claims are not valid because they are supported|believed by the majority of people. Scientists don't vote for|against a theory|model. Nature decides. The scientific method is the only way to question Nature, understand quantitatively how it works and acquire predictive skills.
- Scientific controversies are not resolved with a cross-examination the only one scientific truth is the one deriving from experimentation and|or is consistent with experimentation.

12.01.01.04 How to

- Let us try to apply the assumption that **no interesting open physics problem hinges on getting the fine points right.** - S.Weinberg.
- **Let us try to avoid un-instructive complications and problems of detail which are predominantly in the realm of fine formal points.** - S.Weinberg.
- **First Law of Progress in Theoretical Physics: You will get nowhere by crunching equations.** - S.Weinberg.
- **Lex parsimoniae or Ockham razor**: generally recommends selecting the competing hypothesis that makes the fewest new assumptions, when the hypotheses are equal in other respects; for instance, they must both sufficiently explain available data in the first place. William of Ockham, an English monk of the 14th century, formulated the lex parsimoniae which is a fundamental tool in research: *Entia non sunt multiplicanda praeter necessitatem*. That is, the simpler and cheaper explanations of Nature are to be preferred to those more imaginative and complicated that introduce more assumptions and postulates. It is a principle at the base of physics and of the physical mindset.
- **Look for explanations that are as physical as possible, not just mathematical. Then, remember the explanation.** - R.P.Feynman
- Every topic can only be studied by successive approximations, normally infinite successive approximations...

DRAFT. IN PROGRESS.

- Analytical approach: to do physics and understand physics there is no other way than solve problems.
- Quantitative **numerical results** always are of paramount importance in physics: exercises and problems.
- You understand (better...) a physical law when you learn what happens when it does not apply, when you go beyond it: from the ideal gas to a real gas....
- Build a model of your reality; test, predicts and try to falsify your model; keep it good until you find a better one.
- Any model is an imperfect approximation of reality. Approximation means: decide what can be ignored and what cannot.

12.01.01.05 Some key points

- Question everything, starting from what any teacher is telling you! Don't be afraid to ask stupid questions. Research is ultimately based on asking questions.
- The problem with the world is that the intelligent people are full of doubts, while the stupid ones are full of confidence. - Charles Bukowski
- "There are known knowns" is a phrase from a response United States Secretary of Defense Donald Rumsfeld gave to a question at a U.S. Department of Defense (DoD) news briefing on February 12, 2002 about the lack of evidence linking the government of Iraq with the supply of weapons of mass destruction to terrorist groups. D.Rumsfeld stated: **Reports that say that something hasn't happened are always interesting to me, because as we know, there are known knowns; there are things we know we know. We also know there are known unknowns; that is to say we know there are some things we do not know. But there are also unknown unknowns the ones we don't know we don't know. And if one looks throughout the history of our country and other free countries, it is the latter category that tend to be the difficult ones.**

12.01.04
Physics is not meta-Physics

© - QUOTE

©|J.vonNeumann|Works of the Mind Vol. I no. 1 (University of Chicago Press,Chicago, 1947.)|*WEB - URL* |

I think that it is a relatively good approximation to truth - which is much too complicated to allow anything but approximations-that mathematical ideas originate in empirics, although the genealogy is sometimes long and obscure. But, once they are so conceived, the subject begins to live a peculiar life of its own and is better compared to a creative one, governed by almost entirely aesthetic motivations, than to anything else and, in particular, to an empirical science. There is, however, a further point which, I believe, needs stressing. As a mathematical discipline travels far from its empirical source, or still more, if it is a second and third generation only indirectly inspired by ideas coming from "reality" it is beset with very grave dangers. It becomes more and more purely anesthetizing, more and more purely I'art pour I'art. This need not be bad, if the field is surrounded by correlated subjects, which still have closer empirical connections, or if the discipline is under the influence of men with an exceptionally well-developed taste. But there is a grave danger that the subject will develop along the line of least resistance, that the stream, so far from its source, will separate into a multitude of insignificant branches, and that the discipline will become a disorganized mass of details and complexities. In other words, at a great distance from its empirical source, or after much "abstract" inbreeding, a mathematical subject is in danger of degeneration. At the inception the style is usually classical; when it shows signs of becoming baroque, then the danger signal is up. It would be easy to give examples, to trace specific evolutions into the baroque and the very high baroque, but this, again, would be too technical.
In any event, whenever this stage is reached, the only remedy seems to me to be the rejuvenating return to the source: the re-injection of more or less directly empirical ideas. I am convinced that this was a necessary condition to conserve the freshness and the vitality of the subject and that this will remain equally true in the future.

12.01.05
Taxonomy of Knowledge

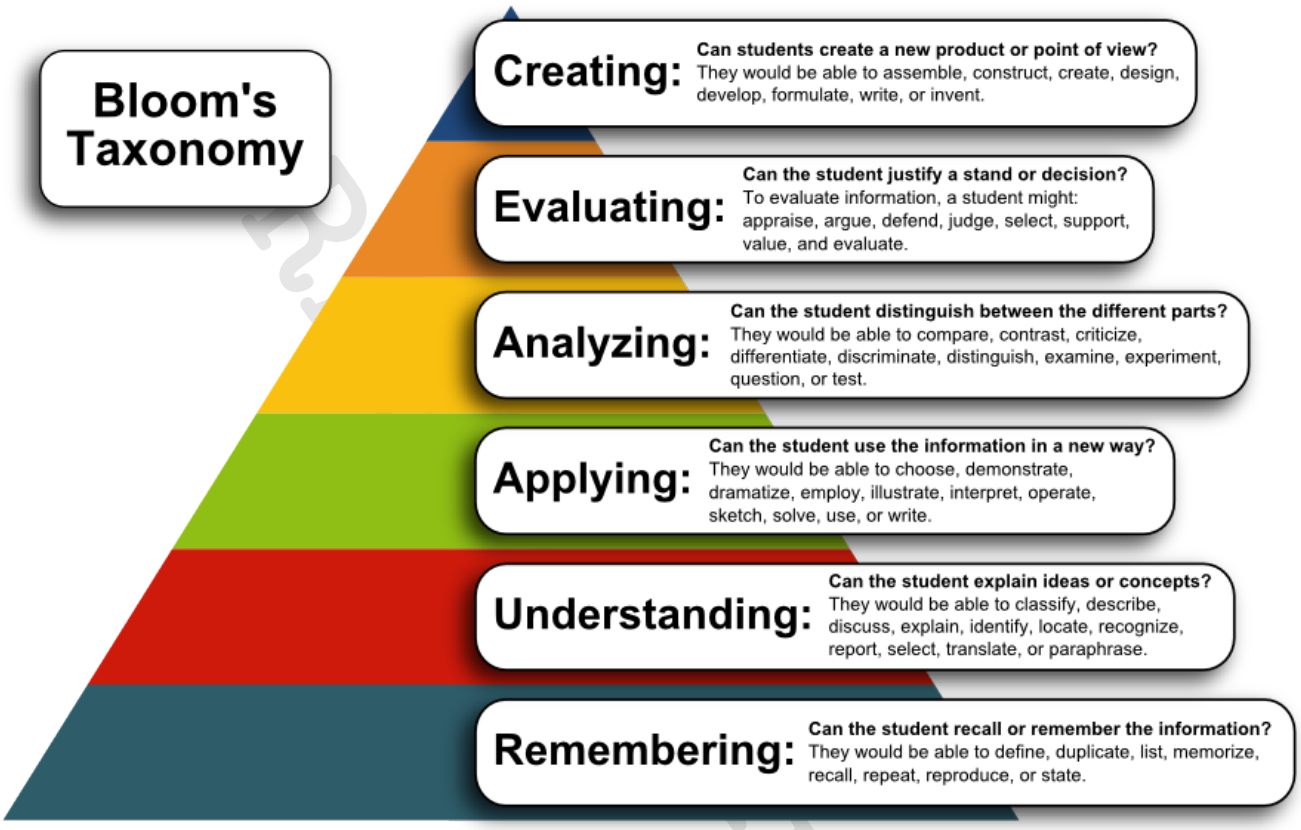

Figure 12.12: Bloom Taxonomy

12.01.06
Publication Bias

© - QUOTE

©|T.Roberts & S.Schleif & J.M.Dlugosz|WEB - URL ||

There are two very different aspects of **publication bias**:

- Unpopular or unexpected results may not be published because either the original experimenters or some journal referees have misgivings or reservations about the results, based on the results themselves and not any independent evaluation of experimental procedures or technique.
- Expected experimental results may not be published because either the original experimenters or some journal referees do not consider them interesting enough to merit publication.

In both cases the experimental record in the literature does not fully and accurately reflect the actual experiments that have been performed. Both of these effects clearly affect the literature on experimental tests of SR. This second aspect is one reason why this list of experiments is incomplete; there have probably been many hundreds of unpublished experiments that agree with SR.
Note that this does not include papers that are rejected for other reasons, such as: inappropriate subject or style, major internal inconsistencies, or downright incompetence on the part of authors or experimenters. Such rejections are not bias, they are the proper functioning of a peer-reviewed

journal.

DRAFT-IN-PROGRESS

12.02 Tentative Anatomy of the Equations of Physics

- Physics has not a strictly logical (mathematics-like) architecture: the **raison d'être** of physics always lies in its confrontation with Nature.
- **Operational definition**. Every physical quantity must be defined (or at least definable in principle) in a operative way: that is, a well defined measurement method, doable at least in principle, has to be agreed.
- Every physical relation must either contain only physical quantities which have been previously defined (a physical law), or it is a definition of one physical quantity in terms of already defined physical quantities (a definition).
- **Definitions**: one quantity is defined in terms of others, all of which had been defined previously; definitions are operative, that is it is necessary to clearly indicate all what to do. A definition must provide the means to get a physical quantity, either by direct measurement or indirect one.
- **Physical laws**: relations among all previously defined quantity.
- It **must be possible to falsify any physical law**, if it has to be a physical law. Any physical law allows either prediction and|or **falsifiability**.
- Physical laws can be divided into:
  - principles (postulates): few, general and important laws which summarize the experimental knowledge;
  - derived laws (theorems), or simply laws: laws which are demonstrated starting from the principles.

  The above names are far from universal use....
- **Constitutive relations | Equations of State**: relations quantifying and characterizing physical property of specific systems, thus limited in validity to the specific system.

SPELLING IN PROGRESS

12.03 On Physics Problem Solving

12.03.01 Some Considerations on Solving Physics Problems

The purpose of studying Physics is to learn to deal with and solve problems.

Solving physics problems can only give maximum benefit if the student solves problems on his own. In the initial phase of the study discussion, comparison and group study can be very useful. However, the final phase of preparation must be carried out completely autonomous by each student. If only because you take the exam alone.

It is essential to address the solutions to Physics exercises and problems only after having adequately studied the theory. This involves taking classes taking notes, studying lecture notes and, necessarily, study the most important and complex parts in textbooks and, above all, the parts that were not fully understood. The arguments come presented by different sources always with a different slant, and each must find the presentation mode that best suits your preferences specifications and your own preparation.

It is essential to tackle exercises and problems gradually, starting out always from the simplest exercises, direct applications of the concepts studied, and then moving on to the problems, where more situations arise complex ones that usually require intermediate steps to reach the final solution. Knowing how to solve the exercises is not enough, it is necessary try to learn to solve problems, where the answer is not immediate application of a concept but requires intermediate steps that are not pre-defined and are not obvious a priori.

It may also be useful, in the final stage of preparation, to try to tackle more difficult problems than required in the exam. Thereby it will be easier to deal with exam problems.

Attempting to tackle complex problems without having adequately studied the theory and without having practiced with the simplest exercises and problems it's very counterproductive. In fact, there is a risk of creating preconceptions and deviations, or to base one's preparation on serious errors. All this can then be difficult to detect and correct later.

It is worth underlining that a key element in solving problems, of any kind, lies in addressing and carrying out the problem with diligence and in order. The **genius and recklessness** belongs much more to legend than reality.

In the initial study phase it is advisable to tackle exercises and problems whose solution or answer is known. This allows you to verify correctness of your solution and gain confidence in your ability to solve the problems correctly, or realize that the arguments do not have been adequately assimilated. The final stage of preparation goes however conducted by addressing problems for which the answer is not known, so as to be able to develop one's critical sense of analysis of problems and solution produced. In fact, it is necessary to prepare for the exam and the real problems, the solution of which is never known, just as we do not know whether the data is available are sufficient or perhaps redundant.

It is often difficult, especially in the initial study phase, to resolve the problems without help. However, even the unsuccessful attempts at solving the problems can be very useful, if faced with sufficient perseverance, as they develop the ability for reflection, elaboration and effort will.

We must not be discouraged by the fact that many problems cannot be solved resolve immediately. It is a recognized fact that the solution of problems, which is a type of creative work, usually proceeds according to the following scheme. The first phase is the preparatory one in which we search assiduously the solution to the problem. If the solution to the problem does not come directly found the problem is temporarily put aside and begins the second phase, that of incubation, in which you don't think about the problem and you do something else. In this phase, however, mental work proceeds unconsciously and often leads, in the long run, to the third phase, enlightenment, which allows for find the solution to the problem. It is clear however that the work is unconscious of the second phase cannot exist without intense work in the first phase preparatory. Paradoxically, therefore, when you don't know where to turn your head It's the moment when you risk learning something new. From the scheme described, it

DRAFT UNDER PEER REVIEW

is clear that it is not appropriate to postpone until the last moment solving problems is useful because in this way the possibility is lost to exploit the incubation phase and therefore risk not being able to solve the most involved and interesting problems.

One warning concerns the classic end-of-chapter problems in books by text. They are obviously very useful but you cannot limit yourself to these for one complete preparation. The typical end-of-chapter exercise or problem of a textbook can be easy to solve because you know where it is located and what concepts are behind it? Every problem, if taken out of its context, it may appear or become much more difficult. In fact the problems end chapter automatically direct you towards a series of concepts, those exposed in the chapter, to solve them, help that does not exist in real problems. The simpler than end-of-chapter problems, if taken out of context, it can be much more difficult. The student, in fact, often has difficulty solve real problems because real problems are often missing from the chapters of textbooks.

During the study it may be useful to create a form that collects in a concise and summary way the fundamental facts. In fact any personal re-elaboration is useful as it allows you to analyse the more critical the problems.

You should always carefully examine and reflect on the statement of the problem. A surprisingly large number of errors arise from one reading superficial and misunderstanding of the text.

With rare exceptions, every problem must be resolved first in its entirety symbolic and numeric values inserted only in the final expression. This allows you to carry out three checks that should never be omitted once obtained a solution.

The first check consists in checking the dimensional correctness of the solution.

The second verification consists in the study of the limiting cases of the solution in which the performance of the solution is examined in the extreme cases in which the solution of problem can be obtained immediately and whose plausibility can be verified immediately.

The third check consists in evaluating the plausibility of the solution obtained by verifying that the dependencies of the result are those expected wait and that the numerical values obtained are plausible.

These three checks, while certainly not guaranteeing the correctness of the solution, they can report trivial errors. It is necessary to pay attention to the fact that in the second and third checks sometimes dependencies and unexpected trends are encountered which however are correct. In this case, the issue needs to be explored further understand what the correct result is.

In exceptional cases, when the complexity of the symbolic solutions becomes prohibitive, it may be appropriate to replace the numerical values of the problem specific at an intermediate stage of the solution and take the solution forward number of the specific problem. This can happen, for example, in presence of systems with many equations with complicated coefficients or in the presence of equations, numerical or differential, not explicitly solvable in form symbolic.

It is often possible to solve a problem or part of it in two or more completely independent ways. This, if possible, allows you to verify that alternative routes provide compatible results and provides confidence in the correctness of the result obtained. Typical examples are the solution of a problem in two different Reference Systems, the solution of a problem in two different Coordinate Systems in the same Reference System o the application of the second Cardinal Equation of mechanics with two poles different.

If the problem contains numerical data it must be solved to the end, up to numerical result. To get correct numerical results you need a good one knowledge of the dimensions and units of measurement of physical quantities is one good calculation ability. Both things can only be achieved with practice. It can be useful to convert for determining numerical results from the beginning all quantities in a single system of units of measurement (usually the International System) and express numerical values in scientific notation with a numerical coefficient of the order of unity.

It is always essential to observe the rules of approximate calculation and use the correct number of significant figures as all quantities physics are always affected by an error. As far as General Physics is concerned Precise error propagation analysis is usually required however, at least compliance with the elementary rules of the propagation of significant figures.

Always check the reasonableness of the order of magnitude of the result numeric obtained. An error in the order of magnitude is in Physics minus acceptable than an error on the significant figures with an order of magnitude Right.

FREE - UNPUBLISHED

When tackling a Physics problem, it is always necessary to keep in mind that the physics builds a model of reality by introducing simplifications and approximations. On the one hand, it is therefore necessary to address real problems by avoiding them useless and inessential complications to the problem that needs to be solved. On the other hand, however, it is always necessary to verify that the simplifications and approximations made are justified.

Follow the procedures and always avoid improvising or jumping intuition: it's the best way to make mistakes.

12.03.02
General points

1. Read the text carefully several times and imagine the physical phenomenon question. Try to extract all the information from the text; often information is not expressed directly or explicitly. In one exercise all information is explicit in the text; they are necessary in a problem information or intermediate steps not explicitly indicated in the text. Note that common physical data (for example mass and radius of the Earth, mass and charge electric current of an electron or common physical constants) are often not explicitly indicated in the text.
2. Convert all numerical data to SI units immediately at the beginning (read § B), to avoid mixes of incompatible units and immediately see the relationships between them homogeneous sizes. Always convert degrees to radians to avoid errors.
3. Try to understand the physics of the problem before diving into the solution in mathematical details. Approximate answers can often be obtained by using hypotheses simplifiers; you can refine the solution later, for subsequent ones approximations.
4. Make the appropriate drawings or diagrams, which are always useful (indispensable).
5. Decide on the Reference System (if non-inertial, take note of the fictitious forces).
6. Choose the Coordinate System within the chosen reference system, the one that seems most comfortable.
7. Decide and define with extreme precision the system (or systems) to which to apply the physical laws.
8. Apply physical laws to the system, trying to translate them all into equations the information that can be deduced from the text.
9. The conserved physical quantities of the problem are always of great help in simplifying the solution of the problem. If they are present it is usually best to use them as a priority.
10. Count the unknowns and variables in written equations: if there are fewer equations and variables look for other equations, both by rereading the text for explicit information, both reflecting on the physical phenomenon for non-information explicitly proposed in the text, and by asking which quantities are conserved.
11. Don't forget that every physics problem is a model, always simplified, of a physical phenomenon. Don't pretend to take everything into account, but adapt to the text and to the hypotheses of the problem and to common sense...
12. Don't make the mistake of trying to answer questions that haven't been asked yet limit yourself to trying to obtain what is asked and why Information to obtain more information may be missing in the text.
13. Always solve equations in symbolic form to the end, replace always the numerical values to obtain the numerical result, but only in the final formula.
14. Check the correct dimensions of the written formulas.
15. Always check that the results, both the symbolic formula and the numerical results, appear to make sense.
16. If the equations give more solutions than expected, be careful to choose the right one for the problem, given the problem text. Try to interpret the other solutions, for greater safety (sometimes the interpretation of the other solutions is not at all simple...).
17. Carefully analyze all the possible limiting cases of the formulas obtained: cases with special values of the various parameters for which the solution is found immediately without solving the equations;

DRAFT - IN PROGRESS

verify that the solution is sensible and in accordance with the formula. Carefully analyze that parameters influence the response in the expected way.

18. Where possible and there is time, solve the same problem with different choices, such as: different reference system, different coordinate system, different choice of system, ...
19. Write everything in an orderly manner and always proceed with diligence; do all the steps in detail to avoid trivial errors.

12.04 Common methods in Physics

12.04.01 Using approximations

12.04.01.01 Using approximate expression of a function to first order

Using approximate expression of a function to first order; sometimes also second or higher orders. For instance: Hooke law is an approximation to first order for the generic/general relation between force and elongation of an elastic medium; read § 32.04 and section § 27.01.01.

12.04.01.02 Using infinitesimal things

12.04.01.03 Large distance

12.04.01.04 Perturbative solutions

12.04.02 Effective theories

12.04.02.01 Averaging discrete things to model as a continuum

12.04.03 Check the result

- dimensions
- limiting cases
- order of magnitude makes sens.

DRAFT - IN-PROGRESS

12.05 General Unifying Concepts in Physics

12.05.01 Covariance of physical laws

It is postulated that physical laws must be independent from the Reference Frame, in the class of Inertial Reference Frame , and/or independent from the Coordinate System. The latter comes from the arbitrariness of the choice of the Coordinate System.

For this to be true, physical laws must be expressed via tensor calculus.

Read § 20.03.06.

12.05.02 Continuity Equations

Read § 21.03.

12.05.02.01 Transport Equations

Read § 65.09.01.01.

12.05.03 Linear Systems

Read § 19.

Linear Systems are relatively easy to solve, with respect to non-linear systems. This motivates the often used linear approximation.

12.05.03.01 Sinusoidal and cosinusoidal solutions to linear equations

Use of sinusoidal and cosinusoidal solutions to linear equations: motivated by the linearity of equations; read § 19.06.

12.05.03.02 The superposition principle

The superposition principle; read § 19.01 and section § 24.03.03.01.

12.05.04 Dimensional Analysis

12.05.05 Symmetries

12.05.05.01 Symmetries and invariance

12.05.05.02 Homogeneity and Isotropy

Connected to invariance under translations and rotations in space.

14.02 Algebraic Equations

14.02.01 Algebraic Equations of Second Degree

$$ax^2 + bx + c = 0$$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad .$$

Solutions satisfy Vieta [1] relations:

$$x_1 + x_2 = -\frac{b}{a} \qquad x_1 x_2 = \frac{c}{a}$$

14.02.02 Algebraic Equations of Third Degree

©|E.W.Weisstein - Cubic Equation.|From MathWorld–A Wolfram Web Resource.|*WEB - URL* |

Third degree (cubic) equations sometimes appear in physics problems, for instance when dealing with second-order tensors in three dimensions.

The solutions of the general algebraic equations of third degree:

$$x^3 + bx^2 + cx + d = 0 \quad ,$$

are given by:

$$x_0 = -\frac{b}{3} + \frac{\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}}{3\,(2)^{1/3}} + \\ - \frac{(2)^{1/3}\left(3c - b^2\right)}{3\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}} \quad ,$$

$$x_+ = -\frac{b}{3} - \frac{\left(1 - i\sqrt{3}\right)\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}}{6\,(2)^{1/3}} + \\ + \frac{\left(1 + i\sqrt{3}\right)\left(3c - b^2\right)}{3 \cdot 2^{2/3}\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}} \quad ,$$

$$x_- = -\frac{b}{3} - \frac{\left(1 + i\sqrt{3}\right)\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}}{6\,(2)^{1/3}} + \\ + \frac{\left(1 - i\sqrt{3}\right)\left(3c - b^2\right)}{3 \cdot 2^{2/3}\left(-2b^3 + 9cb - 27d + 3\sqrt{3}\sqrt{4db^3 - c^2b^2 - 18cdb + 4c^3 + 27d^2}\right)^{1/3}} \quad .$$

Solutions satisfy Vieta [2] relations:

$$x_0 + x_+ + x_- = -b \qquad x_0 x_+ + x_0 x_- + x_+ x_- = c \qquad x_0 x_+ x_- = -d \quad .$$

14.03.01.01 Pythagoras Circular Theorem

$$+\cos^2[\theta]+\sin^2[\theta]=1 \qquad +1+\tan^2\theta=\sec^2\theta \qquad +1+\cot^2\theta=\csc^2\theta \quad .$$

14.03.01.02 Addition Formulas

$$\sin[\alpha\pm\beta]=\sin[\alpha]\cos[\beta]\pm\cos[\alpha]\sin[\beta] \quad , \tag{14.03.04}$$ → 1047

$$\cos[\alpha\pm\beta]=\cos[\alpha]\cos[\beta]\mp\sin[\alpha]\sin[\beta] \quad . \tag{14.03.05}$$ → 1047

From (14.03.04), (14.03.05) one has:

$$\tan[\alpha\pm\beta]=\frac{\tan[\alpha]\pm\tan[\beta]}{1\mp\tan[\alpha]\tan[\beta]} \quad . \tag{14.03.06}$$

All other common trigonometric formulas can be deduced from the addition formulas.

DRAFT - IN - PROGRESS

14.03.02
Hyperbolic Trigonometry

This § is referenced at pages:
[2409]

©|WEB - URL |||

The hyperbolic functions arise in many problems of mathematics and mathematical physics in which integrals involving $\sqrt{1+x^2}$ arise (whereas the circular functions involve $\sqrt{1-x^2}$). For instance, the hyperbolic sine arises in the gravitational potential of a cylinder and the calculation of the Roche limit. The hyperbolic cosine function is the shape of a hanging cable (the so-called catenary). The hyperbolic functions arise in the calculation of rapidity of special relativity (equation (58.09.01.07)). All three appear in the Schwarzschild metric using external isotropic Kruskal coordinates in general relativity. The hyperbolic secant arises in the profile of a laminar jet. The hyperbolic cotangent arises in the Langevin function for magnetic Polarization.

14.03.02.01 Pythagoras Hyperbolic Theorem

$$+\operatorname{coh}^2[\theta]-\operatorname{sih}^2[\theta]=1 \qquad +1-\operatorname{tah}^2\theta=\operatorname{sch}^2\theta \qquad -1+\operatorname{cth}^2\theta=\operatorname{csh}^2\theta \quad .$$

14.03.02.02 Addition Formulas

$$\operatorname{sih}[\alpha\pm\beta]=\operatorname{sih}[\alpha]\operatorname{coh}[\beta]\pm\operatorname{coh}[\alpha]\operatorname{sih}[\beta] \quad , \tag{14.03.07}$$ → 1048

$$\operatorname{coh}[\alpha\pm\beta]=\operatorname{coh}[\alpha]\operatorname{coh}[\beta]\pm\operatorname{sih}[\alpha]\operatorname{sih}[\beta] \quad . \tag{14.03.08}$$ → 1048

From (14.03.07), (14.03.08) one has:

$$\tan[(\alpha\pm\beta)]=\frac{\tan[\alpha]\pm\tan[\beta]}{1\pm\tan[\alpha]\tan[\beta]} \quad . \tag{14.03.09}$$

All other common trigonometric formulas can be deduced from the addition formulas.

15.01 Introduction

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|§ 2||
©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|problem 2.32||
©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|1.1.5||

Vector algebra is part of the basic language of physics.

It is therefore necessary to master the basics of vector algebra in order to understand and use physical laws in the best way.

Necessarily and on purpose, I shall often rely on the intuition of the reader to formalize the ideas, leaving a rigorous development to a more comprehensive mathematical treatment, which is out-of-context for physics.

15.01.01 Notations Definitions and Conventions

This § is referenced at pages:
[1091]

The **convention of sum of repeated indexes** is used: whenever any index appears exactly twice in any monomial term, it is implicitly understood that the term itself is summed over all the possible values of that index, typically:

- either $1, \dots 3$ (for roman type indexes, typically in euclidean three-dimensional space)
- or $0, \dots 3$ (for Greek type indexes, typically in Minkowski pseudo-euclidean space).

The following conventions are therefore adopted:

- whenever exactly two Latin indexes appear, their summation from 1 to 3 will be implied;
- whenever exactly two Greek indexes appear, their summation from 0 to 3 will be implied;
- whenever two or more indexes appear, which must not be summed, they will be normally written inside square brackets, for the sake of clarity, whenever any ambiguity might arise.

As an example:

$$A^{[i]}\mathcal{B}^{[i]}_k g_{\alpha[i]} f_k H^{\alpha\beta}_{\cdot\cdot} \equiv \sum_{k=1}^{3}\sum_{\alpha=0}^{3} A^{[i]}\mathcal{B}^{[i]}_k g_{\alpha[i]} f_k H^{\alpha\beta}_{\cdot\cdot} \qquad \text{the index } [i] \text{ is not summed} \quad .$$

Note that the **name** given to any summed index does not matter at all: it is said to be a dumb index. That is to say, in the above formula the k might be named with any other roman letter and α might be named with any other Greek letter as the sum is implied. In fact, the dummy integration index can take any name as it does not appear in the result. This is exactly the same as for integrals: the dummy integration variable can take any name as it does not appear in the result.

Note that the **vertical position of the indexes (high/low)** might either have or have not a relevance, depending on the context: this must be seen case-by-case. In euclidean 3-space (or n-space) it is not relevant. In Minkowski space it is relevant.

Note: the limitation to **two and only two indexes** is because the summation must be between one contravariant and one covariant indexes, a topic which can only be understood within the general framework described in section § 20.

15.01.02.01 Scalars and Vectors: Physics Versus Mathematics

The discussion is limited to Cartesian Coordinate Coordinate System: for a full discussion read § 20.

One should note that the words **scalar** and **vector** may have a different meaning in Calculus (Mathematics) and Physics.

In Calculus a scalar function is just a real-valued function giving real values and a vector function is a real-valued function giving an n-tuple (an ordered list) or real values.

In physics, one deals with physical quantities and the term scalar/vector has a well defined meaning with respect to changes of systems of coordinates (for a full discussion read § 20). Therefore, in physics, not all real numbers are scalars and not all n-tuples of real numbers (lists of real numbers) are vectors.

15.01.02.02 Scalars and Vectors: the case of three-dimensional euclidean space

Let us consider a orthonormal Cartesian Coordinates Coordinate System.

- a scalar is a physical quantity which does not change its value under a rotation of the orthonormal Cartesian Coordinates Coordinate System (examples: the distance between two points);
- it takes more than an oriented direction ad a magnitude to make a vector; a vector is a physical quantity which:
  - is a member of a vector space;
  - its components transform, under rotation of the orthonormal Cartesian Coordinates Coordinate System, as the position vector $\mathbf{r} \equiv \{x, y, z\}$.

Counter-examples:

- a number which is not a scalar: any single component of a vector;
- a triplet of numbers which is not a vector:
  - a triplet of three distances (the three components do not change as the components of the position vector under rotation, as distances do not change under rotation);
  - the oriented arrows defining finite rotations (magnitude: angle of rotation, direction: the axis of rotation, orientation: given by the right-hand rule) do not add as elements of a vector space, as the addition of finite rotations is not commutative;
  - E.M.Purcell squrl operator is not a vector [a].
  - the wavelength, the fundamental concept for MPW, is a length which cannot be treated as a **wavelength vector** λ , but it is, on the other hand, the reciprocal of the module of the **wave-vector**.

15.02.01
Cartesian Coordinates Coordinate System

Consider an orthonormal Cartesian Coordinates Coordinate System in three dimensions. This type of Coordinate System will always be implicitly used, unless specified otherwise.

Let either $\mathbf{r} \equiv \{x, y, z\}$ or $\mathbf{x} \equiv \{x_1, x_2, x_3\}$ be the three Cartesian coordinates of any point.

The three unit vectors of the three orthonormal Cartesian axes are either $\{\mathbf{i}, \mathbf{j}, \mathbf{k}\}$ or $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$.

The components of a generic vector $\mathbf{v}$ along the three orthonormal Cartesian axes are either $\{v_x, v_y, v_z\}$ or $\{v_1, v_2, v_3\}$.

Le relazioni tra i vettori base, $\mathbf{e}_1$, $\mathbf{e}_2$ ed $\mathbf{e}_3$, di un Coordinate System Cartesiane ortonormali sono:

$$\boxed{\mathbf{e}_i \cdot \mathbf{e}_k \equiv \delta_{ik}^{\cdot\cdot} \qquad i,k = 1,2,3 \qquad \text{orthonormality}} \quad , \tag{15.02.01}$$

→ 1055

$$\boxed{\left\{ \mathbf{e}_i \wedge \mathbf{e}_k \equiv \epsilon_{ikj}^{\cdot\cdot\cdot} \mathbf{e}_j \right\} \quad \Leftrightarrow \quad \left\{ \mathbf{e}_j \cdot (\mathbf{e}_i \wedge \mathbf{e}_k) \equiv \epsilon_{ikj}^{\cdot\cdot\cdot} \right\} \qquad i,j,k = 1,2,3 \qquad \text{right-handedness}} \quad . \tag{15.02.02}$$

→ 1055 1073

Il simbolo $\delta_{ik}^{\cdot\cdot}$ (simbolo delta di **Kronecker symbol**), read § 17.04.

Il simbolo $\delta_{ik}^{\cdot\cdot}$ (simbolo delta di **Kronecker symbol**) è definito qui dalla equazione (15.02.01), come l'oggetto simmetrico nei suoi due indici:

$$\boxed{\delta_{ik}^{\cdot\cdot} = \begin{cases} 1 & \text{se } i = k \\ 0 & \text{se } i \neq k \end{cases} \quad ,} \quad .$$

Il simbolo $\epsilon_{ikj}^{\cdot\cdot\cdot}$ è **Levi-Civita symbol** , read § 17.04.

Il simbolo $\epsilon_{ikj}^{\cdot\cdot\cdot}$ in tre dimensioni (**Levi-Civita symbol** in tre dimensioni) è definito qui dalla equazione (15.02.02), come l'oggetto totalmente antisimmetrico in una qualunque coppia dei suoi tre indici:

$$\boxed{\epsilon_{ijk}^{\cdot\cdot\cdot} = \begin{cases} +1 & \text{se } i,j,k \text{ è una permutazione pari } [1] \text{ di } 1,2,3 \quad , \\ -1 & \text{se } i,j,k \text{ è una permutazione dispari } [2] \text{ di } 1,2,3 \quad , \\ 0 & \text{se almeno due indici uguali} \quad , \end{cases}} \quad .$$

→ 1072

The derivation of equations (15.02.01) can be carried on by explicit calculation from the basic properties of the unit vectors of an orthonormal basis.

In principle, given an orthonormal basis, equations (15.02.01) can be considered to be the definition of the delta and epsilon symbols.

Read § 15-009 for some properties of the delta and epsilon symbols.

Any generic vector is written as:

$$\boxed{\mathbf{v} = v_1 \mathbf{e}_1 + v_2 \mathbf{e}_2 + v_3 \mathbf{e}_3 \equiv v_k \mathbf{e}_k} \quad .$$

Change Between Different Systems of Coordinates

15.03 Vector Algebra - a Short Summary of the Main Results

15.03.01
Prodotto Scalare E Vettoriale in Componenti Cartesiane Ortonormali

Given any two vectors one can define two types of multiplication between them: either a scalar product, giving a scalar, or a vector product, giving a vector, while remaining inside the same vector space.

Il prodotto scalare e vettoriale dei due vettori $\mathbf{a} = a_1\mathbf{e}_1 + a_2\mathbf{e}_2 + a_3\mathbf{e}_3$ e $\mathbf{b} = b_1\mathbf{e}_1 + b_2\mathbf{e}_2 + b_3\mathbf{e}_3$ si può esprimere in termini delle componenti Cartesiane ortonormali.

More generally, given two vectors, $\mathbf{a}$ and $\mathbf{b}$, one can multiply them in three ways:

- one can get a scalar, $\mathbf{a}\cdot\mathbf{b}$;
- one can get a vector, $\mathbf{a}\wedge\mathbf{b}$;
- one can get a symmetrical second order tensor, $(a_r b_s + a_s b_r)$.

Read § 20.06.03.

DRAFT - LW - PROGRESS

15.03.01.01 Prodotto Scalare

Il prodotto scalare si esprime in termini delle componenti cartesiane ortogonali come:

$$\mathbf{a}\cdot\mathbf{b} = \delta_{kj}^{\cdots} a_k b_j = a_k b_k \quad . \tag{15.03.01}$$

15.03.01.02 Prodotto Vettoriale

Le componenti del prodotto vettoriale si esprimono in termini delle componenti Cartesiane ortonormali come:

$$(\mathbf{a}\wedge\mathbf{b})_k = \epsilon_{kij}^{\cdots} a_i b_j \quad . \tag{15.03.02}$$

The vector product is useful, from the geometrical point of view, to create either a vector perpendicular to a given vector or to a pair of vector.

Prodotto Vettoriale Espresso Attraverso Determinante

Il prodotto vettoriale di due vettori, $\mathbf{a} = a_1\mathbf{e}_1 + a_2\mathbf{e}_2 + a_3\mathbf{e}_3$ e $\mathbf{b} = b_1\mathbf{e}_1 + b_2\mathbf{e}_2 + b_3\mathbf{e}_3$, si può esprimere, formalmente, in termini delle componenti Cartesiane ortonormali dei vettori, come il determinante:

$$\mathbf{a}\wedge\mathbf{b} = \begin{vmatrix} \mathbf{e}_1 & \mathbf{e}_2 & \mathbf{e}_3 \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} \quad . \tag{15.03.03}$$

15.03.02 Geometrical Properties Connected to the Multiplication Between Two Vectors

15.03.02.01 Prodotto Vettoriale E Area Di Un Triangolo E Di Un Parallelogramma

Se due vettori **a** e **b** sono applicati nello stesso punto, il loro prodotto vettoriale è un vettore il cui modulo è uguale all'area del parallelogramma, S_P, definito dai due vettori.

Quindi il loro prodotto vettoriale è anche uguale al doppio dell'area, S_T, del triangolo delimitato dai due vettori e avente come terzo lato il segmento che unisce i vertici dei due vettori:

$$S_P = |\,\mathbf{a}\wedge\mathbf{b}| \qquad S_T = \frac{1}{2}|\,\mathbf{a}\wedge\mathbf{b}| \quad . \tag{15.03.04}$$

→ 1057 1078 1239

15.03.02.02 Description of Parallelogram-shaped area by Means of a Vector

This § is referenced at pages:
[1074]

The equation (15.03.04) is at the basis of the description of a parallelogram by means of a vector. In fact, starting from equation (15.03.04), one can describe a parallelogram, in terms of its two sides, **a** and **b**, by means of one of the two vectors:

$$\mathbf{S} = \pm\,(\mathbf{a}\wedge\mathbf{b}) \quad , \tag{15.03.05}$$

→ 1078

whose module gives the area of the parallelogram and whose direction is perpendicular to the parallelogram itself. The choice of the sign, that is orientation, of the vector is usually dictated by other considerations. When, for instance, the parallelogram is just a piece of a closed surface the convention is to orient the vector exiting from the volume enclosed by the surface.

It is obvious that the vector **S** does not completely describe the parallelogram, but only its orientation and area.

DRAFT LIBRO

15.03.02.03 Area Di Un Triangolo

L'area di un triangolo i cui vertici sono individuati dai tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$, aventi lo stesso punto di applicazione, vale:

$$S = \frac{1}{2}|\,\mathbf{a}\wedge\mathbf{b} + \mathbf{b}\wedge\mathbf{c} + \mathbf{c}\wedge\mathbf{a}| \quad . \tag{15.03.06}$$

15.03.02.04 Teorema Dei Coseni

Dati tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ tali che $\mathbf{a} = \mathbf{b} - \mathbf{c}$, e detti rispettivamente α, β e γ gli angoli opposti ai lati $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ del triangolo, si ha il teorema dei coseni:

$$a^2 = b^2 + c^2 - 2bc\cos[\alpha] \quad . \tag{15.03.07}$$

15.03.02.05 Teorema Dei Seni

Dati tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ tali che $\mathbf{a} = \mathbf{b} - \mathbf{c}$, e detti rispettivamente α, β e γ gli angoli opposti ai lati $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ del triangolo, si ha il teorema dei seni:

$$\frac{\sin[\alpha]}{a} = \frac{\sin[\beta]}{b} = \frac{\sin[\gamma]}{c} \quad . \tag{15.03.08}$$

WORKED SOLUTION

$$\mathbf{a} = \mathbf{b} - \mathbf{c} \implies |\,\mathbf{b}\wedge\mathbf{a}| = |-\mathbf{b}\wedge\mathbf{c}|$$

15.03.03 Triple Vector Products

It is possible to define two different products involving three vectors and multiplications among them: a scalar product, giving a scalar, a vector product, giving a vector.

15.03.03.01 Triplo Prodotto Scalare E Volume Di Un Parallelepipedo

This § is referenced at pages:
[1074]

Dati tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ si può formare un triplo prodotto scalare il cui valore è invariante per permutazione dei tre vettori:

$$\mathbf{a}\cdot(\,\mathbf{b}\wedge\mathbf{c}) = \mathbf{b}\cdot(\,\mathbf{c}\wedge\mathbf{a}) = \mathbf{c}\cdot(\,\mathbf{a}\wedge\mathbf{b}) = \epsilon_{ijk}a_ib_jc_k = \begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix} \quad . \tag{15.03.09}$$

→ 1074 1075

Il triplo prodotto scalare $\mathbf{a}\cdot(\,\mathbf{b}\wedge\mathbf{c})$ di tre vettori non nulli si annulla se e solo se i tre vettori sono complanari.

DRAFT - IN PROGRESS

15.03.03.02 Triplo Prodotto Vettoriale

Dati tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ si può formare un triplo prodotto vettoriale. Si hanno le identità, tra loro equivalenti,

$$\boxed{\mathbf{a}\wedge(\mathbf{b}\wedge\mathbf{c}) = \mathbf{b}(\mathbf{a}\cdot\mathbf{c}) - \mathbf{c}(\mathbf{a}\cdot\mathbf{b})} \quad , \qquad \boxed{(\mathbf{a}\wedge\mathbf{b})\wedge\mathbf{c} = \mathbf{b}(\mathbf{a}\cdot\mathbf{c}) - \mathbf{a}(\mathbf{c}\cdot\mathbf{b})} \quad .$$

→ 1059 1066 1074 1075

15.03.04 Geometrical Properties of Multiplication Between Three Vectors

15.03.04.01 Volume Di Un Parallelepipedo

Dati tre vettori $\mathbf{a}$, $\mathbf{b}$ e $\mathbf{c}$ aventi lo stesso punto di applicazione il volume V del parallelepipedo generato dai tre vettori è uguale al modulo del triplo prodotto scalare dei tre vettori:

$$\boxed{V = |\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})|} \quad .$$

15.03.04.02 Scomposizione Di Un Vettore in Componenti Rispetto Ad Un Unit Vector

This § is referenced at pages:
[1142]

Un vettore $\mathbf{x}$ può essere scomposto nelle sue componenti parallela, $\mathbf{x}_{\parallel}$, ed ortogonale, $\mathbf{x}_{\perp}$, ad un unit vector $\hat{\mathbf{n}}$ tramite la relazione:

$$\boxed{\mathbf{x} = (\mathbf{x}\cdot\mathbf{n})\,\hat{\mathbf{n}} + \mathbf{n}\wedge(\mathbf{x}\wedge\mathbf{n}) \equiv \mathbf{x}_{\parallel} + \mathbf{x}_{\perp}} \quad , \tag{15.03.10}$$

→ 1066 1130

che deriva direttamente dalla (15.03.03.02).

- **A free vector is any vector with no specified line of action or point of application**.
- **A sliding vector is any vector that has a specified line of action or axis, but has no specified point of application**.
- An **applied vector** is any vector that has both a specified line of action and a specified point of application.

15.04.01
Applied Vectors and Applied Vector Fields - Vector Spaces

Dato un vettore **f** applicato in un punto P si definisce retta d'azione del vettore la retta parallela al vettore e passante per il punto P.

Dato un punto arbitrario dello spazio, il polo O, si definisce braccio del vettore rispetto al polo O la distanza del punto dalla retta d'azione del vettore.

A vector field is a map such that at any point in some domain is associated a vector (applied at the point).

Important examples of applied vector fields in mechanics are:

- force (momentum of the force);
- momentum of the force (whose momentum is not useful);
- momentum of a mass point (momentum of the momentum aka orbital angular momentum);
- orbital angular momentum of a mass point (whose momentum is not useful);
- gravitational fields.

Important examples of applied vector fields outside mechanics include electric/magnetic fields.

15.04.02
Momentum of an Applied Vector

Both the polar and axial moments of a vector are uniquely defined with respect to a pole (the former) or an oriented straight line, that is an axis, (the latter). Either the pole or the axis must always be specified when dealing with the momentum of a vector.

WORK-IN-PROGRESS

15.04.02.01 Momentum of an Applied Vector With Respect to an Axis (Axial Momentum)

Sia $\mathbf{f}$ un vettore applicato in P. Il momento assiale rispetto ad una retta orientata arbitraria è la proiezione lungo la retta orientata del momento polare del vettore rispetto ad un qualunque polo giacente sulla retta. Se $\hat{\mathbf{u}}$ è un unit vector che individua la retta orientata ed R un qualunque punto della retta:

$$\boxed{\gamma_{\hat{\mathbf{u}}} \equiv \hat{\mathbf{u}} \cdot (\mathbf{x}_{PR} \wedge \mathbf{f})} \quad . \tag{15.04.01}$$

→ 1066

Dalla relazione (15.04.03) segue che il momento assiale così definito è indipendente dalla scelta del polo lungo la retta.

15.04.02.02 Momento of an Applied Vector With Respect to a Point (Polar Momentum)

Sia $\mathbf{f}$ un vettore applicato in P. Il momento (polare) del vettore $\mathbf{f}$ rispetto ad un polo O, γ_O, è definito come

$$\boxed{\gamma_O \equiv \mathbf{x}_{PO} \wedge \mathbf{f} \qquad \text{applied in } P; \qquad \text{with} \qquad \mathbf{x}_{PO} \equiv (\mathbf{x}_P - \mathbf{x}_O)} \quad . \tag{15.04.02}$$

→ 1061

Il vettore $\mathbf{x}_{PO} \equiv (\mathbf{x}_P - \mathbf{x}_O)$ è il vettore che individua la posizione di P rispetto ad O, cioè la posizione di P relativa ad O.

Il momento di un vettore applicato $\mathbf{f}$ è un vettore che va considerato come un **vettore applicato nel punto di applicazione** del vettore $\mathbf{f}$. In tal modo si definisce per un qualunque polo, a partire da un campo vettoriale $\mathbf{f}$, un altro campo vettoriale: il campo vettoriale dei momenti rispetto al polo O, fisso.

Therefore for a given vector field and a pole one can build a second vector field, the field of momentum of the vector with respect to the pole, such that at any point is space two vectors are applied: the vector itself and its momentum with respect to the pole.

Il modulo del momento del vettore è uguale al prodotto tra il modulo del vettore e il braccio del vettore rispetto al polo dato. Equivalentemente il modulo del momento del vettore è uguale alla distanza del punto di applicazione del vettore dal polo moltiplicata per il modulo della proiezione del vettore nella direzione perpendicolare al vettore $\mathbf{x}_{PO}$ nel piano contenente la retta d'azione del vettore e il polo.

Pole-Dependent Momentum - Change of Pole

Il momento di un vettore $\mathbf{f}$ varia al variare del polo secondo la relazione

$$\boxed{\gamma_B = \gamma_A + \mathbf{x}_{AB} \wedge \mathbf{f} = \gamma_A + (\mathbf{x}_A - \mathbf{x}_B) \wedge \mathbf{f}} \quad , \tag{15.04.03}$$

→ 1061 1066 1536

dove $\mathbf{x}_{AB} \equiv \mathbf{x}_A - \mathbf{x}_B$ è il vettore posizione del polo A rispetto al polo B.

The relation shows that the momentum with respect to a certain pole is given by the momentum around any other pole plus the momentum, with respect to the pole, of the vector as if applied at the other pole.

Note that the total momentum includes a contribution from a intrinsic momentum, which is independent from the pole and therefore does not appear in (15.04.03).

When, for a pole-dependent momentum, the pole is not written it is assumed to be the origin of the Coordinate System.

Pole-Independent Momentum (Intrinsic Momentum)

Often in physics, **momenta independent from any pole appear** (**spin** and **torque**, for instance) and have a major role.

Pole-independent momenta will be denoted as:

$$\boxed{\tilde{\gamma}[\mathbf{x}] \qquad \text{with} \qquad \tilde{\gamma}_A[\mathbf{x}] = \tilde{\gamma}_B[\mathbf{x}] \qquad \forall A, B} \quad . \tag{15.04.04}$$

Pole-independent momenta must be thought as real momenta not arising by a vector $\mathbf{f}$, that is not arising from the (15.04.02) relation, applied at a point.

Pole-independent momenta do not affect sums of the applied vectors but do affect total momenta of applied vectors: they must be included in the sum to find the total momentum: see equations (15.04.05) and (15.04.06).

DRAFT IN PROGRESS

15.04.02.02.1 Examples

Force

Let us consider a system of applied forces and call torque a momentum of a system of forces which is independent form the pole. This is a primitive concept, which can be also seen as a limiting case of systems of vectors with zero sum and non-zero total momentum, for instance any set of n identical vectors applied at the vertexes of a regular polygon with n-sides making the same angles with respect the line joining the vertex with the center of the polygon.

Read § 36.05.02.02 and § 36.05.04.

- Force: the force applied vector field.
- Polar momentum of the force.
- Torque: the pole-independent momentum applied vector field; applied vector at the point where the torque acts.
- Total Momentum of the force: torque plus polar momentum of the force.

Linear Momentum

- Linear Momentum: the Linear Momentum applied vector field.
- Polar Linear Momentum: orbital angular momentum.
- Spin: the pole-independent angular momentum applied vector field; applied vector at the point where the spin acts.
- Total Angular Momentum: orbital plus spin angular momentum.

15.04.02.03 Sum and Sum of Momenta of a System of Applied Vectors

Discrete case

Sia dato un sistema di vettori $\mathbf{f}_k$ e di torques $\tilde{\gamma}_k$ applicati nei punti P_k. Si definiscono la risultante, $\mathbf{F}$, e il momento risultante rispetto ad un polo O arbitrario, $\mathbf{\Gamma}_0$, come:

$$\boxed{\mathbf{F} \equiv \sum_k \mathbf{f}_k \qquad \text{a free vector}} \quad ,$$

$$\boxed{\mathbf{\Gamma}_0 \equiv \sum_k \left(\mathbf{x}_{P_k 0} \wedge \mathbf{f}_k + \tilde{\gamma}_k \right) \qquad \text{a vector applied in the pole O;}} \quad . \tag{15.04.05}$$

→ 1061

Continuous case

Let the vector and torque fields, $\mathbf{f}[\mathbf{x}]$, $\tilde{\gamma}[\mathbf{x}]$.

$$\boxed{\mathbf{F} \equiv \iiint \mathrm{d}\mathbf{f}[\mathbf{x}] \qquad \text{a free vector}} \quad ,$$

$$\boxed{\mathbf{\Gamma}_0 \equiv \iiint \left((\mathbf{x} - \mathbf{x}_0) \wedge \mathrm{d}\mathbf{f}[\mathbf{x}] + \mathrm{d}\tilde{\gamma}[\mathbf{x}] \right) \qquad \text{a vector applied in the pole O;}} \quad . \tag{15.04.06}$$

→ 1061

DRAFT-EW-IN-PROGRESS

Properties

La risultante di un sistema di vettori applicati è un vettore libero, non dipendendo la sua definizione da alcun punto privilegiato, mentre **il momento risultante può essere considerato un vettore applicato nel polo**. Il momento risultante può essere quindi considerato un campo vettoriale al variare del polo.

La relazione tra i momenti del sistema rispetto a due poli A e B è data da

$$\boxed{\boldsymbol{\Gamma}_B = \boldsymbol{\Gamma}_A + \mathbf{x}_{AB}\wedge\mathbf{F} = \boldsymbol{\Gamma}_A + (\mathbf{x}_A - \mathbf{x}_B)\wedge\mathbf{F}} \tag{15.04.07}$$

→ 1063 1064 1442

dove $\mathbf{x}_{AB} \equiv \mathbf{x}_A - \mathbf{x}_B$ è il vettore posizione del polo A rispetto al polo B.

In particolare se la risultante è nulla il momento è indipendente dal polo.

Dalla (15.04.07) si deduce che

$$\boxed{I \equiv \mathbf{F}\cdot\boldsymbol{\Gamma}_O = \text{indipendente da } O} \quad .$$

La grandezza $I \equiv \mathbf{F}\cdot\boldsymbol{\Gamma}_O$, indipendente dal polo, è detta invariante scalare del sistema di vettori applicati.

15.04.02.04 Central Axis

If $\mathbf{F} = 0$ the resultant momentum does not depend on the pole.

If $\mathbf{F} \neq 0$ the resultant momentum do depend on the pole but its projection on $\mathbf{F}$ is an invariant for changes of pole.

Let us assume $\mathbf{F} \neq 0$. Consider the projections of $\boldsymbol{\Gamma}_P$ along and perpendicular to $\mathbf{F}$. The component along $\mathbf{F}$ does not depend on the pole while the component perpendicular to $\mathbf{F}$ does depend on it.

Starting from

$$\boldsymbol{\Gamma}_P = \frac{I\mathbf{F}}{F^2} + \frac{\mathbf{F}\wedge(\boldsymbol{\Gamma}_P\wedge\mathbf{F})}{F^2} \quad ,$$

one can write:

$$\boldsymbol{\Gamma}_P = \frac{I\mathbf{F}}{F^2} + \mathbf{F}\wedge\left(\frac{\boldsymbol{\Gamma}_O\wedge\mathbf{F}}{F^2} + (\mathbf{x}_P - \mathbf{x}_O)\right) \quad .$$

The central axis is defined as the locus of the points (poles) in space such that the momentum reduces to the part parallel to $\mathbf{F}$ only. Therefore one can choose an arbitrary point and solve for the unknown point P such that:

$$\mathbf{F}\wedge\left(\frac{\boldsymbol{\Gamma}_O\wedge\mathbf{F}}{F^2} + (\mathbf{x}_P - \mathbf{x}_O)\right) = \mathbf{0} \quad .$$

The vector equation, according to § 17.02, is solved by:

$$\frac{\boldsymbol{\Gamma}_O\wedge\mathbf{F}}{F^2} + (\mathbf{x}_P - \mathbf{x}_O) = \lambda[P]\mathbf{F} \quad ,$$

for any real $\lambda[P]$, that is:

$$\boxed{(\mathbf{x}_P - \mathbf{x}_O) = \lambda[P]\mathbf{F} - \frac{\boldsymbol{\Gamma}_O\wedge\mathbf{F}}{F^2}} \quad , \tag{15.04.08}$$

→ 1063 1064

showing that the result is a straight line parallel to $\mathbf{F}$.

The particular solution of equation (15.04.08)

$$\boxed{(\mathbf{x}_P - \mathbf{x}_O) = \frac{\mathbf{F}\wedge\boldsymbol{\Gamma}_O}{F^2}} \quad ,$$

determines in a unique way the point of the central axis in the plane perpendicular to the vector $\mathbf{F}$ and passing by the pole O.

If any point C belongs to the central axis the resultant momentum can be written as:

$$\boldsymbol{\Gamma}_C = \frac{I\mathbf{F}}{F^2} \quad , \tag{15.04.09}$$

and the transformation law becomes

$$\boldsymbol{\Gamma}_P = \boldsymbol{\Gamma}_C + (\mathbf{x}_C - \mathbf{x}_P)\wedge\mathbf{F} = \frac{I\mathbf{F}}{F^2} + (\mathbf{x}_C - \mathbf{x}_P)\wedge\mathbf{F} \quad . \tag{15.04.10}$$

DRAFT IN PROGRESS

Note that a central axis can be constructed only for systems with non zero resultant, as it is clear from relation (15.04.08).

15.04.02.05 Equivalent Systems of Applied Vectors

Due sistemi di vettori applicati si dicono **equivalenti se hanno lo stesso risultante e lo stesso momento rispetto ad ogni polo**.

Se due sistemi di vettori applicati **hanno la stessa risultante e lo stesso momento rispetto ad un polo qualunque allora sono equivalenti**, grazie alla (15.04.07).

Esistono tre categorie elementari di sistemi di vettori applicati.

1. Il sistema nullo, formato dal vettore nullo, per cui si ha $\mathbf{F} = 0$, $\mathbf{\Gamma}_0 = 0$ ed $I = 0$.
2. Il sistema costituito da un singolo vettore $\mathbf{f}$ applicato in un punto P. Questo sistema ha sempre invariante scalare nullo, $I = 0$. Infatti si ha $\mathbf{F} = \mathbf{f}$ e, in generale, $\mathbf{\Gamma}_0 \neq 0$. Però per ogni punto C della retta d'azione del vettore si ha $\mathbf{\Gamma}_C = 0$. L'invariante scalare è quindi nullo per il polo C e quindi nullo per ogni polo. Alternativamente si può osservare che il momento rispetto ad un polo qualunque è sempre ortogonale al vettore risultante.
3. Una coppia, cioè il sistema costituito da due vettori $\mathbf{f}_1$ e $\mathbf{f}_2$, uguali ed opposti, applicati in due punti P_1 e P_2. La distanza tra le rette d'azione dei due vettori è detto braccio della coppia. Si ha $\mathbf{F} = 0$, e, in generale, $\mathbf{\Gamma}_0 \neq 0$ (eccetto il caso di coppia a braccio nullo, quando cioè le rette d'azione dei due vettori coincidono). Si ha quindi $I = 0$. Il momento non dipende dal polo ed è detto semplicemente momento della coppia.

I tre sistemi sono in generale tra loro non equivalenti, salvo casi particolari di vettori nulli oppure coppia a braccio nullo. Inoltre tutti e tre hanno invariante scalare nullo.

Given any system of vectors with null scalar invariant two cases are possible, as follows.

- Suppose $\mathbf{F} = 0$. In this case the momentum is independent on the pole and the system is equivalent to a torque of momentum Γ_O;
- Suppose $\mathbf{F} \neq 0$. In this case the system admits a central axis. Fixed an arbitrary point, C, on the central axis, as $I = 0$, one has, from equation (15.04.10):

$$\mathbf{\Gamma}_P = (\mathbf{x}_C - \mathbf{x}_P) \wedge \mathbf{F} \quad .$$

The system is thus equivalent to a single force, equal to the resultant, applied at any point on the central axis.

Sistemi Di Vettori Applicati Riducibili Ed Irriducibili

Un sistema di vettori applicati è detto riducibile se è equivalente ad uno dei tre sistemi elementari di vettori.

La condizione di invariante scalare nullo è necessaria e sufficiente affinché un sistema sia riducibile.

Si ha il fondamentale risultato che **un qualunque sistema irriducibile di vettori applicati, cioè ad invariante scalare diverso da zero, può sempre essere ridotto ad un sistema equivalente composto da un vettore applicato e da una coppia**, che è il più semplice sistema equivalente ad un sistema irriducibile.

Let us determine the simplest system to which an irreducible system can be reduced, by equivalence. As $I \neq 0$ one has $\mathbf{F} \neq 0$ and therefore an irreducible system admits a central axis.

- Equation (15.04.10) implies that the system has the same total force and total torque as a system made of a vector, $\mathbf{V}$, applied on the central axis, plus a torque having momentum $\mathbf{\Gamma}$, with:

$$\boxed{\mathbf{V} = \mathbf{F} \qquad \text{applied on the central axis;} \qquad \mathbf{\Gamma} = I\mathbf{F}/F^3} \quad .$$

Note that in this case $\mathbf{V}$ and $\mathbf{\Gamma}$ are collinear.
- One second alternative equivalent set is given by a vector, $\mathbf{V}$, with line of action passing by O, plus a torque having momentum $\mathbf{\Gamma}$, with:

$$\boxed{\mathbf{V} = \mathbf{F} \qquad \text{with line of action passing by } O; \qquad \mathbf{\Gamma} = \mathbf{\Gamma}_0} \quad .$$

- As a particular case of the previous case, and one often used in practice, one can choose:

$$\boxed{\mathbf{V} = \mathbf{F} \qquad \text{applied in } O; \qquad \mathbf{\Gamma} = \mathbf{\Gamma}_0} \quad .$$

DRAFT - IN PROGRESS

15.04.02.06 Effects of a System of Forces on a Mechanical System

The effect of a system of force on a system is the following.

The sum of a system of forces (that is the total force) affects the linear motion of the Center-Of-Mass.

The total torque, that is the sum of the momenta of forces (that is the total momentum of the forces) with respect to any pole, plus the sum of the intrinsic, independent from the pole, torques (that is the total intrinsic torque), affect the angular momentum of the system with respect to that pole.

Any system of Force|Torque with zero total force and zero total torque with respect to any pole has no effect on the total momentum nor on the total angular momentum of the system around the pole. Nevertheless, it may have important effects on the motion, causing deformations of the system.

15.05 Examples and Physical Applications

DRAFT - TW - PRACE

15.05.01

✓ Change of Pole in the Momentum

Demonstrate equation (15.04.03).

15.05.02

✓ Arm of an Applied Vector With Respect to a Pole

Let the vector $\mathbf{f}$ be applied in the pole P. Write a vector relation giving the vector originating from the pole P and directed to the point of closest approach of the line of action of the vector to the pole, whose module is the arm.

15.05.03

✓ Axial Moment

Show that the axial moment defined in (15.04.01) is independent from the choice of the point R.

15.05.04

✓ Independence From the Origin of the Center-Of-Mass

Show that the position of the Center-Of-Mass of a set of point particles is independent from the choice of the origin of the Coordinate System.

15.05.05

✓ Centrifugal Force

Consider a non-inertial Rest Frame such that $\boldsymbol{\Omega}$ has a constant fixed direction. Let the origin of the Coordinate System located on the rotation axis. Let $\mathbf{r}$ be the position vector of a point with respect to the non-Inertial Reference Frame . Consider the expression of the centrifugal force,

$$\mathbf{f}_c = -m\,\boldsymbol{\Omega}\wedge(\boldsymbol{\Omega}\wedge\mathbf{r}) = +m\,\boldsymbol{\Omega}\wedge(\mathbf{r}\wedge\boldsymbol{\Omega}) = +m\Omega^2\,\mathbf{n}\wedge(\mathbf{r}\wedge\mathbf{n}) \quad ,$$

in terms of the unit vector in the direction of the angular velocity Ω, $\widehat{\mathbf{n}}$, and write it in a suitable alternative form.

What happens if the Coordinate System has its origin outside the axis of rotation? Is the above formula still exact?

WORKED SOLUTION

Use (15.03.03.02):

$$\mathbf{f}_c = m\left(\Omega^2\mathbf{r} - \boldsymbol{\Omega}\,(\mathbf{r}\cdot\boldsymbol{\Omega})\right) \quad .$$

This shows that the force only depends on the distance from the rotation axis and is always radially directed away from it. It follows from equation (15.03.10) that the centrifugal force is proportional to the component of $\mathbf{r}$ perpendicular to the direction of $\boldsymbol{\Omega}$.
Equation (15.03.10) shows that the centrifugal force is proportional to the component of the position vector $\mathbf{r}$ perpendicular to the direction of $\boldsymbol{\Omega}$.

15.05.09
☒ (Non-)Relativistic Charged Particle in a Uniform and Constant Magnetic Field

This § is referenced at pages:
[1070, 1070, 2425, 2475]

Consider a charged point particle inside a constant and uniform magnetic field $\mathbf{B}$. The particle has, at time t_0, the velocity $\mathbf{v}_0$. Determine the trajectory of the particle:

1. for a low-speed motion;
2. for a relativistic motion.

DRAFT - IN PROGRESS

WORKED SOLUTION

The non-relativistic motion is just special case of the generic relativistic one:

1. for a low-speed motion assume, in the calculations below, $\gamma[v] = 1$;
2. for a relativistic motion assume, in the calculations below, $\gamma[v] = 1/\sqrt{1-v^2}$.

Let $\mathbf{B} \equiv B\widehat{\mathbf{e}}_z$ and decompose the velocity and linear momentum in its components parallel and perpendicular to the magnetic field:

$$\begin{aligned} \mathbf{v} &\equiv \mathbf{v}_\parallel + \mathbf{v}_\perp \quad , \\ \gamma = \gamma[v] &\neq \gamma[\mathbf{v}_\parallel] \quad , \\ \gamma = \gamma[v] &\neq \gamma[\mathbf{v}_\perp] \quad , \\ \mathbf{p} \equiv m\gamma\mathbf{v} \equiv m\gamma\left(\mathbf{v}_\parallel + \mathbf{v}_\perp\right) &\equiv m\gamma\mathbf{v}_\parallel + m\gamma\mathbf{v}_\perp \equiv \mathbf{p}_\parallel + \mathbf{p}_\perp \quad . \end{aligned}$$

The equation of motion in presence of magnetic field only is:

$$\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = q\,\mathbf{v}\wedge\mathbf{B} = q\left(\mathbf{v}_\perp + \mathbf{v}_\parallel\right)\wedge\mathbf{B} = q\,\mathbf{v}_\perp\wedge\mathbf{B} = \frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} + \frac{\mathrm{d}\mathbf{p}_\perp}{\mathrm{d}t} = \frac{\mathrm{d}\mathbf{p}_\perp}{\mathrm{d}t} \quad , \tag{15.05.03}$$

→ 1068

where the last passage derives from the fact that the Lorentz force lies in the plane perpendicular to $\mathbf{B}$ and therefore

$$\frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} = 0 \quad ,$$

because

$$\frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} \parallel \mathbf{B} \quad ,$$

due to the fact that

$$\mathbf{v}_\parallel \equiv v_\parallel\widehat{\mathbf{e}}_z \implies \frac{\mathrm{d}\mathbf{v}_\parallel}{\mathrm{d}t} = \frac{\mathrm{d}v_\parallel}{\mathrm{d}t}\widehat{\mathbf{e}}_z \parallel \widehat{\mathbf{e}}_z \implies \frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} = m\frac{\mathrm{d}\gamma[v]\mathbf{v}_\parallel}{\mathrm{d}t} = m\gamma[v]\frac{\mathrm{d}\mathbf{v}_\parallel}{\mathrm{d}t} \equiv m\gamma[v]\frac{\mathrm{d}v_\parallel}{\mathrm{d}t}\widehat{\mathbf{e}}_z \parallel \mathbf{B} \quad ,$$

because energy conservation implies:

$$\frac{\mathrm{d}\gamma[v]}{\mathrm{d}t} = 0 \quad .$$

In other words the equation of motion (15.05.03) implies:

$$\widehat{\mathbf{e}}_z\cdot(\,\mathbf{v}_\perp\wedge\mathbf{B}) = 0 \implies 0 = \frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} = m\gamma\frac{\mathrm{d}\mathbf{v}_\parallel}{\mathrm{d}t} = m\gamma\frac{\mathrm{d}v_\parallel}{\mathrm{d}t}\widehat{\mathbf{e}}_z = 0 \implies \boxed{v_\parallel = \text{constant}} \quad .$$

Alternatively, in a simpler way, one can write:

$$0 = \mathbf{v}\cdot\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = m\gamma\,\mathbf{v}\cdot\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = \mathbf{p}\cdot\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\,\mathbf{p}\cdot\mathbf{p}) \implies |\mathbf{p}| = \text{constant} \implies |\mathbf{v}| = \text{constant} \quad ,$$

to find again that that the module of the velocity is constant, as well as the γ factor.
The same result could be obtained from the energy equation for a point particle:

$$\frac{\mathrm{d}\epsilon}{\mathrm{d}t} = \pi = \mathbf{f}\cdot\mathbf{v} \quad .$$

The equation of motion (15.05.03) is reduced to a plane equation of motion in the plane perpendicular to the magnetic field plus a constant velocity motion along the direction of the magnetic field:

$$\frac{\mathrm{d}\mathbf{p}_\perp}{\mathrm{d}t} = q\,\mathbf{v}_\perp\wedge\mathbf{B} \quad ,$$

$$\frac{\mathrm{d}\mathbf{p}_\parallel}{\mathrm{d}t} = 0 \implies \mathbf{p}_\parallel = \text{constant} \implies \mathbf{v}_\parallel = \text{constant} \qquad \text{because } \gamma \text{ is constant} \quad .$$

Therefore not only the module of the velocity is constant but also the module of the component of the velocity parallel to the magnetic field is constant and thus also the module of the component of the velocity perpendicular to the magnetic field is constant as well:

$$|\mathbf{p}_\perp| = \text{constant} \quad .$$

CC BY NC ND

We can therefore limit ourselves to only study motion in the plane perpendicular to $\mathbf{B}$. In this plane:

$$\frac{\mathrm{d}\mathbf{v}_\perp}{\mathrm{d}t} = \widehat{\mathbf{T}}\frac{\mathrm{d}v_\perp}{\mathrm{d}t} + \widehat{\mathbf{N}}\frac{v_\perp^2}{\rho} = 0 + \widehat{\mathbf{N}}\frac{v_\perp^2}{\rho} = \frac{q}{m\gamma}(\mathbf{v}_\perp \wedge \mathbf{B}) = \frac{qv_\perp B}{m\gamma}\left(\widehat{\mathbf{T}}\wedge\widehat{\mathbf{e}}_z\right) \quad .$$

Taking the modules of the resulting equation,

$$\boxed{\widehat{\mathbf{N}}\frac{v_\perp^2}{\rho} = \frac{q}{m\gamma}(\mathbf{v}_\perp \wedge \mathbf{B})} \quad ,$$

where all quantities are already known to be constant except for the radius of curvature, ρ, and accounting for the fact that $\mathbf{v}_\perp$ and $\mathbf{B}$ are perpendicular, one finds:

$$\boxed{q\rho B = m\gamma[v]v_\perp \equiv p_\perp} \quad , \tag{15.05.04}$$

→ 1069

showing that the radius of curvature is also constant, that is the trajectory is a circumference. Note that in this relation (15.05.04): $\gamma = \gamma[v]$ and $\gamma \neq \gamma[v_\perp]$.
The **Larmor Frequency** follows from equation (15.05.04):

$$\boxed{\Omega_\mathrm{L} \equiv \frac{2\pi}{T} = \frac{v_\perp}{\rho} = \frac{qB}{m\gamma}} \quad . \tag{15.05.05}$$

→ 1069

The **Larmor Frequency** equation (15.05.05) determines, among many other things, the way circular particle accelerators work, showing, in particular, that the revolution frequency is only constant for non-relativistic particles (cyclotron) while it changes for relativistic particles (synchrotron, sometimes known as a synchro-cyclotron).
Equation (15.05.04) shows that in a circular particle accelerator the final energy for any given particle will only depend on the product ρB: this is one of reasons why one is lead to build larger and larger circular particle accelerators to get higher energies; another reason is that increasing ρ the energy irradiated by the particles tends to decrease.
As in a cyclotron the magnetic field does not depend on time the radius of the orbit will increase, as it is shown by equation (15.05.05).
When the particle becomes relativistic the **Larmor Frequency** changes and the orbital period changes: the synchro-cyclotron is built to change the frequency of the acceleration fields to be synchronous with the **Larmor Frequency** .
As in a synchrotron the radius of the orbit is kept constant the magnetic field has to increase.
See[a] for more details.
The equation in vector form also determines the handedness of the curvature of the trajectory in the plane, showing that its sign depends on the charge of the particle.
Another way to obtain the same result is the one proposed in problem § 15.05.10.
If an electric field is also present the motion due to the electric field can be superimposed to the motion due to the magnetic field. However, in this case:

$$\frac{\mathrm{d}\epsilon}{\mathrm{d}t} = \pi = q\,\mathbf{v}\cdot\mathbf{E} \quad .$$

15.05.10
☒ Spin Precession in a Constant and uniform magnetic field

This § is referenced at pages:
[1067, 2425, 2475]

Determine the solution to the (classical) spin-precession equation:

$$\boxed{\frac{\mathrm{d}\mathbf{s}}{\mathrm{d}t} = g\,\mathbf{s}\wedge\mathbf{B}} \quad , \tag{15.05.06}$$

→ 1070

for a fixed spin vector, s, where g is a constant and $\mathbf{B}$ is a constant and uniform magnetic field.

WORKED SOLUTION

One can take the advantage of using complex vectors as follows.

First Solution

$$\dot{\mathbf{s}} = g\,\mathbf{s}\wedge\mathbf{B} \quad ,$$
$$\mathbf{s} = \mathbf{s}_0 \exp[\mathrm{i}\omega t] \qquad \text{with } \mathbf{s} \text{ and } \mathbf{s}_0 \text{ complex vectors;} \quad ,$$
$$\mathbf{s}_0 = \frac{g}{\mathrm{i}\omega}\mathbf{s}_0\wedge\mathbf{B} \quad ,$$
$$\mathbf{s} \equiv \mathbf{s}_\mathrm{R} + \mathrm{i}\mathbf{s}_\mathrm{I} \quad ,$$
$$\mathbf{s}_\mathrm{R} = +\frac{g}{\omega}\mathbf{s}_\mathrm{I}\wedge\mathbf{B} \tag{15.05.07}$$

→ 1070

$$\mathbf{s}_\mathrm{I} = -\frac{g}{\omega}\mathbf{s}_\mathrm{R}\wedge\mathbf{B} \tag{15.05.08}$$

→ 1070

$$\Longrightarrow \mathbf{s}_\mathrm{R}\cdot\mathbf{s}_\mathrm{I} = 0 \quad ,$$
$$\Longrightarrow \mathbf{s}_\mathrm{R}\cdot\mathbf{B} = 0 \quad ,$$
$$\Longrightarrow \mathbf{s}_\mathrm{I}\cdot\mathbf{B} = 0 \quad .$$

From (15.05.07), (15.05.08) (take one of either $\mathbf{s}_\mathrm{R}$ or $\mathbf{s}_\mathrm{I}$ and replace in the other equation) one finds that, in order to have a non zero s, it is required that $\omega = \gamma B$.
Then take $\mathbf{B} = B\widehat{\mathbf{e}}_3$ and

$$\mathbf{s}_\mathrm{R} = |\mathbf{s}_0|\{+\cos[\alpha], +\sin[\alpha], 0\} \quad ,$$
$$\mathbf{s}_\mathrm{I} = |\mathbf{s}_0|\{-\sin[\alpha], +\cos[\alpha], 0\} \quad .$$

that is a solution. Finally:

$$\mathbf{s}_0 = \exp[\mathrm{i}\omega t](\mathbf{s}_\mathrm{R} + \mathrm{i}\mathbf{s}_\mathrm{I}) \Longrightarrow \begin{cases} \mathbf{s}_0\big|_x = |\mathbf{s}_0|\exp[\mathrm{i}\omega t]\exp[\mathrm{i}\alpha] & , \\ \mathbf{s}_0\big|_y = |\mathbf{s}_0|\exp[\mathrm{i}\omega t]\exp[\mathrm{i}(\alpha - \pi/2)] \end{cases} .$$

Second Solution

By following exactly the same steps and usign the same conventions as in problem § 15.05.09, with the simplification given by $\gamma \equiv 1$ in the curretn case, one passes from equation (15.05.06) to equation:

$$\frac{\mathrm{d}\mathbf{s}_\perp}{\mathrm{d}t} = g\,\mathbf{s}_\perp\wedge\mathbf{B} \qquad \frac{\mathrm{d}\mathbf{s}_\parallel}{\mathrm{d}t} = 0 \qquad \text{with} \qquad \mathbf{s} = s_\parallel\widehat{\mathbf{e}}_\parallel + s_\perp\widehat{\mathbf{e}}_\perp \quad . \tag{15.05.09}$$

It follows:

$$g\,\mathbf{s}_\perp\wedge\mathbf{B} = \frac{\mathrm{d}\mathbf{s}_\perp}{\mathrm{d}t} \quad ,$$

and

$$0 = \mathbf{s}_\perp \cdot \frac{\mathrm{d}\mathbf{s}_\perp}{\mathrm{d}t} \qquad \Longrightarrow \qquad |\mathbf{s}_\perp| = \text{constant} \quad .$$

Now, in the plane perpendicular to $\mathbf{B}$, one can write:

$$\mathbf{s}_\perp = s_\perp \widehat{\mathbf{e}}_r \quad ,$$

$$\frac{\mathrm{d}\mathbf{s}_\perp}{\mathrm{d}t} = s_\perp \dot{\theta} \widehat{\mathbf{e}}_\theta = g\, \mathbf{s}_\perp \wedge \mathbf{B} = -g s_\perp B \widehat{\mathbf{e}}_\theta \quad .$$

Note the minus sign deriving from the vector product:

$$\widehat{\mathbf{e}}_r \wedge \mathbf{B} \sim -\widehat{\mathbf{e}}_\theta \quad .$$

The **Larmor Frequency** is thus:

$$\boxed{\dot{\theta} = -gB} \quad .$$

This is coherent with the results of problem § 15.05.09 as

$$g \Leftrightarrow \frac{q}{m\gamma} \quad .$$

15.05.11

✓ Center of Gravity

Consider an extended mass body with mass density $\rho[\mathbf{x}]$. Weight acts on every infinitesimal mass as $\mathrm{d}\mathbf{f} = \mathbf{g}\ \mathrm{d}m$.

Show that the total force and total momentum with respect to a pole O are:

$$\mathbf{F} = M\mathbf{g} \qquad \boldsymbol{\Gamma}_0 = M\,(\mathbf{X}_{\mathrm{CM}} - \mathbf{x}_0) \wedge \mathbf{g} \quad . \tag{15.05.10}$$

15.05.12

☒ Distributed Load

Su un segmento orizzontale AB di lunghezza L (asse x orizzontale) agisce un sistema continuo di vettori applicati, distribuito con densità $\mathbf{f}[x] = -p\,(x/L)\,\widehat{\mathbf{e}}_2$ dove la costante p ha le dimensioni di una forza ed x è la distanza da A del generico punto P di AB. Determinare risultante e momento risultante rispetto ad A del sistema di forze e determinare un sistema di vettori applicati equivalente formato da un solo vettore.

$$\epsilon^{\cdot\cdot\cdot}_{ijk}\epsilon^{\cdot\cdot\cdot}_{ijk} = 6 \quad ,$$
$$\boxed{\epsilon^{\cdot\cdot\cdot}_{ijk}\epsilon^{\cdot\cdot\cdot}_{pqk} = \delta^{\cdot\cdot}_{ip}\delta^{\cdot\cdot}_{jq} - \delta^{\cdot\cdot}_{iq}\delta^{\cdot\cdot}_{jp}} \quad .$$

15-010 Properties of the Levi-Civita symbol for hyper-volume calculations

This § is referenced at pages:
[Never referenced.]

1. Show how the 2D **Levi-Civita symbol** can be used to calculate the hyper-volume in 2 dimensions, that is area, by using it to express the area spanned by two vectors. Read § 15.03.02.02
2. Show how the 3D **Levi-Civita symbol** can be used to calculate the hyper-volume in 3 dimensions, that is volume, by using it to express the volume spanned by three vectors. Read § 15.03.03.01.

15-011 ☒ Perpendicularity of Vectors

Show that two vectors $\mathbf{a}$ and $\mathbf{b}$ are perpendicular if and only if:

$$|\mathbf{a}+\mathbf{b}| = |\mathbf{a}-\mathbf{b}| \quad .$$

15-012 ✓ Some Algebraic Vector Identities

Let the vectors $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, $\mathbf{d}$, $\mathbf{p}$ and the unit vector $\widehat{\mathbf{n}}$.
Show that:

$$|\,\mathbf{n}\wedge\mathbf{p}| = |\,\mathbf{n}\wedge(\,\mathbf{p}\wedge\mathbf{n})| \quad .$$

WORKED SOLUTION

Show that:

$$|\,\mathbf{a}\wedge\mathbf{b}|^2 = a^2b^2 - (\,\mathbf{a}\cdot\mathbf{b})^2 \quad .$$

WORKED SOLUTION

Show that:

$$(\,\mathbf{a}\wedge\mathbf{b})\cdot(\,\mathbf{a}\wedge\mathbf{c}) = a^2\,(\,\mathbf{b}\cdot\mathbf{c}) - (\,\mathbf{a}\cdot\mathbf{c})\,(\,\mathbf{a}\cdot\mathbf{b}) \quad . \qquad (15.06.04)$$

→ 1080

WORKED SOLUTION

Deriva dalla (15.03.09) e dalla (15.03.03.02).

Show that:

$$(\,\mathbf{a}\wedge\mathbf{b})\wedge(\,\mathbf{a}\wedge\mathbf{c}) = \mathbf{a}\,(\,\mathbf{c}\cdot(\,\mathbf{a}\wedge\mathbf{b})) \quad . \qquad (15.06.05)$$

→ 1080

BRIEF NEW-PROGRESS

WORKED SOLUTION

Deriva dalla (15.03.09) e dalla (15.03.03.02).

Show that:

$$(\mathbf{a}\wedge\mathbf{b})\cdot(\mathbf{c}\wedge\mathbf{d}) = (\mathbf{a}\cdot\mathbf{c})(\mathbf{b}\cdot\mathbf{d}) - (\mathbf{a}\cdot\mathbf{d})(\mathbf{b}\cdot\mathbf{c}) \quad . \tag{15.06.06}$$

WORKED SOLUTION

Deriva dalla (15.03.09) e dalla (15.03.03.02).

Show that:

$$(\mathbf{a}\wedge\mathbf{b})\wedge(\mathbf{c}\wedge\mathbf{d}) = \mathbf{b}(\mathbf{a}\cdot(\mathbf{c}\wedge\mathbf{d})) - \mathbf{a}(\mathbf{b}\cdot(\mathbf{c}\wedge\mathbf{d})) = \mathbf{c}(\mathbf{d}\cdot(\mathbf{a}\wedge\mathbf{b})) - \mathbf{d}(\mathbf{c}\cdot(\mathbf{a}\wedge\mathbf{b})) \quad . \tag{15.06.07}$$

→ 1077

WORKED SOLUTION

Deriva dalla (15.03.09) e dalla (15.03.03.02).

Show that:

$$(\mathbf{a}\wedge(\mathbf{b}\wedge\mathbf{c}))\wedge\mathbf{c} = (\mathbf{a}\cdot\mathbf{c})(\mathbf{b}\wedge\mathbf{c}) \quad . \tag{15.06.08}$$

WORKED SOLUTION

Show that:

$$(\mathbf{a}\wedge(\mathbf{b}\wedge\mathbf{c}))\cdot(\mathbf{a}\wedge(\mathbf{b}\wedge\mathbf{c})) = (\mathbf{a}\cdot\mathbf{c})^2 b^2 + (\mathbf{a}\cdot\mathbf{b})^2 b^2 c^2 - 2(\mathbf{a}\cdot\mathbf{b})(\mathbf{b}\cdot\mathbf{c})(\mathbf{c}\cdot\mathbf{a}) \quad . \tag{15.06.09}$$

WORKED SOLUTION

Show that:

$$\mathbf{a}\wedge(\mathbf{b}\wedge(\mathbf{c}\wedge\mathbf{d})) = \mathbf{b}(\mathbf{a}\cdot(\mathbf{c}\wedge\mathbf{d})) - \mathbf{a}\cdot\mathbf{b}\,\mathbf{c}\wedge\mathbf{d} \quad . \tag{15.06.10}$$

→ 2252

WORKED SOLUTION

15-013 ✓ Distance of a Point From a Line

This § is referenced at pages:
[1142]

Consider a line passing through the point O, whose position vector is $\mathbf{r}_0$, and is parallel to the unit vector $\widehat{\mathbf{n}}$. If the point P has position vector $\mathbf{r}$ demonstrate that the distance of P from the line is:

$$\boxed{d = |(\mathbf{r}-\mathbf{r}_0)\wedge\widehat{\mathbf{n}}|} \quad .$$

DRAFT - NOT FOR DISTRIBUTION

15-014 ✓ Distance of a Point From a Plane

This § is referenced at pages:
[Never referenced.]

Write a formula for the distance of a point from a plane as a function of the three vectors, $\widehat{\mathbf{n}}$, $\mathbf{x}_0$, $\mathbf{r}_0$:

$$0 = \widehat{\mathbf{n}}\cdot(\mathbf{x}-\mathbf{x}_0) \qquad \mathbf{r}_0 \quad , \tag{15.06.11}$$

defining the point and the plane.

15-015 ✓ Distance Between Two Lines

This § is referenced at pages:
[1142, 1601]

Consider a line that passes through the point (1), and is parallel to the vector $\widehat{\mathbf{n}}_1$, and a second line passes through (2), and is parallel to the vector $\widehat{\mathbf{n}}_2$.

If $\widehat{\mathbf{n}}_1$ and $\widehat{\mathbf{n}}_2$ and are not parallel show that the distance between the lines is:

$$\boxed{d = \frac{|\,(\mathbf{r}_1-\mathbf{r}_2)\cdot(\,\widehat{\mathbf{n}}_1\wedge\widehat{\mathbf{n}}_2)|}{|(\,\widehat{\mathbf{n}}_1\wedge\widehat{\mathbf{n}}_2)|}} \quad .$$

If $\widehat{\mathbf{n}}_1$ and $\widehat{\mathbf{n}}_2$ and are parallel ($\widehat{\mathbf{n}}_1 = \widehat{\mathbf{n}}_2 \equiv \widehat{\mathbf{n}}$) show that the distance between the lines is:

$$\boxed{d_{\parallel} = \frac{|\,(\mathbf{r}_1-\mathbf{r}_2)\cdot\widehat{\mathbf{n}}|}{|\widehat{\mathbf{n}}|}} \quad .$$

15-016 ✓ Coplanarity of Two Straight Lines

This § is referenced at pages:
[1142]

Let

$$\mathbf{r}_1[t] = \mathbf{r}_{1|0} + \mathbf{v}_1 t \quad ,$$
$$\mathbf{r}_2[t] = \mathbf{r}_{2|0} + \mathbf{v}_2 t \quad .$$

Show that they are co-planar if and only if:

$$\Delta\mathbf{r}\cdot(\,\mathbf{v}_2\wedge\mathbf{v}_1) = 0 \quad ,$$

for any $\Delta\mathbf{r} \equiv \mathbf{r}_2[t_2] - \mathbf{r}_1[t_1]$.

WORKED SOLUTION

Co-planarity condition for 3 vectors: $\mathbf{a}\cdot(\,\mathbf{b}\wedge\mathbf{c}) = 0$.

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|3.29||

Sia N un numero intero, $N > 1$. Dimostrare che

$$\sum_{k=0}^{k=N-1} \cos\left[\frac{2\pi k}{N}\right] = 0 \quad ,$$

$$\sum_{k=0}^{k=N-1} \sin\left[\frac{2\pi k}{N}\right] = 0 \quad .$$

WORKED SOLUTION

Si consideri la somma di N vettori applicati nell'origine e aventi lo stesso modulo ciascuno dei quali forma un angolo $2\pi/N$ con il precedente.

DRAFT IN PROGRESS

15-021 ✓ A Triangle

This § is referenced at pages:
[Never referenced.]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2.11||
©|M.R.Spiegel *et al.*, *Vector Analysis*, 2009, McGraw-Hill, 2ndEd., ...|2.34||

A triangle, that is a plane figure with three vertexes and three sides is the simplest plane figure, that is the one with the smaller number of sides and vertexes. Denote by $\boldsymbol{\ell}_k$, with $k = 1, \dots 3$, the three vectors describing the three sides.

1. Show that one has:
$$\sum_{k=1}^{3} \boldsymbol{\ell}_k = 0 \quad . \tag{15.06.12}$$
This result can be generalised to generic closed polygon and, in the limiting case, to any closed curve.
2. Consider, in the plane, the three vectors perpendicular to each side and module proportional to the length of the side. Show that they sum to zero

15-022 ✓ A Tetrahedron

This § is referenced at pages:
[Never referenced.]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2.11||
©|M.R.Spiegel *et al.*, *Vector Analysis*, 2009, McGraw-Hill, 2ndEd., ...|2.34||

A tetrahedron, that is a solid figure with four vertexes and four triangular faces is the simpler solid figure, that is the one with the smaller number of sides, vertexes and faces. Denote by $\mathbf{a}_k$, with $k = 1, \dots 4$, the four vectors describing the four faces, according to a straightforward generalisation of equation (15.03.05): the vector is normal to the triangular face and its modulus is equal to the are of the face.

Show that one has:
$$\sum_{k=1}^{4} \mathbf{a}_k = 0 \quad . \tag{15.06.13}$$
This result can be generalised to generic closed polyhedra and, in the limiting case, to any closed surface; read § 16-005.

WORKED SOLUTION

The tetrahedron can be generated by any of the three sides with a common vertex, by the three position vectors originating at the common vertex and ending on the opposite vertex of each side. Express $\mathbf{a}_k$ in terms of the six sides via (15.03.04), (15.03.05) and sum.
Consider any closed regular surface approximated by triangulation. Consider any triangular face, an additional point on the surface and the corresponding tetrahedron. Thanks to the relation demonstrated for the tetrahedron, the original face has a surface vector equal to the sum of the three new faces.
By induction, the property is true for four faces and if true for n faces is also true for $n + 1$.

15-023 ✓ A corner reflector

This § is referenced at pages:
[Never referenced.]

Read § 48.02.

Three mutually perpendicular plane reflecting surfaces are hit by a ray of light striking all three surfaces and reflected back. Show that it is reflected back along a direction parallel to the direction of incidence.

15-024 Random Walk

This § is referenced at pages:
[2753]

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|problem 2.19||

A point follows a path in space that consists of N equal steps, each of length s. The direction in space of each step is entirely random, with no relation or correlation between any two steps.

Show that the mean square displacement between the initial and the final positions is: $\langle S^2 \rangle = Ns^2$.

WORKED SOLUTION

The assumption that the direction of every step is independent of the direction of every other step means that $\langle \mathbf{s}_k \cdot \mathbf{s}_j \rangle = s^2 \delta_{kj}^{\cdot\cdot}$.

15-025 Interaction Energy Between Two Dipoles

This § is referenced at pages:
[1761]

Read § 36.20.12.

The interaction energy between two dipoles is given in equation (36.20.12).

Show that it can be written:

$$\mathcal{E}[\mathbf{r} \equiv (\mathbf{r}_2 - \mathbf{r}_1), \mathbf{d}_1, \mathbf{d}_2] \propto \frac{|\mathbf{d}_1||\mathbf{d}_2|}{r^3}(2\cos\theta_1 \cos\theta_2 - \sin\theta_1 \sin\theta_2 \cos\phi) \quad , \tag{15.06.14}$$

where θ_1 and θ_2 are the polar angles of $\mathbf{d}_1$ and $\mathbf{d}_2$ relative to $\mathbf{r}$, while ϕ is the azimuth of the azimuth of $\mathbf{d}_2$ relative to the $\mathbf{d}_1$-+$\mathbf{r}$ plane or the azimuth of $\mathbf{d}_1$ relative to the $\mathbf{d}_2$-−$\mathbf{r}$ plane.

WORKED SOLUTION

The addition theorem for spherical harmonics can be useful.

©|H.C.Ohanian, , ..., ..., ...Ed., ...|3.12||

Un possibile metodo per misurare la distanza di una nave da un faro è il seguente. Si supponga che la nave si muova su una traiettoria rettilinea e si misuri l'angolo α tra la traiettoria della nave e la direzione in cui è visto il faro. Si misuri lo spazio percorso dalla nave dall'istante in cui si misura l'angolo α fino a quando lo stesso angolo, tra la traiettoria della nave e la direzione in cui è visto il faro vale, 2α. Dimostrare che la distanza dal faro in questo istante vale quanto lo spazio percorso dalla nave tra le due misure.

UNDER PEER REVIEW - IN PROGRESS

15-030 Property of the Ellipse

Consider an ellipses with foci F_1 and F_2. Let P be any point of the ellipses.

1. Show that the vectors $\overrightarrow{\mathbf{PF_1}}$ and $\overrightarrow{\mathbf{PF_2}}$ form equal angles with the tangent to the ellipse.
2. Interpret the result in relation with Snell law of reflection by describing what happens if a point light source is placed at one of the foci of an elliptical mirror.

15-031 Reciprocal Vectors

©|M.R.Spiegel *et al.*, *Vector Analysis*, 2009, McGraw-Hill, 2ndEd., ...|1.11 2.53 2.54 2.103 2.104||
©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|||

Reciprocal vectors enter in the study of crystalline solids.

Consider three non-coplanar vectors, $\mathbf{A}$, $\mathbf{B}$ and $\mathbf{C}$. Express any vector $\mathbf{v}$ as a linear combination of the vectors $\mathbf{A}$, $\mathbf{B}$ and $\mathbf{C}$:

$$\mathbf{v} = a\mathbf{A} + b\mathbf{B} + c\mathbf{C} \qquad \mathbf{A}\cdot(\mathbf{B}\wedge\mathbf{C}) = 0 \quad .$$

1. Consider the reciprocal vectors $\mathbf{A}'$, $\mathbf{B}'$ and $\mathbf{C}'$ defined as:

$$\mathbf{A}' \equiv \frac{\mathbf{B}\wedge\mathbf{C}}{\mathbf{A}\cdot(\mathbf{B}\wedge\mathbf{C})} \quad ,$$

$$\mathbf{B}' \equiv \frac{\mathbf{C}\wedge\mathbf{A}}{\mathbf{A}\cdot(\mathbf{B}\wedge\mathbf{C})} \quad ,$$

$$\mathbf{C}' \equiv \frac{\mathbf{A}\wedge\mathbf{B}}{\mathbf{A}\cdot(\mathbf{B}\wedge\mathbf{C})} \quad .$$

2. Show that:

$$\mathbf{A}\cdot\mathbf{A}' = \mathbf{B}\cdot\mathbf{B}' = \mathbf{C}\cdot\mathbf{C}' = 1 \quad ,$$
$$\mathbf{B}\cdot\mathbf{A}' = \mathbf{C}\cdot\mathbf{A}' = \mathbf{C}\cdot\mathbf{B}' = \mathbf{A}\cdot\mathbf{B}' = \mathbf{A}\cdot\mathbf{C}' = \mathbf{B}\cdot\mathbf{C}' = 0 \quad ,$$

.

3. Show that the volume of the parallelepiped spanned by the three vectors $\mathbf{A}$, $\mathbf{B}$ and $\mathbf{C}$ is the reciprocal of the volume of the parallelepiped spanned by the three reciprocal vectors.
4. Show that:

$$a = \mathbf{v}\cdot\mathbf{A}' \quad ,$$
$$b = \mathbf{v}\cdot\mathbf{B}' \quad ,$$
$$c = \mathbf{v}\cdot\mathbf{C}' \quad .$$

5. Show that the set of vectors $\mathbf{A}$, $\mathbf{B}$ and $\mathbf{C}$ are the reciprocal vectors of the set $\mathbf{A}'$, $\mathbf{B}'$ and $\mathbf{C}'$.
6. Show that the only right handed set of vectors which are self-reciprocal are the unit vectors $\widehat{\mathbf{e}}_1$, $\widehat{\mathbf{e}}_2$ and $\widehat{\mathbf{e}}_3$.

15-032 System of Forces

Find examples of a system of forces having zero total force and zero total momentum but capable to determine a strain and|or induce a deformation on a system.

WORKED SOLUTION

Some examples follow.

DRAFT - IN PROGRESS

- – $\mathbf{f}_1 = -2a\widehat{\mathbf{e}}_3$, applied in $\{0, 0, 0\}$;
  – $\mathbf{f}_2 = a\widehat{\mathbf{e}}_3$, applied in $\{+1, 0, 0\}$;
  – $\mathbf{f}_3 = a\widehat{\mathbf{e}}_3$, applied in $\{-1, 0, 0\}$.
- Consider a spherical mass of plasma like a star. Any shell spherical shell suffers a pressure form the external layers. The total force and total torque with respect to the center are zero but the external layers tend to compress the spherical shell of plasma.
- Consider a spring which is acted by two opposite and identical forces at its extremes.
- Consider the surface tension of an inflated ball.

16.01 Introduction

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|Vol. 2,3||

Vector calculus is part of the basic language of physics; vector calculus is in fact a subset of **tensor calculus, the basic language of physics**.

It is therefore necessary to master the basics of vector calculus in order to understand and use physical laws in the best way.

Necessarily and on purpose, I shall often rely on the intuition of the reader to formalize the ideas, leaving a rigorous development to a more comprehensive mathematical treatment, which is out-of-context for physics.

In general, **assume all functions to be sufficiently regular**, such as C^∞, unless specified otherwise.

Heuristically, carry on derivation/integration of vectors as follows. Use an **orthonormal Cartesian Coordinates Coordinate System** and write any vector in components; then take the derivative|integral as if every components were a scalar, for all the components, while keeping the Cartesian unit vectors fixed. By definition, this is the derivative|integral of a vector, in a **orthonormal Cartesian Coordinates Coordinate System**.

DRAFT-IN-PROGRESS

16.02 Calculus in Many Variables - Differentiation - Cartesian Coordinates

©|R.B.McQuistan|Scalar and Vector Fields: A Physical Interpretation|*Eccellente introduzione avanzata*|

DRAFT - IN-PROGRESS

- Partial derivative, easy.
- Differentiation (more difficult than derivation).
- Differentiation and derivation are not the same: the former implies the latter, not vice-versa.
- Vector gradient, shear, rotor, divergence: read § 16.06.01.01.
- Second derivatives: quadrupole moments.
- Taylor formula in many variables, scalar:

$$\boxed{\phi[\mathbf{x}] \simeq \phi[\mathbf{x}_0] + (\mathbf{x}-\mathbf{x}_0)\cdot\boldsymbol{\nabla}\phi[\mathbf{x}_0]} \quad .$$

  Example: potential energy, stability of small oscillations.
- Taylor formula in many variables, vector:

$$\boxed{V_j[\mathbf{x}] \simeq V_j[\mathbf{x}_0] + (\mathbf{x}-\mathbf{x}_0)\cdot\boldsymbol{\nabla}V_j[\mathbf{x}_0] \implies \mathbf{V}[\mathbf{x}] \simeq \mathbf{V}[\mathbf{x}_0] + (\mathbf{x}-\mathbf{x}_0)\cdot\boldsymbol{\nabla}\mathbf{V}[\mathbf{x}_0]} \quad .$$

  Example: force|torque on a **Electric Dipole** | **Magnetic Dipole** in external field. Read § 36.05.06.01 and § 36.05.06.02

By definition:

$$\boxed{(\mathbf{x}-\mathbf{x}_0)\cdot\boldsymbol{\nabla} \equiv (\mathbf{x}-\mathbf{x}_0)_j\,(\boldsymbol{\nabla})_j \equiv \sum_j (\mathbf{x}-\mathbf{x}_0)_j\,(\boldsymbol{\nabla})_j} \quad . \tag{16.02.01}$$

Examples in physics:

-

16.03 Calculus in Many Variables - Integration - Cartesian Coordinates

©|R.B.McQuistan|Scalar and Vector Fields: A Physical Interpretation|*Eccellente introduzione avanzata*|

It is exceedingly important to understand the concept definitions of integrals in this section, because it is the way integration is written down in physics.

16.03.01
Integration on a 1D 2D 3D Domain

- Integral in n dimensions of a scalar:

$$\int f[x]\,\mathrm{d}x \equiv \lim_{\max\{\Delta L(x)\}\to 0}\sum_k \Delta L(x)_k f[x_k] \qquad \Delta L(x)_k \equiv (\Delta x)_k \quad ,$$

$$\iint f[x,y]\,\mathrm{d}x\,\mathrm{d}y \equiv \lim_{\max\{\Delta S(x,y)\}\to 0}\sum_k \Delta S(x,y)_k f[x_k,y_k] \qquad \Delta S(x,y)_k \equiv (\Delta x\Delta y)_k \quad ,$$

$$\iiint f[x,y,z]\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z \equiv \lim_{\max\{\Delta V(x,y,z)\}\to 0}\sum_k \Delta V(x,y,z)_k f[\mathbf{x}_k] \qquad \Delta V(x,y,z)_k \equiv (\Delta x\Delta y\Delta z)_k \quad .$$

  Examples:
  - line, surface, volume: charge and|or mass;
  - quadrupole tensors, equation (36.14.04), (36.14.05).

- Integral in n dimensions of a vector:

$$\int \mathbf{V}[x]\,\mathrm{d}x \equiv \lim_{\max\{\Delta L(x)\}\to 0}\sum_k \Delta L(x)_k \mathbf{V}[x_k] \qquad \Delta L(x)_k \equiv (\Delta x)_k \quad ,$$

$$\iint \mathbf{V}[x,y]\,\mathrm{d}x\,\mathrm{d}y \equiv \lim_{\max\{\Delta S(x,y)\}\to 0}\sum_k \Delta S(x,y)_k \mathbf{V}[x_k,y_k] \qquad \Delta S(x,y)_k \equiv (\Delta x\Delta y)_k \quad ,$$

$$\iiint \mathbf{V}[x,y,z]\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z \equiv \lim_{\max\{\Delta V(x,y,z)\}\to 0}\sum_k \Delta V(x,y,z)_k \mathbf{V}[\mathbf{x}_k] \qquad \Delta V(x,y,z)_k \equiv (\Delta x\Delta y\Delta z)_k \quad .$$

  Examples:
  - average Electric|Magnetic field in matter;
  - position of the Center-Of-Mass;
  - force on a volume current;

16.04.01 General Orthonormal Coordinate System

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...||*Appendix A*|

No sum over repeated indexes in this section.

In this section the convention of sum of repeated indexes defined in section § 15.01.01 is temporarily suspended.

Let the three coordinates of a generic orthonormal Coordinate System in three-dimensional space be u^i, with $i = 1, 2, 3$.

Every point in space, $\mathbf{r}$, shall be described by the bi-univocal (at least locally) transformation:

$$\mathbf{r} = \mathbf{r}[u^1, u^2, u^3] \equiv \mathbf{r}[u^k] \quad ,$$

which functionally relates the coordinates of the generic orthonormal coordinate system to a orthonormal Cartesian Coordinates Coordinate System system.

The three unit vectors are defined in terms of the scale factors, h_i, as:

$$\mathbf{e}_i \equiv \frac{1}{h_i}\frac{\partial \mathbf{r}}{\partial u^i} \qquad \text{with} \qquad h_i \equiv \left|\frac{\partial \mathbf{r}}{\partial u^i}\right| \quad .$$

For an orthonormal Coordinate System the three unit vectors satisfy:

$$\mathbf{e}_i \cdot \mathbf{e}_j = \delta_{ij}^{\cdot\cdot} \qquad \mathbf{e}_i \wedge \mathbf{e}_j = \epsilon_{ijk}^{\cdot\cdot\cdot}\mathbf{e}_k \quad .$$

The infinitesimal displacement, $\mathbb{d}\mathbf{r}$, is:

$$\mathbb{d}\mathbf{r} = \sum_{i=1}^{3} \frac{\partial \mathbf{r}}{\partial u^i}\,\mathbb{d}u^i = \sum_{i=1}^{3} \mathbf{e}_i h_i\,\mathbb{d}u^i \quad .$$

The squared infinitesimal line element for the orthonormal Coordinate System becomes:

$$\mathbb{d}s^2 \equiv \mathbb{d}\mathbf{r}\cdot\,\mathbb{d}\mathbf{r} \equiv \sum_{i,j=1}^{3} \delta_{ij}^{\cdot\cdot} h_i h_j\,\mathbb{d}u^i\,\mathbb{d}u^j = \sum_{i=1}^{3} h_i^2\left(\mathbb{d}u^i\right)^2 \quad .$$

DRAFT - IN-PROGRESS

The surface elements on the surfaces $u^s = \text{constant}$ are given by:

$$\mathbb{d}\boldsymbol{\Sigma}_1 = \left(\frac{\partial \mathbf{r}}{\partial u^2} \wedge \frac{\partial \mathbf{r}}{\partial u^3}\right) \mathbb{d}u^2\, \mathbb{d}u^3 = \mathbf{e}_1 h_2 h_3\, \mathbb{d}u^2\, \mathbb{d}u^3 \qquad u^1 = \text{constant} \quad ,$$

$$\mathbb{d}\boldsymbol{\Sigma}_2 = \left(\frac{\partial \mathbf{r}}{\partial u^3} \wedge \frac{\partial \mathbf{r}}{\partial u^1}\right) \mathbb{d}u^3\, \mathbb{d}u^1 = \mathbf{e}_2 h_3 h_1\, \mathbb{d}u^3\, \mathbb{d}u^1 \qquad u^2 = \text{constant} \quad ,$$

$$\mathbb{d}\boldsymbol{\Sigma}_3 = \left(\frac{\partial \mathbf{r}}{\partial u^1} \wedge \frac{\partial \mathbf{r}}{\partial u^2}\right) \mathbb{d}u^1\, \mathbb{d}u^2 = \mathbf{e}_3 h_1 h_2\, \mathbb{d}u^1\, \mathbb{d}u^2 \qquad u^3 = \text{constant} \quad .$$

In case two coordinates parameterize a surface (for instance u^s is constant) the $\mathbb{d}\boldsymbol{\Sigma}_s$ gives the area of the infinitesimal element of surface.

One can also write the above oriented projection on the plane perpendicular to the Cartesian axis k of the area spanned by an infinitesimal change of coordinates $\mathbb{d}u^p$ and $\mathbb{d}u^q$ as:

$$\boxed{\mathbb{d}\mathbf{S}_k = \sum_{r,s=1}^{3} \epsilon_{krs}^{\cdots} \frac{\partial r_r}{\partial u^p} \frac{\partial r_s}{\partial u^q}\, \mathbb{d}u^p\, \mathbb{d}u^q}$$

The infinitesimal volume element for the orthonormal Coordinate System becomes:

$$\boxed{\mathbb{d}V = h_1 h_2 h_3\, \mathbb{d}u^1\, \mathbb{d}u^2\, \mathbb{d}u^3} \quad .$$

16.04.01.01 Cartesian Coordinates Coordinate System

16.04.01.02 Cylindrical Coordinate System

$$\{r, \theta, z\} \implies h_r = 1 \qquad h_\theta = r \qquad h_z = 1 \quad .$$

See figure **??**.

16.04.01.03 Spherical Coordinate System

$$\{r, \theta, \phi\} \implies h_r = 1 \qquad h_\theta = r \qquad h_\phi = r \sin[\theta] \quad .$$

16.05 Integral Operators for Vector Fields

This § is referenced at pages:
[Never referenced.]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||

16.05.01 Circulation

This § is referenced at pages:
[Never referenced.]

Consider a vector field $\mathbf{V}[\mathbf{x}]$.
Its circulation around any line, C, which is partitioned by segments $\Delta\mathbf{L}_k$, is defined as:

$$\Gamma_C \equiv \int_C \mathbf{V}[\mathbf{x}]\cdot \mathbb{d}\mathbf{L} \equiv \lim_{\max\{|\Delta\mathbf{L}_k|\}\to 0} \sum_k \mathbf{V}_k[\mathbf{x}]\cdot\Delta\mathbf{L}_k \quad .$$

The circulation around a closed line, which is the boundary of a surface Σ ($C = \partial\Sigma$), is:

$$\Gamma_{C=\partial\Sigma} \equiv \oint_{C=\partial\Sigma} \mathbf{V}[\mathbf{x}]\cdot \mathbb{d}\mathbf{L} \quad .$$

Orientation of the curve and surface must be compatible with the usual **right-hand rule**.
If the surface is partitioned in two parts,

$$\Sigma_1 \quad \Sigma_2 \quad : \quad \Sigma = \Sigma_1 \cup \Sigma_2 \quad \& \quad \Sigma_1 \cap \Sigma_2 = \emptyset \quad ,$$

the circulation over C is the sum of the circulations over the boundaries of C_1 and C_2, as the common line gives two equal and opposite contributions to the two circulations:

$$\Gamma_{C=\partial\Sigma} = \Gamma_{C_1=\partial\Sigma_1} + \Gamma_{C_2=\partial\Sigma_2} \quad ,$$

provided consistent orientations for the lines are chosen.
This can be generalized to partitioning into any number of surfaces/circulations.

16.05.02 Flux

This § is referenced at pages:
[1004]

Consider a vector field $\mathbf{V}[\mathbf{x}]$.
Its flux across any surface, Σ, which is partitioned by triangles $\Delta\mathbf{S}_k$, is defined as:

$$\Phi_\Sigma \equiv \iint_\Sigma \mathbf{V}[\mathbf{x}]\cdot \mathbb{d}\mathbf{S} \equiv \lim_{\max\{|\Delta\mathbf{S}_k|\}\to 0} \sum_k \mathbf{V}_k[\mathbf{x}]\cdot\Delta\mathbf{S}_k \quad .$$

The flux across a closed surface, which is the boundary of a volume Ω ($\Sigma = \partial\Omega$), is:

$$\Phi_{\Sigma=\partial\Omega} \equiv \oiint_{\Sigma=\partial\Omega} \mathbf{V}[\mathbf{x}]\cdot \mathbb{d}\mathbf{S} \quad .$$

Orientation of the surface and volume must be compatible with the usual **right-hand rule**.
If the volume is partitioned in two parts,

$$\Omega_1 \quad \Omega_2 \quad : \quad \Omega = \Omega_1 \cup \Omega_2 \quad \& \quad \Omega_1 \cap \Omega_2 = \emptyset \quad ,$$

DRAFT - IN PROGRESS

the flux over Σ is the sum of the fluxes over the boundaries of Ω_1 and Ω_2, as the common surface gives two equal and opposite contributions to the two fluxes:

$$\Phi_{\Sigma=\partial\Omega} = \Phi_{\Sigma_1=\partial\Omega_1} + \Phi_{\Sigma_2=\partial\Omega_2} \quad ,$$

provided consistent orientations for the surfaces are chosen.

This can be generalized to partitioning into any number of volumes/fluxes.

DRAFT-IN-PROGRESS

16.06 Linear First-Order Differential Operators

This § is referenced at pages:
[1118]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||
©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|Vol. 2, 2,3||
©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|Appendix A||

Linear first-order differential operators can be thought as deriving from the attempt to derive point properties from the well-known integral properties:

- of scalar fields (the difference of the values at two points);
- of vector fields (flux and circulation).

In the case of vector fields in orthonormal Cartesian Coordinates Coordinate System one might consider the partial derivatives to get the Jacobian matrix. However, it has been found that some suitable combinations of the pure partial derivatives are much more useful. These gives rise to divergence, rotor and strain. The latter, while very important in general, is not relevant in ElectroMagnetism.

Moreover, it is necessary to generalize to the case of arbitrary Coordinate Systems.

16.06.01 General Definition of Linear First-Order Differential Operators in 3D

©|Invariant Definitions for Vector Calculus|WEB - URL ||

One can build three different linear first-order differential operators linking scalar and|or (at least one) vector functions:

- the gradient: scalar $\longrightarrow$ vector;
- the divergence: vector $\longrightarrow$ scalar, it is the flux volume density (in 3 dimensions) as flux is additive and therefore there exists a flux density;
- the rotor: vector $\longrightarrow$ vector, it is the circulation surface density (in 3 dimensions) as circulation is additive and therefore there exists a circulation density.

These operators are often introduced by giving their expression in Cartesian coordinates. However, in physics it is better to use a coordinate-independent description: a coordinate-independent definition of the differential operators is more useful. Moreover, it gives a direct physical interpretation.

Once one has introduced the differential operators in a coordinate-free way the three fundamental integral theorems of calculus (see section § 16.07) provide the expressions of the operators in the chosen Coordinate System.

In short: while always using a small (infinitesimal) sphere around the point; then:

- **the flux across a spherical surface per unit volume gives the divergence at the point**;
- **the circulation around a great circle per unit area gives the rotor component in the direction perpendicular to the circle at the point**.

WORK IN PROGRESS

16.06.01.01 General First-Order Vector Derivatives

This § is referenced at pages:
[1086, 1101]

©|J.D.Romano and R.H.Price - *Why no shear in "Div, grad, rotor, and all that"?* |WEB - URL |*A MUST*|

Gradient:

$$\boxed{\frac{\partial V_j}{\partial x_i}} \quad . \tag{16.06.01}$$

Shear, traceless symmetrical second-order tensor:

$$\boxed{\frac{1}{2}\left(\frac{\partial V_r}{\partial x_s}+\frac{\partial V_s}{\partial x_r}\right)-\frac{1}{3}\delta_{rs}\mathbf{div}\,\mathbf{V}} \quad . \tag{16.06.02}$$

© - QUOTE

... remind the reader that div and rotor are not the entire story when it comes to vector derivatives ...
... After learning about div, grad, and rotor ..., one might end up with the impression that these differential operators contain all there is to know about the differential calculus of scalar and vector fields. But this is not the case. For example, the gradient of a vector field $\mathbf{V}$, or equivalently the derivative of $\mathbf{V}$ in the (arbitrary) direction of $\mathbf{n}$ at a point $\mathbf{x}$, is defined by:

$$\boxed{\boldsymbol{\nabla}_{\mathbf{n}}\mathbf{V}\equiv(\,\mathbf{n}\cdot\boldsymbol{\nabla}\,)\,\mathbf{V}\equiv\lim_{\epsilon\to 0}\left(\frac{\mathbf{V}[\mathbf{x}+\epsilon\mathbf{n}]-\mathbf{V}[\mathbf{x}]}{\epsilon}\right)} \quad . \tag{16.06.03}$$

This operation is not simply contained in the divergence and rotor operations. ... The reader should note that our statement about the necessity of knowing the gradient of a vector field does not conflict with Helmholtz theorem..... ... To see that the divergence and rotor of a vector field do not suffice to specify it... This leaves five components unaccounted for, and these correspond to a symmetric, trace-free derivative operation that has the physical interpretation of shear. ...

Read § 16.12.17.

DRAFT
PROGRESS

16.06.01.02 General Definition of the Gradient

This § is referenced at pages:
[1100]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||

Consider a scalar field $U[\mathbf{x}]$. The gradient is defined by the relation:

$$\boxed{\mathbf{grad}U\cdot \mathbb{d}\mathbf{L} \equiv (\widehat{\mathbf{n}}\cdot\mathbf{grad}U)\ \mathbb{d}L \equiv\ \mathbb{d}U[\mathbf{x}] \qquad \text{a vector field}} \quad . \tag{16.06.04}$$

The projection of the gradient of a scalar field along any infinitesimal displacement, $\mathbb{d}\mathbf{L}$, at any given point, thus provides the infinitesimal change of the value of the scalar field along the infinitesimal displacement $\mathbb{d}\mathbf{L}$.

In detail, the projection of the grad of a scalar field along the direction $\widehat{\mathbf{n}}$ is defined as the limit, for infinitesimally small path starting from the given point along the direction $\widehat{\mathbf{n}}$, of the ratio

$$\boxed{\widehat{\mathbf{n}}\cdot\mathbf{grad}U[\mathbf{x}] = \lim_{\Delta L\longrightarrow 0}\frac{U[\mathbf{x}+\widehat{\mathbf{n}}\Delta L]-U[\mathbf{x}]}{\Delta L} \qquad \text{a vector field}} \quad , \tag{16.06.05}$$

for any path ΔL starting from the point P and directed along $\widehat{\mathbf{n}}$.

DRAFT – IN-PROGRESS

16.06.01.03 General Definition of the Divergence

This § is referenced at pages:
[1107]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||
©|T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...|Vol. 2, 2nd edition, § 12.20|*Excellent*|
©|WEB - URL |ElectroMagnetic Field and Energy - H.A.Haus & J.R.Melcher||
©|WEB - URL |ElectroMagnetic Field and Energy - H.A.Haus & J.R.Melcher|*Appendix 2*|
©|D.Styer|Geometrical definition of divergence and curl|*WEB - URL*|

Consider a vector field $\mathbf{V}[\mathbf{x}]$ and its flux across any closed surface, Σ:

$$\Phi_\Sigma \equiv \oiint_\Sigma \mathbf{V} \cdot \mathbb{d}\mathbf{S} \quad .$$

In order to pick-up a property of the field in the neighborhood of some point, $\mathbf{x}$, consider the flux across the boundary (frontier) of smaller and smaller volumes enclosing the given point, that is, containing the given point.

As the flux is additive with respect to partitioning of the volume one may wonder what about the limit for infinitesimally small volume.

The divergence of a vector field is defined as the limit, for infinitesimally small volume containing the given point, of the ratio

$$\mathbf{div}\,\mathbf{V}[\mathbf{x}] \equiv \lim_{\Delta V_\mathbf{x} \longrightarrow 0} \frac{1}{\Delta V_\mathbf{x}} \oiint_{\partial\Omega_\mathbf{x}} \mathbf{V} \cdot \mathbb{d}\mathbf{S} \qquad \text{a scalar field} \quad , \tag{16.06.06}$$

→ 1098 1107

for any volume $\Omega_\mathbf{x}$ surrounding the point P.

It can be shown that, if the limit exists, it does not depend neither on the shape of the volume chosen to perform the limit, nor on the limiting procedure.

The divergence of a vector field, at any given point, is thus the flux of the vector field per unit volume around the point.

It can be shown that the divergence is indeed a scalar [1], that is it transforms as a scalar under coordinate transformations § 20.

Defining the divergence via definition (16.06.06) makes it possible to give an immediate physical interpretation to the concept of divergence. Moreover, that definition does not depend on any specific Coordinate System. If one chooses a orthonormal Cartesian Coordinates Coordinate System and a cubic volume with edges parallel to the xyz axes it is easy to deduce the expression of the divergence in Cartesian coordinates. In a similar way the expression of the divergence in any other Coordinate System can be determined.

Following the terminology of hydrodynamics it is often said that **points where divergence is different from zero give the Sources|Sinks of the field**.

The divergence can be also viewed as a weighted derivative along the direction of the field, or along the field hose [2]

©|WEB - URL |ElectroMagnetic Field and Energy - H.A.Haus & J.R.Melcher|*Appendix 2*|
©|D.Styer|Geometrical definition of divergence and curl|*WEB - URL*|

Consider a vector field $\mathbf{V}[\mathbf{x}]$ and its circulation around any closed line, C:

$$\Gamma_C \equiv \oint_C \mathbf{V}\cdot \mathbb{d}\mathbf{L} \quad .$$

In order to pick-up a property of the field in the neighborhood of some point, $\mathbf{x}$, consider the circulation around the boundary (frontier) of smaller and smaller surfaces enclosing the given point, that is, containing the given point. However, since the loops can have different orientations one is forced to consider surfaces in a plane passing for the given point and with fixed orientation in space, perpendicular to the unit vector $\widehat{\mathbf{n}}$.

As the circulation is additive with respect to partitioning of the area one may wonder what about the limit for infinitesimally small area.

The projection of the rotor of a vector field along the direction $\widehat{\mathbf{n}}$ is defined as the limit, for infinitesimally small area containing the given point, of the ratio

$$\boxed{\widehat{\mathbf{n}}\cdot\mathbf{rot}\,\mathbf{V}[\mathbf{x}] \equiv \lim_{|\Delta\mathbf{S}_\mathbf{x}|\longrightarrow 0} \frac{1}{|\Delta\mathbf{S}_\mathbf{x}|}\oint_{\partial\Sigma_\mathbf{x}} \mathbf{V}\cdot \mathbb{d}\mathbf{L} \qquad \text{a vector field}} \quad , \tag{16.06.07}$$

→ 1099

for any surface $\Sigma_\mathbf{x}$ lying in the plane perpendicular to $\widehat{\mathbf{n}}$ and surrounding the point P.

It can be shown that, if the limit exists, it does not depend neither on the shape of the surface chosen to perform the limit, nor on the limiting procedure.

The projection of the rotor of a vector field along any unit vector, at any given point, is thus the circulation of the vector field per unit area in the plane passing by the point and perpendicular to the unit vector.

The direction of the rotor vector is perpendicular to the plane such that the limit in equation (16.06.07) is maximum.

It can be shown that the rotor is indeed a vector [1], that is it transforms as a vector under coordinate transformations § 20.

Defining the rotor via definition (16.06.07) makes it possible to give an immediate physical interpretation to the concept of rotor. Moreover, that definition does not depend on any specific Coordinate System. If one chooses a orthonormal Cartesian Coordinates Coordinate System and a square surface with edges parallel to the xyz axes it is easy to deduce the expression of the rotor in Cartesian coordinates. In a similar way the expression of the rotor in any other Coordinate System can be determined.

Following the terminology of hydrodynamics it is often said that **points where rotor is different from zero give the vortexes of the field**. Nothing enters/exits vertexes.

The rotor can be viewed in terms of a field hose: the transverse components of the rotor can be regarded as derivatives with respect to transverse directions of the vector field weighted by incremental line elements [2]

[2] ©|WEB - URL |ElectroMagnetic Field and Energy - H.A.Haus & J.R.Melcher|*A must...*|

16.06.01.05 Alternative Definitions in Terms of Volume Integrals Only

©|T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...|||
©|M.R.Spiegel *et al.*, *Vector Analysis*, 2009, McGraw-Hill, 2ndEd., ...|||
©|Vector and Tensor Analysis with Applications - Borisenko, A.I. and Tarapov, I.E. |||

Alternative definitions can be given in terms of volume integral only, for instance, by exploiting the vector operators theorem to get equivalent expressions:

$$\mathbf{div}\,\mathbf{V}[\mathbf{x}] = \lim_{\Delta V_{\mathbf{x}} \longrightarrow 0} \frac{1}{\Delta V_{\mathbf{x}}} \oiint_{\partial\Omega_{\mathbf{x}}} \mathbb{d}\mathbf{S}\cdot\mathbf{V} \quad \text{weighted radial flux on a surface surrounding } P \quad ,$$

$$\mathbf{rot}\,\mathbf{V}[\mathbf{x}] = \lim_{\Delta V_{\mathbf{x}} \longrightarrow 0} \frac{1}{\Delta V_{\mathbf{x}}} \oiint_{\partial\Omega_{\mathbf{x}}} \mathbb{d}\mathbf{S}\wedge\mathbf{V} \quad \text{weighted tangential circulation on a surface surrounding } P \quad ,$$

$$\mathbf{grad}\,U[\mathbf{x}] = \lim_{\Delta V_{\mathbf{x}} \longrightarrow 0} \frac{1}{\Delta V_{\mathbf{x}}} \oiint_{\partial\Omega_{\mathbf{x}}} U\ \mathbb{d}\mathbf{S} \quad \text{weighted mean on a surface surrounding } P \quad ,$$

for any volume $\Omega_{\mathbf{x}}$ surrounding the point P.

16.06.02 General Definition of Linear First-Order Differential Operators in 2D

This § is referenced at pages:
[1004, 1723]

16.06.02.01 2D Gradient

The gradient is defined as the two-dimensional scalar product, just as in section § 16.06.01.02.

16.06.02.02 2D Flux and Divergence

Flux and Divergence, in 2D, are the only concepts requiring some modification with respect to 3D.

Flux and Divergence, **on a surface, measure the flow of the vector field across a curve, on the surface**. Here, flow is used on purpose as a qualitative term, waiting for a quantitative definition below.

Flux in two dimensions is defined as follows. In a plane, consider a vector field $\mathbf{V}[\mathbf{x}]$ and its flux around any line, C, 2D flux is defined as:

$$\widehat{\mathbf{N}} \equiv \frac{\mathbb{d}\mathbf{L}\wedge\widehat{\mathbf{n}}}{\mathbb{d}L} \qquad \Phi_C^{(2)} \equiv \int_C \left(\mathbf{V}\cdot\widehat{\mathbf{N}}\right)\mathbb{d}L \qquad \Phi_C^{(2)} = \int_C (\widehat{\mathbf{n}}\wedge\mathbf{V})\cdot\mathbb{d}\mathbf{L} \quad , \tag{16.06.08}$$

→ 1100

with $\widehat{\mathbf{n}}$ a function which gives an outward-facing normal unit vector on the surface at each point on the curve, and the implicit usual limiting definition of the integral.

Orientation of the curve and surface must be compatible with the usual **right-hand rule**.

Equation (16.06.08) shows how the flux can be calculated via a circulation, the circulation of $\widehat{\mathbf{n}}\wedge\mathbf{V}$.

It is used in the concept of surface current density § 36.03.02.02.

The divergence is defined as the two-dimensional flux per unit area as follows. On a surface consider a small area $\Sigma_{\mathbf{x}}$ around the point $\mathbf{x}$ and let the area tend to zero to find the limit

$$\mathbf{div}_{\mathbf{S}}\mathbf{F}[\mathbf{x}] = \lim_{\Delta S_{\mathbf{x}} \longrightarrow 0} \frac{1}{\Delta S_{\mathbf{x}}} \oint_{\partial\Sigma_{\mathbf{x}}} \left(\mathbf{V}\cdot\widehat{\mathbf{N}}\right)\mathbb{d}L \qquad \text{a scalar field} \quad , \tag{16.06.09}$$

for any area $\Sigma_{\mathbf{x}}$ surrounding the point $\mathbf{x}$ and where $\widehat{\mathbf{N}}$ is a unit-vector tangent to the surface and perpendicular to the curve at any point.

It is a scalar field, in a pure two-dimensional space.

DRAFT In Progress

16.06.02.03 2D Circulation and Rotor

Circulation in two dimensions is obviously defined as in 3D.

The rotor is defined as the two-dimensional circulation per unit area as follows, exactly as the projection on a plane of the three-dimensional rotor.

$$\mathbf{rot}_S\mathbf{F}[\mathbf{x}] = \lim_{\Delta S_\mathbf{x}\longrightarrow 0} \frac{1}{\Delta S_\mathbf{x}} \oint_{\partial\Sigma_\mathbf{x}} \mathbf{V}\cdot \mathbb{d}\mathbf{L} \qquad \text{a scalar field} \quad , \tag{16.06.10}$$

for any surface $\Sigma_\mathbf{x}$ surrounding the point P.

It is a scalar field, in a pure two-dimensional space.

Let x_i $(i = 1, 2, 3)$, a system of orthonormal Cartesian Coordinates Coordinate System. It can be shown that the following relations apply. Read also § 16.06.04 for a derivation of these results.

$$\mathbf{grad}\phi[\mathbf{x}] = \frac{\partial\phi}{\partial x_1}\mathbf{e}_1 + \frac{\partial\phi}{\partial x_2}\mathbf{e}_2 + \frac{\partial\phi}{\partial x_3}\mathbf{e}_3 = \frac{\partial\phi}{\partial x_i}\mathbf{e}_i \equiv \mathbf{e}_i\partial_i\phi \quad . \tag{16.06.11}$$

$$\mathbf{div}\,\mathbf{V}[\mathbf{x}] = \frac{\partial V_1}{\partial x_1} + \frac{\partial V_2}{\partial x_2} + \frac{\partial V_3}{\partial x_3} = \frac{\partial V_i}{\partial x_i} \equiv \partial_i V_i \quad . \tag{16.06.12}$$

$$\mathbf{rot}\,\mathbf{V}[\mathbf{x}] = \left(\frac{\partial V_2}{\partial x_3} - \frac{\partial V_3}{\partial x_2}\right)\mathbf{e}_1 + \left(\frac{\partial V_3}{\partial x_1} - \frac{\partial V_1}{\partial x_3}\right)\mathbf{e}_2 + \left(\frac{\partial V_1}{\partial x_2} - \frac{\partial V_2}{\partial x_1}\right)\mathbf{e}_3 = \epsilon^{\dots}_{ijk}\frac{\partial V_k}{\partial x_j}\mathbf{e}_i \equiv \mathbf{e}_i\epsilon^{\dots}_{ijk}\partial_j V_k \quad . \tag{16.06.13}$$

Second-Order Tensor of Derivatives in Cartesian Coordinates Coordinate System

The second-order Cartesian tensor

$$\frac{\partial V_i}{\partial x_j} \quad ,$$

can be decomposed into its:

- trace, a scalar: the divergence;
- anti-symmetrical part, a second-order anti-symmetrical tensor: the rotor;
- symmetrical part, a second-order trace-less symmetrical tensor: the shear tensor.

Read § 16.06.01.01 and section § 16.12.17.

DRAFT-WIP-PRESS

Nabla Vector Operator and Its Pitfalls

This § is referenced at pages:
[Never referenced.]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.8||

In orthonormal Cartesian Coordinates Coordinate System the linear first-order differential operators can be expressed via the nabla vector operator:

$$\boldsymbol{\nabla} \equiv \mathbf{e}_1 \frac{\partial}{\partial x_1} + \mathbf{e}_2 \frac{\partial}{\partial x_2} + \mathbf{e}_3 \frac{\partial}{\partial x_3} \quad . \tag{16.06.14}$$

Then one has:

$$\mathbf{grad}\phi \equiv \boldsymbol{\nabla}\phi \qquad \mathbf{div}\,\mathbf{A} \equiv \boldsymbol{\nabla}\cdot\mathbf{A} \qquad \mathbf{rot}\,\mathbf{A} \equiv \boldsymbol{\nabla}\wedge\mathbf{A} \quad .$$

Note that the straightforward algebraic use of the nabla vector operator gives sometimes wrong results [1].

A simple example is: $\mathbf{grad}a \wedge \mathbf{grad}b$. In general this is not zero while the blind use of nabla would give zero as the direction would seem to be carried by nabla so that the vector product of two vectors with the same direction is zero.

Read § 16.11.

16.06.03.04 Linear First-Order Differential Operators in General Orthonormal Curvilinear Coordinates

The gradient of a function $\phi[\mathbf{r}]$ is given in orthonormal curvilinear coordinates by:

$$\mathbf{grad}\phi[\mathbf{r}] = \frac{1}{h_1}\frac{\partial\phi}{\partial u^1}\mathbf{e}_1 + \frac{1}{h_2}\frac{\partial\phi}{\partial u^2}\mathbf{e}_2 + \frac{1}{h_3}\frac{\partial\phi}{\partial u^3}\mathbf{e}_3 \quad .$$

The divergence of a vector field $\mathbf{V}[\mathbf{r}]$ is given in orthonormal curvilinear coordinates by:

$$\mathbf{div}\,\mathbf{V}[\mathbf{r}] = \frac{1}{h_1 h_2 h_3}\left(\frac{\partial\left(h^2 h^3 V_1\right)}{\partial u^1} + \frac{\partial\left(h^3 h^1 V_2\right)}{\partial u^2} + \frac{\partial\left(h^1 h^2 V_3\right)}{\partial u^3}\right) \quad . \quad \rightarrow 1103$$

The rotor of a vector field $\mathbf{V}[\mathbf{r}]$ is given in orthonormal curvilinear coordinates by:

$$\mathbf{rot}\,\mathbf{V}[\mathbf{r}] = \frac{\mathbf{e}_1}{h_2 h_3}\left(\frac{\partial\left(h^3 V_3\right)}{\partial u^2} - \frac{\partial\left(h^2 V_2\right)}{\partial u^3}\right) + \frac{\mathbf{e}_2}{h_3 h_1}\left(\frac{\partial\left(h^2 V_2\right)}{\partial u^3} - \frac{\partial\left(h^3 V_3\right)}{\partial u^1}\right) + \frac{\mathbf{e}_3}{h_1 h_2}\left(\frac{\partial\left(h^1 V_1\right)}{\partial u^1} - \frac{\partial\left(h^1 V_1\right)}{\partial u^2}\right) \quad . \quad \rightarrow 1103$$

The Laplacian of a scalar field $\phi[\mathbf{r}]$ is given in orthonormal curvilinear coordinates by:

$$\nabla^2\phi[\mathbf{r}] = \frac{1}{h_1 h_2 h_3}\left(\frac{\partial}{\partial u^1}\left(\frac{h_2 h_3}{h_1}\frac{\partial\phi}{\partial u^1}\right) + \frac{\partial}{\partial u^2}\left(\frac{h_3 h_1}{h_2}\frac{\partial\phi}{\partial u^2}\right) + \frac{\partial}{\partial u^3}\left(\frac{h_1 h_2}{h_3}\frac{\partial\phi}{\partial u^3}\right)\right) \quad .$$

DRAFT-IN-PROGRESS

16.06.04
Meaning of Linear First-Order Differential Operators

This § is referenced at pages:
[1101]

The interpretation of the gradient of a scalar field is well known from Calculus: the gradient gives, at any point, the direction along which the scalar field is increasing most rapidly.

The expressions in general orthonormal coordinates of the divergence and rotor (equations (16.06.03.04), (16.06.03.04)) clarify in the general case the interpretation of the meaning of the two operators which can be suspected from the analysis of the special cases of orthonormal Cartesian Coordinates Coordinate System, as well as in Cylindrical and Spherical coordinates. In fact it is clear that the divergence measures the rate of change of each component of the field along the direction defined by the component itself. On the other hand the rotor measures the rate of change of each component of the field along the two directions orthogonal to the one defined by the component itself.

Following the terminology of hydrodynamics it is often said that

- points where the divergence is different from zero give the **Sources|Sinks** of the field;
- points where the rotor is different from zero give the **Vortexes** of the field.

Note that also saddle points are significant points for a function of more variables, that is critical points (zero gradient) which are not local extrema.

16.06.05
Expressions of Divergence and Rotor in Cartesian Coordinates

This § is referenced at pages:
[1139]

Consider the flow of a fluid in Hydrodynamics as it provides an intuitive example.

The mass flux is expressed in terms of the mass density, ρ, and the velocity field of the fluid, $\mathbf{v}[\mathbf{x},t]$, a vector field giving, at any point and time, the velocity of the fluid particles passing by that point at time t.

The mass flux is given by the current density of mass

$$\boxed{\mathbf{j}_{\mathrm{M}}[\mathbf{x},t] \equiv \rho[\mathbf{x},t]\mathbf{v}[\mathbf{x},t]} \quad , \tag{16.06.15}$$

which can be expressed, in the case of all identical particles, also in terms of the number density, $\rho_{\mathrm{N}}[\mathbf{x},t]$, and mass of the single particle, m, as:

$$\mathbf{j}_{\mathrm{M}}[\mathbf{x},t] \equiv \rho_{\mathrm{M}}[\mathbf{x},t]\mathbf{v}[\mathbf{x},t] \longrightarrow m\rho_{\mathrm{N}}[\mathbf{x},t]\mathbf{v}[\mathbf{x},t] \quad ,$$

This is to be compared with the definition of current density of particles (section § 30.06) and the current density of charge, the usual current density of ElectroMagnetism (section § 36.03.04.01). In the present case one has a current density of mass, instead of a current density charge of particles or a current density of charges.

In a similar way one can consider the particle flux, that is the number of particles per unit area per unit time.

The particle flux is given by the current density of particles

$$\boxed{\mathbf{j}_{\mathrm{N}}[\mathbf{x},t] \equiv \rho_{\mathrm{N}}[\mathbf{x},t]\mathbf{v}[\mathbf{x},t]} \quad . \tag{16.06.16}$$

→ 2735

PREPRINT-IN PROGRESS

16.06.05.01 Divergence in Cartesian Coordinates Coordinate System: Hydrodynamics

The flux of $\mathbf{j}_{\mathtt{M}}$ across any closed surface gives the **mass out-flow per unit time**: if it is positive there is an overall out-flow of mass, if it is negative there is an overall in-flow of mass.

In order to appreciate the meaning of the divergence let us consider its application to particle fluxes.

Consider a small rectangular parallelepiped with sides along the x, y and z axis and length Δx, Δy and Δz.

It is understood that a limit will be taken such that: $\Delta x \to 0$, $\Delta y \to 0$ and $\Delta z \to 0$.

From the definition of current density of particles the number of particles crossing a surface described by $\hat{\mathbf{n}}\ \mathbb{d}\mathbf{S}$ in time $\mathbb{d}t$,

$$\boxed{\mathbb{d}N = (\mathbf{j}\cdot\mathbf{n})\ \mathbb{d}S\ \mathbb{d}t} \quad ,$$

one finds, by applying the theorem of the mean of integral calculus:

$$\mathbb{d}N^x_{\mathtt{OUT}} \simeq (j_x[x+\Delta x, \widetilde{y}_+, \widetilde{z}_+] - j_x[x, \widetilde{y}_-, \widetilde{z}_-])\,\Delta y\Delta z\ \mathbb{d}t \to \frac{\partial j_x}{\partial x}[x,y,z]\Delta x\Delta y\Delta z\ \mathbb{d}t + \mathcal{O}\left(\Delta x\Delta y\Delta z\right)^2 \quad ,$$

$$\mathbb{d}N^y_{\mathtt{OUT}} \simeq (j_y[\widetilde{x}_+, y+\Delta y, \widetilde{z}_+] - j_x[\widetilde{x}_-, y, \widetilde{z}_-])\,\Delta z\Delta x\ \mathbb{d}t \to \frac{\partial j_y}{\partial y}[x,y,z]\Delta x\Delta y\Delta z\ \mathbb{d}t + \mathcal{O}\left(\Delta x\Delta y\Delta z\right)^2 \quad ,$$

$$\mathbb{d}N^z_{\mathtt{OUT}} \simeq (j_z[\widetilde{x}_+, \widetilde{y}_+, z+\Delta z] - j_z[\widetilde{x}_-, \widetilde{y}_-, z])\,\Delta x\Delta y\ \mathbb{d}t \to \frac{\partial j_z}{\partial z}[x,y,z]\Delta x\Delta y\Delta z\ \mathbb{d}t + \mathcal{O}\left(\Delta x\Delta y\Delta z\right)^2 \quad .$$

In general:

$$\begin{aligned} \widetilde{x}_+ \neq \widetilde{x}_- \qquad & 0 \leq \widetilde{x}_+ | \widetilde{x}_- \leq x + \Delta x \quad , \\ \widetilde{y}_+ \neq \widetilde{y}_- \qquad & 0 \leq \widetilde{y}_+ | \widetilde{y}_- \leq y + \Delta y \quad , \\ \widetilde{z}_+ \neq \widetilde{z}_- \qquad & 0 \leq \widetilde{z}_+ | \widetilde{z}_- \leq z + \Delta z \quad . \end{aligned}$$

The total particle out-flow is (definition of divergence):

$$\boxed{\mathbb{d}N_{\mathtt{OUT}} \equiv\ \mathbb{d}t \oiint_{\Omega} \mathbf{j}\cdot\ \mathbb{d}\mathbf{S} \simeq \Delta x\Delta y\Delta z\ \mathbb{d}t \left(\frac{\partial j_x}{\partial x} + \frac{\partial j_y}{\partial y} + \frac{\partial j_z}{\partial z}\right) = (\mathbf{div}\mathbf{j})\,\Delta x\Delta y\Delta z\ \mathbb{d}t} \quad .$$

Therefore the infinitesimal particle flux per unit volume is given by the divergence.

One can then write:

$$\oiint_{\Omega} \mathbf{j}\cdot\mathbf{n}\ \mathbb{d}\mathbf{S} \simeq \Delta x\Delta y\Delta z \left(\frac{\partial j_x}{\partial x} + \frac{\partial j_y}{\partial y} + \frac{\partial j_z}{\partial z}\right) = \Delta x\Delta y\Delta z \mathbf{div}\mathbf{j} \quad .$$

Note that the total out-flow from any closed surface might be, for instance, positive, but some of its components might be, for instance, negative.

16.06.05.02 Rotor in Cartesian Coordinates Coordinate System: Hydrodynamics

Consider a 2D flow of fluid, in the xy plane. The circulation of $\mathbf{j}_{\mathtt{M}}$ around any point gives the **vorticity**: if it is positive there is an overall fluid vortex circulation in the clockwise direction; if it is negative there is an overall fluid vortex circulation in the counterclockwise direction;

Consider a small ship floating on the fluid. The tendency to rotate as a consequence of the different velocity of the fluid at different points can be approximately calculated as follows. Approximate the ship as a small rectangle, with sides, of length Δx and Δy, respectively in the directions parallel to the x and y axes.

It is understood that a limit will be taken such that: $\Delta x \to 0$ and $\Delta y \to 0$.

The contributions to the circulation of the velocity field can be approximately estimated as follows, taking only first-order expressions, thanks to Lagrange mean value theorem.

The two contributions along x at the two sides parallel to the x axis are, thanks to Lagrange mean value theorem:

$$\Delta x v_x[\widetilde{x}_-, y] \qquad \Delta x \left(v_x[\widetilde{x}_-, y] + \Delta y \frac{\partial v_x}{\partial y}[\widetilde{x}_+, y+\Delta y]\right) \qquad \text{for some } x \leq \widetilde{x}_- | \widetilde{x}_+ \leq x + \Delta x \quad ,$$

tending to rotate in opposite directions, with an overall result that only depends on the derivative term.

DRAFT - IN PROGRESS

CC BY NC ND

The two contributions along y at the two sides parallel to the x axis are, thanks to Lagrange mean value theorem:

$$\Delta y v_y[x, \widetilde{y}_+] \qquad \Delta y \left(v_y[x, \widetilde{y}_+] + \Delta x \frac{\partial v_y}{\partial x}[x + \Delta x, \widetilde{y}_-] \right) \qquad \text{for some } y \leq \widetilde{y}_- | \widetilde{y}_+ \leq y + \Delta y \quad ,$$

tending to rotate in opposite directions, with an overall result that only depends on the derivative term.

The overall effect is thus given by the combined effect of the two derivative terms, whose effect is to tend to rotate in opposite directions. Therefore the overall effect is given by the difference of the two derivative terms, that is just the z component of the rotor, that is the circulation per unit area:

$$\oint_C \mathbf{v} \cdot \mathrm{d}\mathbf{L} \approx \Delta x \Delta y \left(\frac{\partial v_y}{\partial x} - \frac{\partial v_x}{\partial y} \right) \equiv \Delta x \Delta y \, \mathbf{rot}\mathbf{v}\Big|_z \quad .$$

D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...
Geometrical Interpretation: Suppose you wanted to determine the height of the Eiffel Tower. You could climb the stairs, using a ruler to measure the rise at each step, and adding them all up (that's the left side of Eq. 1.55), or you could place altimeters at the top and the bottom, and subtract the two readings (that's the right side); you should get the same answer either way (that's the fundamental theorem).

WORK IN PROGRESS

16.07.02
Divergence Theorem

The volume integral of the divergence of some function can be evaluated from from the knowledge of the function on the boundaries of the volume alone.

$$\iiint_{\Omega} \mathbf{div}\,\mathbf{A}\ \mathrm{d}V = \iiint_{\Omega} \boldsymbol{\nabla}\cdot\mathbf{A}\ \mathrm{d}V = \oiint_{\partial\Omega} \mathbf{A}\cdot\mathrm{d}\mathbf{S} \quad . \tag{16.07.02}$$

→ 1107

16.07.02.01 Two Corollaries to the Divergence Theorem

©|G.B.Arfken & H.J.Weber, *Mathematical Methods For Physicists*, 2005, Elsevier, 6thEd., ...|||

Show that:

$$\iiint_{\Omega} \boldsymbol{\nabla}\phi\ \mathrm{d}V = \oiint_{\partial\Omega} \phi\hat{\mathbf{n}}\ \mathrm{d}S = \oiint_{\partial\Omega} \phi\ \mathrm{d}\mathbf{S} \quad . \tag{16.07.03}$$

→ 1107 1131 1847

Show that:

$$\iiint_{\Omega} \boldsymbol{\nabla}\wedge\mathbf{A}\ \mathrm{d}V = \oiint_{\partial\Omega} (\hat{\mathbf{n}}\wedge\mathbf{A})\ \mathrm{d}S = \oiint_{\partial\Omega} \mathrm{d}\mathbf{S}\wedge\mathbf{A} \quad . \tag{16.07.04}$$

→ 1107 1131 1889

Note that the two theorems (16.07.03), (16.07.04) might be used as alternative definitions for gradient and rotor, as it is done in (16.06.06) for defining the divergence.

Note that the two theorems (16.07.03), (16.07.04) as well as the **divergence theorem** (16.07.02) are all three of the form:

$$\iiint_{\Omega} \boldsymbol{\nabla}\otimes(\ldots)\ \mathrm{d}V = \oiint_{\partial\Omega} \hat{\mathbf{n}}\otimes(\ldots)\ \mathrm{d}S = \oiint_{\partial\Omega} \mathrm{d}\mathbf{S}\otimes(\ldots) \quad , \tag{16.07.05}$$

where the $\otimes$ operator is the kind of multiplication defined by the nabla vector operator on the left-side.

16.07.02.02 Examples and Applications

When using $\phi = 1$ in equation (16.07.03) one finds the simple result

$$\oiint_{\partial\Omega} \mathrm{d}\mathbf{S} = 0 \quad . \tag{16.07.06}$$

The two corollaries (16.07.03), (16.07.04) provide an alternative coordinate-independent definition of the gradient and rotor, based on a volume integral, that is similar to the original coordinate-independent definition of the divergence in section § 16.06.01.03.

The corollary (16.07.03) can be used to demonstrate the Archimedes principle of hydrostatics.

DRAFT WORK IN PROGRESS

16.07.03
Rotor Theorem

The surface integral of the rotor of some function can be evaluated from from the knowledge of the function on the boundaries of the surface alone.

$$\iint_{\Sigma} \mathbf{rot}\,\mathbf{A}\cdot \mathbb{d}\mathbf{S} = \iint_{\Sigma} \boldsymbol{\nabla}\wedge\mathbf{A}\cdot \mathbb{d}\mathbf{S} = \oint_{\partial\Sigma} \mathbf{A}\cdot \mathbb{d}\mathbf{L} \quad . \tag{16.07.07}$$

→ 1108 1131 1711

The orientations of the surface Σ and its boundary $\partial\Sigma$ must be compatible.

16.07.03.01 Two Corollaries to the Rotor Theorem

©|G.B.Arfken & H.J.Weber, *Mathematical Methods For Physicists*, 2005, Elsevier, 6thEd., ...|||

Show that:

$$\iint_{\Sigma} \mathbb{d}\mathbf{S}\wedge\boldsymbol{\nabla}\phi = \iint_{\Sigma} \widehat{\mathbf{n}}\wedge\boldsymbol{\nabla}\phi\ \mathbb{d}S = \oint_{\partial\Sigma} \phi\ \mathbb{d}\mathbf{L} \quad . \tag{16.07.08}$$

→ 1108 1711 1739

Show that:

$$\iint_{\Sigma} (\ \mathbb{d}\mathbf{S}\wedge\boldsymbol{\nabla})\wedge\mathbf{A} = \iint_{\Sigma} (\widehat{\mathbf{n}}\wedge\boldsymbol{\nabla})\wedge\mathbf{A}\ \mathbb{d}S = \oint_{\partial\Sigma} \mathbb{d}\mathbf{L}\wedge\mathbf{A} \quad . \tag{16.07.09}$$

→ 1108 1781

Note that the two theorems (16.07.08), (16.07.09) as well as the **rotor theorem** (16.07.07) are all three of the form:

$$\iint_{\Sigma} (\ \mathbb{d}\mathbf{S}\wedge\boldsymbol{\nabla})\otimes(\ldots) = \iint_{\Sigma} (\widehat{\mathbf{n}}\wedge\boldsymbol{\nabla})\otimes(\ldots)\ \mathbb{d}S = \oint_{\partial\Sigma} \mathbb{d}\mathbf{L}\otimes(\ldots) \quad , \tag{16.07.10}$$

→ 1781

where the $\otimes$ operator is the kind of multiplication defined by the nabla vector operator on the left-side.

16.07.03.02 Examples and Applications

When using $\phi = 1$ in equation (16.07.08) one finds the simple result:

$$\oint_{\partial\Sigma} \mathbb{d}\mathbf{L} = 0 \quad . \tag{16.07.11}$$

The three theorems (16.07.08), (16.07.09) as well as the **rotor theorem** (16.07.07) all show that the left-hand side integrals are independent of the specific surface of integration chosen, once the boundary is fixed to $\partial\Sigma$.

16.07.05
Helmholtz Theorem

This § is referenced at pages:
[1662, 1852, 1894]

Helmholtz theorem, under the appropriate hypotheses, provides the explicit expressions for a vector field when the field divergence and rotor are given, showing that, under the appropriate hypotheses, any vector field can be reconstructed from its divergence and rotor.

Suppose a vector field is defined by the set of equations:

$$\mathbf{div}\,\mathbf{V} = \rho \quad ,$$
$$\mathbf{rot}\,\mathbf{V} = \mathbf{J} \qquad \text{this implies, for consistency,} \qquad \mathbf{div}\,\mathbf{J} = 0 \quad ,$$

with

$$\mathbf{div}\,\mathbf{V}\Big|_{\infty} = 0 \qquad \mathbf{rot}\,\mathbf{V}\Big|_{\infty} = 0 \quad ,$$

that is the divergence and rotor vanish at infinity.

The vector field may be written as the sum of an irrotational part plus a solenoidal part:

$$\boxed{\mathbf{V} = -\mathbf{grad}\phi + \mathbf{rot}\,\mathbf{A}} \quad ,$$

where for a Vector Field, $\mathbf{V}$, one has

$$\boxed{\phi[\mathbf{x}] = \frac{1}{4\pi}\iiint\limits_{\Omega} \frac{\rho[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}}} \quad ,$$

$$\boxed{\mathbf{A}[\mathbf{x}] = \frac{1}{4\pi}\iiint\limits_{\Omega} \frac{\mathbf{J}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}}} \quad ,$$

with the integral extended to any region Ω including the set of points where $\mathbf{div}\,\mathbf{V}$ and $\mathbf{rot}\,\mathbf{V}$ are different from zero.

In other words Helmholtz theorem states that **any sufficiently smooth, rapidly decaying vector field can be resolved into an irrotational (rotor-free) component plus a solenoidal (divergence-free) component**. It is also known as the fundamental theorem of vector calculus.

16.08 Second-Order Differential Operators

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|2||
©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|Vol. 2, 2,3||

One can build five second-order differential operators:

$$\textbf{divgrad}\,\phi \equiv \nabla^2\phi \tag{16.08.01}$$ → 1110

$$\textbf{rotgrad}\,\phi = 0 \tag{16.08.02}$$

$$\textbf{graddiv}\,\mathbf{A} \tag{16.08.03}$$ → 1110

$$\textbf{divrot}\,\mathbf{A} = 0 \tag{16.08.04}$$

$$\textbf{rotrot}\,\mathbf{A} \equiv \textbf{graddiv}\,\mathbf{A} - \boldsymbol{\nabla}^2\mathbf{A} \qquad \text{a definition for } \boldsymbol{\nabla}^2\mathbf{A} \quad . \tag{16.08.05}$$ → 1110 1133

Equation (16.08.01) is actually the definition of the scalar Laplacian operator:

$$\boxed{\textbf{divgrad}\,\phi = \frac{\partial}{\partial x_i}\frac{\partial}{\partial x_i}\phi \equiv \nabla^2\phi} \quad . \tag{16.08.06}$$

Equation (16.08.05) is actually the definition of the vector Laplacian operator:

$$\boxed{\boldsymbol{\nabla}^2\mathbf{A} \equiv \textbf{graddiv}\,\mathbf{A} - \textbf{rotrot}\,\mathbf{A}} \quad . \tag{16.08.07}$$ → 1110

In fact, in orthonormal Cartesian Coordinates Coordinate System, equation (16.08.05) can be straightforwardly derived for each of the orthonormal Cartesian Coordinates Coordinate System of the vector field by developing the **rotrot**(...):

$$\{\textbf{rotrot}\,\mathbf{A}\}_k = \frac{\partial}{\partial x_k}(\textbf{div}\,\mathbf{A}) - \nabla^2 A_k \quad . \tag{16.08.08}$$ → 1110

Equation (16.08.07) is then taken as the definition of the vector Laplacian in any generic Coordinate System. In a general Coordinate System the expression of the vector Laplacian has nothing to do with the Cartesian Coordinate expression (16.08.08) but it has to be worked-out explicitly from equation (16.08.05). In Cartesian Coordinates one finds:

$$\boxed{\left\{\boldsymbol{\nabla}^2\mathbf{A}\right\}_k = \nabla^2 A_k \qquad \text{in orthonormal Cartesian Coordinates Coordinate System only}} \quad . \tag{16.08.09}$$ → 2087

Note that equations (16.08.03), (16.08.05) both include the same operator: **graddiv**$\mathbf{A}$.

The operators which are identically zero are those two which are built with one and only one rotor operator. In fact the rotor definition includes the **Levi-Civita symbol** and the second-order operator has two ∂. It follows that this kind of operator is identically zero because it is a product made of an anti-symmetrical and a symmetrical part.

©|J.Cantarella *et al.*|Vector Calculus and the Topology of Domains in 3-Space|*§ 6, 16, 17; DOI: 10.2307/2695643* - ...

Given a vector field defined on a bounded domain in 3D-space one may ask whether the vector field is the gradient of some function or the rotor of another vector field. The answer to these and similar questions requires to understand the relationship between the calculus of vector fields and the topology of their domains of definition and, therefore, it is not a trivial matter at all. Unfortunately in most books, and not only physics books, the topic is treated in a simplified and partly wrong way.

16.09.01 Domain and Connectedness

©|T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...||*Fair discussion.*|

In the following definitions the word **regular** is intended in a non-technical sense, as the detailed discussion of the properties required to the domains is far beyond what can be presented here. For a fair discussion and more details, see the references.

- A subset $\Omega \subseteq \mathbb{R}^3$ is said to be 0-connected (or path-wise connected) if there exist a curve $\mathcal{C} \subseteq \Omega$ connecting every two points belonging to Ω such that the two points are the boundary of the curve.
- A subset $\Omega \subseteq \mathbb{R}^3$ is said to be 1-connected if every **regular** closed curve $\mathcal{C} \subseteq \Omega$ is the boundary of an oriented **regular** surface $\mathcal{S} \subseteq \Omega$ such that $\mathcal{C} = \partial\mathcal{S}$.
- A subset $\Omega \subseteq \mathbb{R}^3$ is said to be 2-connected if every **regular** closed surface $\mathcal{S} \subseteq \Omega$ is the boundary of a **regular** domain $\mathcal{D} \subseteq \Omega$ such that $\mathcal{S} = \partial\mathcal{D}$.

16.09.02 Conservative Fields

Note that usage of names may be not universal.

16.09.02.01 Conservative - Irrotational Fields

This § is referenced at pages:
[Never referenced.]

A field, $\mathbf{V}$, is said to be **conservative for the circulation** if the circulation around any closed line is zero.
In this case: $\mathbf{rot}\mathbf{V} = 0$, that is **the field is rotor-less**, commonly named irrotational. The circulation is conserved in the sense that, given any two points, it does not depend on the path having the two points as the boundary.
If the field can be written as the gradient of a scalar potential, it is just known as, in short terms, **a conservative field**, the name deriving from mechanical energy conservation in point mechanics. Read § 16.09.03 form more details.

DRAFT - IN PROGRESS

16.09.02.02 Conservative - Divergenceless Fields

This § is referenced at pages:
[1132]

A field, $\mathbf{V}$, is said to be **conservative for the flux** if the flux across any closed surface is zero. In this case: $\mathbf{div}\mathbf{V} = 0$, that is **the field is divergence-less**.

The flux is conserved in the sense that, given any closed line, it does not depend on the surface having the closed line as the boundary.

If the field can be written as the rotor of a **vector potential** , it is just known as, in short terms, **a solenoidal field** or an incompressible (fluid) field. Read § 16.09.03 form more details.

16.09.03.01 Gradient-less fields

This § is referenced at pages:
[Never referenced.]

Theorem

A scalar field defined on all of a 0-connected set, has vanishing gradient if and only if it has a fixed value.

16.09.03.02 Scalar Potential and Reconstruction of a Scalar Field From Its Gradient

This § is referenced at pages:
[1114]

Let us determine under which conditions a vector field is the gradient of a scalar field.

A vector field, $\mathbf{V}$, defined on a subset $\mathcal{D}$ of $\mathbb{R}^3$ with simple linear connection (1-connected), admits a (non-unique) scalar potential if and only if it is irrotational:

$$\mathcal{D} \text{ is 1-connected : } \quad \{\mathbf{rot}\,\mathbf{V} = 0 \quad \Leftrightarrow \quad \mathbf{V} = -\mathbf{grad}\,\phi\} \quad .$$

The scalar potential is defined to within an arbitrary constant.

In any convex domain, an explicit expression to deduce the scalar potential from the field, is given by:

$$\phi[x,y,z] - \phi[0] = -\int_0^{\{x,y,z\}} \mathbf{F}\cdot \mathbb{d}\mathbf{L} \quad . \tag{16.09.01}$$

This expression can be applied in any convex sub-domain but, for a generic domain, one might be forced to use different vector potentials in different convex sub-domains.

Note that the minus sign in the definition is just conventional in physics. In mathematics the definition is often given without the minus sign.

cc BY NC ND

Theorem

A vector field defined on all of a 1-connected set, has vanishing rotor if and only if a scalar field exists (the scalar potential) whose gradient is the vector field itself; the scalar potential is defined to within a fixed term.

Counterexample

C. Amrouche, C. Bernardi, M. Dauge, and V. Girault,
Vector potentials in three dimensional non-smooth domains,
Math. Methods Appl. Sci., 21, No. 9, 823-864 (1998).
WEB - URL
However, in the three-dimensional case, the situation is much more complicated: a potential can also be used for handling the divergence-free property, However, the conditions that must be enforced in order to ensure its existence and uniqueness are not so simple. Three main difficulties appear:
(i) In contrast to the two-dimensional case, the potential is no longer a scalar function, but a vector function with three components, so it is known as vector potential. As the rotor of a gradient is always zero, a global condition must be added to eliminate such gradients; it is known as the "**gauge fixing condition** " and it usually concerns the divergence of the potential. More precisely, the condition that we propose imposes that the vector potential is itself divergence-free. But such a condition is generally not sufficient for uniqueness: for instance, the gradient of any harmonic scalar function is rotor-free and divergence-free.
(ii) Adequate boundary conditions must be enforced on the vector potential: they concern either its normal or its tangential component (but not both). Consequently, the functional spaces in which the vector potential is sought for, are no longer standard Sobolev spaces and their embedding in these Sobolev spaces depend on the boundary conditions and on the regularity of the domain.
(iii) The geometry of the domain is more complex than in the two-dimensional case, even when it is bounded, since the simple-connexity is no longer linked to the number of connected components of the boundary. So, two different parameters are necessary to characterize the geometry of the domain, related to the number of components of the boundary and to the homotopy group of the domain. They are closely related to the dimensions of the kernels of the problems that we consider, which are spaces of rotor- and divergence-free vector fields with null boundary conditions.

16.09.03.03 Vector Potential and Reconstruction of a Vector Field From Its Rotor

This § is referenced at pages:
[1114, 1743, 1807]

©|T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...|Vol. 2 - § 12.16|*Explicit discussion*|

Let us determine under which conditions a vector field is the rotor of a vector field.

A vector field, $\mathbf{F}$, defined on a subset $\mathcal{D}$ of $\mathbb{R}^3$ with simple surface connection (2-connected), admits a (non-unique) vector potential if and only if it is divergence-less:

$$\mathcal{D} \text{ is 2-connected : } \quad \{\mathbf{div}\,\mathbf{V} = 0 \quad \Leftrightarrow \quad \mathbf{F} = \mathbf{rot}\,\mathbf{A}\} \quad .$$

The vector potential is defined to within the gradient of an arbitrary scalar function.

An explicit expression to deduce the vector potential from the field, the analogous of equation (16.07.01), can be found in [1]. In fact, in any convex domain, an explicit expression to deduce the vector potential

[1] T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...

from the field, is given by:

$$\mathbf{A}[x,y,z] = \int_0^1 t\,\mathbf{F}[tx,ty,tz]\wedge(x\widehat{\mathbf{e}}_1 + y\widehat{\mathbf{e}}_2 + z\widehat{\mathbf{e}}_3)\,\mathrm{d}t \quad . \tag{16.09.02}$$

→ 1807

This expression can be applied in any convex sub-domain but, for a generic domain, one might be forced to use different vector potentials in different convex sub-domains.

Theorem

A vector field defined on all of a 2-connected set, has vanishing divergence if and only if a vector field exists (the vector potential) whose rotor is the vector field itself; the vector potential is defined to within the gradient of an arbitrary function.

Counterexample

16.09.03.04 Independence of Line|Surface Integrals From the Path/surface

According to sections § 16.09.03.02, § 16.09.03.03 the following propositions apply:

- A line integral on a 1-connected domain is independent of the integration line, and only depends on the boundaries of the integration line, if and only if the vector fields is irrotational. In this case the circulation along all curves having the same extremes is the same, and one can just speak of circulation between two points.
- A surface integral on a 2-connected domain is independent of the integration surface, and only depends on the boundaries of the integration surface, if and only if the vector fields is solenoidal. In this case the flux across all surfaces having the same boundary is the same, and one can just speak of flux across a line or flux concatenated to a line.

16.09.03.05 Connections Between the Three Fundamental Theorems

In order for the **rotor theorem** to be well defined it is necessary that the surface-integral of the rotor must be independent of the surface having as a boundary the chosen closed line. That is the flux of a rotor across a closed surface must be zero. Applying the **divergence theorem** to the rotor gives zero as the divergence of a rotor is zero. But it is necessary that the domain is 2-connected.

In order for the fundamental theorem to be be well defined it is necessary that the line-integral of the gradient must be independent of the line having as a boundary the two chosen points. That is the circulation of a gradient across a closed line must be zero. Applying the **rotor theorem** to the gradient gives zero as the rotor of a gradient is zero. But it is necessary that the domain is 1-connected.

DRAFT IN PROGRESS

The ∇-operator

In cartesian coordinates (x, y, z) holds:

$$\vec{\nabla} = \frac{\partial}{\partial x}\vec{e}_x + \frac{\partial}{\partial y}\vec{e}_y + \frac{\partial}{\partial z}\vec{e}_z \ , \ \text{grad} f = \vec{\nabla} f = \frac{\partial f}{\partial x}\vec{e}_x + \frac{\partial f}{\partial y}\vec{e}_y + \frac{\partial f}{\partial z}\vec{e}_z$$

$$\text{div}\ \vec{a} = \vec{\nabla}\cdot\vec{a} = \frac{\partial a_x}{\partial x} + \frac{\partial a_y}{\partial y} + \frac{\partial a_z}{\partial z} \ , \ \nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$$

$$\text{rot}\ \vec{a} = \vec{\nabla}\times\vec{a} = \left(\frac{\partial a_z}{\partial y} - \frac{\partial a_y}{\partial z}\right)\vec{e}_x + \left(\frac{\partial a_x}{\partial z} - \frac{\partial a_z}{\partial x}\right)\vec{e}_y + \left(\frac{\partial a_y}{\partial x} - \frac{\partial a_x}{\partial y}\right)\vec{e}_z$$

In cylinder coordinates (r, φ, z) holds:

$$\vec{\nabla} = \frac{\partial}{\partial r}\vec{e}_r + \frac{1}{r}\frac{\partial}{\partial \varphi}\vec{e}_\varphi + \frac{\partial}{\partial z}\vec{e}_z \ , \ \text{grad} f = \frac{\partial f}{\partial r}\vec{e}_r + \frac{1}{r}\frac{\partial f}{\partial \varphi}\vec{e}_\varphi + \frac{\partial f}{\partial z}\vec{e}_z$$

$$\text{div}\ \vec{a} = \frac{\partial a_r}{\partial r} + \frac{a_r}{r} + \frac{1}{r}\frac{\partial a_\varphi}{\partial \varphi} + \frac{\partial a_z}{\partial z} \ , \ \nabla^2 f = \frac{\partial^2 f}{\partial r^2} + \frac{1}{r}\frac{\partial f}{\partial r} + \frac{1}{r^2}\frac{\partial^2 f}{\partial \varphi^2} + \frac{\partial^2 f}{\partial z^2}$$

$$\text{rot}\ \vec{a} = \left(\frac{1}{r}\frac{\partial a_z}{\partial \varphi} - \frac{\partial a_\varphi}{\partial z}\right)\vec{e}_r + \left(\frac{\partial a_r}{\partial z} - \frac{\partial a_z}{\partial r}\right)\vec{e}_\varphi + \left(\frac{\partial a_\varphi}{\partial r} + \frac{a_\varphi}{r} - \frac{1}{r}\frac{\partial a_r}{\partial \varphi}\right)\vec{e}_z$$

In spherical coordinates (r, θ, φ) holds:

$$\begin{aligned}
\vec{\nabla} &= \frac{\partial}{\partial r}\vec{e}_r + \frac{1}{r}\frac{\partial}{\partial \theta}\vec{e}_\theta + \frac{1}{r\sin\theta}\frac{\partial}{\partial \varphi}\vec{e}_\varphi \\
\text{grad} f &= \frac{\partial f}{\partial r}\vec{e}_r + \frac{1}{r}\frac{\partial f}{\partial \theta}\vec{e}_\theta + \frac{1}{r\sin\theta}\frac{\partial f}{\partial \varphi}\vec{e}_\varphi \\
\text{div}\ \vec{a} &= \frac{\partial a_r}{\partial r} + \frac{2a_r}{r} + \frac{1}{r}\frac{\partial a_\theta}{\partial \theta} + \frac{a_\theta}{r\tan\theta} + \frac{1}{r\sin\theta}\frac{\partial a_\varphi}{\partial \varphi} \\
\text{rot}\ \vec{a} &= \left(\frac{1}{r}\frac{\partial a_\varphi}{\partial \theta} + \frac{a_\theta}{r\tan\theta} - \frac{1}{r\sin\theta}\frac{\partial a_\theta}{\partial \varphi}\right)\vec{e}_r + \left(\frac{1}{r\sin\theta}\frac{\partial a_r}{\partial \varphi} - \frac{\partial a_\varphi}{\partial r} - \frac{a_\varphi}{r}\right)\vec{e}_\theta + \\
&\quad \left(\frac{\partial a_\theta}{\partial r} + \frac{a_\theta}{r} - \frac{1}{r}\frac{\partial a_r}{\partial \theta}\right)\vec{e}_\varphi \\
\nabla^2 f &= \frac{\partial^2 f}{\partial r^2} + \frac{2}{r}\frac{\partial f}{\partial r} + \frac{1}{r^2}\frac{\partial^2 f}{\partial \theta^2} + \frac{1}{r^2\tan\theta}\frac{\partial f}{\partial \theta} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 f}{\partial \varphi^2}
\end{aligned}$$

General orthonormal curvelinear coordinates (u, v, w) can be obtained from cartesian coordinates by the transformation $\vec{x} = \vec{x}(u, v, w)$. The unit vectors are then given by:

$$\vec{e}_u = \frac{1}{h_1}\frac{\partial \vec{x}}{\partial u} \ , \ \vec{e}_v = \frac{1}{h_2}\frac{\partial \vec{x}}{\partial v} \ , \ \vec{e}_w = \frac{1}{h_3}\frac{\partial \vec{x}}{\partial w}$$

where the factors h_i set the norm to 1. Then holds:

$$\begin{aligned}
\text{grad} f &= \frac{1}{h_1}\frac{\partial f}{\partial u}\vec{e}_u + \frac{1}{h_2}\frac{\partial f}{\partial v}\vec{e}_v + \frac{1}{h_3}\frac{\partial f}{\partial w}\vec{e}_w \\
\text{div}\ \vec{a} &= \frac{1}{h_1 h_2 h_3}\left(\frac{\partial}{\partial u}(h_2 h_3 a_u) + \frac{\partial}{\partial v}(h_3 h_1 a_v) + \frac{\partial}{\partial w}(h_1 h_2 a_w)\right) \\
\text{rot}\ \vec{a} &= \frac{1}{h_2 h_3}\left(\frac{\partial(h_3 a_w)}{\partial v} - \frac{\partial(h_2 a_v)}{\partial w}\right)\vec{e}_u + \frac{1}{h_3 h_1}\left(\frac{\partial(h_1 a_u)}{\partial w} - \frac{\partial(h_3 a_w)}{\partial u}\right)\vec{e}_v + \\
&\quad \frac{1}{h_1 h_2}\left(\frac{\partial(h_2 a_v)}{\partial u} - \frac{\partial(h_1 a_u)}{\partial v}\right)\vec{e}_w \\
\nabla^2 f &= \frac{1}{h_1 h_2 h_3}\left[\frac{\partial}{\partial u}\left(\frac{h_2 h_3}{h_1}\frac{\partial f}{\partial u}\right) + \frac{\partial}{\partial v}\left(\frac{h_3 h_1}{h_2}\frac{\partial f}{\partial v}\right) + \frac{\partial}{\partial w}\left(\frac{h_1 h_2}{h_3}\frac{\partial f}{\partial w}\right)\right]
\end{aligned}$$

16.12 Examples and Physical Applications

16.12.01
Unit Vectors in the Plane in Polar Coordinates

Given the time derivative of one of the two unit vectors for polar coordinates in the plane, $\widehat{\mathbf{e}}_r$ and $\widehat{\mathbf{e}}_\theta$, deduce the second one from the orthonormality condition.

WORKED SOLUTION

$$0 = \widehat{\mathbf{e}}_r \cdot \widehat{\mathbf{e}}_\theta \quad ,$$

take the time derivative

In 3D the trick generalizes as in section § 23.06.02.02 and equation (23.06.03).

16.12.02
☒ Gradient in Spherical Coordinates

Esprimere il gradiente in coordinate sferiche e in coordinate curvilinee generiche.

WORKED SOLUTION

Dato un campo scalare $U[\mathbf{r}]$ si ha, per definizione di gradiente:

$$\mathrm{d}U[\mathbf{r}] \equiv \mathbf{grad}U \cdot \mathrm{d}\mathbf{r} \quad ,$$

che è invariante, cioé indipendente dal Coordinate System.
Esprimendo $\mathrm{d}\mathbf{r}$ in coordinate polari si ha:

$$\mathrm{d}\mathbf{r} = \mathrm{d}r\widehat{\mathbf{e}}_r + r\,\mathrm{d}\theta\widehat{\mathbf{e}}_\theta + r\sin[\theta]\,\mathrm{d}\phi\widehat{\mathbf{e}}_\phi \quad ,$$

da cui seguono le componenti di $\mathbf{grad}U$ in coordinate sferiche:

$$\mathbf{grad}U = \begin{cases} \mathbf{grad}U\big|_r = \dfrac{\partial U}{\partial r} \quad , \\ \mathbf{grad}U\big|_\theta = \dfrac{1}{r}\dfrac{\partial U}{\partial \theta} \quad , \\ \mathbf{grad}U\big|_\phi = \dfrac{1}{r\sin[\theta]}\dfrac{\partial U}{\partial \phi} \quad . \end{cases}$$

Per un generale sistema di coordinate ortonormali si ha:

$$\mathrm{d}\mathbf{r} = \sum_{k=1}^{3} h_k\,\mathrm{d}\ell_k \mathbf{e}_k \quad ,$$

da cui

$$\mathrm{d}U \equiv \mathbf{grad}U \cdot \mathrm{d}\mathbf{r} = \sum_{k=1}^{3} h_k\,\mathbf{grad}U\Big|_k\,\mathrm{d}\ell_k = \sum_{k=1}^{3}\frac{\partial U}{\partial \ell_k}\,\mathrm{d}\ell_k \quad ,$$

da cui segue

$$\mathbf{grad}U\Big|_k = \frac{1}{h_k}\frac{\partial U}{\partial \ell_k} \quad .$$

✓ Graphical Examples of Vector Fields in 2D

In this section a number of graphical representations of two-dimensional vector fields are shown. The limitation to two-dimensional fields is not essential and it is used only to simplify and make clearer the graphical representations. In fact the general definitions in section § 16.06 can be straightforwardly restricted to two-dimensional fields. Alternatively one can consider the fields as three-dimensional fields with no z-dependence, $\frac{\partial}{\partial z}\{\ldots\} = 0$, and zero z-component, $V_z = 0$. In this case the expressions in section § 16.06.03.01 show that the gradient has a zero z-component, the divergence is limited to the partial derivatives with respect to x and y while the rotor only has a non-zero z-component.

16.12.07
Properties of a Distribution of Currents with compact support

This § is referenced at pages:
[1739]

Consider an arbitrary current distribution, with limited extension in space, that is:

$$\text{a sphere of radius } R \text{ exists such that} \qquad \mathbf{j}[\mathbf{r}] = 0 \qquad \text{for} \qquad |\mathbf{r}| > R \quad ,$$

that is **a function with compact support**, that is **a function which vanishes at infinity**.

1. Assume a steady current distribution, that is:

$$\mathbf{j}[\mathbf{r}, t] = \mathbf{j}[\mathbf{r}] \quad .$$

The following identity can be derived integrating over the sphere of radius R (volume Ω), at the frontier of which $\mathbf{j}[\mathbf{r}] = 0$:

$$0 = \oiint_{\partial\Omega} g[\mathbf{r}]\mathbf{j}[\mathbf{r}] \cdot \mathbb{d}\mathbf{S} = \iiint_{\Omega} \mathbf{div}(g[\mathbf{r}]\mathbf{j}[\mathbf{r}])\, \mathbb{d}V = \iiint_{\Omega} \mathbf{j}[\mathbf{r}] \cdot \mathbf{grad} g[\mathbf{r}]\, \mathbb{d}V + \iiint_{\Omega} g[\mathbf{r}] \mathbf{div}\mathbf{j}[\mathbf{r}]\, \mathbb{d}V \quad .$$

From the steady condition and the continuity equation one has:

$$\mathbf{div}\mathbf{j}[\mathbf{r}] = 0 \quad .$$

It follows:

$$\boxed{\iiint_{\Omega} \mathbf{j}[\mathbf{r}] \cdot \mathbf{grad} g[\mathbf{r}]\, \mathbb{d}V = 0 \qquad \text{for any function } g[\mathbf{r}]} \quad . \qquad (16.12.01) \quad \rightarrow 1736$$

A particular case:

$$g[\mathbf{r}] = \mathbf{n}\cdot\mathbf{r} \implies \boxed{\mathbf{n} \cdot \iiint_{\Omega} \mathbf{j}\, \mathbb{d}V = 0 \qquad \text{for any function } \widehat{\mathbf{n}} \implies 0 = \iiint_{\Omega} \mathbf{j}\, \mathbb{d}V} \quad . \qquad (16.12.02) \quad \rightarrow 1782$$

2. With no further assumptions than compact support:

$$\boxed{\iiint_{\Omega} \mathbf{div}\mathbf{j}[\mathbf{r}, t]\, \mathbb{d}V = 0} \quad , \qquad (16.12.03) \quad \rightarrow 1740$$

as it is easily shown with the above derivation and $g[\mathbf{r}] = 1$.

Applications to Equations of Physics

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.12||

16.12.09
☒ Coulomb Law

Deduce the Coulomb law from the expression of the electric potential in ElectroStatics:

$$\mathbf{E} = -\mathbf{grad}\Phi \qquad \Phi[\mathbf{x}] = \frac{1}{4\pi\varepsilon_0}\iiint \frac{\rho[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathrm{y}} \quad .$$

Use equation (16.13.01).

16.12.10
☒ Biot-Savart Law

Deduce the Biot-Savart law from the expression of the **vector magnetic potential** in MagnetoStatics:

$$\mathbf{B} = \mathbf{rot}\,\mathbf{A} \qquad \mathbf{A}[\mathbf{x}] = \frac{\mu_0}{4\pi}\iiint \frac{\mathbf{j}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathrm{y}} \quad .$$

Use equation (16.13.01).

16.12.11
A Rigid Motion

Consider the velocity field, $\mathbf{v}[\mathbf{x}]$, of the points at rest with a Rest Frame in arbitrary motion with respect to another fixed Rest Frame:

$$\mathbf{v}[\mathbf{x}] = \mathbf{v}_0 + \boldsymbol{\omega}\wedge(\mathbf{x}-\mathbf{x}_0) \quad ,$$

with $\mathbf{x}_0$, $\mathbf{v}_0$ and $\boldsymbol{\omega}$ (angular velocity) fixed vectors. Note that this is, in fact, the distrobution of the velocities of a rigid body, see equation (26.03.02).

Show that the rotor of the vector field is twice the angular velocity:

$$\mathbf{rot}\,\mathbf{v}[\mathbf{x}] = 2\boldsymbol{\omega} \quad . \tag{16.12.04}$$

This problem shows that the rotor of a vector field has to do with *rotational* properties of the field.

WORKED SOLUTION

By direct computation:

$$\mathbf{rot}\,\mathbf{v}[\mathbf{x}] = \mathbf{rot}(\boldsymbol{\omega}\wedge\mathbf{x}) = 2\boldsymbol{\omega} \quad .$$

DRAFT LW-PROCESS

16.12.12

☒ Electric Dipole | Magnetic Dipole - From Potentials to Fields

This § is referenced at pages:
[1714, 1714, 2506]

1. Determine the electric field, equation (36.07.01), produced by an **Electric Dipole** $\mathbf{p}$ whose electric potential is:

$$\Phi[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{p}\cdot\mathbf{r}}{r^3} \quad . \tag{16.12.05}$$ → 1759

2. Determine the magnetic field, equation (36.07.02), produced by a **Magnetic Dipole** $\mathbf{m}$ whose **vector magnetic potential** is:

$$\mathbf{A}[\mathbf{r}] = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\wedge\mathbf{r}}{r^3} \quad . \tag{16.12.06}$$

16.12.13

☒ Dipole Field Lines

Determinare l'equazione delle linee di forza del campo prodotto da un dipolo ideale.

WORKED SOLUTION

Consideriamo, per fissare le idee, il campo elettrico di dipolo elettrico ideale:

$$\mathbf{E}[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(\frac{3\,(\mathbf{p}\cdot\mathbf{r})\,\mathbf{r}}{r^5} - \frac{\mathbf{p}}{r^3}\right) \quad .$$

è la somma di un termine radiale non isotropo e di un termine a direzione e verso fissati, entrambi con dipendenza dall'inverso del cubo della distanza dal dipolo.
Si consideri un Coordinate System sferiche centrato sul dipolo e con asse z parallelo al momento di dipolo $\mathbf{p}$. Proiezione sul unit vector radiale del campo elettrico:

$$E_r\widehat{\mathbf{e}}_r \equiv (\,\mathbf{E}\cdot\widehat{\mathbf{e}}_r\,)\,\widehat{\mathbf{e}}_r = \frac{1}{4\pi\varepsilon_0}\left(\frac{2\,(\,\mathbf{p}\cdot\mathbf{r}\,)}{r^4}\right)\widehat{\mathbf{e}}_r = \frac{1}{4\pi\varepsilon_0}\left(\frac{2p\cos[\theta]}{r^3}\right)\widehat{\mathbf{e}}_r \quad . \tag{16.12.07}$$

Proiezione sul unit vector polare del campo elettrico:

$$E_\theta\widehat{\mathbf{e}}_\theta \equiv (\,\mathbf{E}\cdot\widehat{\mathbf{e}}_\theta\,)\,\widehat{\mathbf{e}}_\theta = \mathbf{E} - E_r\widehat{\mathbf{e}}_r = \frac{1}{4\pi\varepsilon_0}\left(\frac{(\,\mathbf{p}\cdot\mathbf{r}\,)\,\mathbf{r}}{r^5} - \frac{\mathbf{p}}{r^3}\right) \quad . \tag{16.12.08}$$ → 1130

The radial component of the field is thus:

$$E_r = \frac{1}{4\pi\varepsilon_0}\left(\frac{2p\cos[\theta]}{r^3}\right) \quad . \tag{16.12.09}$$

In order to find an explicit expression for the component E_θ one can proceed in three ways, at least. The result is:

$$E_\theta = \frac{1}{4\pi\varepsilon_0}\left(\frac{p\sin[\theta]}{r^3}\right) \quad . \tag{16.12.10}$$ → 1130

A first method to find an explicit expression for the component E_θ is the following.
Data la scelta del Coordinate System si ha:

$$\widehat{\mathbf{e}}_3 \parallel \mathbf{p} \quad .$$

Allora si può scrivere:

$$\widehat{\mathbf{e}}_\psi \parallel \mathbf{r}\wedge\widehat{\mathbf{e}}_3 \quad ,$$
$$\widehat{\mathbf{e}}_\theta \parallel \widehat{\mathbf{e}}_r\wedge\widehat{\mathbf{e}}_\psi$$

DRAFT

ovvero

$$\widehat{\mathbf{e}}_\theta \parallel \mathbf{r}\wedge(\mathbf{p}\wedge\mathbf{r}) = r^2\mathbf{p} - \mathbf{r}\,(\mathbf{p}\cdot\mathbf{r}) \quad .$$

Normalizzando e definendo il segno nel modo corretto ($\widehat{\mathbf{e}}_\theta$ nel verso di θ crescente) si ha:

$$\widehat{\mathbf{e}}_\theta = \frac{\mathbf{r}\,(\mathbf{p}\cdot\mathbf{r}) - r^2\mathbf{p}}{pr^2\sin[\theta]} \qquad \text{per } \theta \neq (0,\pi) \quad . \tag{16.12.11}$$

→ 1130

Dal confronto tra (16.12.11), (16.12.08) si deduce il risultato (16.12.10). One should keep in mind that $\sin[\theta]$ is always positive in this problem. The sign to assign to E_θ has to be checked carefully.
A second method to find the explicit expression (16.12.10) for the component E_θ is the following. It consists in calculating $\mathbf{E}_\theta$ directly from the module of expression (16.12.08) by taking the scalar product of expression (16.12.08) with itself.
A third method to find an explicit expression (16.12.10) for the component E_θ is the following. It consists in calculating calculating $\mathbf{E}_\theta$ as the components of vector $\mathbf{E}$ perpendicular to $\mathbf{r}$, as in expression (15.03.10).
Le linee di forza del campo elettrico, $\mathbf{r}[s]$, sono determinate dall'equazione:

$$\boxed{\frac{\mathrm{d}\mathbf{r}}{\mathrm{d}s} = \mathbf{E}} \quad . \tag{16.12.12}$$

→ 1796

One has:

$$\mathrm{d}\mathbf{r} = \mathrm{d}r\widehat{\mathbf{e}}_r + r\,\mathrm{d}\theta\widehat{\mathbf{e}}_\theta \quad .$$

Da quanto ricavato sopra si scrivono dunque le componenti del vettore campo elettrico in coordinate polari e si eguagliano alle componenti del campo di linee di forza (taking into account that the factor $\frac{1}{4\pi\varepsilon_0}$ is irrelevant):

$$\frac{\mathrm{d}r}{\mathrm{d}s} = \frac{2p\cos[\theta]}{r^3} \quad ,$$
$$r\frac{\mathrm{d}\theta}{\mathrm{d}s} = \frac{p\sin[\theta]}{r^3} \quad .$$

Per risolvere il sistema di equazioni si divide membro a membro e si separano le variabili:

$$r = r[\theta[s]] \quad \Longrightarrow \quad \frac{\mathrm{d}r}{\mathrm{d}s} = \frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}s} \quad \Longrightarrow \quad \frac{\mathrm{d}r}{\mathrm{d}s}\frac{1}{r} = 2\frac{\mathrm{d}\theta}{\mathrm{d}s}\cot\theta \quad ,$$

da cui la soluzione:

$$r = c\,(\sin[\theta])^2 \quad ,$$

dove la costante di integrazione, c, corrisponde alla distanza della linea di forza dal dipolo sul piano equatoriale dello stesso ($\theta = \pi/2$). Nota: $\int\cot\theta = \log[|\sin[\theta]|]$.
In orthonormal Cartesian Coordinates Coordinate System the equation becomes:

$$\left(x^2+y^2\right)^3 = c^2y^4 \quad .$$

16.12.14

☒ Dipole Field in Spherical Coordinates

Show that a **Dipole** field (either electric or magnetic), $\mathbf{F}$,

$$\mathbf{F}[\mathbf{r}] \propto (2\cos[\theta]\,\widehat{\mathbf{e}}_r + \sin[\theta]\,\widehat{\mathbf{e}}_\theta) \quad ,$$

where the **Dipole** moment, $\mathbf{p}$, located at the origin of the Coordinate System, is either the **Electric Dipole** moment, $\mathbf{p}$, or the **Magnetic Dipole** moment, $\mathbf{m}$, can be written, in spherical coordinates, as:

$$\mathbf{F}[\mathbf{r}] \propto \frac{|\mathbf{p}|}{r^3}\left(3\frac{(\mathbf{p}\cdot\mathbf{r})}{r^5}\mathbf{r} - \frac{\mathbf{p}}{r^3}\right) \quad .$$

CC BY NC ND

16.12.15
☒ Archimedes Principle

This § is referenced at pages:
[1514, 1516, 1662]

Demonstrate the Archimedes' principle using equation (16.07.03):
1. calculate the total force on an object immersed in a fluid, given the pressure field;
2. calculate the total torque on an object immersed in a fluid, given the pressure field.

WORKED SOLUTION

1. Apply equation (16.07.03) using as $\phi[\mathbf{x}]$ the pressure field.
2. Use as a pole the origin of the Coordinate System.

$$\boldsymbol{\Gamma} = \oiint \mathbf{r} \wedge \mathbb{d}\mathbf{f}[\mathbf{r}] = \quad ,$$

$$\oiint \mathbf{r} \wedge (-p[\mathbf{r}]\, \mathbb{d}\mathbf{S}) = \quad ,$$

$$\iiint \mathbf{rot}(-p[\mathbf{r}]\mathbf{r})\, \mathbb{d}V = \quad ,$$

$$\mathbf{e}_i \iiint -\epsilon_{ijk}^{\cdot\cdot\cdot} \frac{\partial}{\partial x^j}(p[\mathbf{r}] x_k)\, \mathbb{d}V = \quad ,$$

$$\mathbf{e}_i \iiint -\epsilon_{ijk}^{\cdot\cdot\cdot} \left(x_k \frac{\partial}{\partial x_j} p + p \delta_{kj}^{\cdot\cdot} \right) \mathbb{d}V = \quad ,$$

$$\mathbf{e}_i \iiint -\epsilon_{ijk}^{\cdot\cdot\cdot} x_k \frac{\partial}{\partial x_j} p\, \mathbb{d}V \quad ,$$

so that:

$$\boxed{\boldsymbol{\Gamma} = \iiint \mathbf{r} \wedge (-\mathbf{grad} p[\mathbf{r}])\, \mathbb{d}V} \quad . \tag{16.12.13}$$

Compare the result with the one obtained via (16.07.04) and (16.13.08). It follows that the force per unit volume $-\mathbf{grad} p[\mathbf{r}]$ can be used to calculate the total torque of the pressure forces, in addition to the total force.

16.12.16
☒ Green formula in 2D

Rotor theorem (16.07.07) in 2D becomes Green formula:

$$\mathbf{A} = A_x[y]\hat{\mathbf{e}}_1 + A_y[x]\hat{\mathbf{e}}_2 \quad ,$$

$$\mathbf{rot}\,\mathbf{A} = \hat{\mathbf{e}}_3 \left(\frac{\partial A_y[x]}{\partial x} - \frac{\partial A_x[y]}{\partial y} \right) \quad ,$$

$$\boxed{\iint \left(\frac{\partial A_y[x]}{\partial x} - \frac{\partial A_x[y]}{\partial y} \right) \mathbb{d}S = \oint (A_x\, \mathbb{d}x + A_y\, \mathbb{d}y) \qquad \text{Green formula in 2D}} \quad . \tag{16.12.14}$$

→ 1135

It is also called Gauss theorem or the **divergence theorem** in the plane, others call it Stokes theorem in the plane.

16.12.17
Example of shear

This § is referenced at pages:
[1096, 1101, 1490]

©|J.D.Romano and R.H.Price - *Why no shear in "Div, grad, rotor, and all that"?* |WEB - URL |*A MUST*|

For a cube of moving fluid, the shear represents the rate at which each side is deviating from a square, and the nature of that deviation. A simple example is the two-dimensional flow given by the velocity field:

$$\mathbf{v} = (x + y)\,\widehat{\mathbf{e}}_1 + (x - y)\,\widehat{\mathbf{e}}_2 + 0\widehat{\mathbf{e}}_3 \quad . \tag{16.12.15}$$

It is easy to verify that both the divergence and the rotor of this vector field are zero, but the shearing of the fluid represents a real physical effect.

16.12.18
Shear and Gradient in cylindrical and spherical coordinates

This § is referenced at pages:

©|M.Lieberherr|The magnetic field lines of a helical coil are not simple loops|*Am. J. Phys. 1 November 2010; 78 (11):* ...

Read § 16.09.02.02.
If any field is such that its flux across any closed surface is zero, it is called a solenoidal field.
However, this does not mean that its field lines are necessarily closed curves.
See, for instance:

- a uniform and constant magnetic field (with sources at infinity);
- or the magnetic field on the axis of a real solenoid with circular cross-section (whose sources are not at infinity);
- or the field lines around a toroidal current which can, under suitable conditions, loop around the toroid without closing (sources not at infinity and field lines not going to infinity).

DRAFT - IN - PROGRESS

16-001 ☒ Second-Order Differential Operators - Rotor of Rotor

Demonstrate equation (16.08.05) in orthonormal Cartesian Coordinates Coordinate System.

WORKED SOLUTION

$$\{\mathbf{rotrot}\,\mathbf{A}\}_p = \epsilon_{pji}\epsilon_{irs}\partial_j\partial_r A_s = \partial_p\partial_j A_j - \partial_j\partial_j A_p \quad .$$

16-002 ✓ Irrotational Fields

Consider an irrotational field:

$$\epsilon_{pji}\frac{\partial V_i}{\partial x_j} = 0 \quad ,$$

and demonstrate, using the relations in section § 15-009, that it can be written as:

$$\frac{\partial V_i}{\partial x_j} = \frac{\partial V_j}{\partial x_i} \quad .$$

16-003 ✓ Some Useful Identities

Demonstrate the following relations (where $\widehat{\mathbf{n}} \equiv \mathbf{r}/r$ is the radial unit vector):

$$\frac{\partial r}{\partial x^k} = \frac{x^k}{r} \quad ,$$
$$\mathbf{grad}\, r = \mathbf{r}/r \quad ,$$
$$\mathbf{grad}\, r^2 = 2\mathbf{r} \quad ,$$
$$\mathbf{div}\,\mathbf{r} = 3 \quad ,$$
$$\mathbf{rot}\,\mathbf{r} = 0 \quad ,$$
$$\mathbf{div}\,\mathbf{n} = 2/r \quad ,$$
$$\mathbf{rot}\,\mathbf{n} = 0 \quad ,$$
$$\mathbf{grad}\, r^\alpha = \alpha r^{\alpha-2}\mathbf{r} \quad .$$

16-004 ☒ Identity for ElectroMagnetism

Demonstrate the following relation:

$$\mathbf{grad}_{\mathbf{x}}\frac{1}{|\mathbf{x}-\mathbf{a}|} = -\frac{(\mathbf{x}-\mathbf{a})}{|\mathbf{x}-\mathbf{a}|^3} = -\mathbf{grad}_{\mathbf{a}}\frac{1}{|\mathbf{x}-\mathbf{a}|} \qquad \text{for any} \qquad \mathbf{x} \neq \mathbf{a} \quad . \tag{16.13.01}$$

→ 1128 1847 1889

Be careful with the signs above: the values of the function $|\mathbf{x}-\mathbf{a}|^{-1}$ is symmetrical in $\mathbf{x}$ and $\mathbf{a}$ and the symmetry of the result is broken by the variable of the gradient.

CC BY NC ND

16-005 ✓ Some Identities From the Divergence Theorem

This § is referenced at pages:
[1078]

Let Ω be an arbitrary volume and Σ a closed surface; let Σ_1 and Σ_2 be two arbitrary open surfaces with the same closed curve as boundary: $\partial\Sigma_1 = \partial\Sigma_2 = \Gamma$.

Demonstrate the following relations:

$$\Omega = \iiint_{\Omega} \mathrm{d}V = \frac{1}{3} \oiint_{\partial\Omega} \mathbf{r} \cdot \mathrm{d}\mathbf{S} \quad ,$$

$$\oiint_{\Sigma} \mathrm{d}\mathbf{S} = 0 \qquad \text{apply to a fixed vector field} \quad ,$$

$$\iint_{\Sigma_1} \mathrm{d}\mathbf{S} = \iint_{\Sigma_2} \mathrm{d}\mathbf{S} \quad .$$

Read § 16-006 for a geometrical application.

16-006 ✓ Volume of a Generic Pyramid or Cone

This § is referenced at pages:
[1134]

Calculate the volume of a generic pyramid or cone, with a generic base of surface A and height H, by means of the corollary to the divergence theorem:

$$\Omega = \iiint_{\Omega} \mathrm{d}V = \frac{1}{3} \oiint_{\partial\Omega} \mathbf{r} \cdot \mathrm{d}\mathbf{S} \quad .$$

WORKED SOLUTION

Take the origin of the Coordinate System at the vertex of the pyramid/cone and the base of the pyramid/cone parallel to the xy plane. In the surface integral

$$\frac{1}{3} \oiint_{\partial\Omega} \mathbf{r} \cdot \mathrm{d}\mathbf{S} \quad ,$$

the lateral surface give no contribution at all. The contribution of the base of the pyramid/cone can be written as:

$$\frac{1}{3} \oiint_{\partial\Omega} z \, \mathrm{d}x \, \mathrm{d}y = \frac{H}{3} \oiint_{\partial\Omega} \mathrm{d}x \, \mathrm{d}y = \frac{AH}{3} \quad .$$

PRELIMINARY PROOFS

CC BY NC ND

16-007 ✓ Some Identities From the Rotor Theorem

Demonstrate that:

$$\oint_C \mathbb{d}\mathbf{L} = 0 \quad . \tag{16.13.02}$$

Demonstrate that given two different curves C_1 and C_2 joining two points:

$$\int_{C_1} \mathbb{d}\mathbf{L} = \int_{C_2} \mathbb{d}\mathbf{L} \quad . \tag{16.13.03}$$

16-008 ✓ Area of a plane surface - Ellipse and Hyperbola

1. Consider a plane surface in the xy plane and use (16.12.14) in the xy plane to express the area of the surface in terms of a line integral over the contour as follows:
$$\iint \left(\frac{\partial A_y[x]}{\partial x} - \frac{\partial A_x[y]}{\partial y} \right) \mathbb{d}S = \frac{1}{2} \oint (y\, \mathbb{d}x - x\, \mathbb{d}y) \quad . \tag{16.13.04}$$
Compare with equation (16.13.05).
2. An ellipse is described by:
$$\mathbf{r}[t] = a_x \widehat{\mathbf{e}}_1 \cos t + a_y \widehat{\mathbf{e}}_2 \sin t \qquad a_x > 0 \qquad a_y > 0 \quad .$$
Show that the area of the ellipse is $\pi a_x a_y$.
3. Set the origin at one of the focii of the ellipse and use the formula to discuss the second Kepler law, equation (29.02.03).
4. An hyperbola is described by:
$$\mathbf{r}[t] = a_x \widehat{\mathbf{e}}_1 \coh t + a_y \widehat{\mathbf{e}}_2 \sih t \qquad a_x > 0 \qquad a_y > 0 \quad .$$
Calculate the area of a sector of hyperbola (a region of the Cartesian plane bounded by a hyperbola and two segments from the origin to it) symmetrical with respect to the x axis, as a function of the x coordinate of the point on the hyperbola.
5. Set the origin at one of the focii of the hyperbola and use the formula to discuss the second Kepler law, equation (29.02.03).

16-010 ✓ Gradient of a product

Demonstrate that:

$$\boxed{\mathbf{grad}(\phi_1\phi_2) = \phi_1\mathbf{grad}\phi_2 + \phi_2\mathbf{grad}\phi_1} \quad .$$

16-011 ✓ Divergence of a product

Dimostrare che:

$$\boxed{\mathbf{div}(f[\mathrm{x}]\mathbf{A}[\mathrm{x}]) = f[\mathrm{x}]\mathbf{div}\,\mathbf{A}[\mathrm{x}] + \mathbf{grad}\,f[\mathrm{x}]\cdot\mathbf{A}[\mathrm{x}]} \quad . \qquad (16.13.07)$$

→ 1847

16-012 ✓ Rotor of a product

Dimostrare che:

$$\boxed{\mathbf{rot}(f[\mathrm{x}]\mathbf{A}[\mathrm{x}]) = f[\mathrm{x}]\mathbf{rot}\,\mathbf{A}[\mathrm{x}] + \mathbf{grad}\,f[\mathrm{x}]\wedge\mathbf{A}[\mathrm{x}]} \quad . \qquad (16.13.08)$$

→ 1131 1889

16-013 ☒ Radial and Conservative Force Fields

This § is referenced at pages:
[1137, 1550]

Consider the radial force field:

$$\mathbf{f} = f_r[r,\theta,\phi]\widehat{\mathbf{e}}_r \quad ,$$

where $f_r[r,\theta,\phi]$ is an arbitrary function, and show that, in order to be conservative, in a 1-connected domain, it is necessary and sufficient that:

$$\frac{\partial f_r}{\partial\theta} = \frac{\partial f_r}{\partial\phi} = 0 \quad .$$

Such a field is known as a Central Force Field, read § 29.

Explain the physical meaning of this result showing that, if the above condition is not satisfied, it is easy to find a closed path along which the work done by the force is not zero.

Read also § 16-017.

WORKED SOLUTION

Use the expression of the rotor in spherical coordinates.
For a central field any trajectory at fixed distance from the force center implies no work. If the module of the force depends on the orientation one could find a closed trajectory going along a radial path, followed by a constant r path up to a point where the radial path to the starting distance gives a non null value, to close the path at fixed r. In this way a closed path with non zero work is found, demonstrating that the field is non-conservative.

DRAFT TEN-BRIDGE PRESS

16-014 ☒ Vector Identity for use with the Poynting vector

Demonstrate that:

$$\boxed{\mathbf{div}(\mathbf{A}\wedge\mathbf{B}) = \mathbf{B}\cdot\mathbf{rot}\,\mathbf{A} - \mathbf{A}\cdot\mathbf{rot}\,\mathbf{B}} \tag{16.13.09}$$

16-015 ☒ Care With Nabla

This § is referenced at pages:
[1102]

Demonstrate that the naive application of the nabla vector operator brings to the wrong result.

1.
$$\mathbf{grad}(\mathbf{A}\cdot\mathbf{B}) \neq \mathbf{B}\mathbf{div}\,\mathbf{A} + \mathbf{A}\mathbf{div}\,\mathbf{B} \quad .$$

2.
$$\mathbf{grad}\phi_1\wedge\mathbf{grad}\phi_2 \neq 0 \quad ,$$
as one would naively say that the vector product of two **parallel** ∇ is zero.

16-016 Use of the Divergence Theorem

Verify the **divergence theorem** for the vector field

$$\mathbf{f}[\mathbf{x}] = |\mathbf{x}|^{\alpha}\widehat{\mathbf{e}}_r \qquad \alpha > -2 \quad ,$$

on a sphere of radius R centered on the origin.

WORKED SOLUTION

Use $\alpha > -2$ to avoid problems of convergence at the origin.
One finds: $4\pi R^{2+\alpha}$.

16-017 ☒ Divergence and Rotor of a central power Law 3D field

This § is referenced at pages:
[1136, 1138, 1550]

Dimostrare che un campo del tipo:

$$\mathbf{A}[\mathbf{r}] \propto \mathbf{r}r^{\alpha} \quad ,$$

è irrotazionale e calcolarne la divergenza.

Quindi se il campo rappresenta una forza è una forza conservativa, essendo la forza definita definito su un insieme 1-connesso (tutto lo spazio per $\alpha \geq 0$; tutto lo spazio meno l'origine per $\alpha \leq 0$).

Read also § 16-013.

Note that this problem does not show that a conservative field does not depend on the angles, but only that if it is a power-law in the distance then it is a conservative field.

WORKED SOLUTION

Si consideri, per $i \neq j$, la derivata:

$$\frac{\partial}{\partial x_j}A_i = \frac{\partial}{\partial x_j}(x_i r^{\alpha}) = \alpha x_i x_j r^{\alpha-1} \quad .$$

Essendo il risultato simmetrico in (i,j) il rotore fa zero, a causa della definizione di rotore in coordinate cartesiane:

$$\mathbf{rot}\,\mathbf{A}[\mathbf{x}]\Big|_k = \epsilon^{\cdots}_{kij}\frac{\partial A_j}{\partial x_i} \quad .$$

KAFFE IN PROGRESS

CC BY NC ND

La divergenza risulta:

$$\mathbf{div}\,\mathbf{A} = (\alpha + 3)\, r^{\alpha} \quad .$$

La divergenza è nulla per $\alpha = -3$, che corrisponde al campo gravitazionale ed elettrico.

16-018 ☒ Divergence and Rotor of a central power Law 2D field

This § is referenced at pages:
[Never referenced.]

Si risolva il problema § 16-017 nel caso di due dimensioni. Cambia qualcosa rispetto al caso di tre dimensioni?

WORKED SOLUTION

Il campo è irrotazionale.
La divergenza risuta:

$$\mathbf{div}\,\mathbf{A} = (\alpha + 2)\, r^{\alpha} \quad .$$

La divergenza è nulla per $\alpha = -2$.

16-019 ✓ Field Lines and Equipotential Surfaces

Show that the equation defining the field lines of a vector field can be written as:

$$\mathbf{u}\cdot\mathbf{rot}\,\mathbf{u} = 0 \quad .$$

17.01.01
Equazione Della Retta

L'equazione parametrica di una retta nello spazio si esprime in termini di un parametro t, di un vettore $\mathbf{u}$ la cui direzione coincide con quella della retta e di un punto $\mathbf{x}_0$ per cui passa la retta:

$$\mathbf{x} = \mathbf{x}_0 + t\mathbf{u} \quad .$$

La corrispondente equazione cartesiana è

$$(\mathbf{x} - \mathbf{x}_0) \wedge \mathbf{u} = 0 \quad .$$

L'equazione parametrica della retta passante per due punti assegnati, $\mathbf{x}_A$ e $\mathbf{x}_B$, è data, in forma parametrica, da ciascuna delle due relazioni:

$$\mathbf{x} - \mathbf{x}_A = \lambda\,(\mathbf{x}_B - \mathbf{x}_A) \qquad || \qquad \mathbf{x} - \mathbf{x}_B = \lambda\,(\mathbf{x}_A - \mathbf{x}_B) \quad ,$$

con λ che varia nell'intervallo $(-\infty, +\infty)$.

La corrispondente equazione cartesiana è ciascuna delle due relazioni:

$$(\mathbf{x} - \mathbf{x}_A) \wedge (\mathbf{x}_B - \mathbf{x}_A) = 0 \qquad || \qquad (\mathbf{x} - \mathbf{x}_B) \wedge (\mathbf{x}_A - \mathbf{x}_B) = 0 \quad .$$

17.01.02
Equazione Del Piano

L'equazione parametrica di un piano, in termini dei due parametri t_1 e t_2, si esprime attraverso due vettori paralleli al piano e tra loro non paralleli, $\mathbf{u}_1$ e $\mathbf{u}_2$:

$$\mathbf{x} = \mathbf{x}_0 + t_1\mathbf{u}_1 + t_2\mathbf{u}_2 \qquad \text{con } \mathbf{u}_1 \wedge \mathbf{u}_2 \neq 0 \quad .$$

L'equazione di un piano ortogonale ad un vettore $\mathbf{n}$ è:

$$\mathbf{n} \cdot (\mathbf{x} - \mathbf{x}_0) = 0 \qquad \Leftrightarrow \qquad \mathbf{n} \cdot \mathbf{x} + b = 0 \qquad \text{con } b = -\,\mathbf{n} \cdot \mathbf{x}_0 \quad .$$

Valori diversi di b individuano piani diversi tra loro paralleli.

L'equazione del piano passante per tre punti non allineati, $\mathbf{x}_A$, $\mathbf{x}_B$ e $\mathbf{x}_C$, si esprime in termini del triplo prodotto scalare come

$$(\mathbf{x} - \mathbf{x}_A) \cdot (\,(\mathbf{x}_B - \mathbf{x}_A) \wedge (\mathbf{x}_C - \mathbf{x}_A)) = 0 \qquad \text{and/or similar permutations of the three points} \quad .$$

17.01.03
Lines and Planes intersections

$$\mathbf{x}[t] = \mathbf{x}_0 + t\mathbf{u} \tag{17.01.01}$$

$$\mathbf{a} \cdot (\mathbf{x} - \mathbf{a}_0) = 0 \tag{17.01.02}$$

$$\boxed{\mathbf{x}^\star = \frac{\mathbf{u}}{\mathbf{a} \cdot \mathbf{u}} \mathbf{a} \cdot (\mathbf{a}_0 - \mathbf{x}_0) + \mathbf{x}_0} \quad . \tag{17.01.03}$$

17.02.01 First-Order Vector Equations

17.02.01.01 Solution of First-Order Vector Equation: Scalar Product

Dimostrare che l'equazione vettoriale

$$\mathbf{A}\cdot\mathbf{X} = p \tag{17.02.01}$$

→ 1143 1144

può venire risolta univocamente rispetto a $\mathbf{X}$ se e solo se

$$\mathbf{A} \neq 0 \quad . \tag{17.02.02}$$

Dimostrare che in tal caso la soluzione generale è

$$\mathbf{X} = \frac{p\mathbf{A}}{A^2} + \mathbf{V}\wedge\mathbf{A} \qquad \text{con } \mathbf{V} \text{ vettore arbitrario} \quad . \tag{17.02.03}$$

→ 1143 1144

WORKED SOLUTION

Discussione dell'equazione (17.02.01).

- Se $\mathbf{A} = 0$ e $p \neq 0$ l'equazione è impossibile.
- Se $\mathbf{A} = 0$ e $p = 0$ l'equazione è indeterminata, qualunque vettore $\mathbf{X}$ la soddisfa.
- Se $\mathbf{A} \neq 0$ l'equazione è determinata e la soluzione generale è la (17.02.03), qualunque sia p.

In fact the homogeneous equation $\mathbf{A}\cdot\mathbf{X} = 0$ admits as a solution $\mathbf{X}_\mathrm{H}$ any $\mathbf{X}$ perpendicular to $\mathbf{A}$, that is $\mathbf{X}_\mathrm{H} = \mathbf{V}\wedge\mathbf{A}$ with $\mathbf{V}$ any arbitrary vector. Note that actually only the component of $\mathbf{V}$ perpendicular to $\mathbf{A}$ is relevant in the expression of $\mathbf{X}_\mathrm{H}$.
The expression (17.02.03) is obviously a solution of the equation.
To demonstrate that expression (17.02.03) includes all the solutions consider any two solutions of the non-homogeneous equation (17.02.01): their difference satisfies the homogeneous equation

$$\mathbf{A}\cdot\mathbf{X} = 0 \quad . \tag{17.02.04}$$

→ 1143

The general solution to the homogeneous equation (17.02.04), $\mathbf{X}_\mathrm{H}$, can be easily found via geometrical methods: it is given by all and only all the non null vectors perpendicular to $\mathbf{A}$. This can be written as:

$$\mathbf{X}_\mathrm{H} = \mathbf{V}\wedge\mathbf{A} \qquad \text{with } \mathbf{V} \text{ any arbitrary vector} \quad .$$

In fact the above solution gives only vectors $\mathbf{X}_\mathrm{H}$ perpendicular to $\mathbf{A}$ and any vector perpendicular to $\mathbf{A}$, let us say $\mathbf{Y}$, can be written in the above form, for a suitable choice of the vector $\mathbf{V}$, such as:

$$\mathbf{V} = -\frac{1}{A^2}\mathbf{Y}\wedge\mathbf{A} \qquad \mathbf{Y}\cdot\mathbf{A} = 0 \quad .$$

A particular solution of the non-homogeneous equation is: $\mathbf{X}_\mathrm{P} = \frac{p\mathbf{A}}{A^2}$.
Any other solution differs from $\mathbf{X}_\mathrm{P}$ by $\mathbf{X}_\mathrm{H}$.

Equation (17.02.03) represents thus the full set of solutions.
Note that only the component of $\mathbf{V}$ perpendicular to $\mathbf{A}$ is relevant and therefore there are only two degrees of freedom involved in the choice of $\mathbf{V}$. This is consistent with the fact that equation (17.02.01) is one linear equation with three unknowns.

Geometrical Interpretation
The geometrical interpretation is very useful.
One is looking for a vector, $\mathbf{X}$, whose projection along $\mathbf{A}$ is p.

There are clearly infinite solutions. The solution has a component along $\mathbf{A}$, $\frac{p\mathbf{A}}{A^2}$, and an arbitrary component perpendicular to $\mathbf{A}$, $\mathbf{V}\wedge\mathbf{A}$.

17.02.01.02 Solution of First-Order Vector Equation: Vector Product

Dimostrare che l'equazione vettoriale

$$\boxed{\mathbf{A}\wedge\mathbf{X}=\mathbf{B}} \tag{17.02.05}$$

→ 1144 1145

può venire risolta univocamente rispetto a $\mathbf{X}$ se e solo se

$$\boxed{\mathbf{A}\cdot\mathbf{B}=0 \qquad \text{e} \qquad \mathbf{A}\neq 0} \quad . \tag{17.02.06}$$

Dimostrare che in tal caso la soluzione generale è

$$\boxed{\mathbf{X}=\lambda\mathbf{A}+\frac{\mathbf{B}\wedge\mathbf{A}}{A^2} \qquad \lambda \text{ scalare arbitrario}} \quad . \tag{17.02.07}$$

→ 1144 1145

Notare che il risultato precedente dimostra l'impossibilità di definire in modo univoco il quoziente di due vettori. Infatti il risultato precedente dimostra che una generica equazione vettoriale come la (17.02.05) non può mai ammettere una ed una sola soluzione: o non ha soluzione o ne ha infinite.
Il risultato mostra anche che, come ci si aspetta, $\mathbf{B}\cdot\mathbf{X}=0$ in quanto si ha $\mathbf{A}\cdot\mathbf{B}=0$.

WORKED SOLUTION

Discussione dell'equazione (17.02.05).

- Se $\mathbf{A}=0$ e $\mathbf{B}\neq 0$ l'equazione è impossibile.
- Se $\mathbf{A}\cdot\mathbf{B}\neq 0$ l'equazione è impossibile, perchè il triplo prodotto che si ottiene moltiplicando entrambi i membri scalarmente per $\mathbf{A}$ si annulla. Questo è ovvio se si considera che $\mathbf{A}\wedge\mathbf{X}$ è perpendicolare ad $\mathbf{A}$ e quindi solo se $\mathbf{C}$ è perpendicolare ad $\mathbf{A}$ (cioè $\mathbf{A}\cdot\mathbf{B}=0$) può esistere una soluzione.
- Se $\mathbf{A}=0$ e $\mathbf{B}=0$ l'equazione è indeterminata, qualunque vettore $\mathbf{X}$ la soddisfa.
- Se $\mathbf{A}\neq 0$ e $\mathbf{A}\cdot\mathbf{B}=0$ l'equazione è determinata e la soluzione generale è la (17.02.07), qualunque sia $\mathbf{B}$.

In fact the homogeneous equation $\mathbf{A}\wedge\mathbf{X}=0$ admits as a solution $\mathbf{X}_H$ any $\mathbf{X}$ parallel to $\mathbf{A}$, that is $\mathbf{X}_H=\lambda\mathbf{A}$ with λ any arbitrary real number.
The expression (17.02.07) is obviously a solution of the equation.
To demonstrate that expression (17.02.07) includes all the solutions consider any two solutions of the non-homogeneous equation (17.02.05): their difference satisfies the homogeneous equation

$$\boxed{\mathbf{A}\wedge\mathbf{X}=0} \quad . \tag{17.02.08}$$

→ 1144

The general solution to the homogeneous equation (17.02.08), $\mathbf{X}_H$, can be easily found via geometrical methods: it is given by all and only all the non null vectors parallel to $\mathbf{A}$. This can be written as:

$$\mathbf{X}_H=\lambda\mathbf{A} \qquad \text{with } \lambda \text{ any arbitrary scalar} \quad .$$

To determine the particular solution one should consider that one needs a vector function of the two vectors $\mathbf{A}$ and $\mathbf{B}$. The simplest possibility is just a vector proportional to $\mathbf{B}\wedge\mathbf{A}$. A particular solution of the non-homogeneous equation is then: $\mathbf{X}_P=\frac{\mathbf{B}\wedge\mathbf{A}}{A^2}$, thanks to the condition $\mathbf{A}\cdot\mathbf{B}=0$.

CC BY NC ND

Any other solution differs from $\mathbf{X}_P$ by $\mathbf{X}_H$.
Equation (17.02.07) represents thus the full set of solutions.
Note that there is only one degree of freedom involved in the general solution of the homogeneous equation.
This is consistent with the fact that equation (17.02.05) is a set of three linear equations with three unknowns and the rank of the incomplete matrix of the coefficients is two, as it can be easily shown by noting that the determinant of the incomplete matrix of the coefficients is zero but it has minors of rank two.

Geometrical Interpretation
The geometrical interpretation is very useful.
One is looking for a vector, $\mathbf{X}$, which is perpendicular to $\mathbf{B}$, as $\mathbf{B}$ comes out as the result af the vector product between $\mathbf{A}$ and $\mathbf{X}$. Moreover, $\mathbf{B}$ must be perpendicular to $\mathbf{A}$ for the same reason.
We need a vector perpendicular to both $\mathbf{A}$ and $\mathbf{C}$ in order to re-obtain the direction of $\mathbf{C}$ after vector product with $\mathbf{A}$. Any component of $\mathbf{X}$ along $\mathbf{A}$ can be added to the solution so that there are clearly infinite solutions.

17.02.02
Miscellaneous Linear Vector Equations and Systems of Equations

This § is referenced at pages:
[Never referenced.]

©|P.I.Richards|Manual of Mathematics for Physics|*ch. 10*|

The following results can be demonstrated. Note the precise statements on the conditions imposed on the coefficients to make the results valid.

For the demonstration one can assume that the solution must be expressed as a linear combination of all the vectors which can be formed with $\mathbf{a}$ and $\mathbf{b}$, that is:

$$\alpha\mathbf{a} + \beta\mathbf{b} + \gamma\,\mathbf{a}\wedge\mathbf{b} \quad .$$

Equations are special cases of the general linear first order system of equations.

17.02.02.01 System of Linear vector equations (1)

Under suitable conditions on the coefficients one has:

$$\{\mathbf{a}\neq 0 \qquad \mathbf{b}\neq 0 \qquad \mathbf{b}\cdot\mathbf{c}=0\} \qquad \Longrightarrow \begin{cases} \mathbf{x}\cdot\mathbf{a} = p & , \\ \mathbf{x}\wedge\mathbf{b} = \mathbf{c} \end{cases} \qquad \Longrightarrow \mathbf{x} = \frac{\mathbf{a}\wedge\mathbf{c} + p\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}} \quad .$$

17.02.02.02 System of Linear vector equations (2)

Under suitable conditions on the coefficients one has:

$$\{\mathbf{a}\neq 0 \qquad \mathbf{b}\neq 0 \qquad \mathbf{c}\neq 0\} \qquad \begin{cases} \mathbf{x}\cdot\mathbf{a} = \alpha & , \\ \mathbf{x}\cdot\mathbf{b} = \beta & , \\ \mathbf{x}\cdot\mathbf{c} = \gamma & , \end{cases} \qquad \Longrightarrow \mathbf{x} = \frac{\alpha\,\mathbf{b}\wedge\mathbf{c} + \beta\,\mathbf{c}\wedge\mathbf{a} + \gamma\,\mathbf{a}\wedge\mathbf{b}}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} \quad .$$

PLEASE-PROGRESS

17.02.02.03 Linear vector equation (1)

Under suitable conditions on the coefficients one has:

$$\mathbf{x} + \mathbf{b}\wedge\mathbf{x} = \mathbf{a} \implies \mathbf{x} = \frac{\mathbf{a} + \mathbf{a}\wedge\mathbf{b} + (\mathbf{a}\cdot\mathbf{b})\,\mathbf{b}}{1 + b^2} \quad .$$

17.02.02.04 Linear vector equation (2)

Under suitable conditions on the coefficients one has:

$$\mathbf{a}\wedge\mathbf{x} + \mathbf{b}\,(\mathbf{c}\cdot\mathbf{x}) = \mathbf{d} \implies \mathbf{x} = \frac{\mathbf{d}\wedge\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}} + \mathbf{a}\left(\frac{\mathbf{a}\cdot\mathbf{d} + \mathbf{c}\cdot(\mathbf{b}\wedge\mathbf{d})}{(\mathbf{a}\cdot\mathbf{c})\,(\mathbf{a}\cdot\mathbf{b})}\right) \quad .$$

17.02.02.05 Coefficients for linear combination of vectors

Under suitable conditions on the coefficients one has:

$$\mathbf{p} = \alpha\mathbf{a} + \beta\mathbf{b} + \gamma\mathbf{c} \implies \begin{cases} \alpha = \dfrac{\mathbf{p}\cdot(\mathbf{b}\wedge\mathbf{c})}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & , \\ \beta = \dfrac{\mathbf{p}\cdot(\mathbf{c}\wedge\mathbf{a})}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & , \\ \gamma = \dfrac{\mathbf{p}\cdot(\mathbf{a}\wedge\mathbf{b})}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & \end{cases} \quad .$$

17.02.02.06 ☒ Coefficients for linear combination of scalar products

Under suitable conditions on the coefficients one has:

$$\mathbf{p} = \alpha\,\mathbf{b}\wedge\mathbf{c} + \beta\,\mathbf{c}\wedge\mathbf{a} + \gamma\,\mathbf{a}\wedge\mathbf{b} \implies \begin{cases} \alpha = \dfrac{\mathbf{p}\cdot\mathbf{a}}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & , \\ \beta = \dfrac{\mathbf{p}\cdot\mathbf{b}}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & , \\ \gamma = \dfrac{\mathbf{p}\cdot\mathbf{c}}{\mathbf{a}\cdot(\mathbf{b}\wedge\mathbf{c})} & \end{cases} \quad .$$

Solutions of Some Vector Equations

$$\left.\begin{aligned}(\mathbf{x}\cdot\mathbf{c}) &= p\\ (\mathbf{x}\times\mathbf{a}) &= \mathbf{b}\end{aligned}\right\}: \qquad \mathbf{x} = \frac{\mathbf{c}\times\mathbf{b} + p\mathbf{a}}{\mathbf{a}\cdot\mathbf{c}} \tag{10–13}$$

(Here $\mathbf{a}\cdot\mathbf{b} = 0$ if the original equations are possible.)

$$\left.\begin{aligned}\mathbf{x}\cdot\mathbf{a} &= \alpha\\ \mathbf{x}\cdot\mathbf{b} &= \beta\\ \mathbf{x}\cdot\mathbf{c} &= \gamma\end{aligned}\right\}: \qquad \mathbf{x} = \frac{\alpha\mathbf{b}\times\mathbf{c} + \beta\mathbf{c}\times\mathbf{a} + \gamma\mathbf{a}\times\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}} \tag{10–14}$$

$$\mathbf{x} + \mathbf{b}\times\mathbf{x} = \mathbf{a}: \qquad \mathbf{x} = \frac{\mathbf{a} + \mathbf{a}\times\mathbf{b} + (\mathbf{a}\cdot\mathbf{b})\mathbf{b}}{1 + b^2} \tag{10–15}$$

$$\mathbf{a}\times\mathbf{x} + \mathbf{b}(\mathbf{c}\cdot\mathbf{x}) = \mathbf{d}: \qquad \mathbf{x} = \frac{\mathbf{d}\times\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}} + \mathbf{a}\left[\frac{\mathbf{a}\cdot\mathbf{d} + \mathbf{c}\cdot\mathbf{b}\times\mathbf{d}}{(\mathbf{a}\cdot\mathbf{c})(\mathbf{a}\cdot\mathbf{b})}\right] \tag{10–16}$$

$$\mathbf{p} = x\mathbf{a} + y\mathbf{b} + z\mathbf{c}: \begin{cases} x = \dfrac{\mathbf{p}\cdot\mathbf{b}\times\mathbf{c}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}} \\ y = \dfrac{\mathbf{p}\cdot\mathbf{c}\times\mathbf{a}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}} \\ z = \dfrac{\mathbf{p}\cdot\mathbf{a}\times\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}} \end{cases} \tag{10–17}$$

$$\mathbf{p} = x(\mathbf{b}\times\mathbf{c}) + y(\mathbf{c}\times\mathbf{a}) + z(\mathbf{a}\times\mathbf{b}):$$

$$x = \frac{\mathbf{p}\cdot\mathbf{a}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}}, \quad y = \frac{\mathbf{p}\cdot\mathbf{b}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}}, \quad z = \frac{\mathbf{p}\cdot\mathbf{c}}{\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}} \tag{10–18}$$

Rotations

If all of space is rotated about an axis along $\boldsymbol{\delta}$ and by an angle of δ radians (clockwise, looking out along $\boldsymbol{\delta}$ and not necessarily less than 2π), then $\mathbf{r}$ goes into $\mathbf{r}'$ where

$$\mathbf{r}' = \mathbf{r} + \boldsymbol{\delta}\times\mathbf{r}\,\frac{\sin\delta}{\delta} + \boldsymbol{\delta}\times(\boldsymbol{\delta}\times\mathbf{r})\,\frac{1-\cos\delta}{\delta^2} \tag{10–19}$$

The inverse, of course, is given by changing the sign of $\boldsymbol{\delta}$. (Proof: resolve $\mathbf{r}$ into a sum of two vectors, one parallel to and one perpendicular to $\boldsymbol{\delta}$.)

17.03 Rotations of a Vector Around an Axis - Geometrical Approach

This § is referenced at pages:
[1192, 1196, 1241, 1439]

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|4.7|*Demonstration*|

Read also sections § 20.05, § 23.06, § 26.03. This section presents the geometrical/vector-algebra approach.

Let us use here the so-called **active approach**: the Coordinate System is kept fixed while the vectors are **rotated**.

17.03.01 Rotation of a Vector With Origin on the Rotation Axis

This § is referenced at pages:
[1142]

If one vector, $\mathbf{v}$, having origin on an axis defined by the unit vector $\widehat{\mathbf{n}}$, is rotated by an angle $\Delta\phi$ around the axis $\widehat{\mathbf{n}}$, with sign convention defined by the right-hand rule, then $\mathbf{v}$ goes into $\mathbf{v}'$ where:

$$\boxed{\mathbf{v}' = \mathbf{v} + \Delta\mathbf{v} = \mathbf{v} + \sin[\Delta\phi]\,(\mathbf{n}\wedge\mathbf{v}) + (1-\cos[\Delta\phi])\,(\mathbf{n}\wedge(\mathbf{n}\wedge\mathbf{v}))} \quad , \tag{17.03.01}$$

→ 1149 1150

sometimes known as the Rodrigues rotation formula, which can be derived by geometry and a suitable geometrical construction [1] by observing that the components of the original and rotated vectors on the rotation axis are the same and the components perpendicular to the rotation axis can be deduced from geometrical considerations in the plane perpendicular to the rotation axis.

The expression of an infinitesimal rotation can be deduced from equation (17.03.01). To first-order in $\delta\phi$ one obtains:

$$\boxed{\mathbf{v}' = \mathbf{v} + \delta\mathbf{v} = \mathbf{v} + \delta\boldsymbol{\phi}\wedge\mathbf{v} + \mathcal{O}(\delta\phi)^2 \quad \Leftrightarrow \quad \delta\mathbf{v} = \delta\boldsymbol{\phi}\wedge\mathbf{v} + \mathcal{O}(\delta\phi)^2} \quad . \tag{17.03.02}$$

→ 1149 1150

The above expression for the infinitesimal rotation, equation (17.03.02), can be used to show easily that infinitesimal (first-order) rotations commute. It cannot be obviously used to show that finite rotations do not commute, as the expression is limited to infinitesimal (first-order) rotations.

To first order, rotations (that is infinitesimal rotations) do commute; in fact:

$$\mathbf{v}' \equiv \mathbf{v} + \delta\mathbf{v} \simeq \mathbf{v} + \delta\boldsymbol{\phi}'\wedge\mathbf{v} \quad ,$$
$$\mathbf{v}'' \equiv \mathbf{v}' + \delta\mathbf{v}' \simeq \mathbf{v}' + \delta\boldsymbol{\phi}''\wedge\mathbf{v}' \quad ,$$
$$\mathbf{v}'' \simeq \mathbf{v} + \delta\boldsymbol{\phi}'\wedge\mathbf{v} + \delta\boldsymbol{\phi}''\wedge(\mathbf{v} + \delta\boldsymbol{\phi}'\wedge\mathbf{v}) = \mathbf{v} + \delta\boldsymbol{\phi}'\wedge\mathbf{v} + \delta\boldsymbol{\phi}''\wedge\mathbf{v} + \delta\boldsymbol{\phi}''\wedge(\delta\boldsymbol{\phi}'\wedge\mathbf{v}) \simeq \mathbf{v} + (\delta\boldsymbol{\phi}' + \delta\boldsymbol{\phi}'')\wedge\mathbf{v} \quad ,$$
$$\mathbf{v}'' \simeq \mathbf{v} + (\delta\boldsymbol{\phi}' + \delta\boldsymbol{\phi}'')\wedge\mathbf{v} \quad .$$

In order to show that finite rotation do not commute it is enough to think of two successive rotations by $\pi/2$ around two perpendicular axes to see that the final result is different depending on which rotation has been performed first.

From the algebraic point of view one knows that rotations are described by a non-commutative group, SO(3), read § 20.05.

Non-commutativity can also be shown by using the expression to second-order in $\delta\phi$ of equation (17.03.02)

$$\boxed{\mathbf{v}' \equiv \mathbf{v} + \delta\mathbf{v} = \mathbf{v} + \delta\boldsymbol{\phi}\wedge\mathbf{v} + \frac{\delta\boldsymbol{\phi}\wedge(\delta\boldsymbol{\phi}\wedge\mathbf{v})}{2} + \mathcal{O}(\delta\phi)^3} \quad . \tag{17.03.03}$$

[1] See: ...

CC BY NC ND

It can be easily shown that, when performing two successive rotations, the second-order expression gives a result depending on the order of the two rotations. Clearly, it might be even possible that successive orders restore the commutativity, but this is not the case as SO(3) is a non-commutative group.

Note finally that, $\delta\phi$ is indeed a vector, while there is no such vector as ϕ, as finite rotations do not belong to a vector space, being non commutative.

17.03.02
Relation of Angle and Oriented Direction With the Rotation Matrix

Using equation (17.03.02) in components and converting vector products into anti-symmetric matrices one can write the rotation equations in matrix form. Let

$$\mathbb{K} \equiv \begin{pmatrix} 0 & -n_3 & +n_2 \\ n_3 & 0 & -n_1 \\ -n_2 & +n_1 & 0 \end{pmatrix} \propto \epsilon^{\cdot\cdot\cdot}_{ikj} n^j_{\cdot} \quad ,$$

then the rotation matrix is:

$$\mathbb{R} = \mathbb{I} + \sin[\Delta\phi]\,\mathbb{K} + (1 - \cos[\Delta\phi])\,\mathbb{K}^2$$

Even if the derivation usually involves the position vector, the formula (17.03.01) can be applied for the rotation of any vector.

17.03.03
Rotation of a Vector With Origin Outside the Rotation Axis

It is sufficient to note that, give any point, O, on the rotation axis, the vector with origin at A and end at B can be written as $\mathbf{v}_B - \mathbf{v}_A = (\mathbf{v}_B - \mathbf{v}_O) - (\mathbf{v}_A - \mathbf{v}_O)$.

As the formula for infinitesimal rotations is linear in the angle, the use of the linearity results in the rotation formula being unchanged.

For finite rotations, due to the non-linearity of the general rotation formula, the above simple result does not apply.

DRAFT - IN PROGRESS

17.04 General Kronecker symbol and Levi-Civita symbols

This § is referenced at pages:
[1055, 1055, 1072, 1072]

The extension of the **Kronecker symbol** and **Levi-Civita symbol** to a generic number of dimensions is straightforward.

The general **Kronecker symbol** in n dimensions is defined as:

$$\delta^{\cdot\cdot}_{ij} = \begin{cases} 1 & \text{if and only if } i = j \\ 0 & \text{if and only if } i \neq j \end{cases} \quad , \quad \text{for } i,j = 1,n \quad ,$$

The general **Levi-Civita symbol** in n dimensions is defined as:

$$\epsilon^{\cdot\cdot\cdot\cdot}_{i_1 i_2 \ldots i_n} = \begin{cases} +1 & \text{if and only if } i_1, i_2, \ldots i_n \text{ is an even permutation of } 1, 2, \ldots n \\ -1 & \text{if and only if } i_1, i_2, \ldots i_n \text{ is an odd permutation of } 1, 2, \ldots n \\ 0 & \text{if any two indexes are equal} \end{cases} \quad ,$$

.

The latter enters the determinant:

$$\det[\mathbb{A}] = \frac{1}{n!} \epsilon^{\cdot\cdot\cdot\cdot}_{r_1 r_2 \ldots r_n} \epsilon^{\cdot\cdot\cdot\cdot}_{s_1 s_2 \ldots s_n} A^{\cdot\cdot}_{r_1 s_1} A^{\cdot\cdot}_{r_2 s_2} \ldots A^{\cdot\cdot}_{r_n s_n} \quad . \tag{17.04.01}$$

Fourier analysis is a crucial tool in many branches of physics.

One case where Fourier analysis intervene is wave propagation. In this case one should be careful to distinguish between:

- at fixed time: the wave function must be considered as a function of the position, the spatial **Fourier Transform** must be considered;
- at a fixed position: the wave function must be considered as a function of time, the time **Fourier Transform** must be considered.

DRAFT-IN-PROGRESS

18.02 Functions Periodic in Time/Space

This § is referenced at pages:
[1406]

Any **periodic function** of period $\mathcal{P}$ can be expressed as a **series of harmonic functions**.
The periodicity is most often:

- either a periodicity in time (in this case the period will be a time: $\mathcal{P} = T$);
- or in space (in this case the period will be a length: $\mathcal{P} = L$).

In case of a periodic function in time, ($\mathcal{P} = T$), one often introduces the **angular frequency**:

$$\omega \equiv \frac{2\pi}{T} \quad .$$

In case of a periodic function in space, ($\mathcal{P} = L$), one often introduces the **wave-number**:

$$k \equiv \frac{2\pi}{L} \quad .$$

18.02.01 Real Fourier Series for Periodic Functions

The **Fourier Series** of a periodic function with period $\mathcal{P}$ is given in terms of a **quantised frequency spectrum**:

$$f[w] = f_0 + \sum_{n=1}^{\infty} \left(a_n \sin\left[\frac{2\pi n w}{\mathcal{P}}\right] + b_n \cos\left[\frac{2\pi n w}{\mathcal{P}}\right] \right) \quad . \tag{18.02.01}$$

→ 1157

Note that the difference between two neighboring space/time frequencies are:

$$\Delta k \equiv k_{n+1} - k_n = \frac{2\pi}{\mathcal{P}} \equiv k \qquad \Delta\omega \equiv \omega_{n+1} - \omega_n = \frac{2\pi}{\mathcal{P}} \equiv \omega \quad ,$$

and this tends to zero when the period goes to infinity.

Assuming that the series is convergent the coefficients can be calculated (u arbitrary) from:

$$a_m \equiv \frac{2}{\mathcal{P}} \int_u^{u+\mathcal{P}} f[w] \sin\left[\frac{2\pi m w}{\mathcal{P}}\right] \, \mathrm{d}w \quad , \tag{18.02.02}$$

→ 1157

$$b_m \equiv \frac{2}{\mathcal{P}} \int_u^{u+\mathcal{P}} f[w] \cos\left[\frac{2\pi m w}{\mathcal{P}}\right] \, \mathrm{d}w \quad , \tag{18.02.03}$$

→ 1157

$$f_0 \equiv \frac{1}{\mathcal{P}} \int_u^{u+\mathcal{P}} f[w] \, \mathrm{d}w \qquad \text{mean value of the function} \quad . \tag{18.02.04}$$

→ 1157

The integration must be carried on one period but the starting point is not relevant thanks to the periodicity. In fact integrating in the interval $u \le w \le u + \mathcal{P}$ the **Fourier Series** (18.02.01), the **Fourier Series** (18.02.01) multiplied by $\sin[2\pi m w/\mathcal{P}]$ and the **Fourier Series** (18.02.01) multiplied by $\cos[2\pi m w/\mathcal{P}]$, one can find, respectively, the expression of the coefficients in equations (18.02.04), (18.02.02), (18.02.03).

While the coefficients a_n, b_n and f_0 can be formally defined for any function for which the integrals make sense, whether the series so defined actually converges to $f[w]$ depends on the properties of $f[w]$.

Sufficient conditions for the expandibility in a convergent Fourier Series of a periodic function in the interval $w_0 \le w \le w_0 + \mathcal{P}$ are provided by the Dirichlet conditions: the interval can be subdivided

DRAFT - IN PROGRESS

into a finite number of intervals such that in any interval the function is continuous and monotone. Such a function can be expanded in a **Fourier Series** which converges to the function at the points where the function is continuous and it converges to the mean of the positive and negative limits at the points of discontinuity of the function.

Note that any realistic and physically reasonable function can be expanded in **Fourier Series** convergent at any point.

18.02.01.01 Asymptotic Behavior of the Fourier Coefficients

It can be shown that for a piece-wise continuous limited function the large n behavior of the coefficients is:

$$a_n \sim \mathcal{O}\left(1/n\right) \qquad b_n \sim \mathcal{O}\left(1/n\right) \quad .$$

In case the first derivative of the function is a piece-wise continuous limited function the large n behavior of the coefficients is:

$$a_n \sim \mathcal{O}\left(1/n^2\right) \qquad b_n \sim \mathcal{O}\left(1/n^2\right) \quad ,$$

and so on for higher derivatives.

18.02.01.02 Asymptotic Behavior of the Fourier Coefficients

If a periodic function and its derivatives up to k-th order are continuous then for $n \to \infty$ both expressions $a_n n^{k+1}$ and $b_n n^{k+1}$ tend to zero.

18.02.02
Complex Fourier Series for Periodic Functions

©|Berkeley Physics Course, Vol. 3, *Waves*, 1968, McGraw-Hill, ...Ed., ...|2.3||

The **Fourier Series** can be expressed as a **complex Fourier series** as:

$$f[w] = f_0 + \sum_{n=1}^{\infty}\left(a_n \sin\left[\frac{2\pi n w}{\mathcal{P}}\right] + b_n \cos\left[\frac{2\pi n w}{\mathcal{P}}\right]\right) = \sum_{m=-\infty}^{m=+\infty} c_m \exp\left[\frac{2\mathrm{i}\pi m w}{\mathcal{P}}\right] \quad . \tag{18.02.05}$$

The coefficients are given by:

$$c_m \equiv \frac{1}{\mathcal{P}}\int_{u}^{u+\mathcal{P}} f[w] \exp\left[\frac{-2\mathrm{i}\pi m w}{\mathcal{P}}\right] \mathrm{d}w \quad . \tag{18.02.06}$$

$$c_0 = f_0 \qquad c_m = \frac{b_{+m} - \mathrm{i}a_{+m}}{2} \quad \text{for } m \geq +1 \qquad c_m = \frac{b_{-m} + \mathrm{i}a_{-m}}{2} \quad \text{for } m \leq -1 \quad . \tag{18.02.07}$$

18.02.03
Frequency and Phase Spectrum for Periodic Functions

The **amplitude of the Fourier coefficients**, that is the modulus, gives the so-called **frequency spectrum**, a discrete spectrum in case of a periodic function. Note, however, that the phase of the coefficients is necessary as well to reconstruct the function. The **phase of the Fourier coefficients** gives the so-called **phase spectrum**, a discrete spectrum in case of a periodic function.

DRAFT - IN PROGRESS

18.02.04
Energy for Periodic Functions

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|1-50.5||

The energy of a signal might have both terms proportional to its amplitude squared and terms proportional to the time derivative of the amplitude squared. It is of interest to express them in terms of the Fourier coefficients (Parseval theorem).

One has:

$$\int_u^{u+\mathcal{P}} f^2[w]\,\mathrm{d}w = \int_u^{u+\mathcal{P}} \left(f_0 + \sum_{n=1}^{\infty} \left(a_n \sin\left[\frac{2\pi n w}{\mathcal{P}}\right] + b_n \cos\left[\frac{2\pi n w}{\mathcal{P}}\right] \right) \right)^2 \mathrm{d}w = \mathcal{P} f_0^2 + \frac{\mathcal{P}}{2} \sum_{n=1}^{\infty} \left(a_n^2 + b_n^2\right) \quad , \tag{18.02.08}$$

→ 1167

because all the cross terms vanish when integrated.

One also has:

$$\int_u^{u+\mathcal{P}} \dot{f}^2[w]\,\mathrm{d}w = \int_u^{u+\mathcal{P}} \left(\sum_{n=1}^{\infty} \left(a_n \frac{2n\pi}{\mathcal{P}} \cos\left[\frac{2\pi n w}{\mathcal{P}}\right] - b_n \frac{2n\pi}{\mathcal{P}} \sin\left[\frac{2\pi n w}{\mathcal{P}}\right] \right) \right)^2 \mathrm{d}w = \frac{\mathcal{P}}{2} \left(\frac{2\pi}{\mathcal{P}}\right)^2 \sum_{n=1}^{\infty} n^2 \left(a_n^2 + b_n^2\right) \quad . \tag{18.02.09}$$

→ 1167

D.A.F. – TN–PROGRESS

18.03 Fourier Integral (Fourier Transform) for Non-Periodic Functions

©|Berkeley Physics Course, Vol. 3, *Waves*, 1968, McGraw-Hill, ...Ed., ...|6.4||

A **non periodic function** can be considered as a **periodic function with very large, actually infinite, period**.

Consider then a periodic function, develop it in **Fourier Series** and then let the period go to infinity.

The discussion about **Fourier Series** of periodic functions leads to the expectation that the spacing between the different frequencies reduces to zero, at the limit of infinite period, and that the frequency spectrum becomes an essentially continuous spectrum, as the spacing decreases. In fact the spacing between time/space frequencies is $2\pi/\mathcal{P}$.

Consider a piece-wise continuous function such that $\int_{-\infty}^{+\infty} |f[w]| \, \mathrm{d}w$ exist.

The following relation is valid (**Fourier integral** or **Fourier transform** theorem):

$$f[w] = \left(\frac{1}{2\pi}\right) \int_{-\infty}^{+\infty} \left(\int_{-\infty}^{+\infty} f[s] \exp\left[\mp \mathrm{i} p s\right] \, \mathrm{d}s \right) \exp\left[\pm \mathrm{i} p w\right] \, \mathrm{d}p \quad .$$

Different conventions exist for both the choice of the factors and the sign in the exponential. One often used in physics is the following (symmetrical) one (ω for the case of a time function, k for the case of a space-function):

$$\widetilde{f}[\omega] \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} f[s] \exp\left[-\mathrm{i}\omega s\right] \, \mathrm{d}s \qquad \widetilde{f}[k] \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} f[s] \exp\left[-\mathrm{i} k s\right] \, \mathrm{d}s \quad ,$$

corresponding to:

$$f[w] \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} \widetilde{f}[\omega] \exp\left[+\mathrm{i}\omega w\right] \, \mathrm{d}\omega \qquad f[w] \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} \widetilde{f}[k] \exp\left[+\mathrm{i} k w\right] \, \mathrm{d}k \quad .$$

18.03.01 Frequency and Phase Spectrum for Non-Periodic Functions

The **module of the Fourier transform**, gives the so-called **frequency spectrum**, a continuous spectrum in case of a non-periodic function. Note, however, that the phase of the coefficients is necessary as well to reconstruct the function. The **phase of the Fourier transform** gives the so-called **phase spectrum**, a continuous spectrum in case of a non-periodic function.

The frequency spectrum may be either a time-frequency spectrum (in case of the transform of a time function), or a space-frequency spectrum (in case of the transform of a space function).

18.03.02 Indeterminacy Relation

One has the indeterminacy relations, in terms of the mean squared deviation, $\Delta\ldots$, for a generic function $f[s]$ with **Fourier Transform** $\widetilde{f}[p]$:

$$(\Delta s)^2 \equiv \frac{\int_{-\infty}^{+\infty} (s-\overline{s})^2 \, |f[s]|^2 \, \mathrm{d}s}{\int_{-\infty}^{+\infty} |f[s]|^2 \, \mathrm{d}s} \qquad (\Delta p)^2 \equiv \frac{\int_{-\infty}^{+\infty} (p-\overline{p})^2 \left|\widetilde{f}[p]\right|^2 \, \mathrm{d}p}{\int_{-\infty}^{+\infty} \left|\widetilde{f}[p]\right|^2 \, \mathrm{d}p} \quad , \qquad (18.03.01)$$

and (the indeterminacy relations)

$$\Delta s \Delta p \geq 1/2 \implies \{ \quad \text{space function } \Delta z \Delta k \geq 1/2 \qquad \text{time function } \Delta t \Delta\omega \geq 1/2 \quad \} \quad .$$

DRAFT-IN-PROGRESS

Sinusoidal Signal of Finite Duration

This § is referenced at pages:
[Never referenced.]

©|J.P.Pérez *et al.*, *Optique*, ..., DUNOD, ...Ed., WEB - URL.|18||

Consider a Sinusoidal|Cosinusoidal signal of finite duration and frequency Ω (truncated sinusoid):

$$f[t] = \begin{cases} f_0 \cos[\Omega t] & |t| \leq \dfrac{T_0}{2} \\ 0 & |t| > \dfrac{T_0}{2} \end{cases} , \qquad \Omega > 0 \quad .$$

The **Fourier Transform** is:

$$\widetilde{f}[\omega] = \frac{f_0}{\sqrt{2\pi}} \left(\frac{\sin\left[\dfrac{T_0(\Omega-\omega)}{2}\right]}{\Omega-\omega} + \frac{\sin\left[\dfrac{T_0(\Omega+\omega)}{2}\right]}{\Omega+\omega} \right) \quad .$$

The **Fourier Transform** is an even function, as it should be, because the function is an even function. Thus the function has two parts, peaked at $\omega = \pm\Omega$, as $\cos[+\Omega t] = \cos[-\Omega t]$. In fact the original function is not changed when replacing $\Omega \to -\Omega$.

The result shows that most energy is contained in the region between the first two zeros of the frequency distribution, around $\omega = \pm\Omega$, defined by:

$$\omega = +\Omega \pm \frac{2\pi}{T_0} \qquad \omega = -\Omega \pm \frac{2\pi}{T_0} \quad .$$

The width of the frequency spectrum can thus be estimated as: $\Delta\omega \approx \dfrac{2\pi}{T_0}$. It decreases when T_0 increases. The time-length on the pulse is $\Delta t = T_0$. Thus one has: $\Delta\omega\Delta t \approx 2\pi$.

A parallel discussion can be carried on for a finite Sinusoidal|Cosinusoidal signal in space.

Square Signal of Finite Duration

Consider a square signal of finite duration and duration T_0:

$$f[t] = \begin{cases} f_0 & |t| \leq \dfrac{T_0}{2} \\ 0 & |t| > \dfrac{T_0}{2} \end{cases} , \qquad .$$

The **Fourier Transform** is:

$$\widetilde{f}[\omega] = f_0 \sqrt{\frac{2}{\pi}} \frac{\sin\left[\dfrac{\omega T_0}{2}\right]}{\omega} \quad .$$

The **Fourier Transform** is an even function, as it should be, because the function is an even function.

The result shows that most energy is contained in the region between the first two zeros of the frequency distribution, defined by:

$$\omega = \pm\frac{2\pi}{T_0} \quad .$$

The width of the frequency spectrum can thus be estimated as: $\Delta\omega \approx \dfrac{2\pi}{T_0}$. It decreases when T_0 increases The time-length on the pulse is $\Delta t = T_0$. Thus one has: $\Delta\omega\Delta t \approx 2\pi$.

A parallel discussion can be carried on for a finite square signal in space.

18.04.01
Superposition of MPW solution to D'Alembert wave-equation

A general solution to the **D'Alembert wave-equation** can be built from the superposition of MPW:

$$\xi[z,t] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} A[k] \exp\left[\mathtt{i}\,(kz - \omega[k]t)\right] \,\mathrm{d}k \quad .$$

Moreover, the uncertainty principle states:

$$\Delta z \Delta k \geq 1/2 \quad .$$

There is a tendency for the original shape to be lost and for the pulse to become distorted in shape.

One may verify that, for reasonable pulses or wave-packets that do not cut off too violently, the values of the root-mean squares lie near the lower limiting value, so that the equality sign can be often used.

18.04.02
Group-Velocity and pulse propagation

This § is referenced at pages:
[1165, 2010, 2010, 2149, 2164, 2164]

Read § 18.05.05.
Read § 46.17.12.
Read § 44.03.11 and equation (44.03.08).

The general cases of a highly dispersive medium and of a very sharp pulse with a great spread of wave-numbers are very difficult to treat.

On the contrary, the propagation of a pulse which is not too broad in its wave-number spectrum in a medium for which the frequency depends weakly on the wave-number, can be easily handled in an approximate way:

$$\omega[k] = \omega_0 + \left.\frac{\mathrm{d}\omega}{\mathrm{d}k}\right|_{k=k_0} (k - k_0) + \mathcal{O}\,(k - k_0)^2 \quad .$$

The integral gives:

$$\xi[z,t] \simeq \frac{1}{\sqrt{2\pi}} \exp\left[\mathtt{i}\left(k_0 t \left.\frac{\mathrm{d}\omega}{\mathrm{d}k}\right|_{k=k_0} - \omega_0 t\right)\right] \int_{-\infty}^{+\infty} A[k] \exp\left[\mathtt{i}\left(kz - kt \left.\frac{\mathrm{d}\omega}{\mathrm{d}k}\right|_{k=k_0}\right)\right] \,\mathrm{d}k \quad ,$$

which is a rigidly moving profile with velocity given by the **group-velocity** :

$$v_g[k=k_0] \equiv \left.\frac{\mathrm{d}\omega}{\mathrm{d}k}\right|_{k=k_0} = \frac{\mathrm{d}(kv_p)}{\mathrm{d}k}[k=k_0] = v_p[k=k_0] + k_0 \frac{\mathrm{d}v_p}{\mathrm{d}k}[k=k_0] \quad .$$

WORK-IN-PROGRESS

If an energy is associated with the amplitude of the wave (typically to its absolute square), in this approximation the transport of energy then occurs with the **group-velocity** , since that is the rate at which the pulse travels along.

The **group-velocity** may differ greatly from the **phase-velocity** , often becoming larger, or even negative.

group-velocity is generally not a useful concept in regions of strong dispersion as the approximations made are no longer valid.

For a Gaussian wave-packet, to second-order in k, with $\omega = \omega[k]$, it can be shown that the packet propagates at the **group-velocity** while its spread (standard deviation) increased with time as:

$$\sigma[t] = \sigma\sqrt{1+\left(\frac{\omega_0'' t}{\sigma^2}\right)^2} \qquad \omega'' \equiv \frac{\mathrm{d}v_g}{\mathrm{d}k} = \frac{d^2\omega}{\mathrm{d}k^2} \quad . \tag{18.04.01}$$

18.05.02 Functions of Finite Duration (Pulses)

This applies to both functions in time and functions in space. A function of finite duration (a pulse) is defined as a function such that for both large enough and small enough values of w the function is zero:

$$f[w] = 0 \qquad \text{if, for some } W,\ |w| \geq W/2 \quad .$$

From the physical point of view functions of finite duration are the rule, as it is hardly conceivable any real physical function which has an infinite duration either in space or in time.

One can describe such a kind of functions as a periodic function with period, for instance, $\mathcal{P} = W$.

©|G.Bekefi & A.H.Barrett, *Vibrazioni Elettromagnetiche Onde E Radiazione*, 1981, Zanichelli, ...Ed., ...|Appendix||

Read also § 44.04.01.

19.02.01
Addition of Two Real Sinusoidal|Cosinusoidal Functions of the Same Frequency

Consider the cosinusoidal functions:

$$f_1[s] = A_1 \cos[\alpha s - \phi_1] \qquad f_2[s] = A_2 \cos[\alpha s - \phi_2] \qquad \text{with } A_1 > 0 \text{ and } A_2 > 0 \quad . \tag{19.02.01}$$

→ 1171

The positiveness condition on A_1 and A_2 is not limiting at all because one can always make them positive via a suitable change of the **phase constants** ϕ_1 and ϕ_2.

$$f[s] = f_1[s] + f_2[s] = A \cos[\alpha s - \phi] \quad ,$$

$$A = \sqrt{A_1^2 + A_1^2 + 2A_1 A_2 \cos[\phi_2 - \phi_1]} \geq 0 \tag{19.02.02}$$

→ 1172

$$\cos[\phi] = \frac{A_1 \cos[\phi_1] + A_2 \cos[\phi_2]}{A} \qquad \sin[\phi] = \frac{A_1 \sin[\phi_1] + A_2 \sin[\phi_2]}{A} \quad .$$

→ 1172 2022

19.02.02
Addition of Two Complex Sinusoidal|Cosinusoidal Functions of the Same Frequency

The complex representation of the cosinusoidal functions (19.02.01), in terms of the so-called **phasors**, is:

$$\overline{f}_1 = A_1 \exp[+\mathtt{i}(\alpha s - \phi_1)] = A_1 \exp[-\mathtt{i}\phi_1] \exp[\mathtt{i}\alpha s] \equiv \overline{A}_1 \exp[+\mathtt{i}\alpha s] \quad ,$$

$$\overline{f}_2 = A_2 \exp[+\mathtt{i}(\alpha s - \phi_2)] = A_2 \exp[-\mathtt{i}\phi_2] \exp[\mathtt{i}\alpha s] \equiv \overline{A}_2 \exp[+\mathtt{i}\alpha s] \quad .$$

It is implicit in the complex representation that the phase information is kept in the complex constant:

$$\overline{A} \equiv A \exp[-\mathtt{i}\phi] \quad .$$

The sum in terms of the complex representation of cosinusoidal functions reads:

$$\overline{f} = \overline{f}_1 + \overline{f}_2 = (A_1 \exp[-\mathtt{i}\phi_1] + A_2 \exp[-\mathtt{i}\phi_2]) \exp[\mathtt{i}\alpha s] \equiv \overline{A} \exp[\mathtt{i}\alpha s] \quad ,$$

and:

$$\overline{A} \equiv A_1 \exp[-\mathtt{i}\phi_1] + A_2 \exp[-\mathtt{i}\phi_2] \quad , \tag{19.02.03}$$

→ 1172

and then:

$$f[s] \equiv f_1[s] + f_2[s] \equiv \mathfrak{Re}[\overline{f}] = \frac{1}{2}\left(\overline{A} \exp[+\mathtt{i}\alpha s] + \overline{A}^\star \exp[-\mathtt{i}\alpha s]\right) \equiv A \cos[\alpha s - \phi] \quad .$$

DRAFT - PRELIMINARY

19.02.03
Addition of an Arbitrary Number of Sinusoidal|Cosinusoidal Functions of the Same Frequency

©|WEB - URL |||

The result will be obtained by iteration of the results (19.02.02), (19.02.01), (19.02.03).
The real representation gives:

$$f[s] = \sum_{k=1}^{n} f_k[s] = \sum_{k=1}^{n} A_k \cos[\alpha s - \phi_k] = A \cos[\alpha s - \phi] \quad ,$$

$$A^2 = \sum_{r=1}^{n} \sum_{s=1}^{n} A_r A_s \cos[\phi_r - \phi_s] \geq 0 \tag{19.02.04}$$

$$\cos[\phi] = \frac{1}{A} \sum_{q=1}^{n} A_q \cos[\phi_q] \qquad \sin[\phi] = \frac{1}{A} \sum_{q=1}^{n} A_q \sin[\phi_q] \quad .$$

The complex representation gives:

$$\overline{A} \equiv \sum_{q=1}^{n} A_q \exp[-\mathtt{i}\phi_q] \quad . \tag{19.02.05}$$

DRAFT-IN-PROGRESS

19.03 Algebra of Complex Scalars

This § is referenced at pages:
[2018, 2061, 2067, 2086, 2086]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|1.22||

It is just similar to, and simpler of, the case of complex vectors, as in section § 19.04.

DRAFT-IN-PROGRESS

19.04 Algebra of Complex Vectors

This § is referenced at pages:
[1173, 2018, 2061, 2067, 2076]

Complex three-vectors are defined either as triplets of complex numbers,

$$\overline{\mathbf{V}} \equiv \{\overline{V}_1, \overline{V}_2, \overline{V}_3\} \quad ,$$

or by building a complex vector from two real vectors,

$$\overline{\mathbf{V}} \equiv \mathbf{V}_{\mathrm{R}} + \mathrm{i}\mathbf{V}_{\mathrm{I}} \quad ,$$

the two definitions being clearly equivalent.

Moreover:

$$\mathbf{V}_{\mathrm{R}} = \frac{1}{2}\left(\overline{\mathbf{V}} + \overline{\mathbf{V}}^{\star}\right) \equiv \mathfrak{Re}\left[\overline{\mathbf{V}}\right] \qquad \mathbf{V}_{\mathrm{I}} = \frac{1}{2}\left(\overline{\mathbf{V}} - \overline{\mathbf{V}}^{\star}\right) \equiv \mathfrak{Im}\left[\overline{\mathbf{V}}\right] \quad .$$

Sum is defined as the usual sum of complex numbers.

The product of a vector with a complex number is calculated as the usual product of complex numbers.

The scalar product of two vectors:

$$\overline{\mathbf{A}} \equiv \{\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}}\} \qquad \overline{\mathbf{B}} \equiv \{\mathbf{B}_{\mathrm{R}} + \mathrm{i}\mathbf{B}_{\mathrm{I}}\} \quad ,$$

is defined, exploiting the distributive property of the scalar product, as the complex number:

$$\overline{\mathbf{A}}\cdot\overline{\mathbf{B}} \equiv \overline{\mathbf{B}}\cdot\overline{\mathbf{A}} \equiv (\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}})\cdot(\mathbf{B}_{\mathrm{R}} + \mathrm{i}\mathbf{B}_{\mathrm{I}}) = (\mathbf{A}_{\mathrm{R}}\cdot\mathbf{B}_{\mathrm{R}} - \mathbf{A}_{\mathrm{I}}\cdot\mathbf{B}_{\mathrm{I}}) + \mathrm{i}\,(\mathbf{A}_{\mathrm{R}}\cdot\mathbf{B}_{\mathrm{I}} + \mathbf{A}_{\mathrm{I}}\cdot\mathbf{B}_{\mathrm{R}}) \quad .$$

Note that this is **different from the Hermitian scalar product defined for a complex vector space**:

$$\cancel{\langle\overline{\mathbf{A}\mathbf{B}}\rangle \equiv \overline{\mathbf{A}}^{\star}\cdot\overline{\mathbf{B}} \neq \overline{\mathbf{B}}^{\star}\cdot\overline{\mathbf{A}} \equiv \langle\overline{\mathbf{B}\mathbf{A}}\rangle} \quad .$$

In the latter case, in fact, the scalar product of the vector with itself must be real and positive to define the norm.

The vector product of two vectors:

$$\overline{\mathbf{A}} \equiv \{\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}}\} \qquad \overline{\mathbf{B}} \equiv \{\mathbf{B}_{\mathrm{R}} + \mathrm{i}\mathbf{B}_{\mathrm{I}}\} \quad ,$$

is defined, in a similar way to the scalar product, exploiting the distributive property of the vector product as the complex vector:

$$\overline{\mathbf{A}}\wedge\overline{\mathbf{B}} \equiv (\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}})\wedge(\mathbf{B}_{\mathrm{R}} + \mathrm{i}\mathbf{B}_{\mathrm{I}}) = (\mathbf{A}_{\mathrm{R}}\wedge\mathbf{B}_{\mathrm{R}} - \mathbf{A}_{\mathrm{I}}\wedge\mathbf{B}_{\mathrm{I}}) + \mathrm{i}\,(\mathbf{A}_{\mathrm{R}}\wedge\mathbf{B}_{\mathrm{I}} + \mathbf{A}_{\mathrm{I}}\wedge\mathbf{B}_{\mathrm{R}}) \quad .$$

The scalar product of a complex vector with its complex conjugate is calculated with standard algebra, and it provides the definition of the positive squared module of the vector:

$$\left|\overline{\mathbf{A}}\right|^2 \equiv \overline{\mathbf{A}}\cdot\overline{\mathbf{A}}^{\star} = \overline{\mathbf{A}}^{\star}\cdot\overline{\mathbf{A}} = (\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}})\cdot(\mathbf{A}_{\mathrm{R}} - \mathrm{i}\mathbf{A}_{\mathrm{I}}) = \mathbf{A}_{\mathrm{R}}^2 + \mathbf{A}_{\mathrm{I}}^2 \geq 0 \quad .$$

Note that for a complex vector $\overline{\mathbf{A}}$ the two conditions $\overline{\mathbf{A}}\cdot\overline{\mathbf{A}} = 1$ and $\left|\overline{\mathbf{A}}\right|^2 = 1$ are not equivalent. In fact:

$$\overline{\mathbf{A}}^2 \equiv \overline{\mathbf{A}}\cdot\overline{\mathbf{A}} = (\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}})\cdot(\mathbf{A}_{\mathrm{R}} + \mathrm{i}\mathbf{A}_{\mathrm{I}}) = \mathbf{A}_{\mathrm{R}}^2 - \mathbf{A}_{\mathrm{I}}^2 + 2\mathrm{i}\,\mathbf{A}_{\mathrm{R}}\cdot\mathbf{A}_{\mathrm{I}} \in \mathbb{C} \quad ,$$

$$\left|\overline{\mathbf{A}}\right|^2 = \mathbf{A}_{\mathrm{R}}^2 + \mathbf{A}_{\mathrm{I}}^2 \geq 0 \quad , \tag{19.04.01}$$

which are different, unless $\mathbf{A}_{\mathrm{I}} = 0$. All in all:

$$\overline{\mathbf{A}}^2 = \mathbf{A}_{\mathrm{R}}^2 - \mathbf{A}_{\mathrm{I}}^2 + 2\mathrm{i}\,\mathbf{A}_{\mathrm{R}}\cdot\mathbf{A}_{\mathrm{I}} \in \mathbb{C} \quad ,$$

$$\left|\overline{\mathbf{A}}\right|^2 = \mathbf{A}_{\mathrm{R}}^2 + \mathbf{A}_{\mathrm{I}}^2 \geq 0 \quad . \tag{19.04.02}$$

Note, in particular, that if the scalar product of a complex vector with itself is zero this does not imply that the complex vector is zero but only that:

$$\overline{\mathbf{A}}\cdot\overline{\mathbf{A}} = 0 \implies \{ \quad \mathbf{A}_{\mathrm{R}}\cdot\mathbf{A}_{\mathrm{I}} = 0 \quad \text{and} \quad |\mathbf{A}_{\mathrm{R}}| = |\mathbf{A}_{\mathrm{I}}| \quad \} \quad ,$$

DRAFT - IN PROGRESS

CC BY NC ND

19.04.01
Complex Direction Angles

This § is referenced at pages:
[2087]

Direction angles are better defined via $k \equiv \sqrt{\mathbf{k}\cdot\mathbf{k}}$ and not via the module of the complex vector, $|\overline{\mathbf{k}}|$:

$$\boxed{k \equiv \sqrt{\mathbf{k}\cdot\mathbf{k}} \qquad k \in \mathbb{C}} \quad ,$$

$$\boxed{k_x \equiv k\cos[\alpha_x] \equiv k\sin[\theta]\cos[\phi]} \quad ,$$

$$\boxed{k_y \equiv k\cos[\alpha_y] \equiv k\sin[\theta]\sin[\phi]} \quad ,$$

$$\boxed{k_z \equiv k\cos[\alpha_z] \equiv k\cos[\theta]} \quad .$$

Similarly, the complex direction cosines are defined as:

$$\boxed{\cos[\alpha_k] \equiv \frac{\overline{V}_k}{\sqrt{\overline{\mathbf{V}}\cdot\overline{\mathbf{V}}}}} \quad .$$

DRAFT-IN-PROGRESS

19.05 Algebra With Time-Harmonic Quantities and Their Complex Representation

This § is referenced at pages:
[Never referenced.]

Physical quantities varying in a harmonic way are often well represented by complex numbers. Read § 46. The usual convention is that the physical quantity is represented by the real part of the complex number.

A Sinusoidal|Cosinusoidal varying quantity can be expressed as a complex number, denoted conventionally with $\overline{A}$, which keeps the information on both the amplitude, ρ, and phase, θ. The convention is used that the real quantity is given by the real part of the complex number:

$$A\cos[\omega t+\phi] \quad \Leftrightarrow \quad A\exp[\mathtt{i}(\omega t+\phi)] \equiv \overline{A}\exp[\mathtt{i}\omega t] \quad \text{with} \quad \overline{A} \equiv A\exp[\mathtt{i}\phi] \quad .$$

The convention to use $\exp[-\mathtt{i}\omega t]$, instead of $\exp[+\mathtt{i}\omega t]$, is the one normally used in Relativistic Quantum Physics, and most often in Optics. In Electric Engineering the other convention is most often used.

Moreover, one has:

$$\overline{A} \equiv A\exp[\mathtt{i}\phi] \equiv A(\cos[\phi]+\mathtt{i}\sin[\phi]) = A\cos[\phi]+\mathtt{i}A\sin[\phi] \equiv A_R+\mathtt{i}A_I \quad ,$$

as well as:

$$A = \mathfrak{Re}\left[\overline{A}\exp[\mathtt{i}\omega t]\right] = \frac{1}{2}\left(\overline{A}\exp[+\mathtt{i}\omega t]+\overline{A}^{\star}\exp[-\mathtt{i}\omega t]\right) \quad .$$

Whenever the product of two physical time-harmonic quantities is expressed with the complex representation, one has to be careful to select the correct expression for the result.

The time-averaged value of the product of two time-harmonic quantities having the same frequency, averaged over an integer number of periods, is found as follows:

$$A\cos[\omega t+\phi_A]\,B\cos[\omega t+\phi_B] = \frac{AB}{2}(\cos[\phi_A-\phi_B]+\cos[2\omega t+\phi_A+\phi_B]) \quad \longrightarrow \quad \frac{AB}{2}\cos[\phi_A-\phi_B] \quad . \tag{19.05.01}$$

→ 1176

It can be easily shown, by direct calculation with the polar representation of complex numbers, that the above result (19.05.01) can be expressed, via complex numbers, as:

$$\langle A\cos[\omega t+\phi_A]\,B\cos[\omega t+\phi_B]\rangle = \frac{AB}{2}\cos[\phi_A-\phi_B] = \frac{1}{2}\mathfrak{Re}\left[\overline{AB}^{\star}\right] = \frac{1}{2}\mathfrak{Re}\left[\overline{A}^{\star}\overline{B}\right] = \frac{\overline{AB}^{\star}+\overline{A}^{\star}\overline{B}}{4} \quad . \tag{19.05.02}$$

→ 1176

The same result applies for the time averaged value of scalar and vector products of vector fields.

The same important result in equation (19.05.02) cam be obtained as follows.

Suppose to have two time-harmonic quantities:

$$\overline{A}[t] = \overline{A}_0\exp[-\mathtt{i}\omega t] \qquad \overline{B}[t] = \overline{B}_0\exp[-\mathtt{i}\omega t] \quad .$$

The quantities are assumed to be scalar, but the result will be easily generalized to the scalar and vector product of two vectors. Typical application are for the power per unit volume transferred by the ElectroMagnetic fields on matter ($\mathbf{j}\cdot\mathbf{E}$) and the Poynting vector (energy flow via ElectroMagnetic fields).

By definition the product of the two real quantities is:

$$A[t]B[t] \equiv \mathfrak{Re}\left[\overline{A}[t]\right]\mathfrak{Re}\left[\overline{B}[t]\right] \equiv \left(\frac{\overline{A}[t]+\overline{A}^{\star}[t]}{2}\right)\left(\frac{\overline{B}[t]+\overline{B}^{\star}[t]}{2}\right) = \frac{\overline{A}[t]\overline{B}[t]+\overline{A}^{\star}[t]\overline{B}^{\star}[t]+\overline{A}[t]\overline{B}^{\star}[t]+\overline{A}^{\star}[t]\overline{B}[t]}{4} \quad .$$

The time-averaged expression is now easily found to be:

$$\langle A[t]B[t]\rangle = \langle\frac{\overline{A}[t]\overline{B}[t]+\overline{A}^{\star}[t]\overline{B}^{\star}[t]+\overline{A}[t]\overline{B}^{\star}[t]+\overline{A}^{\star}[t]\overline{B}[t]}{4}\rangle = \frac{\overline{A}_0\overline{B}_0{}^{\star}+\overline{A}_0{}^{\star}\overline{B}_0}{4} = \frac{1}{2}\mathfrak{Re}\left[\overline{A}_0\overline{B}_0{}^{\star}\right] = \frac{1}{2}\mathfrak{Re}\left[\overline{A}_0{}^{\star}\overline{B}_0\right] \quad .$$

CC BY NC ND

Therefore:

$$\boxed{\langle A[t]B[t]\rangle = \frac{1}{2}\mathfrak{Re}\left[\overline{A}_0\overline{B}_0^{\star}\right] = \frac{1}{2}\mathfrak{Re}\left[\overline{A}_0{}^{\star}\overline{B}_0\right] = \frac{\overline{A}_0\overline{B}_0{}^{\star} + \overline{A}_0{}^{\star}\overline{B}_0}{4}} \quad .$$

The eigenfunctions of Linear and Time Invariant systems (LTI) are Sinusoids|Cosinusoids (or, in complex form, exponentials).

© - QUOTE

©|WEB - URL |||

©|WEB - URL |||

An important property of sinusoids at a particular frequency is that they are closed with respect to addition. In other words, if you take a sinusoid, make many copies of it, scale them all by different gains, delay them all by different time intervals, and add them up, you always get a sinusoid at the same original frequency. This is a non-trivial property. It obviously holds for any constant signal (which we may regard as a sinusoid at zero frequency), but it is not obvious for non constant functions.
Since every linear and time-invariant (LTI) system operates by copying, scaling, delaying, and summing its input signals to create its output signals, it follows that when a sinusoid at a particular frequency is input to an LTI system, a sinusoid at that same frequency always appears at the output. Only the amplitude and phase can be changed by the system. Therefore sinusoids are eigenfunctions of LTI systems. Conversely, if the system is non-linear or time-varying, new frequencies are created at the system output.

WORK-IN-PROGRESS

20.01 Introduction

Note that in mathematics the word scalar is typically used for a generic one-component quantity, and the word vector for a generic n-uple of scalar quantities.
In physics the terms scalars and vectors (as well as tensors) are used in a more restrictive way referring to quantities which transform in a well defined way under coordinate transformations, as described in this section.

In fact not any physical quantity defined by a single number is a scalar. A typical counterexample is any componente of a vector, which is not a scalar. Scalars must be invariant under the set of prescribed transformation of coordinates.

There are also physical quantities which require a magnitude and an oriented direction for their complete specification. Not any physical quantity defined by a magnitude and an oriented direction (or, equivalently, by an n-uple of numbers) is a vector. Vectors must transform as prescribed by the set of prescribed transformation of coordinates. Moreover, vectors must obey all the properties of mathematical vectors in linear spaces. A typical counterexample is any finite angular displacement, which may be characterized by magnitude and oriented direction but is not a vector, for the addition of two or more angular displacements is not, in general, commutative.

DRAFT IN-PROGRESS

20.02 General Definition of Tensors

Tensors are of paramount importance in connection with transformations of coordinates. They serve to isolate intrinsic geometric and physical properties from those that merely depend on the choice of the coordinates, which always has a degree of arbitrariness.

Physical laws must be expressed in terms that do not depend at all on the arbitrary choice of the Coordinate System. Note that Coordinate System must be interpreted here in the most general sense of space-time Coordinate System, because in most important situations (relativity) the time is a coordinate on the same footing as space coordinates.

It must be clear, however, that in many cases it can be useful to introduce explicitly a Coordinate System, but valuable results must be finally expressed in terms of tensors law, independent of any preferred Coordinate System.

There are (at least) two ways of approaching the definition of tensors.

- Physicists usually define tensors in terms of objects whose components transform according to certain rules, introducing the ideas of contravariant and covariant transformations.
- Mathematicians usually define tensors in a way which involves defining certain vector spaces without fixing any Coordinate Systems until suitable bases are introduced when needed. contravariant vectors are just the elements of the vector space while covariant vectors (or just co-vectors) are the one-forms, the elements of the dual space to the contravariant vectors.

Physicists and engineers are among the first to recognise that vectors and tensors have a physical significance as entities, which goes beyond the (often arbitrary) co-ordinate system in which their components are enumerated. Similarly, mathematicians find there are some tensor relations which are more conveniently derived in a co-ordinate notation.

Since a sensible physical law must not depend upon an arbitrary choice of coordinates system, physical laws must be expressed in terms of tensors, that is objects which transform in a suitable way under coordinate transformations.

One should first note that by coordinate transformations we usually mean transformations of both the space and time coordinates.

20.02.01 Changes of Coordinates

This § is referenced at pages:
[Never referenced.]

Consider the set of n coordinates,

$$x^a \qquad \text{with } a = 1, \dots n \quad ,$$

and a general coordinate transformation

$$x^a \longrightarrow \overline{x}^a = \overline{x}^a[x^b] \qquad a, b = 1, \dots n \quad , \tag{20.02.01}$$

→ 1184

which is locally invertible at P:

$$\frac{\partial \overline{x}^a}{\partial x^b}[P] \equiv M^a_{\cdot b} \neq 0 \quad , \tag{20.02.02}$$

where the partial derivatives matrix (Jacobian) is defined in such a way that its first (row) index labels the new coordinate, while its second (column) index labels the old coordinate.

In parallel we consider the inverse coordinate transformation:

$$\overline{x}^a \longrightarrow x^a = x^a[\overline{x}^b] \qquad a, b = 1, \dots n \quad , \tag{20.02.03}$$

PREFINAL PROCESS

Consequently the partial derivatives matrix (Jacobian) of the inverse coordinate transformation is by the above definition,

$$\boxed{\frac{\partial x^a}{\partial \overline{x}^b}[P] \equiv \overline{M}^{a\cdot}_{\cdot b} \neq 0} \quad . \tag{20.02.04}$$

20.02.02 Some Conventions

We will introduce the recipe that up and low indexes are different and that summation can be done only on a up and a low index. The full understanding of this recipe will gradually show up in the following, with the understanding that up/low indexes represent different ways of transformation.

We will use the recipe to label the first index of a matrix as the row index (irrespective of its up/low level) and the second index of a matrix as the column index (irrespective of its up/low level).

20.02.03 Two Types of Transformations

This § is referenced at pages:
[2411]

20.02.03.01 Transformation of Contravariant Indexes

Differentials, locally at P, transforms like:

$$\boxed{\mathrm{d}x^a \longrightarrow \mathrm{d}\overline{x}^a = \frac{\partial \overline{x}^a}{\partial x^b}[P]\, \mathrm{d}x^b = \frac{\partial \overline{x}^a}{\partial x^b}\, \mathrm{d}x^b \equiv M^{a\cdot}_{\cdot b}\, \mathrm{d}x^b} \quad ,$$

where the Jacobian matrix, $\dfrac{\partial \overline{x}^a}{\partial x^b}[P]$, is evaluated at the point P. This is known as a contravariant transformation. Since now on the explicit mention of point P will be avoided and implicit.

20.02.03.02 Transformation of Covariant Indexes

Partial derivatives, locally at P, transforms like:

$$\boxed{\frac{\partial}{\partial x^a} \equiv \partial_a \longrightarrow \frac{\partial}{\partial \overline{x}^a} \equiv \overline{\partial}_a = \frac{\partial x^b}{\partial \overline{x}^a}[P]\frac{\partial}{\partial x^b} = \frac{\partial x^b}{\partial \overline{x}^a}\frac{\partial}{\partial x^b} \equiv \overline{M}^{b\cdot}_{\cdot a}\frac{\partial}{\partial x^b} = \overline{M}^{b\cdot}_{\cdot a}\partial_b} \quad ,$$

where the Jacobian matrix, $\dfrac{\partial x^b}{\partial \overline{x}^a}[P]$, is evaluated at the point P. This is known as a covariant transformation. Since now on the explicit mention of point P will be avoided and implicit.

20.02.03.03 Relations Between Contravariant and Covariant Transformations

One has:

$$\boxed{\frac{\partial \overline{x}^a}{\partial x^r}\frac{\partial x^r}{\partial \overline{x}^b} = M^{a\cdot}_{\cdot r}\overline{M}^{r\cdot}_{\cdot b} = \delta^{a\cdot}_{\cdot b}} \quad ,$$

and

$$\boxed{\frac{\partial x^a}{\partial \overline{x}^r}\frac{\partial \overline{x}^r}{\partial x^b} = \overline{M}^{a\cdot}_{\cdot r}M^{r\cdot}_{\cdot b} = \delta^{a\cdot}_{\cdot b}} \quad .$$

The two equations imply that $\overline{\mathbb{M}}$ is the inverse of $\mathbb{M}$:

$$\boxed{\left(\overline{\mathbb{M}}\right)^{a\cdot}_{\cdot b} = \left(\mathbb{M}^{-1}\right)^{a\cdot}_{\cdot b}} \quad .$$

and that in general one needs both relations to demonstrate the $\overline{\mathbb{M}}$ is both the inverse right and inverse left matrix of $\mathbb{M}$.

DRAFT IN PROGRESS

Therefore, for a given coordinate transformation (20.02.01), contravariant indexes transform like the Jacobian matrix of the transformation, $\mathbb{M}$, while covariant indexes transform like the inverse of the Jacobian matrix of the transformation.

Note the conventional location of indexes: upper contravariant indexes and lower covariant indexes.

Note that:

- in the case of contravariant indexes the matrix is summed on the second index, that is the normal multiplication between the $\mathbb{M}$ matrix on the left and the column vector of the coordinates on the right;
- in the case of covariant indexes the matrix is summed on the first index, that is the normal multiplication between the row vector of the coordinates on the left and the the $\overline{\mathbb{M}}$ matrix on the right.

Given the above comments if one wants to express both transformations in the same way, for instance as the normal multiplication between a matrix on the left and the column vector of the coordinates on the right, one needs to introduce an additional transposition of indexes:

$$\{.\}^a_{\cdot} = M^a_{\cdot b}\{.\}^b_{\cdot} = \left(\overline{\mathbb{M}}^{-1}\right)^{a\cdot}_{\cdot b}\{.\}^b_{\cdot} = \left(\overline{\mathbb{M}}^{-1^{\mathsf{T}}}\right)^{\cdot a}_{b\cdot}\{.\}^b_{\cdot} \quad ,$$

$$\{.\}^{\cdot}_a = \overline{M}^{b\cdot}_{\cdot a}\{.\}^{\cdot}_b = \left(\mathbb{M}^{-1}\right)^{b\cdot}_{\cdot a}\{.\}^{\cdot}_b = \left(\mathbb{M}^{-1^{\mathsf{T}}}\right)^{\cdot b}_{a\cdot}\{.\}^{\cdot}_b \quad .$$

The reason why one uses two different types of indexes, upper contravariant indexes and lower covariant indexes, is just the fact that we have discovered that there are two different ways of transforming under a change of coordinates.

When handling matrices and indexes one should carefully remember the following rules/conventions:

- the first index of the matrix is the row index, while the second index is the column index: that is the horizontal location of the index refers to the matrix;
- the first index of both matrices, $\mathbb{M}$ and $\overline{\mathbb{M}}$, is taken from the numerator of the Jacobian matrix of the coordinate transformation, while the second one is taken from the denominator;
- the vertical location of the index, that is high or low, has nothing to do with the matrix itself but it only reminds the way that index transforms;

In many significant cases the coordinate transformation is a linear one and the transformation matrix, therefore, is a matrix which does not depend on the point.

20.02.03.04 Scalars (Rank Zero Tensors)

A scalar is a quantity which does not transform under a change of coordinates $x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q]$:

$$\overline{\phi} = \phi \quad .$$

20.02.03.05 Vectors (Rank One Tensors)

A contravariant Vector is a set of n quantities, V^a, which transforms, under a change of coordinates $x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q]$, as the differentials

$$V^a \longrightarrow \overline{V}^a = \frac{\partial \overline{x}^a}{\partial x^b} V^b \quad . \tag{20.02.05}$$

A covariant Vector is a set of n quantities, V_a, which transforms, under a change of coordinates $x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q]$, as the derivatives

$$V_a \longrightarrow \overline{V}_a = \frac{\partial x^b}{\partial \overline{x}^a} V_b \quad . \tag{20.02.06}$$

If one considers the vectors as **column vectors** and the operation on the right-hand side of equations (20.02.05), (20.02.06) as the standard row times column multiplication of matrices it is evident that the matrix defining the transformation of a covariant vector is just the inverse and transposed of the matrix defining the transformation of a contravariant vector.

DRAFT IN PROGRESS

20.02.03.06 Tensors of Rank Two and Higher Rank (Arbitrary Rank)

A tensor of rank $r \equiv r_u + r_l$, with r_u contravariant (upper) indexes and r_l covariant (lower) indexes, (called a tensor of type $\{r_u, r_l\}$), is a set of n^m quantities, $T^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots}$, which transforms, under a change of coordinates $x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q]$, as m_u contravariant (upper) indexes and m_l covariant (lower) indexes:

$$\{x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q] \qquad p,q = 1,\ldots n\} \Longrightarrow \left\{T^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots} \longrightarrow \overline{T}^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots} = M^{a}_{\cdot A}\overline{M}^{B}_{\cdot b}M^{c}_{\cdot C}M^{d}_{\cdot D}T^{A\cdot CD\ldots\,\cdot}_{\cdot B\cdot\cdot\cdot\ldots}\right\} \quad . \tag{20.02.07}$$

→ 1186

20.02.03.07 Tensors Fields of Arbitrary Rank

A tensor field (of any rank $r \equiv r_u + r_l$, and type $\{r_u, r_l\}$) is defined as a function of the coordinates transforming as a tensor whenever the coordinate argument changes in a way to always describe the same point:

$$\begin{aligned} & x^p \longrightarrow \overline{x}^p \qquad p,q = 1,\ldots n = \overline{x}^p[x^q] \quad , \\ \Longrightarrow \quad & T^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots}[x^p] \longrightarrow \overline{T}^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots}[\overline{x}^p] = M^{a}_{\cdot A}\overline{M}^{B}_{\cdot b}M^{c}_{\cdot C}M^{d}_{\cdot D}T^{A\cdot CD\ldots\,\cdot}_{\cdot B\cdot\cdot\cdot\ldots}[x^p] \quad , \\ \Leftrightarrow \quad & T^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots}[x^p] \longrightarrow \overline{T}^{a\cdot cd\ldots\,\cdot}_{\cdot b\cdot\cdot\cdot\ldots}[\overline{x}^p] = \frac{\partial \overline{x}^a}{\partial x^A}\frac{\partial x^B}{\partial \overline{x}^b}\frac{\partial \overline{x}^c}{\partial x^C}\frac{\partial \overline{x}^c}{\partial x^D}T^{A\cdot CD\ldots\,\cdot}_{\cdot B\cdot\cdot\cdot\ldots}[x^p] \quad . \end{aligned}$$

As a mnemonics it can be emphasised that the indexes on the left, $\{a, b, c, d, \ldots\}$, appear attached to the new coordinate set $\overline{x}$ in the Jacobian derivative matrix on the right-hand side.

20.02.03.08 Tensors Fields: A More General Definition

This § is referenced at pages:
[1185]

©|S.Weinberg, *The Quantum Theory of Fields, Vol. 1,2,3*, 1995, CUP, ...Ed., WEB - URL.|2.12||

Consider a locally invertible coordinate transformation

$$x^p \longrightarrow \overline{x}^p = \overline{x}^p[x^q] \qquad p,q = 1,\ldots n \quad ,$$

in a space of dimension n. and an arbitrary set of m functions of the coordinates

$$f_i[x^p], \qquad i = 1,\ldots m \quad .$$

Suppose that there exist a mapping of the set of functions $f_i[x^p]$ that is isomorphic to the coordinate transformation. The m functions then represent the m components of a tensor.

In particular, if the coordinate transformations form a group, the group representations can be used as the $f_i[x^p]$ functions.

20.02.03.09 Tensors Under Linear Transformations of Coordinates

In many significant cases the relevant coordinate transformation is a set of linear transformations forming a group. In this case what introduced in section § 20.02.03.08 is straightforwardly applied via any representation of the group.

It is in fact possible to start to define a tensor from linear transformations only, as it is often done. In this way, however, one loses the possibility to use non linear transformations of the coordinates, quite often important (non Cartesian set of coordinates, for instance).

Note that any quantity transforming like a tensor for general transformation of coordinates will transform as a tensor for linear transformations, obviously. However, there might be quantities, (namely the coordinates themselves) which are vectors for linear transformations but are not vectors for general non-linear transformations.

Also in Euclidean space one can find non-linear coordinates transformations, for instance when changing from orthonormal Cartesian Coordinates Coordinate System to Spherical Coordinates.

DRAFT - IN PROGRESS

20.03 Tensor Algebra and Calculus

20.03.01 Linear Combination of Tensors

Any linear combination with constant coefficients of tensors with the same kind of indexes is still a tensor of the same kind. It follows straightforwardly from (20.02.07).

20.03.02 Tensor (Direct) Product of Tensors

Given any two tensors, of rank m and n, the set of quantities produced by the tensor (direct) product of the two sets of numbers is a tensor of rank $m+n$ with contravariant/covariant indexes as in the original tensors. It follows straightforwardly from (20.02.07).

20.03.03 Contraction

This § is referenced at pages:
[1191]

The contraction between any contravariant index and any other covariant index is defined by summing the pair of indexes. This gives a tensor of rank two units less than the original tensor:

$$T^{a\cdot cs\ldots\cdot}_{\cdot\,s\cdot\cdot\cdot\ldots} \longrightarrow \overline{T}^{a\cdot cs\ldots\cdot}_{\cdot\,s\cdot\cdot\cdot\ldots} = M^{a\cdot}_{\cdot A}\overline{M}^{B\cdot}_{\cdot\,s}M^{c\cdot}_{\cdot C}M^{s\cdot}_{\cdot D}T^{A\cdot CD\ldots\cdot}_{\cdot\,B\cdot\cdot\cdot\ldots} = M^{a\cdot}_{\cdot A}M^{c\cdot}_{\cdot C}\delta^{B\cdot}_{\cdot\,D}T^{A\cdot CD\ldots\cdot}_{\cdot\,B\cdot\cdot\cdot\ldots} = M^{a\cdot}_{\cdot A}M^{c\cdot}_{\cdot C}T^{A\cdot CS\ldots\cdot}_{\cdot\,S\cdot\cdot\cdot\ldots} \quad .$$

The conclusion obviously comes from the fact that the contraction introduces a product of the transformation matrix times its inverse, giving a **Kronecker tensor** .

This shows that, in order to get a tensor, one contravariant index and one covariant index must be contracted.

20.03.04 Zero Tensor

Any zero tensor is invariant, that is it is zero after any coordinate transformation. It follows straightforwardly from (20.02.07).

20.03.05 Kronecker tensor

The **Kronecker tensor** is an invariant tensor:

$$\delta^{a\cdot}_{\cdot\,b} \longrightarrow \overline{\delta}^{a\cdot}_{\cdot\,b} = M^{a\cdot}_{\cdot A}\overline{M}^{B\cdot}_{\cdot\,b}\delta^{A\cdot}_{\cdot\,B} = M^{a\cdot}_{\cdot S}\overline{M}^{S\cdot}_{\cdot\,b} = \delta^{a\cdot}_{\cdot\,b} \quad .$$

DRAFT - IN PROGRESS

20.03.06
Principle of Covariance

This § is referenced at pages:
[1033, 1523, 1740, 2417, 2422]

If a particular law, written in tensor form, is valid in a particular Coordinate System, then it is valid in any general Coordinate System.

Note that, depending on the group of transformation considered, Coordinate System must be taken in its most general form, that is, not necessarily space-coordinates only:

- when one considers classical tensors, that is based on the group of rotation in space, SO(3), a change of Coordinate System is a rotation of a Cartesian Coordinates Coordinate System, or, more generally, a rotation plus translation;
- when one considers special-relativistic tensors, that is based on the Lorentz group, a change of Coordinate System is a **Lorentz Transformation** between Inertial Reference Frame , or, more generally, a **Poincaré Transformation** ;
- when one considers general-relativistic tensors, a general change of space-time Coordinate System is considered.

Read § 58.11.09.

WORKED SOLUTION

First Demonstration

Assume that the following equation is valid, with $T^{ab}_{\cdot\cdot}$ and $S^{ab}_{\cdot\cdot}$ tensors,

$$T^{ab}_{\cdot\cdot} = S^{ab}_{\cdot\cdot} \quad .$$

Then we can multiply both members by $M^{p\cdot}_{\cdot a} M^{q\cdot}_{\cdot b}$

$$M^{p\cdot}_{\cdot a} M^{q\cdot}_{\cdot b} T^{ab}_{\cdot\cdot} = M^{p\cdot}_{\cdot a} M^{q\cdot}_{\cdot b} S^{ab}_{\cdot\cdot} \implies \overline{T}^{pq}_{\cdot\cdot} = \overline{S}^{pq}_{\cdot\cdot} \quad .$$

Second Demonstration

Another alternative derivation follows.

Assume that the tensor quantity assumes a certain expression $\mathcal{F}^{a\cdot\cdot}_{\cdot bc}$ in a certain special Coordinate System. Then the expression in an arbitrary Coordinate System is jut obtained by tensor transformation:

$$x^a \longrightarrow \overline{x}^a = \overline{x}^a[x^b] \implies \mathcal{F}^{a\cdot\cdot}_{\cdot bc} \longrightarrow \overline{\mathcal{F}}^{p\cdot\cdot}_{\cdot qr} = M^{p\cdot}_{\cdot a} \overline{M}^{b\cdot}_{\cdot q} \overline{M}^{c\cdot}_{\cdot r} \mathcal{F}^{a\cdot\cdot}_{\cdot bc} \quad .$$

The demonstration goes by assuming, ab-absurdo, that, in an arbitrary Coordinate System, there might exist two different expressions, $\overline{\mathcal{F}}^{a\cdot\cdot}_{\cdot bc}$ and $\overline{\mathcal{F}}^{a\cdot\cdot}_{\cdot bc}$, reducing to $\mathcal{F}^{a\cdot\cdot}_{\cdot bc}$ in the special Rest Frame. Consider then the transformation of the difference $\overline{\mathcal{F}_1}^{a\cdot\cdot}_{\cdot bc} - \overline{\mathcal{F}_2}^{a\cdot\cdot}_{\cdot bc}$ back to the special Rest Frame: this gives zero, by hypothesis, because both $\overline{\mathcal{F}_1}^{a\cdot\cdot}_{\cdot bc}$ and $\overline{\mathcal{F}_2}^{a\cdot\cdot}_{\cdot bc}$ have the same expression in the special Rest Frame. It follows, form the invariance of the zero tensor, that the difference between the two expressions is the same in any Rest Frame, that is $\overline{\mathcal{F}_1}^{a\cdot\cdot}_{\cdot bc} = \overline{\mathcal{F}_1}^{a\cdot\cdot}_{\cdot bc}$.

This second derivation can be seen as an application of the first one when one of the two members of the tensor equality is the zero tensor.

It follows that:

- **if a tensor expression reduces to the correct particular expression in a certain Coordinate System, then that is the only correct covariant extension of that particular expression**;
- if all the components of a tensor vanish in one frame, they vanish in every frame;
- **two tensors equal in one Coordinate System are equal in every Coordinate System**.

Read § 20.10.02 for counter-examples.

CC BY NC ND

20.03.07
Quotient Law

This § is referenced at pages:
[1444, 1652, 2417, 2438, 2489]

©|H.Jeffreys and B.S.Jeffreys, *Mathematics for Physics*, ..., ..., ...Ed., ...|§ 3.05||

Consider any tensor relation among tensors such as, for instance:

$$K^a_{\cdot\cdot} A^{\cdot\cdot}_{aj} = B^{\cdot}_{j} \qquad \text{or} \qquad K^{a\,\cdot}_{\cdot\,b} T^{\cdot\cdot}_{aj} = S^{\cdot\cdot}_{bj} \qquad \dots \quad ,$$

where $A^{\cdot\cdot}_{aj}$ and $B^{\cdot}_{j}$, or $T^{\cdot\cdot}_{aj}$ and $S^{\cdot\cdot}_{bj}$, are known to be tensors. One can then infer that K is a tensor provided that all the components of A_k or $T^{\cdot\cdot}_{km}$, that is the tensor multiplying the quantity with unknown properties, K, can be varied independently.

Note, in particular, that the tensors A_k or $T^{\cdot\cdot}_{km}$ must be absolutely arbitrary, no symmetry or anti-symmetry, for instance, because one must be able to set any of their components to 1 and, at the same time, all the others to zero in order to demonstrate the theorem.

WORKED SOLUTION

Let us show it for a particular case, which will show that the same demonstration can be applied to any case. Assume we know that the relation

$$T^{\cdot\cdot}_{kj} C^{j}_{\cdot} = A^{\cdot}_{k} \quad ,$$

is always valid, whatever the Coordinate System, and that $A^{\cdot}_{k}$ and $C^{j}_{\cdot}$ are tensors. Let us demonstrate that $T^{\cdot\cdot}_{kj}$ is also a tensor. We know, by hypothesis, that the transformed relation is satisfied,

$$\overline{T}^{\cdot\cdot}_{kj} \overline{C}^{j}_{\cdot} = \overline{A}^{\cdot}_{k} \quad ,$$

with $A^{\cdot}_{k}$ and $C^{j}_{\cdot}$ transforming as tensors, and we want to determine the relation between $T^{\cdot\cdot}_{kj}$ and $\overline{T}^{\cdot\cdot}_{kj}$, showing that $\mathbb{T}$ is actually a tensor.
We can proceed as follows:

$$\begin{aligned}
\overline{T}^{\cdot\cdot}_{kj} \overline{C}^{j}_{\cdot} &= \overline{A}^{\cdot}_{k} \quad , \\
\overline{T}^{\cdot\cdot}_{kj} M^{j\,\cdot}_{\cdot\,b} C^{b}_{\cdot} &= \overline{M}^{a\,\cdot}_{\cdot\,k} A^{\cdot}_{a} \quad , \\
M^{k\,\cdot}_{\cdot\,s} \overline{T}^{\cdot\cdot}_{kj} M^{j\,\cdot}_{\cdot\,b} C^{b}_{\cdot} &= \overline{M}^{a\,\cdot}_{\cdot\,k} A^{\cdot}_{a} M^{k\,\cdot}_{\cdot\,s} \qquad \text{multiplying both members by } M^{k\,\cdot}_{\cdot\,s} \quad , \\
M^{k\,\cdot}_{\cdot\,s} \overline{T}^{\cdot\cdot}_{kj} M^{j\,\cdot}_{\cdot\,b} C^{b}_{\cdot} &= A^{\cdot}_{a} \delta^{a\,\cdot}_{\cdot\,s} \quad , \\
M^{k\,\cdot}_{\cdot\,s} \overline{T}^{\cdot\cdot}_{kj} M^{j\,\cdot}_{\cdot\,b} C^{b}_{\cdot} &= A^{\cdot}_{s} \quad , \\
M^{k\,\cdot}_{\cdot\,s} \overline{T}^{\cdot\cdot}_{kj} M^{j\,\cdot}_{\cdot\,b} C^{b}_{\cdot} &= T^{\cdot\cdot}_{sb} C^{b}_{\cdot} \qquad \text{using } T^{\cdot\cdot}_{kj} C^{j}_{\cdot} = A^{\cdot}_{k} \quad , \\
\left(\overline{T}^{\cdot\cdot}_{kj} M^{k\,\cdot}_{\cdot\,s} M^{j\,\cdot}_{\cdot\,b} - T^{\cdot\cdot}_{sb} \right) C^{b}_{\cdot} &= 0 \quad , \\
\Longrightarrow \; T^{\cdot\cdot}_{sb} &= \overline{T}^{\cdot\cdot}_{kj} M^{k\,\cdot}_{\cdot\,s} M^{j\,\cdot}_{\cdot\,b} \qquad \text{as it is valid for any } C^{j}_{\cdot} \quad , \\
\Longrightarrow \; \overline{T}^{\cdot\cdot}_{pq} &= T^{\cdot\cdot}_{sb} \overline{M}^{s\,\cdot}_{\cdot\,p} \overline{M}^{b\,\cdot}_{\cdot\,q} \qquad \text{multiplying by } \overline{M}^{s\,\cdot}_{\cdot\,p} \overline{M}^{b\,\cdot}_{\cdot\,q} \quad .
\end{aligned}$$

It is stressed again that **it must be possible to vary the components of the tensor C, of arbitrary rank in general, in an arbitrary manner in order to justify the last passage, while no similar condition is necessary on the tensor A.**

20.03.08
Derivative of a Tensor

In general it is not a tensor, because the necessity to derive the Jacobian matrix introduces additional terms. However, it is a tensor in the case of linear transformations.

DRAFT-IN-PROGRESS

20.04 General Curvilinear Coordinates and Metrics

We take as an example a space described by three coordinates because the generalisation to an arbitrary number of coordinates is straightforward.

Consider the problem of representing a generic vector $\mathbf{v}$ in terms of three non orthogonal and non normalized vectors: $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_3$. This bases is naturally induced when one consider a curvilinear system of coordinates: $\{x^1, x^2, x^3\}$. In this case the base vectors are defined by:

$$\boxed{\mathbf{e}_j \equiv \frac{\partial P[x^a]}{\partial x^j}} \quad .$$

One can write:

$$\mathbf{v} = v^k \mathbf{e}_k \quad .$$

But, for a non-orthonormal basis, we do not expect: $v^k = \mathbf{v}\cdot\mathbf{e}_k$. In fact, for general non orthonormal bases,

$$\mathbf{v}\cdot\mathbf{e}_k = v^j\, \mathbf{e}_j\cdot\mathbf{e}_k \neq v^k \quad .$$

However, if we manage to find a set of vectors, $\mathbf{e}^1$, $\mathbf{e}^2$, $\mathbf{e}^3$, such that:

$$\mathbf{e}_j\cdot\mathbf{e}^k = \delta^{k\,\cdot}_{\cdot\,j} = \delta^{\cdot\,k}_{j\,\cdot} \quad , \tag{20.04.01}$$

→ 1206

we can recover:

$$\mathbf{v}\cdot\mathbf{e}^k = v^k \quad .$$

Note, however, that $\{\mathbf{e}_k\} \neq \{\mathbf{e}^k\}$.

Therefore

$$\boxed{\mathbf{v} = v^k\mathbf{e}_k \qquad v^k = \mathbf{v}\cdot\mathbf{e}^k \qquad \mathbf{e}_j\cdot\mathbf{e}^k = \delta^{k\,\cdot}_{\cdot\,j} = \delta^{\cdot\,k}_{j\,\cdot}} \quad .$$

Similarly:

$$\boxed{\mathbf{v} = v_k\mathbf{e}^k \qquad v_k = \mathbf{v}\cdot\mathbf{e}_k \qquad \mathbf{e}_j\cdot\mathbf{e}^k = \delta^{k\,\cdot}_{\cdot\,j} = \delta^{\cdot\,k}_{j\,\cdot}} \quad .$$

The bases $\{\mathbf{e}^k\}$ is known as the reciprocal base of the base $\{\mathbf{e}_k\}$.

20.04.01 A Metric

So far the space to which the coordinates x^a refer to has been without any structure. One can impose a structure by defining the distance between all pairs of neighboring points by means of a metric, not necessarily positive-definite:

$$\boxed{\mathbb{d}s^2 = \mathbb{d}\mathbf{x}\cdot\,\mathbb{d}\mathbf{x} = \mathbb{d}x^a\,\mathbb{d}x^b\,\mathbf{e}_a\cdot\mathbf{e}_b \equiv g^{\cdot\,\cdot}_{ab}[P]\,\mathbb{d}x^a\,\mathbb{d}x^b \qquad \mathbb{d}s^2 = \mathbb{d}x\cdot\,\mathbb{d}x = \mathbb{d}x_a\,\mathbb{d}x_b\,\mathbf{e}^a\cdot\mathbf{e}^b \equiv g^{ab}_{\cdot\,\cdot}[P]\,\mathbb{d}x_a\,\mathbb{d}x_b} \quad .$$

(20.04.02)

→ 1191

where the $g^{\cdot\,\cdot}_{ab}[P]$ and $g^{ab}_{\cdot\,\cdot}[P]$, the metric tensor, are in general, functions of the position:

$$\boxed{g^{\cdot\,\cdot}_{ab}[P] \equiv \mathbf{e}_a\cdot\mathbf{e}_b \qquad g^{ab}_{\cdot\,\cdot}[P] \equiv \mathbf{e}^a\cdot\mathbf{e}^b} \quad .$$

Moreover, we have the prescription for raising and lowering the indexes via the metric tensor:

$$v_k = \mathbf{v}\cdot\mathbf{e}_k \equiv v^j\,\mathbf{e}_j\cdot\mathbf{e}_k = v^j g^{\cdot\,\cdot}_{jk} \qquad v^k = \mathbf{v}\cdot\mathbf{e}^k \equiv v_j\,\mathbf{e}^j\cdot\mathbf{e}^k = v_j g^{jk}_{\cdot\,\cdot} \quad .$$

Finally note that

$$\mathbf{e}^j \equiv e^s[\mathbf{e}^j]\mathbf{e}_s = \delta^{j\,\cdot}_{\cdot\,s}\mathbf{e}^s \quad ,$$

$$e^s[\mathbf{e}^j] = \mathbf{e}^j\cdot\mathbf{e}^s \quad ,$$

$$\delta^{j\,\cdot}_{\cdot\,k} = \mathbf{e}^j\cdot\mathbf{e}_k = e^s[\mathbf{e}^j]\,\mathbf{e}_s\cdot\mathbf{e}_k = e^s[\mathbf{e}^j]g^{\cdot\,\cdot}_{sk} = \left(\mathbf{e}^j\cdot\mathbf{e}^s\right) g^{\cdot\,\cdot}_{sk} = g^{js}_{\cdot\,\cdot}g^{\cdot\,\cdot}_{sk} \quad ,$$

showing that the two contravariant and covariant metric tensor matrices are inverse of one another and that the mixed metric tensor matrices is just the **Kronecker tensor** .

DRAFT-IN-PROGRESS

Note that the difference between contravariant and covariant indexes become noteworthy when the metric tensor is a function of the position.

The $g^{\cdot\cdot}_{ab}[P]$ is in fact a tensor as it is easly shown from the invariance of the distance with respect to the choice of the coordinates implying that $g^{\cdot\cdot}_{ab}[P]$ is a second-rank covariant tensor. We can assume

$$g^{\cdot\cdot}_{ab}[P] = g^{\cdot\cdot}_{ba}[P] \quad .$$

without any loss of generality.

It is straightforward to check the request of invariance of $\mathrm{d}s^2$ implies that $g^{\cdot\cdot}_{ab}$ is a rank-two covariant tensor.

20.04.01.01 Alternative Derivation of the Raising and Lowering Indexes

A less formal but shortened derivation of the raising and lowering indexes via the metric tensor goes as follows.

We know (section § 20.03.03) that in order to get an invariant we can contract one contravariant index with one covariant index from a rank two tensor. It looks then natural, from inspection of equation (20.04.02),

$$\mathrm{d}s^2 = g^{\cdot\cdot}_{ab}[P]\ \mathrm{d}x^a\ \mathrm{d}x^b \sim\ \mathrm{d}x^a\ \mathrm{d}x_a \sim\ \mathrm{d}x_a\ \mathrm{d}x^a \quad .$$

We can then define the general operation of raising and lowering the indexes as:

$$T^{a\cdot c\ldots\cdot}_{\cdot b\cdot\cdot\ldots} \equiv g^{\cdot\cdot}_{bB} T^{\cdot\cdot\cdot\cdot\ldots}_{\cdot\cdot\cdot\cdot\ldots} \qquad T^{abc\ldots\cdot}_{\cdot\cdot\cdot\cdot\ldots} \equiv g^{bB}_{\cdot\cdot} T^{a\cdot c\ldots\cdot}_{\cdot B\cdot\cdot\ldots} \quad .$$

20.04.01.02 Transformations Defined via Invariant Quantities

Proper Rotations in Euclidean Three-Dimensional Space

In Euclidean three-dimensional space, the proper rotation group SO(3) (or, similarly, O(3)), can be defined as the set of linear transformations leaving invariant both the handness, $\det[\mathbb{R}] = 1$, and the distance $\mathrm{d}s^2$ with the Euclidean metric $g^{\cdot\cdot}_{ab} = \delta^{\cdot\cdot}_{ab}$:

$$\boxed{\mathrm{d}s^2 = \mathrm{d}x^a\ \mathrm{d}x_a = \mathrm{d}x_1{}^2 + \mathrm{d}x_2{}^2 + \mathrm{d}x_3{}^2} \quad .$$

It follows that there is no distinction at all between covariant and contravariant indexes under transformations of SO(3).

Proper Lorentz Transformation in Minkowski Space

In Minkowski space the proper **Lorentz Transformation** group (or, similarly, the full **Lorentz Transformation** group), can be defined as the set of linear transformations leaving invariant the time direction, $\mathbb{L}^0_{\cdot 0} \geq 1$, the handness of the space axes, $\det[\mathbb{L}] = 1$, and the Minkowski distance $\mathrm{d}s^2$ with the Minkowski metric $g^{\cdot\cdot}_{ab} = \eta^{\cdot\cdot}_{ab}$:

$$\boxed{\mathrm{d}\tau^2 = \eta^{\cdot\cdot}_{ab}\ \mathrm{d}x^a\ \mathrm{d}x^b = c^2\ \mathrm{d}t^2 - \mathrm{d}x_1{}^2 - \mathrm{d}x_2{}^2 - \mathrm{d}x_3{}^2} \quad .$$

It follows that to change between covariant and contravariant indexes under proper **Lorentz Transformation** one needs to change the sign of the space components of the four-vector.

Note that the metric in Minkowski space is not positive-definite.

The invariant $\mathrm{d}\tau$ is the proper time that is the time measured in the proper Rest Frame, because that gives the time interval when $\mathrm{d}\mathbf{x} = 0$, that is the time measured by an observer at rest with respect to the system.

Read also sections § 17.03, § 23.06, § 26.03. This section presents the algebraic approach.
Let us consider only orthonormal Cartesian Coordinates Coordinate Systems.

20.05.01
Basics: Active and Passive Points of View

Two approaches are possible.

Active Rotations

The **passive** approach: the vector is a fixed fixed and the Coordinate System (that is the basis in the vector space) is rotated. The new components of the same vector in the new basis are given by:

$$\boxed{\mathbf{v} \to \mathbf{v}} \quad \text{unchanged: a vector is defined without reference to any basis} \quad , \quad ,$$

$$\boxed{\{\mathbf{e}_k\} \to \{\overline{\mathbf{e}}_k\}} \quad \text{just a change of basis in the vector space} \quad , \quad ,$$

$$\boxed{\mathbf{v} = v_k \mathbf{e}_k = \overline{v}_k \overline{\mathbf{e}}_k} \quad \text{the same vector represented in two different bases} \quad , \quad ,$$

$$\overline{v}_j = v_k \left(\overline{\mathbf{e}}_j \cdot \mathbf{e}_k\right) \Longrightarrow \boxed{\overline{v}_j \equiv R^{\cdot\cdot}_{jk} v_k} \Longrightarrow \overline{\mathbf{e}}_k = \left(\overline{\mathbf{e}}_k \cdot \mathbf{e}_j\right) \mathbf{e}_j = R^{\cdot\cdot}_{kj} \mathbf{e}_j \quad , \quad ,$$

$$\boxed{R^{\cdot\cdot}_{jk} \equiv \overline{\mathbf{e}}_j \cdot \mathbf{e}_k} \quad ,$$

that is: the same vector is represented in different bases; the new components are the components of the same vector in a different basis.

The matrix in the passive approach will be called $\mathbb{R}$, as this is the most elementary meaning of rotation: a rotation of the Coordinate System.

Passive Rotations

The **active** approach: the Coordinate System (that is the basis in the vector space) is fixed and the vector is rotated. The operator $\mathcal{G}$ **rotates** the vector. The components of the new vector in the old basis are given by:

$$\mathbf{v} \to \overline{\mathbf{v}} \equiv \mathcal{G}[\mathbf{v}] \qquad \text{the rotated vector} \quad , \quad ,$$
$$\{\mathbf{e}_k\} \to \{\overline{\mathbf{e}}_k\} \equiv \mathcal{G}[\{\mathbf{e}_k\}] \qquad \text{the basis vectors rotated as any other vector} \quad , \quad ,$$
$$v_k \equiv \mathbf{v}\cdot\mathbf{e}_k = \overline{\mathbf{v}}\cdot\overline{\mathbf{e}}_k = \mathcal{G}[\mathbf{v}]\cdot\mathcal{G}[\mathbf{e}_k] \implies \mathcal{G}[\mathbf{e}_k] \equiv \overline{\mathbf{e}}_k = \left(\overline{\mathbf{e}}_k\cdot\mathbf{e}_j\right)\mathbf{e}_j \equiv G^{\cdot\cdot}_{jk}\mathbf{e}_j \quad , \quad ,$$
$$\overline{v}_k = \overline{\mathbf{v}}\cdot\mathbf{e}_k = \mathcal{G}[\mathbf{v}]\cdot\mathbf{e}_k = \mathcal{G}\left[\left(\mathbf{v}\cdot\mathbf{e}_j\right)\mathbf{e}_j\right]\cdot\mathbf{e}_k = v_j\left(\mathcal{G}[\mathbf{e}_j]\cdot\mathbf{e}_k\right) \qquad \overline{v}_k = G^{\cdot\cdot}_{kj}v_j \quad , \quad ,$$
$$G^{\cdot\cdot}_{kj} \equiv \overline{\mathbf{e}}_j\cdot\mathbf{e}_k$$

The vector is actively **rotated**, the basis is not changed; the basis vectors are rotated as any other vector.

The rotated vector has on the rotated basis the same components as the original vector in the original basis.

Active Versus Passive Rotations

Clearly:

$$\boxed{\mathbb{R}^{-1} = \mathbb{R}^{\mathsf{T}} \equiv \mathbb{G} \qquad \mathbb{G}^{-1} = \mathbb{G}^{\mathsf{T}} \equiv \mathbb{R}} \quad .$$

Note that, in order to compare the two approaches, it should be emphasized that, geometrically, the correspondence between the basis vectors in the two cases are:

$$\{\{\mathbf{e}_k\} \quad \text{passive}\} \quad \Leftrightarrow \quad \{\{\overline{\mathbf{e}}_k\} \quad \text{active}\} \quad ,$$
$$\{\{\mathbf{e}_k\} \quad \text{active}\} \quad \Leftrightarrow \quad \{\{\overline{\mathbf{e}}_k\} \quad \text{passive}\} \quad .$$

20.05.02

Group of Rotations Algebra

The present discussion is carried on by using the position vector as example; however, by definition of vector, it can be applied to any vector.

Let us use exclusively the passive approach, unless specified otherwise: the same vector as seen by two different rotated Coordinate Systems.

Si considerino due Coordinate System cartesiani ortogonali i cui unit vectors degli assi (due terne ortonormali) siano rispettivamente $\{\mathbf{e}_k\}$, con $k = 1, 2, 3$, e $\{\overline{\mathbf{e}}_k\}$, con $k = 1, 2, 3$.

When the Coordinate System $\{\mathbf{e}_k\}$ is rotated one obtains the Coordinate System $\{\overline{\mathbf{e}}_k\}$.

Si definisca la matrice di trasformazione tra i due Coordinate System come:

$$\mathbf{e}_j \longrightarrow \overline{\mathbf{e}}_j \qquad \implies \qquad \boxed{\mathbb{R}^{\cdot\cdot}_{kj} \equiv \overline{\mathbf{e}}_k\cdot\mathbf{e}_j} \qquad (20.05.01) \quad \to 1193$$

$$\overline{\mathbf{e}}_k \longrightarrow \mathbf{e}_k \qquad \implies \qquad \boxed{\mathbb{R}^{-1\,\cdot\cdot}_{\quad jk} \equiv \mathbf{e}_j\cdot\overline{\mathbf{e}}_k = \mathbb{R}^{\cdot\cdot}_{kj} = \mathbb{R}^{\mathsf{T}\,\cdot\cdot}_{\quad jk}} \qquad (20.05.02)$$

$$\boxed{\mathbb{R}^{-1} = \mathbb{R}^{\mathsf{T}} \equiv \mathbb{G}} \quad .$$

Note that from the very definition (20.05.01) it is clear that the matrix for the inverse transformation is given by the transpose matrix.

La matrice di trasformazione è una matrice ortogonale a determinante unitario (gruppo SO(3)), cioé la sua inversa coincide con la sua trasposta, per cui si ha:

$$\boxed{\mathbb{R}^{\mathsf{T}}\mathbb{R} = \mathbb{R}\mathbb{R}^{\mathsf{T}} = \mathbb{I} \qquad \Leftrightarrow \qquad R^{\cdot\cdot}_{ik}R^{\cdot\cdot}_{jk} = R^{\cdot\cdot}_{ki}R^{\cdot\cdot}_{kj} = \delta^{\cdot\cdot}_{ij} \qquad \implies \qquad \det[\mathbb{R}] = \pm 1} \quad .$$

(20.05.03) → 1198

In forma matriciale si ha:

$$\mathbb{R}^{\mathsf{T}}\mathbb{R} = \mathbb{R}\mathbb{R}^{\mathsf{T}} = \mathbb{I} \qquad \implies \qquad \boxed{\mathbb{R}^{\mathsf{T}} = \mathbb{R}^{-1} \equiv \mathbb{G}} \quad . \qquad (20.05.04) \quad \to 1195$$

Dalla relazione di ortogonalità segue:

$$\mathbb{I} = \mathbb{R}\mathbb{R}^{\mathsf{T}} \implies 0 = \dot{\mathbb{R}}\mathbb{R}^{\mathsf{T}} + \mathbb{R}\dot{\mathbb{R}}^{\mathsf{T}} \implies \mathbb{R}\dot{\mathbb{R}}^{\mathsf{T}} = -\dot{\mathbb{R}}\mathbb{R}^{\mathsf{T}} \implies \dot{\mathbb{R}}\mathbb{R}^{\mathsf{T}} \qquad \text{è antisimmetrica} \quad .$$

DRAFT-LW-PROGRESS

And also:

$$\mathbb{I} = \mathbb{G}\mathbb{G}^{\mathsf{T}} \implies 0 = \dot{\mathbb{G}}\mathbb{G}^{\mathsf{T}} + \mathbb{G}\dot{\mathbb{G}}^{\mathsf{T}} \implies \mathbb{G}\dot{\mathbb{G}}^{\mathsf{T}} = -\dot{\mathbb{G}}\mathbb{G}^{\mathsf{T}} \implies \dot{\mathbb{G}}\mathbb{G}^{\mathsf{T}} \quad \text{è antisimmetrica} \quad .$$

Passive Approach

The direct and inverse transformations are therefore given, in the passive approach, by:

$$\mathbf{x}_{\mathrm{P}} = \mathbb{R}\mathbf{x} \qquad \mathbf{x}_{\mathrm{P}}\text{: new components of the same vector} \quad , \quad ,$$
$$\implies \mathbf{x} = \mathbb{G}\mathbf{x}_{\mathrm{P}} \quad .$$

Therefore, for any vector fixed in the new frame, assumed to be moving with time (the moving frame):

$$\{\mathbf{x} = \mathbb{G}\mathbf{x}_{\mathrm{P}} \qquad \dot{\mathbf{x}}_{\mathrm{P}} = 0\} \implies \dot{\mathbf{x}} = \dot{\mathbb{G}}\mathbf{x}_{\mathrm{P}} = \dot{\mathbb{G}}\mathbb{R}\mathbf{x} = \dot{\mathbb{R}}^{\mathsf{T}}\mathbb{R}\mathbf{x} \equiv \mathbb{A}\mathbf{x} \qquad \mathbb{A} \equiv \dot{\mathbb{R}}^{\mathsf{T}}\mathbb{R} \quad , \tag{20.05.05}$$

so that:

$$\boxed{\dot{\mathbb{R}}^{\mathsf{T}}\mathbb{R}\mathbf{x} = -\dot{\mathbb{R}}^{\mathsf{T}}\dot{\mathbb{R}}\mathbf{x} \equiv \mathbb{A}_{\mathbb{R}}\mathbf{x}} \quad . \tag{20.05.06}$$

→ 1195

The action of any 3×3 anti-symmetrical matrix can be represented as a vector product, read § 20.05.04, and therefore the Poisson relations have been recovered.

Active Approach

The direct and inverse transformations are therefore given, in the active approach, by:

$$\mathbf{x}_{\mathrm{A}} = \mathbb{G}\mathbf{x} \quad ,$$
$$\mathbf{x} = \mathbb{R}\mathbf{x}_{\mathrm{A}} \quad .$$

Therefore, for any moving vector in the absolute frame:

$$\{\mathbf{x}_{\mathrm{A}} = \mathbb{G}\mathbf{x} \qquad \dot{\mathbf{x}} = 0\} \implies \dot{\mathbf{x}}_{\mathrm{A}} = \dot{\mathbb{G}}\mathbf{x} = \dot{\mathbb{G}}\mathbb{R}\mathbf{x}_{\mathrm{A}} = \dot{\mathbb{G}}\mathbb{G}^{\mathsf{T}}\mathbf{x}_{\mathrm{A}} \equiv \mathbb{A}_{\mathbb{G}}\mathbf{x}_{\mathrm{A}} \tag{20.05.07}$$

The action of any 3×3 anti-symmetrical matrix can be represented as a vector product, read § 20.05.04, and therefore the Poisson relations have been recovered.

20.05.03

Angular Velocity

As the matrix $\mathbb{A}$ is anti-symmetric, one can set, without loss of generality:

$$\boxed{A_{kj}^{\cdot\cdot} \equiv \epsilon_{jks}^{\cdot\cdot\cdot}\omega_s = \begin{vmatrix} 0 & -\omega_3 & +\omega_2 & , \\ +\omega_3 & 0 & -\omega_1 & , \\ -\omega_2 & +\omega_1 & 0 & , \end{vmatrix}} \quad .$$

→ 1205

It is then necessary to invert the equation to determine $\boldsymbol{\omega}$:

$$\boxed{\omega_s = \frac{1}{2}\epsilon_{sjk}^{\cdot\cdot\cdot}A_{kj}^{\cdot\cdot}} \quad . \tag{20.05.08}$$

Read § 20.05.04.

20.05.04

Matrici Antisimmetriche Del Secondo Ordine E Prodotto Vettoriale

This § is referenced at pages:
[1194, 1194, 1194, 1198, 1199, 2490]

Let $\mathbb{A}$ be an antisymmetric second-order tensor: $A_{kj}^{\cdot\cdot} = -A_{jk}^{\cdot\cdot}$.

As a 3×3 real antisymmetric matrix has three parameters, one may wonder whether the information carried by the matrix can be expressed in some way via a vector.

Let $\mathbf{x}$ be any vector; the vector $\mathbf{y} = \mathbb{A}\mathbf{x}$ defined as $y_i = A_{ir}^{\cdot\cdot}x_r$ can be expressed as a vector product, in terms of a suitable vector $\boldsymbol{\omega}$, as follows:

$$\boxed{y_i = A_{ir}^{\cdot\cdot}x_r \stackrel{?}{=} \epsilon_{isr}^{\cdot\cdot\cdot}\omega_s x_r \qquad \Leftrightarrow \qquad \mathbf{y} \stackrel{?}{=} \boldsymbol{\omega}\wedge\mathbf{x}} \quad .$$

DRAFT-IN-PROGRESS

CC BY NC ND

In other words we are looking for a vector $\boldsymbol{\omega}$ satisfying:

$$\boxed{A^{\cdot\cdot}_{ir} = \epsilon^{\cdot\cdot\cdot}_{ris}\omega_s \implies -A^{\cdot\cdot}_{ir} = \epsilon^{\cdot\cdot\cdot}_{irs}\omega_s} \quad .$$

In fact, using equation (20.06.05), one finds:

$$-\epsilon^{\cdot\cdot\cdot}_{ipq}A^{\cdot\cdot}_{ir} = \epsilon^{\cdot\cdot\cdot}_{ipq}\epsilon^{\cdot\cdot\cdot}_{irs}\omega_s \quad ,$$
$$-\epsilon^{\cdot\cdot\cdot}_{ipq}A^{\cdot\cdot}_{ir} = \omega_s\left(\delta^{\cdot\cdot}_{pr}\delta^{\cdot\cdot}_{qs} - \delta^{\cdot\cdot}_{ps}\delta^{\cdot\cdot}_{qr}\right) \quad ,$$
$$-\epsilon^{\cdot\cdot\cdot}_{ipq}A^{\cdot\cdot}_{ir} = \omega_q\delta^{\cdot\cdot}_{pr} - \omega_p\delta^{\cdot\cdot}_{qr} \quad .$$

As in the latest equation r, p and q are arbitrary free indexes we can freely chose $p = r$ to find:

$$-\epsilon^{\cdot\cdot\cdot}_{irq}A^{\cdot\cdot}_{ir} = \omega_q\delta^{\cdot\cdot}_{rr} - \omega_r\delta^{\cdot\cdot}_{qr} = 3\omega_q - \omega_q = 2\omega_q \quad ,$$

that is:

$$\boxed{\omega_q = \frac{1}{2}\epsilon^{\cdot\cdot\cdot}_{qri}A^{\cdot\cdot}_{ir}} \tag{20.05.09}$$

Therefore:

$$\mathbf{y} = \mathbb{A}\mathbf{x} \implies y_i = A^{\cdot\cdot}_{ir}x_r = \epsilon^{\cdot\cdot\cdot}_{isr}\omega_s x_r \implies \mathbf{y} = \boldsymbol{\omega}\wedge\mathbf{x}$$

20.05.05
Infinitesimal Transformations and Rotation Matrices

Write the rotation matrix, $\mathbb{U}$ (either $\mathbb{R}$ or $\mathbb{G}$), for an infinitesimal transformation as:

$$\boxed{\mathbb{U} = \mathbb{I} + \mathbb{B} + \mathcal{O}\left(\mathbb{B}\right)^2} \quad ,$$

where $\mathbb{B}$ is matrix depending on small (infinitesimal) parameters, three in the most general case.

The orthogonality relation (20.05.04) reads:

$$\mathbb{I} = \mathbb{U}\mathbb{U}^{\mathsf{T}} = \left(\mathbb{I} + \mathbb{B}\right)\left(\mathbb{I} + \mathbb{B}\right)^{\mathsf{T}} = \mathbb{I} + \left(\mathbb{B} + \mathbb{B}^{\mathsf{T}}\right) + \mathcal{O}\left(\mathbb{B}\right)^2 \qquad \implies \qquad \boxed{\mathbb{B} + \mathbb{B}^{\mathsf{T}} = 0} \quad .$$

The matrix $\mathbb{B}$ is thus antisymmetric.

It follows that for an infinitesimal rotation:

$$\boxed{\delta\mathbf{x} = \mathbb{B}\mathbf{x} \qquad \Delta x_k = \mathbb{B}^{\cdot\cdot}_{kj}x_j} \quad . \tag{20.05.10}$$

→ 1195

Note that the above equation (20.05.10) cannot be used to evaluate $\dot{x}$, because it is a first-order development already. To this end matrix $\mathbb{A}$ defined in equation (20.05.06) must be used. In other words, $\mathbb{A}$ describes exactly any rotation, while $\mathbb{B}$ describes an infinitesimal rotation. One has:

$$\mathbb{A} \equiv \dot{\mathbb{U}}^{\mathsf{T}}\mathbb{U} \simeq \dot{\mathbb{B}}^{\mathsf{T}}\left(\mathbb{I} + \mathbb{B}\right) \simeq \dot{\mathbb{B}}^{\mathsf{T}} \implies \left\{\mathbb{A}^{\mathsf{T}} \simeq \dot{\mathbb{B}} \qquad \mathbb{A} \simeq \dot{\mathbb{B}}^{\mathsf{T}}\right\}$$

20.05.06
Relations Between Rotation Matrix and Rotation Angle-Axis - Euler Theorem

This § is referenced at pages:
[1440]

The following Euler theorem can be demonstrated.

For every proper rotation around a certain point O and described by the matrix $\mathbb{R}$, there exist one axis, passing by O and with unit vector $\hat{\mathbf{n}}$, such that $\mathbb{R}$ results in a rotation about $\{O;\hat{\mathbf{n}}\}$:

- by an angle θ given by
$$\cos\left[\theta\right] = \left(\mathrm{Tr}\, R - 1\right)/2 \quad ,$$
- the three eigenvalues of the proper rotation matrix, $\mathbb{R}$, are:
$$1 \qquad \exp\left[\pm\mathrm{i}\theta\right] \qquad \text{with} \qquad \cos\left[\theta\right] = \left(\mathrm{Tr}\, R - 1\right)/2 \quad .$$

Rotations of a Vector Around an Axis: Geometric Approach

Read § 17.03 for the geometrical approach.

20.05.08
Isotropic Tensors Under Rotation

This § is referenced at pages:
[1208, 1658]

Isotropic tensors under rotation are tensors whose components are invariant under any rotation [1].

All scalars are isotropic rank-zero tensors.

It can be shown that no first rank isotropic tensor exist. In fact, a first rank tensor is just a vector which is endowed with a direction.

It can be shown that there is only one second rank isotropic tensor: the scalar multiples of

$$\boxed{\delta^{\cdot\cdot}_{jk}} \quad .$$

It can be shown that there is only one third rank isotropic tensor: the scalar multiples of

$$\boxed{\epsilon^{\cdots}_{ijk}} \quad .$$

It can be shown that there are three independent fourth rank isotropic tensors: the scalar multiples of

$$\begin{cases} \boxed{\delta^{\cdot\cdot}_{jk}\delta^{\cdot\cdot}_{rs}} \quad , \\ \boxed{\delta^{\cdot\cdot}_{jr}\delta^{\cdot\cdot}_{ks} + \delta^{\cdot\cdot}_{js}\delta^{\cdot\cdot}_{kr}} \quad , \\ \boxed{\delta^{\cdot\cdot}_{jr}\delta^{\cdot\cdot}_{ks} - \delta^{\cdot\cdot}_{js}\delta^{\cdot\cdot}_{kr} = \epsilon^{\cdots}_{jki}\epsilon^{\cdots}_{rsi}} \end{cases}$$

20.06 Cartesian Tensors Under the Group of Rotations

©|Gerrit Coddens. Spinors for everyone. 2017. cea-01572342|WEB - URL |*Full critical discussion.*|

DRAFT IN PROGRESS

Cartesian tensors are often used in various branches of classical physics, such as fluid mechanics and elasticity. In classical continuum mechanics, the space of interest is usually the three-dimensional Euclidean space. If one restricts the local coordinates to be orthonormal Cartesian Coordinates Coordinate System with the same scale centered at the point of interest, the metric tensor is the **Kronecker tensor** . Therefore there is no need to distinguish covariant and contravariant components. Usually all the indexes of Cartesian tensors are written as subscripts. Cartesian tensors achieve considerable computational simplification at the cost of generality and of some theoretical insight.

In generale una grandezza tensoriale è definita in termini delle sue proprietà di trasformazione rispetto ad un gruppo di trasformazioni. In fisica classica il gruppo di trasformazioni è il gruppo di Galilei. In fisica moderna il gruppo di trasformazioni è il gruppo di Poincarè.

Nella fisica classica le grandezze fisiche scalari, vettoriali e tensoriali sono definite, in generale, in termini delle loro proprietà di trasformazione per trasformazioni di Galilei. Nella fisica relativistica si generalizza il concetto di tensore considerando le proprietà di trasformazioni tra Reference Frame Inerziali arbitrari secondo le trasformazioni di Lorentz.

However, only the rotational, SO(3), part of the Galilei group is interesting, as far as tensor transformation properties are concerned, as the boosts and translations are commutative. Similarly only the homogeneous Lorentz group, out of the full Poincarè group, is interesting, as far as tensor transformation properties are concerned, as the translations are commutative.

Le leggi fisiche devono essere espresse tramite relazioni tensoriali in quanto l'espressione funzionale della legge non può dipendere dalla scelta del Coordinate System, o del Reference Frame inerziale, che è arbitraria.

In this section we will describe with some more details a particularly important class of tensors, Cartesian Tensors under SO(3). We restrict our attention to orthonormal Coordinate System in Euclidean space with three dimensions.

Data una generica grandezza fisica sia G la sua espressione nel primo Coordinate System e sia G' la sua espressione nel secondo Coordinate System. La grandezza eventualmente può essere un campo che dipende dalla posizione: $G[\mathbf{r}]$.

20.06.01 Scalari Cartesiani (Tensori Cartesiani Di Ordine Zero)

Una grandezza scalare è una grandezza il cui valore non cambia (è invariante) al cambiare del Coordinate System (Cartesiane ortonormali) dal Coordinate System $\mathbf{r}$ al Coordinate System $\mathbf{r}'$:

$$\phi'[\mathbf{r}'] = \phi[\mathbf{r}] \quad . \tag{20.06.01}$$

→ 1197

Esempio tipico di grandezza scalare è il modulo di un vettore o il prodotto scalare di due vettori. Esempio tipico di grandezza che non è una grandezza scalare è la componente di un vettore rispetto ad un asse qualunque.

Note that it is sometimes said that a scalar is a physical quantity represented by one single number. This is wrong. A scalar is not only represented by a single number, but it has also to satisfy to the definition (20.06.01).

20.06.02
Vettori Cartesiani (Tensori Cartesian Del Primo Ordine)

Al variare dal Coordinate System $\mathbf{r}$ al Coordinate System $\mathbf{r}'$ le componenti di un generico vettore $\mathbf{v}$ rispetto al primo Coordinate System (Cartesiane ortonormali) sono legate alle componenti rispetto al secondo Coordinate System (Cartesiane ortonormali) come segue:

$$v'_k[\mathbf{r}'] = R^{\cdot\cdot}_{kj} v_j[\mathbf{r}] \quad , \tag{20.06.02}$$

→ 1198

dove $R^{\cdot\cdot}_{ij}$ è la matrice di trasformazione tra i due Coordinate System cartesiani ortogonali. Infatti si ha:

$$\boxed{v'_k \equiv \mathbf{v}\cdot\mathbf{e}'_k = \mathbf{v}\cdot\left(R^{\cdot\cdot}_{kj}\mathbf{e}_j\right) = R^{\cdot\cdot}_{kj}\left(\mathbf{v}\cdot\mathbf{e}_j\right) \equiv R^{\cdot\cdot}_{kj} v_j} \quad .$$

La relazione (20.06.02) definisce un insieme di grandezze, v_k, con $k = 1, 2, 3$, (le componenti di un vettore) che, per definizione, costituiscono un vettore (ovvero un tensore del primo ordine).

Dalla (20.05.03) si ricava la relazione inversa:

$$\boxed{v_k = v'_j R^{\cdot\cdot}_{jk}} \quad . \tag{20.06.03}$$

20.06.03
Tensori Cartesiani Del Secondo Ordine

This § is referenced at pages:
[1056, 1204]

Un tensore Cartesiano del secondo ordine è un insieme di grandezze $T^{\cdot\cdot}_{ij}$ con $i, j = 1, 2, 3$ che per un cambiamento del Coordinate System (Cartesiane ortonormali), dal Coordinate System $\mathbf{r}$ al Coordinate System $\mathbf{r}'$, si trasforma come

$$T'^{\cdot\cdot}_{ij}[\mathbf{r}'] = R^{\cdot\cdot}_{ip} R^{\cdot\cdot}_{jq} T^{\cdot\cdot}_{pq}[\mathbf{r}] \quad , \tag{20.06.04}$$

dove $R^{\cdot\cdot}_{ij}$ è la matrice di trasformazione tra i due Coordinate System cartesiani ortogonali. Esempi di comuni tensori del secondo ordine sono: il tensore di inerzia, il tensore di **Electric-Permittivity** , il tensore di **Magnetic-Permeability** il tensore di **conductivity** , il tensore momento di quadrupolo gravitazionale, il tensore momento di quadrupolo elettrico, il tensore momento di quadrupolo magnetico, il tensore di deformazione e il tensore degli sforzi.

Any time there is a linear relation between two vectors one has to expect the relation to pass via a second-order tensor.

Un caso particolare è rappresentato dai tensori simmetrici del secondo ordine ($T^{\cdot\cdot}_{ij} = T^{\cdot\cdot}_{ji}$) che sono costituiti da sei grandezze indipendenti.

Un altro caso particolare è costituito dai tensori antisimmetrici del secondo ordine ($T^{\cdot\cdot}_{ij} = -T^{\cdot\cdot}_{ji}$) che sono costituiti da tre grandezze indipendenti. Le tre componenti indipendenti di un tensore antisimmetrico del secondo ordine si trasformano come le componenti di un opportuno vettore e questo permette quindi di assimilare il tensore antisimmetrico come un vettore opportuno, as shown in section § 20.05.04.

Ogni tensore del secondo ordine può essere espresso come somma di una componente simmetrica ed una antisimmetrica:

$$T^{\cdot\cdot}_{ij} = \frac{T^{\cdot\cdot}_{ij} + T^{\cdot\cdot}_{ji}}{2} + \frac{T^{\cdot\cdot}_{ij} - T^{\cdot\cdot}_{ji}}{2} \equiv \mathbb{T}^{\mathtt{S}}_{\mathtt{ij}} + \mathbb{T}^{\mathtt{A}}_{\mathtt{ij}} \quad .$$

La parte simmetrica, a sua volta, può essere decomposta in una parte a traccia nulla più una parte proporzionale al tensore identità:

$$\boxed{\mathbb{T}^{\mathtt{S}}_{\mathtt{ij}} = \left(\mathbb{T}^{\mathtt{S}}_{\mathtt{ij}} - \frac{1}{3}\mathbb{T}^{\mathtt{S}}_{\mathtt{kk}}\delta^{\cdot\cdot}_{ij}\right) + \frac{1}{3}\mathbb{T}^{\mathtt{S}}_{\mathtt{kk}}\delta^{\cdot\cdot}_{ij}} \quad .$$

DRAFT IN PROGRESS

CC BY NC ND

20.06.03.01 Invarianti Di Un Tensore Simmetrico Del Secondo Ordine

Si consideri un tensore simmetrico del secondo ordine. Questo ha tre invarianti scalari che possono essere formati dalle sue componenti:

- la traccia,
$$I_1 \equiv T_{11} + T_{22} + T_{33} = \delta_{ij}^{\cdot\cdot} T_{ij}^{\cdot\cdot} = T_{ii}^{\cdot\cdot} \quad ,$$
lineare nelle componenti del tensore,
- la somma dei suoi minori diagonali,
$$I_2 \equiv \begin{vmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{vmatrix} + \begin{vmatrix} T_{22} & T_{23} \\ T_{32} & T_{33} \end{vmatrix} + \begin{vmatrix} T_{33} & T_{31} \\ T_{13} & T_{11} \end{vmatrix} = \frac{1}{2}\left(T_{ii}^{\cdot\cdot} T_{jj}^{\cdot\cdot} - T_{ij}^{\cdot\cdot} T_{ij}^{\cdot\cdot}\right) = \frac{1}{2}\epsilon_{ij_1k_1}\epsilon_{ij_2k_2} T_{j_1j_2} T_{k_1k_2} \quad ,$$
quadratica nelle componenti del tensore,
- il determinante,
$$I_3 \equiv \det\left\{T_{ij}^{\cdot\cdot}\right\} = \epsilon_{ijk}^{\cdot\cdot\cdot} T_{1i} T_{2j} T_{3k} \quad ,$$
cubica nelle componenti del tensore.

I tre invarianti scalari sono i coefficienti dell'equazione cubica le cui soluzioni costituiscono gli autovalori del tensore simmetrico del secondo ordine:
$$\lambda^3 - I_1\lambda^2 + I_2\lambda - I_3 = 0 \quad .$$

20.06.03.02 Tensori Antisimmetrici Del Secondo Ordine E Prodotto Vettoriale

Read § 20.05.04

20.06.04
Tensori (Cartesiani) Di Ordine Superiore

Analogamente a quanto mostrato si possono definire tensori di ordine superiore. Intervengono, ad esempio, nella meccanica dei corpi continui.

Il numero di indici di un tensore cartesiano si definisce il rango (rank) del tensore.

20.06.05
Contravariant and Covariant Indices for Cartesian Tensors

While the distinction between covariant and contravariant indices must be made for general tensors, the two are equivalent for tensors in n-dimensional Euclidean space equipped with orthonormal Cartesian Coordinates Coordinate System, and such tensors are known as Cartesian tensors.

In fact the metric tensors for an Euclidean space equipped with Cartesian coordinates is just the **Kronecker tensor** .

20.06.06
Levi-Civita tensor in Euclidean Space With n Dimensions

The **Levi-Civita tensor** in an Euclidean space with n dimensions equipped with an orthonormal basis is defined as (compare with § **??**):

$$\epsilon_{i_1\ldots i_n} = \begin{cases} +1 \text{ if } \{i_1 \ldots i_n\} \text{ is an even permutation of } 1, \ldots n \quad , \\ -1 \text{ if } \{i_1 \ldots i_n\} \text{ is an odd permutation of } 1, \ldots n \quad , \\ 0 \text{ if any two indexes are equal} \quad . \end{cases} \quad .$$

DRAFT - EN-PROGRESS

20.06.06.01 Properties of the Levi-Civita tensor in 3 Dimensions

©|WEB - URL |||

The product of two **Levi-Civita tensor** can be expressed as a function of the **Kronecker tensor** :

$$\epsilon^{\dot{i}\dot{j}\dot{k}}\epsilon^{\dot{l}\dot{m}\dot{n}} =$$

$$+\delta^{\dot{i}\dot{l}}\delta^{\dot{j}\dot{m}}\delta^{\dot{k}\dot{n}} + \delta^{\dot{i}\dot{m}}\delta^{\dot{j}\dot{n}}\delta^{\dot{k}\dot{l}} + \delta^{\dot{i}\dot{n}}\delta^{\dot{j}\dot{l}}\delta^{\dot{k}\dot{m}} - \delta^{\dot{i}\dot{m}}\delta^{\dot{j}\dot{l}}\delta^{\dot{k}\dot{n}} - \delta^{\dot{i}\dot{l}}\delta^{\dot{j}\dot{n}}\delta^{\dot{k}\dot{m}} - \delta^{\dot{i}\dot{n}}\delta^{\dot{j}\dot{m}}\delta^{\dot{k}\dot{l}} \quad .$$

It can be, in fact, written as a 3×3 determinant of **Kronecker tensor** .

Product of two **Levi-Civita tensor** summed on one index:

$$\epsilon^{\dot{i}\dot{p}\dot{q}}\epsilon^{\dot{i}\dot{r}\dot{s}} = \delta^{\dot{p}\dot{r}}\delta^{\dot{q}\dot{s}} - \delta^{\dot{p}\dot{s}}\delta^{\dot{q}\dot{r}} \quad . \tag{20.06.05}$$

→ 1195

Product of two **Levi-Civita tensor** summed on two indexes:

$$\epsilon^{\dot{i}\dot{j}\dot{r}}\epsilon^{\dot{i}\dot{j}\dot{s}} = 2\delta^{\dot{r}\dot{s}} \quad . \tag{20.06.06}$$

Product of two **Levi-Civita tensor** summed on all three indexes:

$$\epsilon^{\dot{i}\dot{j}\dot{k}}\epsilon^{\dot{i}\dot{j}\dot{k}} = 3! \quad . \tag{20.06.07}$$

20.10 Examples and Physical Applications

DRAFT-IN-PROGRESS

20.10.01 Reciprocal Basis in Euclidean Three-Dimensional Space

If $\mathbf{e}_1$, $\mathbf{e}_2$ and $\mathbf{e}_3$ are contravariant basis vectors of the euclidean three-dimensional space (not necessarily orthogonal nor of unit norm) then the covariant basis vectors of their reciprocal system are:

$$\mathbf{e}_1 = \frac{\mathbf{e}^2 \wedge \mathbf{e}^3}{\mathbf{e}^1 \cdot (\mathbf{e}^2 \wedge \mathbf{e}^3)} \quad ,$$

$$\mathbf{e}_2 = \frac{\mathbf{e}^3 \wedge \mathbf{e}^1}{\mathbf{e}^1 \cdot (\mathbf{e}^2 \wedge \mathbf{e}^3)} \quad ,$$

$$\mathbf{e}_3 = \frac{\mathbf{e}^1 \wedge \mathbf{e}^2}{\mathbf{e}^1 \cdot (\mathbf{e}^2 \wedge \mathbf{e}^3)} \quad .$$

Read § 20-006.

Then the contravariant coordinates of any vector can be obtained by the scalar product of the vector with the contravariant basis vectors:

$$q^1 = v \cdot \mathbf{e}^1 \qquad q^2 = v \cdot \mathbf{e}^2 \qquad q^3 = v \cdot \mathbf{e}^3 \quad .$$

Likewise, the covariant components of the vector can be obtained from the dot product with covariant basis vectors:

$$q_1 = \mathbf{v} \cdot \mathbf{e}_1 \qquad q_2 = \mathbf{v} \cdot \mathbf{e}_2 \qquad q_3 = \mathbf{v} \cdot \mathbf{e}_3 \quad .$$

Then the vector can be expressed in two (reciprocal) ways:

$$\mathbf{v} = q_i \mathbf{e}^i = q_1 \mathbf{e}^1 + q_2 \mathbf{e}^2 + q_3 \mathbf{e}^3 \quad ,$$

and

$$\mathbf{v} = q^i \mathbf{e}_i = q^1 \mathbf{e}_1 + q^2 \mathbf{e}_2 + q^3 \mathbf{e}_3 \quad .$$

The indices of covariant coordinates, vectors, and tensors are subscripts (but see above, note on notation convention). If the contravariant basis vectors are orthonormal then they are equivalent to the covariant basis vectors, so there is no need to distinguish between the covariant and contravariant coordinates, and all indices are subscripts.

20.10.02 Counter-Example to the Principle of Covariance

This § is referenced at pages:
[1187]

Consider the momentum of a force with respect to the origin, $\boldsymbol{\gamma} = \mathbf{r} \wedge \mathbf{f}$. Its z component is: $\gamma_z = r_x f_y - r_y f_x$ Other combinations, such as $\gamma_z = r_x f_z - f_y r_z$, would not transform m as the components of a vector, $\boldsymbol{\gamma}$.

Imagine to study the free-fall of a mass-point in the uniform gravity field, with the y axis vertical towards the sky, and trajectory of the falling mass-point: $x[t] = d > 0$, $y[t]$, $z = 0$. Suppose to find that it satisfies, for the angular momentum, a second-cardinal-equation-like, non vector equation $m d \dot{v}_y = -mgd$ and translate it in components as: $\dot{\ell}_z = r_x f_y$. Unless we write our experimental result in a tensor form, we are in trouble because, while $\dot{\ell}_z$ is a component of a vector, $r_x f_y$ is not! In fact, if we decided instead to use a rotated Coordinate System, with $y = y'$, $z = x'$, $x = -z'$, within our freedom for an arbitrary definition of the experimental Coordinate System, we would find a different physical law, and if trying to apply our original law, we would find $\dot{\ell}_{z'} = r_{x'} f_{y'}$, which is, $0 = 0$, at most, useless.

A significant example is the introduction of the viscosity, read § 28.05. The naive definition, equation (28.05.01), must be improved to the real definition, equation (28.05.03), in order to obtain, a relation independent on the choice of the Coordinate System.

Examples of Contravariant and Covariant Vector Components

©|C.W.Misner & K.S.Thorne & J.A.Wheeler, *Gravitation*, 1973, W.H.Freeman and Co., ...Ed., WEB - URL.|||

If no metric exists at all then contravariant Vectors (that is Vectors) and covariant Vectors (that is coVectors) are different objects. If a metric exists then there is a canonical isomorphism between them. So one introduces vectors and, after fixing a Coordinate System, one speaks about their contravariant and covariant components. The distinction is necessary when dealing with non-orthonormal Cartesian Coordinates Coordinate Systems.

DRAFT-IN-PROGRESS

20.10.12
Product of Vectors

Let $\mathbf{A} = \{A_1, A_2, A_3\}$ and $\mathbf{B} = \{B_1, B_2, B_3\}$. To form the product of the two vectors one must use the nine components of the second-order tensor

$$A_j B_k = \begin{pmatrix} A_1B_1 & A_1B_2 & A_1B_3 & , \\ A_2B_1 & A_2B_2 & A_2B_3 & , \\ A_3B_1 & A_3B_2 & A_3B_3 & \end{pmatrix} \quad .$$

The scalar and vector product are a particular combination of those nine quantities. A second-order tensor can be decomposed, as described in section § 20.06.03, into a symmetric second rank tensor (that is a spherical tensor of rank two), plus an anti-symmetric second rank tensor (that is equivalent to a vector, that is a spherical tensor of rank one), plus a scalar, (that is a spherical tensor of rank zero).

The anti-symmetric second rank tensor is equivalent to taking the vector product $\mathbf{A} \wedge \mathbf{B}$ and the scalar is equivalent to taking the scalar product $\mathbf{A} \cdot \mathbf{B}$.

DRAFT-IN-PROGRESS

20.11 Exercises Problems and Physical Applications

20-001 Not a Scalar/Vector Physical Quantity

Read § 15.01.02.

1. Find a examples of physical quantities represented by one single number that are not a scalar physical quantities.
2. Find a examples of physical quantities represented by one single number that are not a vector physical quantities.

20-002 Translation

Show that under a coordinate translation the transformation matrix is just the identity matrix, than the definition implies that there is no change in the components.

20-003 When the Difference Is Not Relevant

Consider the case of linear orthogonal transformations in a linear vector space, that is linear transformations such that the transformation matrix $\mathbb{O}$ satisfies:

$$\mathbb{O}\mathbb{O}^{\mathsf{T}} = \mathbb{O}^{\mathsf{T}}\mathbb{O} = \mathbb{I} \quad .$$

Show that contravariant and covariant indexes transform in the same way, so that there is no difference, and setting indexes high/low makes no difference.

20-004 Rotation About a Fixed Axis - Active Approach

Consider the fixed $\mathcal{I}$ and the moving $\mathcal{I}'$ rotating around the fixed $\mathbf{e}_3 = \mathbf{e}'_3$, that is the common $z = z'$ axes.

$$\mathbb{G} = \mathbb{R}^{\mathsf{T}} = \begin{pmatrix} +\cos[\theta] & -\sin[\theta] & 0 \\ +\sin[\theta] & +\cos[\theta] & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

To first-order:

$$\mathbb{B} \equiv \mathbb{R} - \mathbb{I} = \begin{pmatrix} 0 & +\theta & 0 \\ -\theta & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \Longrightarrow \dot{\mathbb{B}} = \begin{pmatrix} 0 & +\dot{\theta} & 0 \\ -\dot{\theta} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, = \mathbb{A}^{\mathsf{T}} \Longrightarrow \mathbb{A} = \begin{pmatrix} 0 & -\dot{\theta} & 0 \\ +\dot{\theta} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

Comparison with equation (20.05.03) shows that $\omega_3 = \dot{\theta}$ as it should by hypothesis.

20-005 Reciprocal Bases

1. Demonstrate that the reciprocal base of a reciprocal base is the original base.
2. Demonstrate that the reciprocal base of a right-handed reciprocal base is still a right-handed reciprocal base.

DRAFT-IN-PROGRESS

20-006 Reciprocal Basis in Euclidean Three-Dimensional Space

This § is referenced at pages:
[1202]

Determine the reciprocal basis $\{\mathbf{e}^k\}$ of the basis $\{\mathbf{e}_k\}$, defined by (20.04.01).

WORKED SOLUTION

Observe that the requirement (20.04.01) implies that $\mathbf{e}^1$ must be orthogonal to both $\mathbf{e}_2$ and $\mathbf{e}_3$, $\mathbf{e}^2$ must be orthogonal to both $\mathbf{e}_3$ and $\mathbf{e}_2$, $\mathbf{e}^3$ must be orthogonal to both $\mathbf{e}_1$ and $\mathbf{e}_1$.
Therefore we can set

$$\mathbf{e}^k \propto \epsilon^{kij}_{\cdots}\, \mathbf{e}_i \wedge \mathbf{e}_j \quad .$$

The normalisation is determined to be

$$\boxed{\mathbf{e}^k = \frac{\epsilon^{kij}_{\cdots}\, \mathbf{e}_i \wedge \mathbf{e}_j}{\mathbf{e}_1 \cdot (\mathbf{e}_2 \wedge \mathbf{e}_3)}} \quad .$$

20-007 Non-Orthogonal Cartesian Coordinates Coordinate Systems in a Plane

If the two axes form an angle α the metric is given by:

$$\begin{pmatrix} 1 & \cos[\alpha] \\ \cos[\alpha] & 1 \end{pmatrix}$$

From this is clear that contravariant and covariant components are identical if an only if $\alpha = \pi/2$.

20-008 Polar Coordinates in the Plane and Spherical Coordinates in the Space

1. Determine the metric tensor for polar coordinates in the plane.

   WORKED SOLUTION

   $$\begin{pmatrix} 1 & 0 \\ 0 & r^2 \end{pmatrix}$$

2. Determine the metric tensor for spherical coordinates in the space.

20-009 Angular Velocity

1. Show it can be defined as:

   $$\boxed{\boldsymbol{\omega} \equiv \frac{1}{2}\mathbf{e}'_{\mathbf{k}} \wedge \dot{\mathbf{e}}'_{\mathbf{k}}} \quad . \tag{20.11.01}$$

2. Show that il vettore

   $$\boxed{\omega_q = \frac{1}{2}\epsilon^{\cdots}_{ijq} R^{\cdot\cdot}_{js} \dot{R}^{\cdot\cdot}_{is} = \frac{1}{2}\epsilon^{\cdots}_{ijq} R^{\cdot\cdot}_{js} \dot{G}^{\cdot\cdot}_{si} = \frac{1}{2}\epsilon^{\cdots}_{ijq} \left(\mathbb{R}\dot{\mathbb{G}}\right)^{\cdot\cdot}_{ji}} \tag{20.11.02}$$

   è la velocità angolare.

20-010 Angle Preservation Under Rotation

Show that the angle between any two vectors is preserved in a rotation of Euclidean three-dimensional space.

WORKED SOLUTION

The angle between two vectors can be written in terms of lengths only as:

$$2\,\mathbf{x}\cdot\mathbf{y} = |\mathbf{x}+\mathbf{y}|^2 - |\mathbf{x}|^2 - |\mathbf{y}|^2 \quad ,$$

and lengths are preserved in rotations.

20-011 Invarianza per Rotazioni Del Prodotto Scalare Di Due Vettori

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|3.53||

Dimostrare che il prodotto scalare di due vettori, $\mathbf{a}$ e $\mathbf{b}$, è invariante per rotazioni del Coordinate System. Si supponga, per semplicità, di lavorare nel piano xy anziché nello spazio three-dimensionale. Si considerino le componenti dei due vettori $\mathbf{a}$ e $\mathbf{b}$ rispetto ad un sistema di assi $x'y'$ ruotato di una angolo θ rispetto al sistema originale xy. Si calcoli il prodotto scalare usando le componenti dei due vettori rispetto al Coordinate System $x'y'$. Si verifichi che il risultato ottenuto coincide con quello che si ottiene usando le componenti rispetto al sistema xy. Il prodotto dei due vettori è cioè indipendente dall'angolo θ che misura la rotazione del Coordinate System $x'y'$ rispetto al Coordinate System xy.

WORKED SOLUTION

Si ha:

$$a'_i = \mathbb{R}_{ij} a_j \qquad b'_i = \mathbb{R}_{ij} b_j$$

con $\mathbb{R}$ matrice ortogonale speciale. Quindi:

$$\mathbb{R}\mathbb{R}^{\mathsf{T}} = \mathbb{R}^{\mathsf{T}}\mathbb{R} = \mathbb{I} \quad .$$

Allora:

$$\mathbf{a'}\cdot\mathbf{b'} = a'_i b'_i = \mathbb{R}_{is}\mathbb{R}_{ir} a_s b_r = \mathbb{R}_{is}\mathbb{R}^{\mathsf{T}}_{ri} a_s b_r = a_i b_i \quad .$$

20-012 Invariance of the Trace

Demonstrate that the trace of a second-order tensor is an invariant.

20-013 Invariance of the Symmetrical and Anti-Symmetrical Part of a Tensor

Show that a symmetrical tensor is always transformed into a symmetrical tensor, and an anti-symmetrical tensor is always transformed into an anti-symmetrical tensor.

MATERIAL IN PROGRESS

20-014 Levi-Civita tensor and the Determinant

Show how the determinant of any $n \times n$ matrix, $\mathbb{A}^{\cdot\cdot}_{rs}$, can be written in terms of the **Levi-Civita tensor** in n dimensions.

WORKED SOLUTION

$$\det[\mathbb{A}] = \epsilon_{i_1 \ldots i_n} \mathbb{A}_{1i_1} \mathbb{A}_{2i_2} \mathbb{A}_{ni_n} \tag{20.11.03}$$

→ 1208

The **Levi-Civita tensor** is an isotropic, completely anti-symmetric, rank n tensor.

20-015 Levi-Civita tensor Values in Different Coordinate System

Show that the **Levi-Civita tensor** assumes the same value in any Coordinate System

WORKED SOLUTION

Use (20.11.03) and the fact that the determinant is invariant under SO(3) to show that the value of any single element of the **Levi-Civita tensor** transforms to the same value.

20-016 Isotropic Tensors

Read § 20.05.08.

1. Show that **Kronecker tensor** is the only isotropic second-rank tensor by performing explicitly a few suitable rotations and impose that the components do not change.
2. Show that**Levi-Civita tensor** is the only isotropic third-rank tensor by performing explicitly a few suitable rotations and impose that the components do not change.

DRAFT-IN-PROGRESS

21.02 Homogeneity and Isotropy

This § is referenced at pages:
[1033, 1853, 1896]

The two properties are a priori independent.

Homogeneity is linked to invariance under space translation (Poincarè group). It implies that properties are described by quantities (tensors) that do not depend on the position.

Isotropy is linked to invariance under space rotations (SO(3)). It implies that properties are described by isotropic tensors.

Some examples follow.

- Homogeneous but non isotropic.
  - An homogeneous current conducting material with a non isotropic crystalline structure.
- Isotropic but not homogeneous.
  - A non homogeneous fluid has isotropic properties, locally at least. For instance the physical properties of the atmosphere are changing with height but locally isotropic. For a fluid, for instance, the stress tensor is isotropic.

DRAFT-IN-PROGRESS

21.03 Global and Local Balance of Extensive Physical Quantities

This § is referenced at pages:
[1033, 1922, 2461, 2461, 2481, 2493, 2578]

©|R.R.Rosales|WEB - URL |*Excellent*|

21.03.01
Extensive Physical Quantities

Intensive quantities are quantities which do not depend at all on the size of the system considered. Extensive quantities are quantities which do depend on the size of the system considered. Let X be an extensive physical quantity: such a quantity scales proportionally to the size of the system.

For extensive quantities one can define a volume density:

$$x_v \equiv \frac{\mathrm{d}X}{\mathrm{d}V} \Longrightarrow X = \iiint_\Omega x_v \, \mathrm{d}V \quad . \tag{21.03.01}$$

→ 1212

One can equally well define a mass density:

$$x_m \equiv \frac{\mathrm{d}X}{\mathrm{d}M} \Longrightarrow X = \iiint_\Omega \rho x_m \, \mathrm{d}V \quad . \tag{21.03.02}$$

→ 1212

In general the following relation between mass and volume density apply:

$$x_v = \rho x_m \quad .$$

Note that equation (21.03.01) is somewhat more satisfactory than equation (21.03.02), as it refers to a volume density, while mass is an extensive (and conserved) quantity itself.

Some examples follow.

- The number of particles is an extensive quantity:
$$N = \iiint_\Omega n_v \, \mathrm{d}V \quad ,$$
showing that the concentration, n_v, is the volume density of the number of particles.
- The linear momentum of a system is an extensive quantity:
$$\mathbf{P} = \iiint_\Omega \rho \mathbf{v} \, \mathrm{d}V \quad ,$$
showing that the velocity is the mass density of the linear momentum.

WORK IN PROGRESS

21.03.02
Intensive Physical Quantities

Intensive physical quantities can be written in the form of a ratio of the extensive quantities.

They are defined locally, that is at any point, in contrast to extensive quantities which are defined globally for a system.

21.03.03
Kinematics of Transport

Read § 65.09.01.01.

21.03.03.01 Volume Current Density

The transport of an extensive physical quantity X is locally described, at any point and any time, by a vector, $\mathbf{J}_X$, the volume current density, defined in such a way that

$$\boxed{\delta X \equiv (\mathbf{J}_X \cdot \widehat{\mathbf{n}})\ \mathrm{d}S\ \mathrm{d}t = J_X \cos[\theta]\ \mathrm{d}S\ \mathrm{d}t} \quad ,$$

denotes the amount $\mathrm{d}X$ of the quantity X crossing a fixed, small and flat element of surface $\mathrm{d}\mathbf{S} \equiv \widehat{\mathbf{n}}\,\mathrm{d}S$ in the oriented direction of the normal, $\widehat{\mathbf{n}}$, during time $\mathrm{d}t$.

The amount δX_{R} of the quantity X received/entering during time $\mathrm{d}t$ by a system with a fixed closed boundary S is:

$$\boxed{\delta X_{\mathrm{R}} = -\,\mathrm{d}t \oiint (\mathbf{J}_X \cdot \widehat{\mathbf{n}})\ \mathrm{d}S} \quad ,$$

using the usual convention to orient the normal unit vector $\widehat{\mathbf{n}}$ exiting the surface.

The quantity crossing any surface per unit time, along the oriented normal $\widehat{\mathbf{n}}$, is given by the flux of the vector $\mathbf{J}_X$ over the surface:

$$\boxed{\delta X = \mathrm{d}t \iint_S (\mathbf{J}_X \cdot \widehat{\mathbf{n}})\ \mathrm{d}S} \quad .$$

21.03.03.02 Current Density for Omni-Directional Motion

Example: random motion of particles inside fluids.

Example: black-body radiation.

Read § 65.09.01.01.

21.03.03.03 Convective and Non Convective Currents

This § is referenced at pages:
[1894, 2484]

The transport of an extensive physical quantity can be either convective or not convective.

Convective motion exists whenever there is a global motion of matter. This can be seen as the motion of the Center-Of-Mass of any infinitesimal part of the matter. The transport of matter implies a convective transport and a convective contribution to the total current having the form:

$$\boxed{\delta X = x_v\,(\mathbf{v} \cdot \widehat{\mathbf{n}})\ \mathrm{d}S\ \mathrm{d}t} \quad \Longrightarrow \quad \boxed{\mathbf{J}_{X|\mathrm{C}} = x_v \mathbf{v}} \quad .$$

The non convective volume current vector is thus:

$$\boxed{\mathbf{J}_{X|\mathrm{NC}} \equiv \mathbf{J}_X - x_v \mathbf{v}} \quad .$$

The transport of an extensive physical quantity is non convective in a certain Rest Frame, when matter is locally at rest relative to this Rest Frame:

$$\boxed{\langle \mathbf{v} \rangle = 0} \quad \Longrightarrow \quad \boxed{\mathbf{J}_X = \mathbf{J}_{X|\mathrm{NC}}} \quad .$$

Read also § 61.02.02.04.

DRAFT - IN PROGRESS

CC BY NC ND

21.03.04
Global Balance of Extensive Physical Quantities

The global balance of extensive physical quantities, that is the continuity equation, is a general relation which is encountered in many different topics.

Consider a generic system bounded by a closed surface S. The variation ΔX of the amount of an extensive quantity X of a system between two instants has two contributions. The first one comes from the exchanges with the external world, considered as positive if the quantity is given to the system. The second one comes from the production of the quantity inside the system, considered as positive is the quantity is created inside the system.

One has:

$$\boxed{\Delta X = \Delta X_{\mathtt{Received}} + \Delta X_{\mathtt{Created}} \equiv \Delta X_{\mathtt{R}} + \Delta X_{\mathtt{C}}} \quad .$$

The balance is often written in differential form considering two infinitesimally close instants:

$$\boxed{\mathrm{d}X = \delta X_{\mathtt{R}} + \delta X_{\mathtt{C}}} \quad .$$

For instance consider a town bounded by a closed surface and its population. Then $X_{\mathtt{R}}$ is due to the emigrated versus immigrant balance while $X_{\mathtt{C}}$ is due to the balance between newborn and deaths.

An extensive quantity is conservative if it is conserved when the system is isolated, that is:

$$\boxed{X \quad \text{is conservative} \quad \Leftrightarrow \quad \{\{\text{Isolated System} \quad \Leftrightarrow \quad \Delta X_{\mathtt{R}} = 0\} \implies \Delta X_{\mathtt{C}} = 0\}} \quad .$$

One should notice that occasionally a physical quantity might be conserved without being conservative. This is the case, for instance, of the mechanical energy when the internal non conservative forces do no work.

21.03.05
Local Balance of Extensive Physical Quantities

21.03.05.01 Local Sources of an Extensive Physical Quantity

The local creation or destruction of a an extensive physical quantity is described by its creation or destruction rate per unit volume, σ_X. It follows:

$$\boxed{\delta X_{\mathtt{C}} = \mathrm{d}t \iiint_{\Omega} \sigma_X \, \mathrm{d}V} \quad .$$

21.03.05.02 Continuity Equation

Consider the local balance of an extensive physical quantity, X, in a system delimited by a fixed closed surface S. One has:

$$\delta X_{\mathtt{R}} = -\,\mathrm{d}t \oiint (\mathbf{J}_{\mathtt{X}} \cdot \widehat{\mathbf{n}}) \, \mathrm{d}S = -\,\mathrm{d}t \iiint_{\Omega} \mathbf{div}\mathbf{J}_{\mathtt{X}} \, \mathrm{d}V \quad ,$$

$$\delta X_{\mathtt{C}} = \mathrm{d}t \iiint_{\Omega} \sigma_X \, \mathrm{d}V \quad ,$$

$$\mathrm{d}X = X[t + \mathrm{d}t] - X[t] = \iiint_{\Omega} (x_v[M, t + \mathrm{d}t] - x_v[M, t]) \, \mathrm{d}V = \mathrm{d}t \iiint_{\Omega} \partial_t x_v \, \mathrm{d}V \quad .$$

As this is valid for any fixed region of space one can deduce the continuity equation for the extensive physical quantity X:

$$\boxed{\partial_t x_v + \mathbf{div}\mathbf{J}_{\mathtt{X}} = \sigma_{\mathtt{X}}} \quad . \qquad (21.03.03) \quad \rightarrow 2738$$

21.03.06
Local Conservation Laws

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...- 27.1

Consider energy, the same considerations apply to linear momentum and angular momentum.

Energy is conserved, but the ElectroMagnetic field can carry energy, as any other field. Energy is conserved, and the detailed way energy is conserved is based on local conservation. Energy can be transferred only by energy flow. Energy inside the volume enclosed by a closed surface can change if and only if there is energy flow across the boundaries of the region.

This is much stronger than the statement that energy is conserved.

Consider a world-wide conservation law: energy disappears from one closed region and it simultaneously appears inside another closed region, far away from the first one. This world-wide conservation law would be incompatible with relativity as the concept of simultaneity is relative and another inertial observer would not see energy conserved at any time.

The only known way to make conservation law covariant is by making it local.

As a corollary local conservation implies that if anything moves from one place to the other there must be something happening in between.

DRAFT-IN-PROGRESS

21.04 Time Dispersion and Spatial Non-Locality

This § is referenced at pages:

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|||

DRAFT - IN PROGRESS

Let:

- $R[t]$: response
- $S[t]$: stimulus

Response cannot be instantaneous: it takes time. If the stimulus is too rapidly changing with respect to the characteristic response times of the system there is a delay in the response. Therefore the response will depend, a priori, on the stimulus at all the times before, that is from the history of events.

$$R[t] = \int_{w=-\infty}^{t} K[t,w]S[w]\,\mathrm{d}w \quad ,$$

$$K[t,w] \to K[t-w] \qquad \text{if the system is time-invariant, as it often happens} \quad ,$$

$$R[t] = \int_{w=-\infty}^{t} K[t-w]S[w]\,\mathrm{d}w \quad ,$$

$$R[t] = \int_{w=-\infty}^{w=+\infty} K[t-w]S[w]\,\mathrm{d}w \qquad K=0 \qquad \text{for} \qquad t<w \quad ,$$

$$S[w] = S_0 \exp[\mathtt{i}\omega t] \implies R[\omega] = K[\omega]S[\omega] \quad .$$

It sounds reasonable that for harmonic time dependence the answer is simple as an harmonic oscillation has always existed and therefore the transient part of the response has died away.

- Time dispersion: response depends on the stimulus at all the times before t (simply known as dispersion).
- Space dispersion: response depends on the stimulus at all the points in space (non-locality). It is typically less important and less common than time dispersion.

An important examples is in ElectroMagnetism in presence of matter, read § 41.04.05. In fact, the relation between $\mathbf{D}|\mathbf{H}$ and $\mathbf{E}|\mathbf{B}$ may be non-local:

$$\boxed{Y[\mathbf{x},t] = \iiint \mathrm{d}\mathbf{z} \int \mathrm{d}w\,(K[\mathbf{z},w]X[\mathbf{x}-\mathbf{z},t-w])} \quad ,$$

where $K[\mathbf{z},w]$ may be localized around $\mathbf{z} \simeq 0$ and|or $w \simeq 0$ but it is non vanishing for same range away from the origin. In terms of the **Fourier Transforms** it becomes:

$$\boxed{\widetilde{Y}[\mathbf{k},\omega] = \widetilde{K}[\mathbf{k},\omega]\widetilde{X}[\mathbf{k},\omega]} \quad .$$

It is often possible to neglect the non-locality in space.

DRAFT IN-PROGRESS

23.01 Reference Frames and Coordinate Systems

23.01.01 Reference Frames

A Reference Frame is a set of fixed - rigid - axes to be used as reference for defining the position of any point of space plus a clock defining the time, which is an absolute parameter in Galilei-Newton Mechanics . Space, in Galilei-Newton Mechanics , is the euclidean $\mathbb{R}^3$.

23.01.02 Coordinate Systems

A Coordinate System is any specific set of coordinates which can be defined for any given Reference Frame, fixed in time allowing to unambiguously define each point in space in a univocal way. These are not necessarily Cartesian coordinates. For any given Reference Frame, infinite possibility exist to define a coordinate set.

DRAFT - IN-PROGRESS

23.02 Basic Kinematics

23.02.01 Posizione Velocità Accelerazione

Sia x[t] la posizione di un punto in funzione del tempo. Velocità ed accelerazione sono definite da

$$\mathbf{x}[t] \implies \mathbf{v}[t] \equiv \frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} \implies \mathbf{a}[t] \equiv \frac{\mathrm{d}\mathbf{v}}{\mathrm{d}t} = \frac{d^2\mathbf{x}}{\mathrm{d}t^2} \quad .$$

Le relazioni inverse sono

$$\mathbf{x}[t] = \mathbf{x}[t_0] + \int_{t_0}^{t} \mathbf{v}[t]\ \mathrm{d}t \quad ,$$

$$\mathbf{v}[t] = \mathbf{v}[t_0] + \int_{t_0}^{t} \mathbf{a}[t]\ \mathrm{d}t \quad .$$

23.02.02 Posizione Velocità Accelerazione Relative

Date due particelle, A e B, la posizione relativa di A rispetto a B, $\mathbf{x}_{\mathtt{AB}}[t]$ la velocità relativa di A rispetto a B, $\mathbf{v}_{AB}[t]$, e l'accelerazione relativa di A rispetto a B, $\mathbf{a}_{AB}[t]$, sono definite da

$$\mathbf{x}_{\mathtt{AB}}[t] \equiv \mathbf{x}_{\mathtt{A}} - \mathbf{x}_{\mathtt{B}} \implies \mathbf{v}_{AB}[t] \equiv \mathbf{v}_{\mathtt{A}} - \mathbf{v}_{\mathtt{B}} \implies \mathbf{a}_{AB}[t] \equiv \mathbf{a}_{\mathtt{A}} - \mathbf{a}_{\mathtt{B}} \quad .$$

23.02.03 Jerk or Jolt

©|WEB - URL |||

In physics, jerk or jolt is the rate at which an object's acceleration changes with respect to time:

$$\boxed{\mathbf{j}[t] \equiv \dot{\mathbf{a}}} \quad . \tag{23.02.01}$$

It has considerable importance in many fields of engineering.

DRAFT - IN - PROGRESS

23.03 Point Kinematics and Differential Geometry of Curves

©|WEB - URL |A First Course in Curves and Surfaces|*T. Shifrin*|
©|R.N. Jazar|Advanced Dynamics|*Unusually extensive treatment*|

DRAFTING-IN-PROGRESS

23.03.01
Parametrization of Curves

A point of a curve is parametrized by:

$$\mathbf{x}[t] = \begin{cases} x = x[t] & , \\ y = y[t] & , \\ z = z[t] & , \end{cases} \qquad \text{with} \qquad \mathbf{v} \equiv \frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} \neq 0 \qquad \text{and suitable limits on } t\text{, if any} \quad .$$

It is implicitly assumed that the functions involved are differentiable just enough.
A curve is said to be regular when $v \neq 0$ at every point.
A point on the curve such that $v = 0$ is called a singular point on the curve.

23.03.02
Ascissa Curvilinea

L'ascissa curvilinea misura la lunghezza della curva $\mathbf{x}[t]$ ed è definita da

$$s[t] = s[t_0] + \int_{t_0}^{t} v[t]\ \mathrm{d}t = s[t_0] + \int_{t_0}^{t} \sqrt{\mathbf{v}\cdot\mathbf{v}}\ \mathrm{d}t \quad .$$

Si ha dunque

$$\frac{\mathrm{d}s}{\mathrm{d}t} = v \quad .$$

23.03.03
Terna Di Unit Vectors Intrinseci Di Una Curva

Per ogni punto di una curva x[t] si definisce la terna intrinseca di unit vectors ortogonali $\widehat{\mathbf{T}}$, $\widehat{\mathbf{N}}$ e $\widehat{\mathbf{B}}$.

$$\widehat{\mathbf{T}} \equiv \frac{\mathrm{d}\mathbf{x}}{\mathrm{d}s} \equiv \dot{\mathbf{x}}[s] = \frac{1}{v}\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \frac{\mathbf{v}}{v} \quad , \tag{23.03.01}$$

→ 1248 1271

$$\widehat{\mathbf{N}} \equiv \rho\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}s} \equiv \frac{\ddot{\mathbf{x}}[s]}{|\ddot{\mathbf{x}}[s]|} = \frac{\rho}{v}\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}t} \quad , \tag{23.03.02}$$

→ 1228 1248 1271

$$\widehat{\mathbf{B}} \equiv \mathbf{T}\wedge\mathbf{N} = \frac{\dot{\mathbf{x}}[s]\wedge\ddot{\mathbf{x}}[s]}{|\ddot{\mathbf{x}}[s]|} \quad . \tag{23.03.03}$$

→ 1248 1271

Note that, by definition, **the intrinsic unit vectors are dimensionless quantities** as the natural parametrization is given by the curvilinear abscissa. However, in the context of kinematics, the natural parameter is time, and therefore a factor v must be accounted for, whenever the kinematic character matters.

Il unit vector $\widehat{\mathbf{T}}$ è il unit vector tangente alla curva.

La relazione (23.03.02) definisce sia il unit vector $\widehat{\mathbf{N}}$ che il raggio di curvatura ρ (paragrafo § 23.03.04) della curva nel punto dato; ρ è il raggio del cerchio osculatore alla curva nel punto dato. Il unit vector $\widehat{\mathbf{N}}$ è diretto verso il centro di curvatura della curva nel punto dato.

I unit vectors $\widehat{\mathbf{N}}$ e $\widehat{\mathbf{T}}$, ortogonali tra di loro, definiscono il piano osculatore alla curva nel punto dato.

Il unit vector $\widehat{\mathbf{B}}$ è perpendicolare al piano osculatore alla curva nel punto dato.

The following definitions are used.

- Rectifying plane is the plane defined by $\widehat{\mathbf{T}}$ and $\widehat{\mathbf{B}}$.
- Normal plane is the plane defined by $\widehat{\mathbf{N}}$ and $\widehat{\mathbf{B}}$, orthogonal to $\widehat{\mathbf{T}}$.
- Principal normal is line which contains $\widehat{\mathbf{N}}$ and passes through $\mathbf{x}[s]$.
- Binormal is the line which contains $\widehat{\mathbf{B}}$ and passes through $\mathbf{x}[s]$.

23.03.04
Curvatura E Torsione

This § is referenced at pages:
[1228]

La curvatura κ, il raggio di curvatura ρ e la torsione τ, il raggio di torsione σ sono definiti da:

$$\kappa \equiv \frac{1}{\rho} \equiv -\frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}s}\cdot\widehat{\mathbf{T}} = +\widehat{\mathbf{N}}\cdot\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}s} \geq 0 \quad ,$$

$$\tau \equiv \frac{1}{\sigma} \equiv +\frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}s}\cdot\widehat{\mathbf{B}} = -\widehat{\mathbf{N}}\cdot\frac{\mathrm{d}\widehat{\mathbf{B}}}{\mathrm{d}s} \gtreqless 0 \quad .$$

Il raggio di curvatura è un numero positivo; la torsione è un numero positivo per una curva destrorsa ed è un numero negativo per una curva sinistrorsa.

Il raggio di curvatura e di torsione si esprimono in termini di $\mathbf{x}[t]$ tramite le relazioni:

$$\kappa = \frac{1}{\rho} = \frac{|\,\mathbf{x}'\wedge\mathbf{x}''|}{|\mathbf{x}'|^3} = \frac{|\,\mathbf{v}\wedge\mathbf{a}|}{v^3} \qquad (23.03.04)$$

→ 1270

$$\tau = \frac{1}{\sigma} = \frac{\mathbf{x}'\cdot(\,\mathbf{x}''\wedge\mathbf{x}''')}{|\,\mathbf{x}'\wedge\mathbf{x}''|^2} = \frac{\mathbf{v}\cdot(\,\mathbf{a}\wedge\mathbf{x}''')}{|\,\mathbf{v}\wedge\mathbf{a}|^2} \qquad (23.03.05)$$

Si hanno inoltre le proprietà seguenti:

$$\kappa = 0 \quad \Leftrightarrow \quad \text{retta} \quad ,$$
$$\tau = 0 \quad \Leftrightarrow \quad \text{curva piana (se } \kappa \neq 0) \quad .$$

La conoscenza di κ e τ caratterizza completamente la curva a meno di uno spostamento rigido. Cioè due curve che hanno gli stessi κ e τ sono sovrapponibili. Si ha quindi il teorema seguente. If two single-valued continuous functions $\kappa[s]$ (curvature) and $\tau[s]$ (torsion) are given for $s > 0$, then there exists exactly one space curve, determined except for orientation and position in space (i.e., up to a Euclidean motion), where s is the arc length, κ is the curvature, and τ is the torsion.

23.03.05
Frenet Formulas

In termini dell'ascissa curvilinea si hanno le formule di Frenet:

$$\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}s} = +\kappa\widehat{\mathbf{N}} \quad ,$$

→ 1230

$$\frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}s} = -\kappa\widehat{\mathbf{T}} + \tau\widehat{\mathbf{B}} \quad ,$$

$$\frac{\mathrm{d}\widehat{\mathbf{B}}}{\mathrm{d}s} = -\tau\widehat{\mathbf{N}} \quad .$$

→ 1230

DRAFT - In Progress

In forma matriciale

$$\begin{bmatrix} \frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}t} \\ \frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}t} \\ \frac{\mathrm{d}\widehat{\mathbf{B}}}{\mathrm{d}t} \end{bmatrix} = \begin{bmatrix} 0 & +\kappa & 0 \\ -\kappa & 0 & +\tau \\ 0 & -\tau & 0 \end{bmatrix} \begin{bmatrix} \widehat{\mathbf{T}} \\ \widehat{\mathbf{N}} \\ \widehat{\mathbf{B}} \end{bmatrix} \quad . \tag{23.03.06}$$

Inoltre dalle formule di Frenet si hanno le seguenti relazioni:

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}s} = \widehat{\mathbf{T}} \quad ,$$
$$\frac{d^2\mathbf{x}}{\mathrm{d}s^2} = \kappa\widehat{\mathbf{N}} \quad ,$$
$$\frac{d^3\mathbf{x}}{\mathrm{d}s^3} = \frac{\mathrm{d}\kappa}{\mathrm{d}s}\widehat{\mathbf{N}} + \kappa\tau\widehat{\mathbf{B}} - \kappa^2\widehat{\mathbf{T}} \quad ,$$
$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}s}\cdot\left(\frac{d^2\mathbf{x}}{\mathrm{d}s^2}\wedge\frac{d^3\mathbf{x}}{\mathrm{d}s^3}\right) = \kappa^2\tau \quad .$$

23.03.06
Darboux Vector

This § is referenced at pages:
[Never referenced.]

©|WEB - URL |||

Le formule di Frenet-Serret si possono scrivere in forma più compatta in termini del vettore di Darboux, che rappresenta la velocità angolare della terna intrinseca:

$$\boldsymbol{\Omega} = \tau\widehat{\mathbf{T}} + \kappa\widehat{\mathbf{B}} = \frac{\boldsymbol{\omega}}{v} \qquad \boldsymbol{\omega} = v\left(\tau\widehat{\mathbf{T}} + \kappa\widehat{\mathbf{B}}\right) = v\boldsymbol{\Omega} \quad , \tag{23.03.07}$$

→ 1248

where $\boldsymbol{\omega}$ is the real kinematics angular velocity. In fact, κ and τ are just purely geometrical parameters of the curve and the angular velocity also depend on the speed along the curve.

In terms of Darboux vector, the angular velocity of the intrinsic Reference Frame is given by two components: one along $\widehat{\mathbf{B}}$ and the other along $\widehat{\mathbf{T}}$ with angular speed respectively:

$$\omega_B = v\kappa \quad ,$$
$$\omega_T = v\tau \quad .$$

Therefore curvature describes rotation of the intrinsic Coordinate System around the bi-normal vector and torsion describes rotation of the intrinsic Coordinate System around the tangent vector.

The fact that $\omega_N = 0$ is understood from equations (23.03.05), (23.03.05), showing that the changes of $\widehat{\mathbf{T}}$ and $\widehat{\mathbf{B}}$ are along $\widehat{\mathbf{N}}$ and therefore $\widehat{\mathbf{N}}$ is orthogonal to the angular velocity.

Finally:

$$\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}s} = \boldsymbol{\Omega}\wedge\mathbf{T} \qquad \frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}s} = \boldsymbol{\Omega}\wedge\mathbf{N} \qquad \frac{\mathrm{d}\widehat{\mathbf{B}}}{\mathrm{d}s} = \boldsymbol{\Omega}\wedge\mathbf{B} \quad .$$

Darboux vector

From Wikipedia, the free encyclopedia

In differential geometry, especially the theory of space curves, the **Darboux vector** is the angular velocity vector of the Frenet frame of a space curve.[1] It is named after Gaston Darboux who discovered it.[2] It is also called **angular momentum vector**, because it is directly proportional to angular momentum.

In terms of the Frenet-Serret apparatus, the Darboux vector **ω** can be expressed as[3]

$$\boldsymbol{\omega} = \tau \mathbf{T} + \kappa \mathbf{B} \qquad (1)$$

and it has the following symmetrical properties:[2]

$$\boldsymbol{\omega} \times \mathbf{T} = \mathbf{T}',$$
$$\boldsymbol{\omega} \times \mathbf{N} = \mathbf{N}',$$
$$\boldsymbol{\omega} \times \mathbf{B} = \mathbf{B}',$$

which can be derived from Equation (1) by means of the Frenet-Serret theorem (or vice versa).

Let a rigid object move along a regular curve described parametrically by **β**(*t*). This object has its own intrinsic coordinate system. As the object moves along the curve, let its intrinsic coordinate system keep itself aligned with the curve's Frenet frame. As it does so, the object's motion will be described by two vectors: a translation vector, and a rotation vector **ω**, which is an areal velocity vector: the Darboux vector.

Note that this rotation is kinematic, rather than physical, because usually when a rigid object moves freely in space its rotation is independent of its translation. The exception would be if the object's rotation is physically constrained to align itself with the object's translation, as is the case with the cart of a roller coaster.

Consider the rigid object moving smoothly along the regular curve. Once the translation is "factored out", the object is seen to rotate the same way as its Frenet frame. The total rotation of the Frenet frame is the combination of the rotations of each of the three Frenet vectors:

$$\boldsymbol{\omega} = \boldsymbol{\omega}_{\mathbf{T}} + \boldsymbol{\omega}_{\mathbf{N}} + \boldsymbol{\omega}_{\mathbf{B}}.$$

Each Frenet vector moves about an "origin" which is the centre of the rigid object (pick some point within the object and call it its centre). The areal velocity of the tangent vector is:

$$\begin{aligned}\boldsymbol{\omega}_{\mathbf{T}} &= \lim_{\Delta t \to 0} \frac{\mathbf{T}(t) \times \mathbf{T}(t + \Delta t)}{2\,\Delta t} \\ &= \frac{\mathbf{T}(t) \times \mathbf{T}'(t)}{2}.\end{aligned}$$

Likewise,

$$\boldsymbol{\omega}_{\mathbf{N}} = \frac{1}{2}\,\mathbf{N}(t) \times \mathbf{N}'(t),$$
$$\boldsymbol{\omega}_{\mathbf{B}} = \frac{1}{2}\,\mathbf{B}(t) \times \mathbf{B}'(t).$$

Now apply the Frenet-Serret theorem to find the areal velocity components:

$$\boldsymbol{\omega}_{\mathbf{T}} = \frac{1}{2}\mathbf{T} \times \mathbf{T}' = \frac{1}{2}\kappa \mathbf{T} \times \mathbf{N} = \frac{1}{2}\kappa \mathbf{B}$$

$$\boldsymbol{\omega}_{\mathbf{N}} = \frac{1}{2}\mathbf{N}\times\mathbf{N}' = \frac{1}{2}(-\kappa\mathbf{N}\times\mathbf{T} + \tau\mathbf{N}\times\mathbf{B}) = \frac{1}{2}(\kappa\mathbf{B} + \tau\mathbf{T})$$

$$\boldsymbol{\omega}_{\mathbf{B}} = \frac{1}{2}\mathbf{B}\times\mathbf{B}' = -\frac{1}{2}\tau\mathbf{B}\times\mathbf{N} = \frac{1}{2}\tau\mathbf{T}$$

so that

$$\boldsymbol{\omega} = \frac{1}{2}\kappa\mathbf{B} + \frac{1}{2}(\kappa\mathbf{B} + \tau\mathbf{T}) + \frac{1}{2}\tau\mathbf{T} = \kappa\mathbf{B} + \tau\mathbf{T},$$

as claimed.

The Darboux vector provides a concise way of interpreting curvature κ and torsion τ geometrically: curvature is the measure of the rotation of the Frenet frame about the binormal unit vector, whereas torsion is the measure of the rotation of the Frenet frame about the tangent unit vector.[2]

23.03.07
Espressione Della Velocità in Coordinate Intrinseche

In termini della terna di vettori intrinseci alla traiettoria la velocità si esprime come:

$$\boxed{\mathbf{v} \equiv \frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = v\widehat{\mathbf{T}}} \quad .$$

23.03.08
Espressione Dell'accelerazione in Coordinate Intrinseche

In termini della terna di vettori intrinseci alla traiettoria l'accelerazione si esprime come:

$$\frac{\mathrm{d}\mathbf{v}}{\mathrm{d}t} = \frac{\mathrm{d}}{\mathrm{d}t}\left(v\widehat{\mathbf{T}}\right) = \frac{\mathrm{d}v}{\mathrm{d}t}\widehat{\mathbf{T}} + v\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}t} \quad . \tag{23.03.08}$$

$$\boxed{\mathbf{a} = \frac{\mathrm{d}\mathbf{v}}{\mathrm{d}t} = \frac{\mathrm{d}v}{\mathrm{d}t}\widehat{\mathbf{T}} + \frac{v^2}{\rho}\widehat{\mathbf{N}} \equiv a_{\mathrm{T}}\widehat{\mathbf{T}} + a_{\mathrm{R}}\widehat{\mathbf{N}}} \quad . \tag{23.03.09}$$

→ 1270 1591

Il vettore accelerazione giace quindi nel piano definito dai unit vectors $\widehat{\mathbf{T}}$ e $\widehat{\mathbf{N}}$, il piano osculatore.

Dalla relazione sopra si deduce che l'accelerazione tangenziale è legata solo al cambiamento del modulo della velocità mentre quella radiale dipende solo dal cambiamento di direzione. Infatti $\mathbf{a}_{\mathrm{T}}$ esiste se e solo se v non è costante nel tempo, mentre $\mathbf{a}_{\mathrm{N}}$ esiste se e solo se $\kappa \neq 0$ cioè se e solo se cambia la direzione di $\mathbf{v}$.

23.03.09
Rectilinear motion

23.03.09.01 Moto Rettilineo Uniforme

Se $\mathbf{v}$ è costante, motion along the direction of $\mathbf{v}$:

$$\boxed{\mathbf{x}[t] = \mathbf{x}[t_0] + \mathbf{v}\,(t - t_0)} \quad . \tag{23.03.10}$$

23.03.09.02 Moto Rettilineo Uniformemente Accelerato

Se $\mathbf{a}$ è costante:

$$\boxed{\mathbf{x}[t] = \mathbf{x}[t_0] + \mathbf{v}\,(t - t_0) + {}^1\!/_2\mathbf{a}\,(t - t_0)^2} \quad ,$$

$$\boxed{\mathbf{v}[t] = \mathbf{v}[t_0] + \mathbf{a}\,(t - t_0)} \quad ,$$

$$\boxed{v^2 = v_0^2 + 2\,\mathbf{a}\cdot(\mathbf{x} - \mathbf{x}_0)} \quad .$$

→ 1347 1362 1461

La velocità media è

$$\boxed{\langle\mathbf{v}\rangle = \frac{\Delta\mathbf{x}}{\Delta t} = \mathbf{v}_0 + \frac{1}{2}\mathbf{a}\Delta t} \quad . \tag{23.03.11}$$

DRAFT IN PROGRESS

23.04.01 Parametrization of Surfaces

A point of a surface is parametrized by:

$$\mathbf{x}[u,v] = \begin{cases} x = x[u,v] \\ y = y[u,v] \\ z = z[u,v] \end{cases} , \qquad \text{with} \quad \widehat{\mathbf{N}} \equiv \frac{\frac{\partial \mathbf{x}}{\partial u} \wedge \frac{\partial \mathbf{x}}{\partial v}}{\left| \frac{\partial \mathbf{x}}{\partial u} \wedge \frac{\partial \mathbf{x}}{\partial v} \right|} \neq 0 \qquad \text{and suitable limits on } u \text{ and } v, \text{ if any} \quad ,$$

then the three vectors:

$$\left\{ \frac{\partial \mathbf{x}}{\partial u}; \frac{\partial \mathbf{x}}{\partial v}; \widehat{\mathbf{N}} \neq 0 \right\} \quad ,$$

make, at any point on the surface, a basis, in general not orthogonal and made by non normalized vectors. The third vector is always orthogonal to the surface at the point.

Si assume implicitamente che le funzioni che intervengono siano differenziabili quanto basta.

Una superficie è detta regolare quando $\widehat{\mathbf{N}} \neq 0$ in ogni punto.

Un punto della superficie tale che $\widehat{\mathbf{N}} = 0$ è detto punto singolare della superficie.

23.04.02 Curvature

©|Gaussian Curvature - From MathWorld–A Wolfram Web Resource|WEB - URL |*Weisstein, Eric W.*|

© - QUOTE

WIKIPEDIA

At each point P of a differentiable surface in 3-dimensional Euclidean space one may choose a unit normal vector. A normal plane at P is one that contains the normal vector, and will therefore also contain a unique direction tangent to the surface and cut the surface in a plane curve, called normal section. This curve will in general have different curvatures for different normal planes at P. The principal curvatures at P, denoted k_1 and k_2, are the maximum and minimum values of this curvature. Here the curvature of a curve is by definition the reciprocal of the radius of the osculating circle. The curvature is taken to be positive if the curve turns in the same direction as the surface chosen normal, and otherwise negative. The directions in the normal plane where the curvature takes its maximum and minimum values are always perpendicular, if k_1 does not equal k_2, a result of Euler (1760), and are called principal directions. From a modern perspective, this theorem follows from the spectral theorem because these directions are as the principal axes of a symmetric tensor - the second fundamental form.

The product $k_1 k_2$ of the two principal curvatures is the Gaussian curvature, K, and the average $(k_1 + k_2)/2$ is the mean curvature, H. If at least one of the principal curvatures is zero at every point, then the Gaussian curvature will be 0 and the surface is a developable surface. For a minimal surface, the mean curvature is zero at every point.

Convention: angles in a plane are always measured starting from a/the fixed direction on the plane and going towards the mobile direction.

23.04.04.01 Moto Piano Generale in Coordinate Polari

Il vettore posizione in termini dei unit vectors delle coordinate polari $\widehat{\mathbf{e}}_r$ ed $\widehat{\mathbf{e}}_\theta$, è

$$\boxed{\mathbf{r} = r\widehat{\mathbf{e}}_r}$$

(definizione del unit vector radiale $\widehat{\mathbf{e}}_r$). Il unit vector tangenziale $\widehat{\mathbf{e}}_\theta$ è ortogonale ad $\widehat{\mathbf{e}}_r$ e il verso è quello di θ crescente.

In termini dei unit vectors $\widehat{\mathbf{e}}_1$ ed $\widehat{\mathbf{e}}_2$ delle coordinate cartesiane nel ortogonali nel piano si ha

$$\boxed{\widehat{\mathbf{e}}_r = +\widehat{\mathbf{e}}_1 \cos[\theta] + \widehat{\mathbf{e}}_2 \sin[\theta]} \quad ,$$

$$\boxed{\widehat{\mathbf{e}}_\theta = -\widehat{\mathbf{e}}_1 \sin[\theta] + \widehat{\mathbf{e}}_2 \cos[\theta]} \quad .$$

La derivata temporale dei unit vectors posizione è dunque

$$\boxed{\frac{\mathrm{d}\widehat{\mathbf{e}}_r}{\mathrm{d}t} = +\dot{\theta}\widehat{\mathbf{e}}_\theta} \quad ,$$

$$\boxed{\frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}t} = -\dot{\theta}\widehat{\mathbf{e}}_r} \quad .$$

L'espressione della velocità in coordinate polari è:

$$\boxed{\mathbf{v} \equiv \frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \dot{r}\widehat{\mathbf{e}}_r + r\dot{\theta}\widehat{\mathbf{e}}_\theta} \quad . \qquad (23.04.01) \quad \rightarrow 1239$$

L'espressione dell'accelerazione in coordinate polari è:

$$\boxed{\mathbf{a} \equiv \frac{\mathrm{d}\mathbf{v}}{\mathrm{d}t} = \left(\ddot{r} - r\dot{\theta}^2\right)\widehat{\mathbf{e}}_r + \left(2\dot{r}\dot{\theta} + r\ddot{\theta}\right)\widehat{\mathbf{e}}_\theta} \quad . \qquad (23.04.02) \quad \rightarrow 1239$$

DRAFT WORK IN PROGRESS

23.04.04.02 Velocità Areolare

This § is referenced at pages:
[1550]

Sia $\Delta\mathbf{S}[t]$ l'area spazzata dal vettore posizione $\mathbf{x}[t]$ in funzione del tempo. Dalla (15.03.04) si ha

$$\Delta S[t] \simeq \frac{1}{2}|\,\mathbf{x}\wedge\Delta\mathbf{x}|\quad .$$

Ne segue per la velocità areolare

$$\boxed{\frac{\mathrm{d}A}{\mathrm{d}t}=\frac{1}{2}|\,\mathbf{x}\wedge\mathbf{v}|}\quad . \tag{23.04.03}$$

→ 1272 1551 1563

In a more rigorous fashion:

$$\Delta\mathbf{S}[t]\equiv\int\!\!\int \mathrm{d}x\;\mathrm{d}y=\int_{\theta_1}^{\theta_2}\int_{0}^{\rho[\theta]}\rho[\theta]\;\mathrm{d}\rho\;\mathrm{d}\theta=\frac{1}{2}\int_{\theta_1}^{\theta_2}\rho^2[\theta]\;\mathrm{d}\theta\quad ,$$

from which

$$\boxed{\frac{\mathrm{d}A}{\mathrm{d}t}=\dot\theta\frac{\mathrm{d}A}{\mathrm{d}\theta}=\frac{1}{2}\rho^2[\theta]\dot\theta=\frac{1}{2}|\,\mathbf{x}\wedge\mathbf{v}|}\quad .$$

23.04.04.03 Moto Circolare

Nel moto circolare la traiettoria è una circonferenza. Se si sceglie come origine di un sistema di coordinate polari il centro della circonferenza si ha allora $\dot r=0$. Risulta allora dalle espressioni (23.04.01), (23.04.02)

$$\boxed{\mathbf{v}=r\dot\theta\widehat{\mathbf{e}}_\theta\qquad \mathbf{a}=-r\dot\theta^2\widehat{\mathbf{e}}_r+r\ddot\theta\widehat{\mathbf{e}}_\theta}\quad .$$

Se la velocità angolare $\dot\theta$ è costante il moto è detto circolare uniforme.

23.04.04.04 Moto Armonico Bi-Dimensionale

It is just the superposition of two harmonic uni-dimensional motions along the x and y directions, as in section § 23.03.09.03:

$$x[t]=x_0+r_x\cos\left[\omega_x t-\phi_x\right]\quad ,$$
$$y[t]=y_0+r_y\cos\left[\omega_y t-\phi_y\right]\quad .$$

- Same frequencies: $\omega_x=\omega_y$. In general, it gives an ellipse, $r_x\neq r_y$; it is a circle if and only if $r_x=r_y$.
- Different frequencies: $\omega_x\neq\omega_y$. In general, non-closed curves; they are known as Lissajous figures.

23.06.01 Describing Rotations

©|WEB - URL |Excellent!||

Describing rotations via geometrical variables can be obviously accomplished in many ways.

23.06.01.01 Euler Angles

©|**Euler Angles** by Lionel Brits.|WEB - URL ||

©|Euler Angles - Wikipedia |||

©|E.W. Weisstein, **Euler Angles** From MathWorld, a Wolfram Web Resource.|from MathWorld ||

The traditional set of variables used to geometrically describe rotations are the Euler angles. Euler angles representing rotations about $\widehat{\mathbf{z}}$, $\widehat{\mathbf{N}}$, and $\widehat{\mathbf{Z}}$ axes are shown in figure 23.11. The xyz (original) system is shown in blue, the XYZ (rotated) system is shown in red.

The angle α in figure is often called ϕ and named **angle of precession**.

The angle β in figure is often called θ and named **angle of nutation**.

The angle γ in figure is often called ψ and named **angle of proper rotation**.

The line of nodes (N) is the line given by the intersection between the xy and XY planes and shown in green in figure 23.11.

Euler angles are particularly intuitive when the body follows a rotational motion.

DRAFT - IN PROGRESS

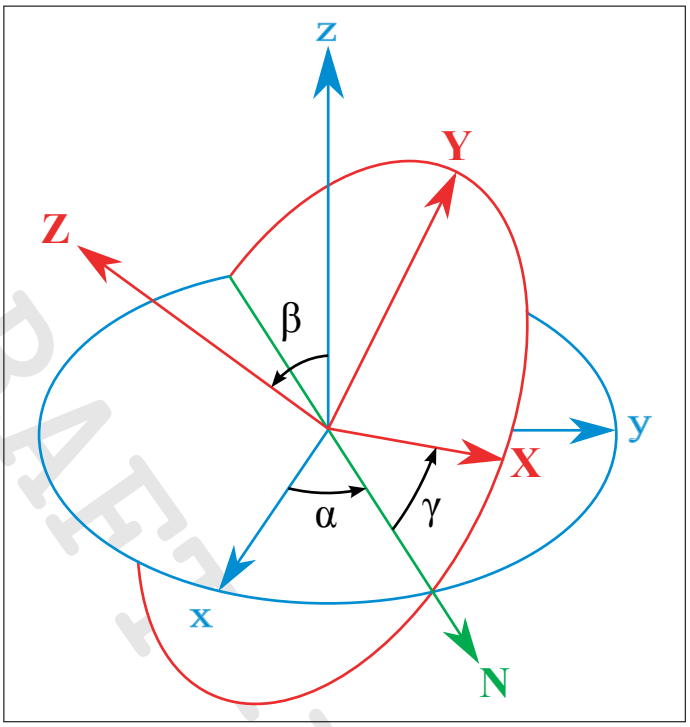

Figure 23.11: FIGURE

23.06.01.02 Yaw Pitch Roll

Another common parametrization, often used in engineering applications and more intuitive is given by the variables yaw, pitch and roll, as shown in figure 23.12.

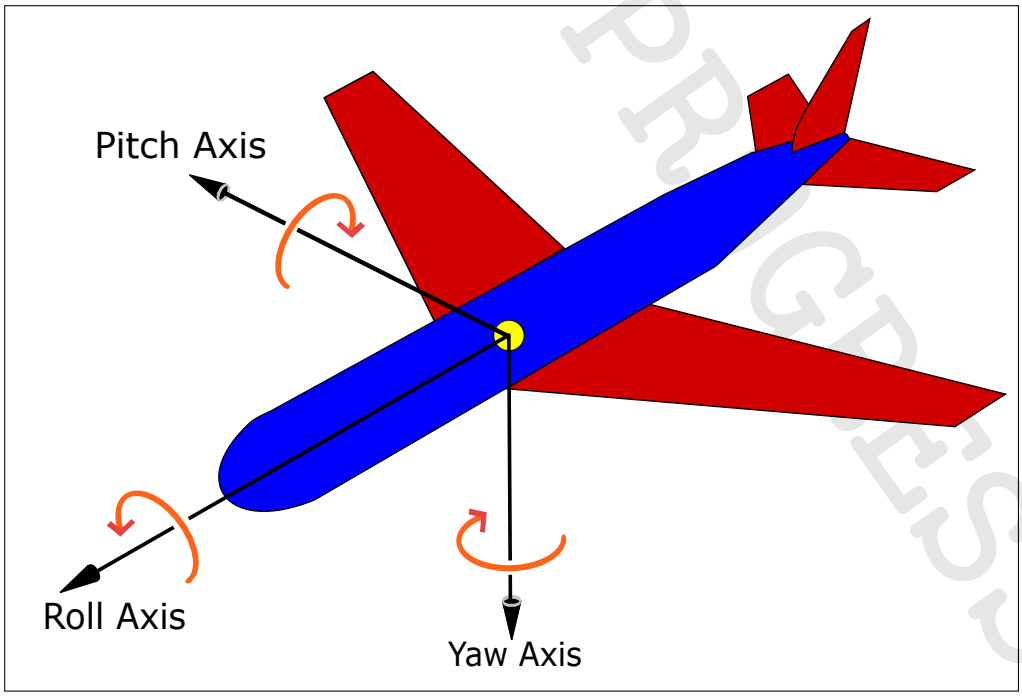

Figure 23.12: FIGURE

These are the three angles of rotation about the xyz axes of the Coordinate System: the roll axis is the longitudinal axis; the roll and pitch axes define the vehicle plane; the yaw axis is the vertical axis.

Yaw, pitch and roll are particularly intuitive when the body follows a translational/rotational motion.

DRAFT - IN PROGRESS

23.06.01.03 Direction Cosines

A generic set of parameters, closely related to the algebraic approach, is given by the direction cosines, that is the elements of the rotation matrix:

$$\boxed{\mathbb{R}^{\cdot\cdot}_{pq} \equiv \mathbf{e}'_p \cdot \mathbf{e}_q} \quad .$$

23.06.01.04 Angle Variables

Note that, at variance with the position vector, it not possible, in general, to define the **angular position** as something as:

$$\cancel{\boldsymbol{\theta} \equiv \alpha\widehat{\mathbf{e}}_\alpha + \beta\widehat{\mathbf{e}}_\beta + \gamma\widehat{\mathbf{e}}_\gamma} \quad ,$$

in terms of three angular positions with respect to three suitable axes, for the simple reason that the sum is not well defined, as finite angles do not form a vector space because addition is not commutative. Clearly this can be possible in special cases, for instance for rotations around one fixed axis.

23.06.02
Time-Derivation Angular Velocity and Poisson Formulas

Consider an Inertial Reference Frame , $\mathcal{I}$, and a generic (in general non-inertial) Reference Frame, $\mathcal{I}'$, such that the origin of the second Reference Frame, $\mathcal{O}'$, moves with respect to the origin, $\mathcal{O}$, of the first one with velocity $\mathbf{u}$ and the angular velocity (to be defined shortly) of the second Reference Frame with respect to the first one is $\boldsymbol{\omega}$. Let $\{\mathbf{e}_k\}$ be an orthonormal basis in $\mathcal{I}$ and $\{\mathbf{e}'_k\}$ be an orthonormal basis in $\mathcal{I}'$. Let us call, conventionally and for clarity purposes only, the Inertial Reference Frame $\mathcal{I}$ **absolute** (A) (or **fixed** or **space**) frame and the moving Reference Frame $\mathcal{I}'$, **relative** (R) (or **moving** or **body**) frame. These are just conventional names, with no physical nor meta-physical significance.

In short, symbolically:

$$\mathcal{I} \equiv \{\mathcal{O}; \mathbf{e}_k\} \qquad \mathcal{I}' \equiv \{\mathcal{O}'; \mathbf{e}'_k\} \quad .$$

Note that, as long as one is limited to the field of pure kinematics (not dynamics) it is not strictly necessary that the first Reference Frame be an Inertial one.

Let us consider how time-changing quantities change from one Reference Frame to another. Time is an absolute parameter. It should be clear that changing of time derivation refers to the fact that different observers, fixed in different Reference Frames, see their own orthonormal base vectors are fixed in time for each of the observers. Therefore, time derivation, for each observer, means to take the time derivative of the components only; however, every other observer can describe the vector in terms of another basis (not its own) such that the orthonormal base vectors are time dependent.

PRELIMINARY-IN-PROGRESS

23.06.02.01 Time-Derivative of Scalar/Numerical Quantities

When one considers time derivation, there is no difference in the absolute and relative time-derivative of a scalar/numerical quantity, because it is independent from any chosen basis:

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} s = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} s \qquad s[\mathbf{x}] = s'[\mathbf{x}'] \qquad \text{for any scalar/numerical quantity} \quad . \tag{23.06.01}$$

In fact no moving base of vectors is involved.

23.06.02.02 Time-Derivative of Vectors and Poisson Formulas

This § is referenced at pages:
[1117]

When one considers time derivation, there is a difference in the absolute and relative time-derivative of a vector, as vectors are referred to the two different bases of the two Reference Frame, which are in relative motion:

$$\mathbf{v}[t] = v_k \mathbf{e}_k = v'_k \mathbf{e}'_k \to v_k[t]\mathbf{e}_k = v'_k \mathbf{e}'_k[t] \qquad \text{fixed vector in the moving frame} \quad ,$$
$$\mathbf{v}[t] = v_k \mathbf{e}_k = v'_k \mathbf{e}'_k \to v_k[t]\mathbf{e}_k = v'_k[t] \mathbf{e}'_k[t] \qquad \text{arbitrary vector in the moving frame} \quad .$$

In fact, every vector, can be described in terms of the fixed orthonormal basis of axes, $\{\mathbf{e}_k\}$, which is time-independent, or in terms of the moving orthonormal basis of axes, $\{\mathbf{e}'_k\}$, fixed with respect to the moving Reference Frame, $\{\mathbf{e}_k\}$, which is time-dependent, whereas the components, with respect to the moving Reference Frame, are constant, by hypothesis.

Vector Fixed in the Moving Frame

For any vector fixed in the moving frame one has:

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \mathbf{v} = \boldsymbol{\omega} \wedge \mathbf{v} \qquad \text{vector fixed in the moving frame} \quad . \tag{23.06.02}$$

→ 1244

Consider, in fact, two unit vectors, $\mathbf{a}$ and $\mathbf{b}$ fixed in the moving frame:

$$\mathbf{a}\cdot\mathbf{a} = 1 \qquad \mathbf{b}\cdot\mathbf{b} = 1 \qquad \mathbf{a}\cdot\mathbf{b} = \text{constant}$$

Therefore:

$$\frac{\mathrm{d}\mathbf{a}}{\mathrm{d}t}\cdot\mathbf{a} = 0 \qquad \frac{\mathrm{d}\mathbf{b}}{\mathrm{d}t}\cdot\mathbf{b} = 0 \qquad \frac{\mathrm{d}\mathbf{a}}{\mathrm{d}t}\cdot\mathbf{b} + \frac{\mathrm{d}\mathbf{b}}{\mathrm{d}t}\cdot\mathbf{a} = 0$$

Now, if $\dot{\mathbf{v}}\cdot\mathbf{v} = 0$ one can always find a vector $\boldsymbol{\omega}[t]$ such that

$$\dot{\mathbf{v}}\cdot\mathbf{v} = 0 \implies \{\dot{\mathbf{v}} = \boldsymbol{\omega}\wedge\mathbf{v} \qquad \text{with} \qquad \boldsymbol{\omega}[t] \equiv \mathbf{v}\wedge\dot{\mathbf{v}}\}$$

A priori, $\boldsymbol{\omega}[t]$ depends on time. However, $\boldsymbol{\omega}[t]$ is the same for any vector fixed in the moving frame. In fact:

$$\left\{\dot{\mathbf{a}} = \boldsymbol{\omega}_{\mathbf{a}}\wedge\mathbf{a} \qquad \dot{\mathbf{b}} = \boldsymbol{\omega}_{\mathbf{b}}\wedge\mathbf{b}\right\} \implies 0 = \frac{\mathrm{d}\mathbf{a}}{\mathrm{d}t}\cdot\mathbf{b} + \frac{\mathrm{d}\mathbf{b}}{\mathrm{d}t}\cdot\mathbf{a} = (\boldsymbol{\omega}_{\mathbf{a}} - \boldsymbol{\omega}_{\mathbf{b}})\cdot(\mathbf{a}\wedge\mathbf{b}) = 0 \quad ,$$

which implies $\boldsymbol{\omega}_{\mathbf{a}} = \boldsymbol{\omega}_{\mathbf{b}}$ as $\mathbf{a}$ and $\mathbf{b}$ are arbitrary vectors fixed in the moving frame. One can take, for instance, the three unit vectors of a base fixed in the moving frame, in pairs, and find that the three corresponding $\boldsymbol{\omega}$ are all equal: $\boldsymbol{\omega} \equiv \boldsymbol{\omega}_1 = \boldsymbol{\omega}_2 = \boldsymbol{\omega}_3$. By decomposing an arbitrary vector on the basis and applying equation (23.06.02), which is a linear one it is found that the same $\boldsymbol{\omega}$ applies to any fixed vector.

The result of the above derivation can be applied to the three unit vectors of the moving base.

Therefore, for any rigid motion, there exist a unique vector, $\boldsymbol{\omega}$, the angular velocity vector, which describes rotation via equation (23.06.02).

For each of the three unit vectors of the moving base, $\mathbf{e}'$, one has:

$$\dot{\mathbf{e}}' = \boldsymbol{\omega}\wedge\mathbf{e}' \implies \mathbf{e}'\wedge\dot{\mathbf{e}}' = \mathbf{e}'\wedge(\boldsymbol{\omega}\wedge\mathbf{e}') = \boldsymbol{\omega} - (\boldsymbol{\omega}\cdot\mathbf{e}')\,\mathbf{e}' \quad . \tag{23.06.03}$$

→ 1117

DRAFT - PROGRESS

Summing over the three orthonormal unit vectors of the moving base, one finds:

$$\boldsymbol{\omega} = \frac{1}{2}\mathbf{e'}_k \wedge \dot{\mathbf{e}}'_k \quad . \tag{23.06.04}$$

→ 1248

Arbitrary Moving Vector in the Moving Frame - Poisson Formula

Consider now any arbitrary moving vector in the moving frame.

To avoid any misunderstanding let us make clear that:

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \mathbf{v} \equiv \dot{v}_k \mathbf{e}_k \qquad \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \mathbf{v} \equiv \dot{v}'_k \mathbf{e}'_k \quad . \tag{23.06.05}$$

→ 1245

Therefore:

$$\mathbf{v} \equiv v_k \mathbf{e}_k = v'_k \mathbf{e}'_k \implies \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \left(v'_k \mathbf{e}'_k\right) = \dot{v}'_k \mathbf{e}'_k + v'_k \dot{\mathbf{e}}'_k = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \mathbf{v} + v'_k \dot{\mathbf{e}}'_k \quad .$$

Poisson relation (23.06.06), accounts for the fact that, in general, both the moving unit vectors of the basis $\{\mathbf{e}'\}$ and the components of any vector with respect to the moving base, v'_k, are time-varying:

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \mathbf{v} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \mathbf{v} + \boldsymbol{\omega} \wedge \mathbf{v} \qquad \text{arbitrary vector in the moving frame - Poisson formula} \quad . \tag{23.06.06}$$

→ 1245 1246 1247

23.06.02.03 Angular Velocity

Angular velocity is a free vector, only depending on the relative motion between two Reference Frame, and not on the position.

Clearly,

$$\boldsymbol{\omega}_{2|1} = -\boldsymbol{\omega}_{1|2} \quad . \tag{23.06.07}$$

→ 1245

In fact, as the choice of the two Reference Frame is arbitrary, Poisson relation (23.06.06) and the definitions in equation (23.06.05), imply that the angular velocity of Reference Frame A with respect to Reference Frame R is $-\boldsymbol{\omega}$, as one can show by moving the $\boldsymbol{\omega} \wedge \mathbf{v}$ on the other side of the equation and expressing $\mathbf{v}$ in terms of the basis vector of Reference Frame A.

As any vector, it can be represented both in terms of the fixed and of the moving basis:

$$\boldsymbol{\omega} = \omega_k \mathbf{e}_k = \omega'_k \mathbf{e}'_k$$

Moreover, it has the very special properties that its time derivative is the same in both Reference Frame, from (23.06.06).

Note that the angular velocity is not the derivative of any vector, as no **angle** vector exists.

23.06.02.04 Angular Acceleration

The time derivative of the angular velocity is the same in both Reference Frame, from (23.06.06); this defines the angular acceleration:

$$\dot{\boldsymbol{\omega}} \equiv \boldsymbol{\alpha} \equiv \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \boldsymbol{\omega} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \boldsymbol{\omega} \quad .$$

Clearly, from equation (23.06.07):

$$\boldsymbol{\alpha}_{2|1} = -\boldsymbol{\alpha}_{1|2} \quad . \tag{23.06.08}$$

DRAFT IN PROGRESS

CC BY NC ND

23.06.02.05 Composition of Angular Velocities

This § is referenced at pages:
[1329]

It can be shown that the angular velocity resulting from the composition of a number of angular velocities is the vector sum of the individual angular velocities.

If the Reference Frame $\mathcal{I}_2$ rotates with angular velocity $\boldsymbol{\omega}_{2|1}$ with respect to the Reference Frame $\mathcal{I}_1$ and the Reference Frame $\mathcal{I}_3$ rotates with angular velocity $\boldsymbol{\omega}_{3|2}$ with respect to the Reference Frame $\mathcal{I}_2$ then the angular velocity of the Reference Frame $\mathcal{I}_3$ with respect to the Reference Frame $\mathcal{I}_1$, $\boldsymbol{\omega}_{3|1}$, is:

$$\boxed{\boldsymbol{\omega}_{3|1} = \boldsymbol{\omega}_{3|2} + \boldsymbol{\omega}_{2|1}} \quad . \tag{23.06.09}$$

→ 1246

The above relation can be extended to the addition of the angular velocities of an arbitrary number of Reference Frame.

It is worth emphasizing here that the above addition formula, equation (23.06.09), if interpreted as the sum component by component, is only valid whenever all the vectors are referred to the same, thought arbitrary, Reference Frame. This is of course always true for the sum of vectors. However, in relative kinematics, due to the constant use of at least two Reference Frame, it might be easier to use it erroneously.

23.06.02.06 Composition of Angular Accelerations

This § is referenced at pages:
[1329]

It can be shown that the angular acceleration resulting from the composition of a number of angular acceleration is not the vector sum of the individual angular acceleration.

If the Reference Frame $\mathcal{I}_2$ rotates with angular acceleration $\dot{\boldsymbol{\omega}}_{2|1}$ with respect to the Reference Frame $\mathcal{I}_1$ and the Reference Frame $\mathcal{I}_3$ rotates with angular acceleration $\dot{\boldsymbol{\omega}}_{3|2}$ with respect to the Reference Frame $\mathcal{I}_2$ then the angular acceleration of the Reference Frame $\mathcal{I}_3$ with respect to the Reference Frame $\mathcal{I}_1$, $\dot{\boldsymbol{\omega}}_{3|1}$, is:

$$\boxed{\dot{\boldsymbol{\omega}}_{3|1} = \dot{\boldsymbol{\omega}}_{3|2} + \dot{\boldsymbol{\omega}}_{2|1} + \boldsymbol{\omega}_{2|1} \wedge \boldsymbol{\omega}_{3|2}} \quad . \tag{23.06.10}$$

In fact:

$$\boldsymbol{\alpha}_{3|1} \equiv \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_1 \boldsymbol{\omega}_{3|1} = \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_1 (\boldsymbol{\omega}_{2|1} + \boldsymbol{\omega}_{3|2}) = \boldsymbol{\alpha}_{2|1} + \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_2 \boldsymbol{\omega}_{3|2} + \boldsymbol{\omega}_{2|1} \wedge \boldsymbol{\omega}_{3|2} = \boldsymbol{\alpha}_{2|1} + \boldsymbol{\alpha}_{3|2} + \boldsymbol{\omega}_{2|1} \wedge \boldsymbol{\omega}_{3|2}$$

Therefore, the angular velocity addition theorem does not extend to angular acceleration.

23.06.02.07 Second-Order Poisson Formula

From equation (23.06.06) it is possible to derive the general relation for the second order time derivative:

$$\boxed{\frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{\mathrm{A}} \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{\mathrm{A}} \mathbf{v} = \dots} \quad . \tag{23.06.11}$$

DRAFT - IN PROGRESS

CC BY NC ND

23.07 Relative Kinematics

23.07.01
Position Velocity Acceleration

Consider two Reference Frame in relative motion: $\mathcal{I}$ and $\mathcal{I}'$.

Siano $\mathbf{X}$, $\mathbf{V}$ and $\mathbf{A}$, rispettivamente, la posizione, velocità e accelerazione dell'origine di $\mathcal{I}'$ rispetto ad $\mathcal{I}$ e $\boldsymbol{\omega}$ la velocità angolare di $\mathcal{I}'$ rispetto ad $\mathcal{I}$.

La relazione tra l'operatore di derivazione temporale in due sistemi di riferimento in moto relativo con velocità angolare $\boldsymbol{\omega}$ è data dalla formula di Poisson (23.06.06).

Siano $\mathbf{x}$, $\mathbf{v}$ and $\mathbf{a}$ la posizione, velocità ed accelerazione di un punto rispetto al Reference Frame $\mathcal{I}$ ed $\mathbf{x}'$, $\mathbf{v}'$ and $\mathbf{a}'$ la posizione, velocità ed accelerazione di un punto rispetto al Reference Frame $\mathcal{I}'$.

La relazione che lega $\mathbf{x}$ e $\mathbf{x}'$, al vettore posizione dell'origine di $\mathcal{I}'$ rispetto ad $\mathcal{I}$, $\mathbf{X}$, è

$$\boxed{\mathbf{x} = \mathbf{x}' + \mathbf{X}} \tag{23.07.01}$$

La velocità rispetto al Reference Frame $\mathcal{I}$ è pari alla somma della velocità rispetto al Reference Frame $\mathcal{I}'$ e della velocità di trascinamento $\mathbf{v}_T$ di $\mathcal{I}'$ rispetto ad $\mathcal{I}$:

$$\boxed{\mathbf{v} = \mathbf{v}' + \mathbf{v}_T \quad \Leftrightarrow \quad \mathbf{v} = \mathbf{v}' + \left(\mathbf{V} + \boldsymbol{\omega}\wedge\mathbf{x}'\right)} \quad . \tag{23.07.02}$$

→ 1439

L'accelerazione rispetto al Reference Frame $\mathcal{I}$ è pari alla somma dell'accelerazione rispetto al Reference Frame $\mathcal{I}'$, dell'accelerazione di trascinamento $\mathbf{a}_T$ di $\mathcal{I}'$ rispetto ad $\mathcal{I}$ e dell'accelerazione di Coriolis $\mathbf{a}_C$:

$$\boxed{\mathbf{a} = \mathbf{a}' + \mathbf{a}_T + \mathbf{a}_C \quad \Leftrightarrow \quad \mathbf{a} = \mathbf{a}' + \left(\mathbf{A} + \dot{\boldsymbol{\omega}}\wedge\mathbf{x}' + \boldsymbol{\omega}\wedge\left(\boldsymbol{\omega}\wedge\mathbf{x}'\right)\right) + 2\,\boldsymbol{\omega}\wedge\mathbf{v}'} \quad . \tag{23.07.03}$$

→ 1329

Note that **the angular velocity is only dependent of the relative motion** of one Reference Frame with respect to the other; that is it does not depend on the reference point used as a CRV nor on anything else.

23.09 Exercises Problems and Physical Applications

DRAFT-IN-PROGRESS

23-001 Angular Velocity Is a Vector

Demonstrate that the angular velocity vector components transform as a vector, equation (23.06.04).

23-002 Perpendicularity Among the Three Unit Vectors Tangent, Normal and Binormal

Show that the three unit vectors, tangent, normal and binormal, form an orthonormal basis.

WORKED SOLUTION

From the definitions (23.03.01), (23.03.02), (23.03.03) it is obvious that only the perpendicularity between $\widehat{\mathbf{T}}$ and $\widehat{\mathbf{N}}$ has to be demonstrated. The demonstrations follows:

$$2\,\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}s}\cdot\widehat{\mathbf{T}}=\frac{\mathrm{d}}{\mathrm{d}s}(\,\mathbf{T}\cdot\mathbf{T})=\frac{\mathrm{d}}{\mathrm{d}s}(1)=0\implies\mathbf{T}\cdot\mathbf{N}=0\quad.$$

23-003 Darboux Vector

Using Frenet formulas to demonstrate equation (23.03.07).
Show that the contributions to the angular velocity of the three intrinsic unit vectors are given by:

$$\boldsymbol{\omega}=\boldsymbol{\omega}_{\mathbf{T}}+\boldsymbol{\omega}_{\mathbf{N}}+\boldsymbol{\omega}_{\mathbf{B}}\quad,$$

$$\boldsymbol{\omega}_{\mathbf{T}}\equiv\frac{1}{2}\widehat{\mathbf{T}}\wedge\frac{\mathrm{d}\widehat{\mathbf{T}}}{\mathrm{d}t}=\frac{1}{2}\kappa\widehat{\mathbf{B}}\quad,$$

$$\boldsymbol{\omega}_{\mathbf{N}}\equiv\frac{1}{2}\widehat{\mathbf{N}}\wedge\frac{\mathrm{d}\widehat{\mathbf{N}}}{\mathrm{d}t}=\frac{1}{2}\left(\kappa\widehat{\mathbf{B}}+\tau\widehat{\mathbf{T}}\right)\quad,$$

$$\boldsymbol{\omega}_{\mathbf{B}}\equiv\frac{1}{2}\widehat{\mathbf{B}}\wedge\frac{\mathrm{d}\widehat{\mathbf{B}}}{\mathrm{d}t}=\frac{1}{2}\tau\widehat{\mathbf{T}}\quad.$$

Write the above expression as the Poisson relations, with Darboux vector as the angular velocity.

23-004 Radius of Curvature

©|M.R.Spiegel *et al.*, *Vector Analysis*, 2009, McGraw-Hill, 2ndEd., ...|3.20||

1. Show that the radius of curvature of a parametric curve,

$$x=x[s]\qquad y=y[s]\qquad z=z[s]\quad,$$

parametrized by the curvilinear abscissa s, is given by:

$$\rho=\sqrt{\left(\frac{d^2x}{\mathrm{d}s^2}\right)^2+\left(\frac{d^2y}{\mathrm{d}s^2}\right)^2+\left(\frac{d^2z}{\mathrm{d}s^2}\right)^2}\quad.$$

2. Show that the radius of curvature of a parametric curve (trajectory) is given by:

$$\boxed{\rho=\frac{v^3}{|\,\mathbf{v}\wedge\mathbf{a}|}}\quad.\tag{23.09.01}$$

23-005 Helix

Consider:

$$x[t] = R\cos[\omega t] \quad ,$$
$$y[t] = R\sin[\omega t] \quad ,$$
$$z[t] = ct \quad .$$

Find the curvature and torsion.

WORKED SOLUTION

$$\kappa = \frac{R}{R^2 + c^2/\omega^2} \quad ,$$
$$\tau = \frac{c/\omega}{R^2 + c^2/\omega^2} \quad .$$

23-006 Il Jet in Volo Radente

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.8||

23-007 L'auto Da Corsa

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.D.4||

Un'automobile da corsa, durante una batteria di qualificazione di due giri, percorre il primo giro con una velocità scalare media di $90\ \mathrm{km/h}$. Il conducente vuole percorrere il secondo giro in modo che la velocità scalare media complessiva sui due giri salga a $180\ \mathrm{km/h}$, per poter ottenere la qualificazione. Dimostrare che ciò è impossibile.

WORKED SOLUTION

Sia L la lunghezza della pista, Δt_1 il tempo impiegato a percorrere il primo giro e Δt_2 il tempo (incognito) con cui deve essere percorso il secondo giro per ottenere la velocità scalare media desiderata. Si ha

$$\overline{v}_1 = \frac{L}{\Delta t_1} \quad ,$$
$$\overline{v} = \frac{2L}{\Delta t_1 + \Delta t_2} = \frac{2}{\dfrac{1}{v_1} + \dfrac{1}{v_2}} \qquad (23.09.02)$$

→ 1249

Ne segue che, qualunque sia $\Delta t_2 > 0$, si ha

$$\overline{v} = \frac{2}{\dfrac{1}{v_1} + \dfrac{1}{v_2}} < \frac{2}{\dfrac{1}{v_1}} = 2v_1 = 180\ \mathrm{km/h}$$

Per ottenere il risultato voluto il conducente dovrebbe percorrere il secondo giro in 0 s.
Nel caso di n giri la (23.09.02) può essere scritta (e generalizzata) come

$$\overline{v} = \frac{nL}{\Delta t_1 + \Delta t_2 + \ldots + \Delta t_n} = \frac{n}{\dfrac{1}{v_1} + \dfrac{1}{v_2} + \ldots + \dfrac{1}{v_n}}$$

23-008 Moto in Una Dimensione

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.12||

23-009 Lo Scontro Fra I Treni

Due treni viaggiano in verso opposto su un binario rettilineo. Se il primo treno si muove a velocità costante $v_1 = 120$ km/h, il secondo a velocità costante $v_2 = 30$ ms e al tempo $t = 0$ si trovano a distanza $a = 80$ km, calcolare dopo quanto tempo avviene lo scontro e la posizione dei treni a quell'istante rispetto alla posizione iniziale del primo treno. Si risolva il problema sia dal punto di vista del capostazione a terra che da quello dei macchinisti. Si risolva inoltre il problema anche per via grafica oltre che analitica.

WORKED SOLUTION

Si scelga un Coordinate System avente l'origine nella posizione del primo treno all'istante iniziale e con l'asse x diretto lungo il binario verso il secondo treno. Per il capostazione a terra le equazioni del moto dei due treni sono:

$$x_1(t) = v_1 t \quad ,$$
$$x_2(t) = -v_2 t + a \quad .$$

I treni si incontrano al tempo t_0 tale che $x_1(t_0) = x_2(t_0)$, cioè:

$$t_0 = \frac{a}{v_1 + v_2} = 1.26{\cdot}10^3 \text{ s} \quad ,$$

$$x_1(t_0) = x_2(t_0) = v_1 t_0 = \frac{a v_1}{v_1 + v_2} = 42.1{\cdot}10^3 \text{ m} \quad .$$

dove si sono usati i fattori di conversione

$$1 \text{ km/h} = 0.2778 \text{ ms} \qquad 1 \text{ ms} = 3.6 \text{ km/h} \tag{23.09.03}$$

Le soluzioni trovate per $x_1(t_0)$, $x_2(t_0)$ e t_0 si riducono ai valori corretti nei casi in cui $v_1 \gg v_2$ e $v_2 \gg v_1$. Inoltre essendo $v_1 \simeq v_2$ i due treni si incontrano quasi a metà strada.
Per analizzare la situazione dal punto di vista del macchinista sul primo treno si scelga un Coordinate System solidale con il primo treno, asse x' parallelo all'asse x e origine coincidente con il primo treno. Dal punto di vista del macchinista del primo treno il secondo treno si trova a distanza a al tempo $t = 0$ e viaggia a velocità, relativa al primo treno, $\mathbf{v}_r = \mathbf{v}_2 - \mathbf{v}_1$ che passando alle componenti lungo l'asse x' diventa $v_r = -(v_1 + v_2)$. In modo del tutto equivalente la velocità relativa del secondo treno rispetto al Reference Frame solidale con il primo treno può essere ricavata dalla legge di composizione delle velocità (23.09.18). Dal punto di vista del macchinista del primo treno le equazioni del moto sono quindi:

$$x''1(t) = 0 \qquad \text{il macchinista sta fermo nell'origine del sistema di coordinate} \quad ,$$
$$x''2(t) = -(v_1 + v_2)t + a \quad .$$

da cui seguono le soluzioni

$$t_0 = \frac{a}{v_1 + v_2} \qquad \text{(la stessa ottenuta dal capostazione)} \quad ,$$
$$x'_1(t_0) = x'_2(t_0) = 0 \qquad \text{(lo scontro avviene nell'origine per il macchinista)}$$

Per cui ne segue lo stesso risultato di sopra (come deve essere) per t_0 e un risultato consistente col precedente per $x'_1(t_0)$ e $x'_2(t_0)$.

WORKED SOLUTION

$t_0 = 1.26{\cdot}10^3$ s; $x_1(t_0) = 42.1{\cdot}10^3$ m.

23-010 ✓ Achille E La Tartaruga

Il filosofo greco Zenone propose nell'antichità il seguente paradosso (di Achille e la tartaruga). Supponiamo che al tempo $t = 0$ Achille si metta a correre per raggiungere una tartaruga che dista da lui a e che si mette a scappare. Sia V la velocità di Achille e v la velocità della tartaruga con $V \gg v$. Il veloce Achille non potrà mai raggiungere la lenta tartaruga perché giunto alla posizione a, occupata dalla tartaruga al tempo $t = 0$, questa si sarà spostata (pur se di poco) in un altra posizione; quando Achille raggiungerà questa seconda posizione la tartaruga si sarà ancora spostata (pur se di poco) in un'altra posizione e così via all'infinito. Achille non raggiungerà dunque mai la tartaruga in quanto per fare ciò sarebbero necessari un numero infinito di passi. Spiegare l'apparente paradosso.

WORKED SOLUTION

Si ricordi la formula della somma della serie geometrica: $S = \sum_{k=0}^{+\infty} x^k = 1/(1-x)$ per $|x| < 1$.

WORKED SOLUTION

Si scelga un sistema di coordinate con origine nella posizione occupata da Achille al tempo $t = 0$ e asse x diretto verso la tartaruga. Sia $X(t)$ la posizione di Achille e $x(t)$ quella della tartaruga:

$$X(t=0) = 0 \quad ,$$
$$x(t=0) = a \quad .$$

L'intervallo di tempo Δt_1 in cui Achille raggiunge la posizione a occupata dalla tartaruga a $t = 0$ e lo spostamento della tartaruga in questo intervallo di tempo valgono:

$$\Delta t_1 = \frac{a}{V} \quad ,$$
$$\Delta x_1 = v\Delta t_1 = \frac{av}{V} \quad .$$

Nei passi seguenti si ha:

$$\Delta t_2 = \frac{\Delta x_1}{V} = \frac{av}{V^2} \quad ,$$
$$\Delta x_2 = v\Delta t_2 = \frac{av^2}{V^2} \quad .$$

In generale, al passo n-esimo si ha:

$$\Delta t_n = \frac{a}{V}\left(\frac{v}{V}\right)^{(n-1)} \quad ,$$
$$\Delta x_n = \frac{av}{V}\left(\frac{v}{V}\right)^{(n-1)} \quad .$$

In generale per passare da Δt_i a Δx_i si moltiplica per v. Per passare da Δx_i a Δt_{i+1} si divide per V. Il tempo totale per questa serie di eventi si può calcolare usando il risultato della somma di una serie geometrica

$$S = \sum_{k=0}^{+\infty} x^k = \frac{1}{1-x} \qquad \text{per } |x| < 1. \tag{23.09.04}$$

si ricava che l'intervallo di tempo dopo cui Achille raggiunge la tartaruga vale

$$\Delta t = \sum_{n=1}^{+\infty} \Delta t_n = \frac{a}{V}\sum_{k=0}^{+\infty}\left(\frac{v}{V}\right)^k = \frac{a}{V}\left(\frac{1}{1-v/V}\right) = \frac{a}{V-v} \qquad \text{per } v < V.$$

CC BY NC ND

Analogamente lo spazio percorso dalla tartaruga prima di essere raggiunta vale

$$\Delta x = \sum_{n=1}^{+\infty} \Delta x_n = \frac{av}{V} \sum_{k=0}^{+\infty} \left(\frac{v}{V}\right)^k = \frac{av}{V-v} \qquad \text{per } v < V.$$

e lo spazio percorso da Achille vale

$$\Delta X = \Delta x + a = \frac{aV}{V-v} \qquad \text{per } v < V.$$

I risultati sono in accordo con quanto si sarebbe ottenuto risolvendo le equazioni del moto:

$$x(t) = vt + a \quad ,$$
$$X(t) = Vt \quad .$$

L'apparente paradosso nasce dal fatto che la somma di un numero infinito di intervalli di tempo (di lunghezza decrescente) può avere somma finita per cui di fatto Achille raggiunge la tartaruga in un tempo finito.

23-011 ✓ Il Problema Del Rimbalzo E Il Principio Del Tempo Minimo

This § is referenced at pages:
[Never referenced.]

Due amici si trovano alle distanze h_1 e h_2 da un muro verticale rettilineo. Uno dei due vuole lanciare orizzontalmente una palla all'altro, facendola rimbalzare sul muro, in modo che la palla raggiunga l'amico nel minor tempo possibile.

Determinare le caratteristiche della traiettoria che deve seguire il la palla per raggiungere l'amico nel minore tempo possibile. Si assuma che i tratti di traiettoria siano rettilinei e orizzontali, e il rimbalzo ideale.

Tale traiettoria è quella che seguirebbe la luce. Il principio analogo in ottica è detto principio di Fermat. La traiettoria risultante soddisfa alla legge della riflessione (di Snell) dell'ottica geometrica, equazione (55.03.01).

Read § 15.05.06.

23-012 ✓ Il Problema Del Bagnino E Il Principio Del Tempo Minimo

This § is referenced at pages:
[2360]

Un bagnino avvista una bagnante che chiede aiuto. La velocità con cui il bagnino può correre sulla spiaggia vale V, la velocità con cui può nuotare vale v, $v < V$, la distanza tra il bagnino e la riva vale D, quella della bagnante dalla riva vale d e la distanza tra il bagnino e la bagnante, misurata lungo la riva supposta rettilinea, vale h.

Determinare le caratteristiche della traiettoria che deve seguire il bagnino per raggiungere la bagnante nel minore tempo possibile.

Tale traiettoria è quella che seguirebbe la luce. Il principio analogo in ottica è detto principio di Fermat. La traiettoria risultante soddisfa alla legge della rifrazione (di Snell) dell'ottica geometrica, equazione (55.03.02).

Read § 15.05.07.

WORKED SOLUTION

Essendo la velocità del bagnino costante in spiaggia e in acqua la traiettoria che consente il tempo minimo di percorrenza sarà una spezzata composta da due tratti rettilinei in spiaggia e in mare. Infatti nel caso di moto con velocità costante il tempo di percorrenza più breve tra due punti corrisponde alla distanza più breve tra i due punti cioè un segmento di retta. Il bagnino percorrerà

cc BY NC ND

allora una traiettoria costituita da una spezzata cambiando direzione al momento del tuffo in mare. Sia x la distanza lungo la riva a cui il bagnino deve tuffarsi in acqua ($0 \le x \le h$). Il tempo, T, che impiega il bagnino a raggiungere la bagnante vale

$$T = \frac{\sqrt{x^2 + D^2}}{V} + \frac{\sqrt{d^2 + (h-x)^2}}{v}$$

Per trovare i punti di stazionarietà si calcola la derivata prima rispetto ad x e la si pone uguale a zero:

$$\frac{dT}{dx} = \frac{x}{V\sqrt{x^2 + D^2}} - \frac{h-x}{v\sqrt{d^2 + (h-x)^2}} = 0$$

Osserviamo che

$$\left.\frac{dT}{dx}\right|_{x=0} < 0 \qquad \left.\frac{dT}{dx}\right|_{x=h} > 0$$

La condizione di stazionarietà può essere riscritta introducendo gli angoli θ_I e θ_R che la traiettoria rettilinea del bagnino forma con la normale alla riva rispettivamente dal lato spiaggia e dal lato mare. Si trova:

$$\boxed{\frac{\sin\theta_I}{V} = \frac{\sin\theta_R}{v}} \tag{23.09.05}$$

→ 1253

Per verificare che il punto di stazionarietà trovato è effettivamente un minimo si può calcolare la derivata seconda di T rispetto ad x:

$$\frac{d^2T}{dx^2} = \frac{D^2}{V(x^2 + D^2)^{3/2}} + \frac{d^2}{v(d^2 + (h-x)^2)^{3/2}} > 0$$

che è sempre positiva per cui il punto di stazionarietà è un punto di minimo e la funzione $T(x)$ è convessa. Il fatto che la derivata seconda sia sempre positiva significa che la derivata prima è crescente ed essendo la derivata prima negativa per $x = 0$ e positiva per $x = h$ ne deduciamo che esiste uno ed un solo valore di x per cui la derivata si annulla, cioè uno ed un solo punto di minimo. L'equazione che pone la derivata prima uguale a zero determina dunque il valore di x che rende minimo il tempo di percorrenza e tale valore è unico. La soluzione esplicita dell'equazione per x non è banale.

Il problema risolto (equazione (23.09.05)) ha un analogo nel Principio di Fermat dell'ottica geometrica che afferma che nell'andare tra due punti un raggio luminoso segue il cammino per cui impiega un tempo stazionario (e non minimo come richiesto nel problema del bagnino). Nel caso dell'ottica geometrica, introducendo l'indice di rifrazione di un mezzo materiale, $n \equiv c/v$, con c la velocità della luce nel vuoto, l'equazione (23.09.05) si riscrive nella forma della legge di Snell della rifrazione:

$$\boxed{n_I \sin\theta_I = n_R \sin\theta_R} \tag{23.09.06}$$

Il problema mostra che la traiettoria cui corrisponde il tempo minimo di percorrenza in un mezzo in cui la velocità è variabile non è rettilineo.

23-013 L'uccello Che Vola Tra I Due Treni

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.12||

Due treni viaggiano lungo un binario rettilineo in versi opposti alla velocità di $34\ \mathrm{km/h}$. Un uccello che vola alla velocità costante di $58\ \mathrm{km/h}$ parte da uno dei treni quando questi si trovano alla distanza di $102\ \mathrm{km}$ e vola verso l'altro treno lungo il binario. Raggiunto il secondo treno inverte il suo moto e si dirige verso il primo treno raggiunto il quale inverte ancora il suo moto e così via. 1) Quanti voli fa l'uccello prima che i due treni si scontrino? 2) Quale è lo spazio totale percorso dall'uccello?

WORKED SOLUTION

1) Infiniti. 2) 87 km

23-014 Il Cane E Il Plotone Di Soldati

Un plotone di soldati si muove in linea retta a velocità costante v_P. Un cane, che cammina a velocità costante v_C, parte dalla coda del plotone diretto verso la testa e quando la raggiunge inverte il suo moto dirigendosi verso la coda. Il cane raggiunge la coda del plotone nell'istante in cui questa si trova nella posizione in cui si trovava la testa del plotone all'istante in cui il cane è partito. Determinare il rapporto tra la velocità del cane e quella del plotone.

WORKED SOLUTION

Sia L la lunghezza del plotone di soldati, T_1 il tempo che il cane impiega ad andare dalla coda alla testa del plotone e T_2 il tempo che il cane impiega per tornare dalla testa alla coda del plotone. Si possono allora scrivere le tre equazioni

$$\begin{aligned} L &= v_P\,(T_1 + T_2) \quad , \\ v_C T_1 &= L + v_F T_1 \quad , \\ v_C T_2 &= L - v_F T_2 \quad . \end{aligned}$$

nelle quattro incognite v_C, v_P, T_1 e T_2. Risolvendo il sistema rispetto al rapporto delle due velocità si trova

$$\frac{v_C}{v_P} = 1 \pm \sqrt{2}$$

di cui solo la soluzione positiva è accettabile per il problema in quanto v_C e v_P sono moduli di velocità cioè sono positivi.

WORKED SOLUTION

$v_C/v_P = 1 + \sqrt{2}$

Un oggetto si muove lungo l'asse x secondo la legge oraria

$$x(t) = at^2 - bt^3 + k \sin \alpha t$$

dove x è espresso in metri e t in secondi. 1) Determinare le dimensioni delle costanti a, b, k e α. Si supponga che, in unità del Sistema Internazionale di unità di misura, le costanti valgano $a = 3$, $b = 1$, $k = 1$ e $\alpha = \pi/2$. 2) Determinare la posizione della particella dopo 4 s. 3) Determinare la velocità della particella al tempo $t = 0$ e dopo 4 s. 4) Determinare la velocità media nell'intervallo di tempo tra $t = 0$ s e $t = 4$ s. 5) Se $k = 0$ determinare dopo quanto tempo l'oggetto raggiunge il massimo valore di x.

WORKED SOLUTION

1) $[a] = \mathcal{L}\mathcal{T}^{-2}$, $[b] = \mathcal{L}\mathcal{T}^{-3}$, $[k] = \mathcal{L}$, $[\alpha] = \mathcal{T}^{-1}$; 2) $x(t = 4) = -16$ m;

23-023 Proprietà Del Moto Di Un Grave

This § is referenced at pages:
[1258]

Un grave è lanciato verso l'alto con velocità iniziale $v_0 = 5\,\mathrm{ms}$ a partire dalla quota $x_0 = 1.8\ \mathrm{m}$. Determinare, trascurando la resistenza dell'aria, 1) dopo quanto tempo il grave raggiunge il punto di quota massima; 2) quanto vale la quota massima; 3) quanto tempo impiega a ridiscendere alla quota da cui è partito; 4) quale è la sua velocità nell'istante in cui si ritrova alla quota da cui è partito; 5) dopo quanto tempo cade a terra. Dimostrare che il moto è simmetrico rispetto all'istante in cui il grave si trova alla quota massima.

WORKED SOLUTION

L'equazione del moto rettilineo uniformemente accelerato nel campo di gravità, avendo scelto un sistema di assi cartesiani con asse x rivolto verso l'alto, e origine al suolo è:

$$x(t) = x_0 + v_0 t - \frac{1}{2} g t^2 \quad ,$$
$$v(t) = v_0 - g t \quad .$$

La quota massima si ha al tempo t_0 a cui $v(t_0) = 0$. Il tempo t_0 e la quota massima sono dunque

DRAFT - IN PROGRESS

dati dalle equazioni

$$t_0 = \frac{v_0}{g} \quad ,$$
$$x(t_0) = x_0 + \frac{v_0^2}{2g} \geq x_0 \quad .$$

Si osservi che il segno di t_0 dipende dal segno della componente x, v_{0x}, della velocità iniziale $\mathbf{v}_0$. Si osservi ora che

$$x(2t_0) = x_0 \quad ,$$
$$v(2t_0) = -v_0 \quad .$$

per cui il grave, nel caso in cui al tempo $t = 0$ fosse in fase ascendente, cioè $\mathbf{v}_0$ diretta verso l'alto e quindi $v_{0x} > 0$, è ricaduto, al tempo $2t_0$, alla stessa quota che aveva al tempo $t = 0$ impiegando nella fase di ricaduta dal punto di massimo, lo stesso tempo che ha impiegato per raggiungere il massimo e ritrovandosi con velocità avente lo stesso modulo e verso opposto rispetto al tempo $t = 0$. Analogo discorso si può fare nel caso in cui il grave al tempo $t = 0$ si trovi in fase discendente, cioè $\mathbf{v}_0$ diretta verso il basso e quindi $v_{0x} < 0$, da cui seguirebbe $t_0 < 0$. Con i dati del problema si trova dunque

$$t_0 = 0.510 \text{ s} \quad ,$$
$$x(t_0) - x_0 = 1.27 \text{ m} \quad ,$$
$$\text{tempo per ricadere alla quota da cui è partito} = t_0 \quad ,$$
$$\text{velocità alla quota da cui è partito} = -v_0 \qquad (23.09.07)$$

→ 1256

L'equazione è simmetrica rispetto a $t = t_0$, infatti detto $t' = t - t_0$, si può riscrivere la (23-023) come

$$x'(t') \equiv x(t' + t_0) = x_0 + \frac{v_0^2}{2g} - \frac{1}{2}gt'^2 \qquad (23.09.08)$$

→ 1256

che è simmetrica per $t' \to -t'$ e dalla quale risulta evidente il valore della quota massima raggiunta dal grave.
Il tempo a cui il grave arriva al suolo si trova imponendo $x = 0$ nell'equazione (23.09.08) (o, alternativamente, nell'equazione (23-023)).

$$t = t_0 + t' = \frac{v_0}{g} \pm \sqrt{\frac{2}{g}\left(x_0 + \frac{v_0^2}{2g}\right)} = \begin{cases} t_1 = -0.282 \text{ s} \\ t_2 = +1.301 \text{ s} \end{cases} \quad ,$$

Delle due soluzioni quella positiva rappresenta l'istante di tempo a cui il grave arriva al suolo. Quella negativa rappresenta l'istante a cui un grave, che si trova al tempo $t = 0$ nelle condizioni iniziali del problema, sarebbe passato per la quota $x = 0$, durante la fase di salita, se il suo moto fosse definito per tempi negativi. Si veda anche il problema § 23-024.
1) $t_0 = 0.510$ s; 2) $x(t_0) - x_0 = 1.27$ m; 3) t_0; 4) $-v_0$; 5) 1.301 s.

23-024 La Palla Lanciata Verso Il Suolo

This § is referenced at pages:
[1255]

Una palla viene lanciata verso il suolo con velocità iniziale $v_0 = 1$ ms diretta verso il basso da una quota $H = 100$ m. 1) Determinare dopo quanto tempo raggiunge il suolo. 2) Determinare da quale quota avrebbe dovuto partire da fermo il grave per trovarsi nelle condizioni iniziali date. 3) Determinare la velocità media del grave nella caduta.

WORKED SOLUTION

Scegliamo un sistema di coordinate con l'asse x orientato verso il basso e origine al suolo. L'equazione del moto e la velocità della palla risultano dunque:

$$x(t) = x_0 + v_0 t + \frac{1}{2} g t^2 = -H + v_0 t + \frac{1}{2} g t^2 \quad ,$$
$$v(t) = v_0 + g t \quad .$$

L'arrivo la suolo è definito dalla condizione $x(t) = 0$ che ha due soluzioni:

$$t_1 = \frac{-v_0 - \sqrt{v_0^2 + 2Hg}}{g} = -4.62 \text{ s} < 0 \quad ,$$
$$t_2 = \frac{-v_0 + \sqrt{v_0^2 + 2Hg}}{g} = +4.41 \text{ s} > 0 \quad .$$

simmetriche rispetto a $t_0 = -v_0/g = -0.10$ s, l'istante in cui la velocità del grave vale zero e la quota è massima. L'equazione presenta due soluzioni; quella cercata è t_2 che è positiva. L'equazione impostata risolve il problema di trovare a quale tempo passa per la quota $x = 0$ un grave che al tempo $t = 0$ si trova a quota H dal suolo ($x = -H$ con il sistema di coordinate scelto) e con velocità v_0 rivolta verso il basso. In altri termini l'equazione così impostata non contiene l'informazione che il grave parte al tempo $t = 0$. Tale informazione va posta in più all'equazione specificando che tale equazione è definita solo per $t > 0$. In altri termini l'insieme di definizione della funzione fisica del tempo $x(t)$ è $t \geq 0$, più ristretto rispetto all'insieme di esistenza della funzione matematica $x(t)$ che è $-\infty < t < +\infty$. In tal modo la soluzione t_1 viene automaticamente ad essere inaccettabile per il problema dato. Il significato della soluzione t_1 è che, date queste condizioni iniziali al tempo $t = 0$, un grave in moto già a $t < 0$ sarebbe transitato per la quota $x = 0$ al tempo $t_1 < 0$ nella fase di salita antecedente la ricaduta.

Sia $h + H$ la quota massima a cui si troverebbe il grave al tempo t_0, $x(t_0) = -(h + H)$. Ricaviamo h per determinare a che quota si trova il grave al tempo t_0. Sostituendo l'espressione per t_0, che sappiamo essere l'istante in cui la quota è massima, nell'equazione del moto si trova

$$-(h + H) = -H - \frac{v_0^2}{g} + \frac{v_0^2}{2g}$$

da cui segue

$$h = \frac{v_0^2}{2g} = 5.10 \cdot 10^{-2} \text{ m}$$

L'ipotetico tempo di caduta da $x(t_0) = -(h + H)$ al suolo sarebbe in tal caso:

$$\Delta T = \sqrt{\frac{2(H + h)}{g}} = \frac{\sqrt{v_0^2 + 2Hg}}{g} = t_2 - t_0$$

La prima espressione per ΔT nell'equazione sopra è quella canonica per un grave che cade da altezza $H + h$ con velocità iniziale nulla. La seconda si ottiene introducendo nella prima l'espressione di h ricavata sopra e permette di verificare che il risultato è proprio uguale a $t_2 - t_0$, come deve.

Calcoliamo la velocità media della caduta:

$$\overline{v} \equiv \frac{H}{t_2} = 22.7 \text{ ms}$$

La velocità media in un moto rettilineo uniformemente accelerato vale, in base alla definizione generale di velocità media,

$$\boxed{\overline{v} = \frac{\Delta x}{\Delta t} = v_0 + \frac{1}{2} a \Delta t}$$

la quale fornisce, con $a = g$, $\overline{v} = 22.7$ ms, come il calcolo precedente. Nel caso di moto rettilineo uniformemente accelerato (e solo in questo caso) la velocità media si può calcolare come il valore

CC BY NC ND

medio della velocità iniziale e finale, poiché la velocità cresce linearmente col tempo:

$$\overline{v} = \frac{v + v_0}{2} = v_0 + \frac{1}{2}a\Delta t$$

WORKED SOLUTION

1) 4.41 s; 2) 100.051 m; 3) 22.7 ms.

23-025 Metodo per Misurare L'accelerazione Di Gravità

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.73||

Il seguente metodo è stato impiegato per misurare il valore dell'accelerazione di gravità g. Si lancia una palla verticalmente verso l'alto entro un tubo a vuoto e la si osserva mentre, salendo prima e ricadendo poi, passa davanti a due traguardi U e L posti a distanza nota H. Se Δt_L rappresenta l'intervallo di tempo tra i due passaggi al livello L e Δt_U rappresenta l'intervallo di tempo tra i due passaggi al livello U, dimostrare che l'accelerazione di gravità g vale:

$$g = \frac{8H}{\Delta t_L^2 - \Delta t_U^2}$$

WORKED SOLUTION

Siano v_U e v_L i moduli della velocità della palla quando passa davanti la traguardo U ed L rispettivamente. Come discusso nel problema § 23-023, in assenza della resistenza dell'aria il modulo della velocità della palla mentre passa davanti al traguardo è lo stesso sia nella fase di salita che in quella di discesa. Inoltre il tempo che la palla impiega ad arrivare al punto di massima altezza (quando $v = 0$) partendo dal traguardo è lo stesso che impiega a ridiscendere e vale quindi metà dell'intervallo totale (Δt_L o Δt_U). Scegliendo un sistema di coordinate con asse x orientato verso l'alto si hanno le tre equazioni:

$$\begin{aligned} v_U^2 - v_L^2 &= -2gH \quad , \\ 0 &= v_U - g\frac{\Delta t_U}{2} \quad , \\ 0 &= v_L - g\frac{\Delta t_L}{2} \quad . \end{aligned}$$

che risolte forniscono l'equazione per g richiesta.

23-026 La Palla Che Cade Davanti Alla Finestra

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.74||

Una palla d'acciaio viene lasciata cadere dal tetto di un edificio con velocità iniziale nulla. Un osservatore ad una finestra alta $d = 120$ cm nota che la palla impiega $\Delta t = 0.125$ s ad attraversare in lunghezza la finestra. La palla continua a cadere, urta il suolo elasticamente (si supponga istantaneo l'urto) e riappare al bordo inferiore della finestra $\Delta T = 2$ s dopo essere passata per lo stesso punto durante la caduta. Quanto è alto l'edificio?

WORKED SOLUTION

Sia H l'altezza dal suolo del davanzale della finestra e sia h la distanza dal bordo superiore della finestra al tetto dell'edificio. L'altezza dell'edificio è dunque $H+d+h$. Il tempo che la palla impiega a cadere dal davanzale al suolo è uguale a quello che impiega a risalire e vale dunque $\Delta T/2$. Siano v_1 e v_2 rispettivamente le velocità della palla al passaggio al bordo superiore della finestra e al davanzale. Si usi un sistema di coordinate con asse x diretto verticalmente verso il basso e origine al suolo. Sia il tempo $t=0$ l'istante in cui la palla passa al davanzale della finestra. Si ha:

$$v_2 - v_1 = g\Delta t \quad ,$$
$$v_2^2 - v_1^2 = 2gd \quad ,$$
$$0 = -H + v_2\frac{\Delta T}{2} + \frac{g}{2}\left(\frac{\Delta T}{2}\right)^2 \quad ,$$
$$0 = -(H+d) + v_1\left(\frac{\Delta T}{2}+\Delta t\right) + \frac{g}{2}\left(\frac{\Delta T}{2}+\Delta t\right)^2 \quad ,$$
$$v_1^2 = 2gh \quad ,$$
$$v_2^2 = 2g(h+d) \quad .$$

Dalle prime due equazioni si ricavano i valori di v_1 e v_2:

$$v_1 = \frac{1}{2}\left[\frac{2d}{\Delta t} - g\Delta t\right] = 8.99\,\text{ms} \quad ,$$
$$v_2 = \frac{1}{2}\left[\frac{2d}{\Delta t} + g\Delta t\right] = 10.2\,\text{ms} \quad .$$

Dalla terza e quinta equazione si ricavano poi i valori di H e h.

$$H = +v_2\frac{\Delta T}{2} + \frac{g}{2}\left(\frac{\Delta T}{2}\right)^2 = 15.1\ \text{m} \quad ,$$
$$h = \frac{v_1^2}{2g} = 4.12\ \text{m} \quad .$$

Tali risultati sono cosistenti con la quarta e sesta equazione scritta sopra. L'altezza globale del palazzo risulta dunque

$$H+d+h = (15.1+1.2+4.12)\ \text{m} = 20.4\ \text{m}$$

WORKED SOLUTION

20.4 m.

23-027 Oggetto Visto Da Una Finestra

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|2.75||

23-028 Moto in Fluido Viscoso

Si supponga che un punto materiale sia in caduta non libera nel campo di gravità terrestre con equazione del moto

$$x(t) = \frac{m}{k}\left(\frac{mg}{k} - v_0\right)\left[\exp -\frac{kt}{m} - 1\right] + \frac{mgt}{k} + x_0$$

dove m è la massa del corpo, g l'accelerazione di gravità e k una costante assegnata. 1) Si determini le dimensioni della costante k, 2) il significato fisico delle due costanti x_0 e v_0, 3) il valore limite cui tendono la velocità e l'accelerazione in funzione del tempo.

WORKED SOLUTION

Le dimensioni della costante k si possono determinare in vari modi dalla equazione del moto data. Una possibilità è considerare l'argomento dell'esponenziale che deve essere adimensionale. Ne segue

$$[k] = \mathcal{MT}^{-1}$$

Il significato fisico della costante x_0 è manifesto se si calcola

$$x(t=0) = x_0$$

Il significato fisico della costante v_0 può essere determinato calcolando l'andamento della velocità

$$v(t) \equiv \frac{dx(t)}{dt} = -\left(\frac{mg}{k} - v_0\right)\exp -\frac{kt}{m} + \frac{mg}{k}$$

Ne segue

$$v(t=0) = v_0$$

La velocità tende, per $t \to \infty$ al valore limite

$$\lim_{t\to\infty} v(t) = \frac{mg}{k}$$

L'accelerazione vale

$$a(t) \equiv \frac{dv(t)}{dt} = \frac{k}{m}\left(\frac{mg}{k} - v_0\right)\exp -\frac{kt}{m}$$

e tende a zero al crescere del tempo. Il moto può essere descritto qualitativamente come segue. Il corpo accelera con accelerazione sempre decrescente e che tende a zero, mentre la velocità aumenta finché non raggiunge, asintoticamente, una velocità limite e accelerazione nulla.
Questo moto è il moto di un corpo in un fluido viscoso descritto in section § 24-040

WORKED SOLUTION

1) $[k] = \mathcal{MT}^{-1}$; 2) x_0 e v_0 sono rispettivamente posizione e velocità al tempo $t = 0$; 3) $\lim_{t\to\infty} v(t) = mg/k$ e $\lim_{t\to\infty} a(t) = 0$.

CC BY NC ND

23-029 Oggetto Che Cade E Rimbalza

Un grave è lasciato cadere con velocità iniziale nulla, rimbalza elasticamente al suolo, invertendo istantaneamente la propria velocità, e risale. 1) Determinare l'espressione del tempo T che impiega dal momento del lancio, alla quota x, fino al momento in cui risale ad una quota h assegnata 2) Determinare da quale quota va lasciato cadere affinché tale tempi sia minimo.

WORKED SOLUTION

1) $T = \sqrt{2/g}\left[2\sqrt{x} - \sqrt{x-h}\right]$; 2) Il tempo minimo si ha per $x = 4h/3$.

23-037 Il Bombardiere E La Contraerea - Il Cacciatore E La Lepre

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.9 - 4.47||

Si supponga di avvistare un bombardiere che, volando a quota $h = 1600$ m e con velocità $v = 500$ km/h, si dirige verso una postazione di contraerea. Si vuole colpire l'aereo quando si trova sopra un punto a distanza $a = 2$ km dalla postazione, cioè appena entrato entro la portata della batteria di contraerea ma prima che si avvicini troppo. Si trascura inizialmente l'effetto della forza di gravità sul moto del proiettile e si punta perciò il cannone nella direzione del bombardiere con alzo pari a $\theta = \arctan(h/a)$. 1) Sapendo che la velocità con cui vengono sparati i proiettili dalla contraerea vale $v_0 = 600$ ms a che distanza b (misurata al suolo) deve essere l'aereo al momento dello sparo? 2) Si discuta l'errore commesso con questa approssimazione. 3) Se immediatamente prima di essere colpito l'aereo sgancia una bomba dove cadrà la bomba rispetto alla postazione? Si applichi il risultato trovato al problema del cacciatore che, avvistata una lepre in corsa con $v = 15$ ms, punta il fucile perpendicolarmente alla traiettoria rettilinea della lepre e si calcoli l'angolo di anticipo con cui deve sparare per colpirla nel momento un cui questa passa davanti al fucile.

WORKED SOLUTION

Si scelga un sistema di assi cartesiani con l'asse x avente origine nella postazione e diretto verso il bombardiere e asse y verticale. Sia $t = 0$ l'istante in cui il proiettile colpisce il bombardiere e $t_0 < 0$ l'istante in cui si deve sparare. Le equazioni del moto del bombardiere e del proiettile sono:

$$\begin{aligned} x_a(t) &= -vt + a \quad , \\ y_a(t) &= h \quad , \\ x_p(t) &= (t - t_0) v_0 \cos\theta \quad , \\ y_p(t) &= (t - t_0) v_0 \sin\theta \quad . \end{aligned}$$

con $\tan\theta = h/a$ e $\theta = 38.7°$. Il bombardiere viene colpito quando $x_a(t) = x_p(t)$ e $y_a(t) = y_p(t)$. La sola incognita risulta essere t_0, essendo già noto che l'istante in cui il proiettile colpisce il bombardiere è $t = 0$ per come è stata scelta l'origine dei tempi. La seconda incognita cinematica sarebbe l'angolo di puntamento θ che è già stato determinato come $\tan\theta = h/a$. Si trova

$$t_0 = \frac{-h}{v_0 \sin\theta} = -\frac{\sqrt{a^2 + h^2}}{v_0} = -4.27 \text{ s} \qquad \text{non dipende da } v \text{ per come è posto il problema}$$

Il valore t_0 risulta, come deve, uguale allo spazio percorso dal proiettile diviso la sua velocità. Valutando la posizione dell'aereo al tempo $t = t_0$ si trova:

$$\begin{aligned} x_a(t_0) &= \frac{v\sqrt{a^2 + h^2}}{v_0} + a \equiv b = 2.59 \text{ km} \quad , \\ y_a(t_0) &= h = 1.6 \text{ km} \quad . \end{aligned}$$

Per soddisfare le richieste si deve quindi sparare con un anticipo di $|t_0|$ rispetto all'istante in cui il bombardiere raggiunge la posizione stabilita per l'abbattimento mentre questo si trova alla posizione b. L'angolo di vista del bombardiere al momento dello sparo (α) vale dunque:

$$\alpha = \arctan\left[\frac{h}{\frac{v\sqrt{a^2 + h^2}}{v_0} + a}\right] = 31.7°$$

Nel limite $v_0 \gg v$ si ha $\tan\alpha \to \tan\theta$. Nel limite $v \gg v_0$ si ha $\tan\alpha \to 0$.

cc BY NC ND

Per valutare l'errore commesso nel trascurare l'effetto della gravità sul proiettile si consideri che il proiettile vola per un tempo $\Delta t = \sqrt{a^2+h^2}/v_0$ e che in tale intervallo di tempo cade sulla verticale di una distanza

$$\Delta y_{\texttt{corr}} = -\frac{g}{2}(\Delta t)^2 = -\frac{g}{2}\left(\frac{a^2+h^2}{v_0^2}\right) = -89.4 \text{ m} < 0$$

Questo risultato significa che sparando con le condizioni calcolate il proiettile si ritrova, all'istante $t = 0$, all'ascissa x prevista, essendo le equazioni del moto orizzontale indipendenti da g, ma con una ordinata y che differisce di $\Delta y_{\texttt{corr}}$ rispetto a quella desiderata. L'approssimazione fatta è dunque non accettabile essendo l'errore commesso paragonabile con le dimensioni del bombardiere. Il calcolo andrebbe rifatto correttamente considerando l'effetto della forza peso sul moto del proiettile. Come prima approssimazione si può pensare di correggere il tiro modificando la puntata del cannone in modo da mirare ad una posizione $-\Delta y_{\texttt{corr}}$ rispetto a quella calcolata ignorando l'effetto dell'accelerazione di gravità, cioè puntando $|\Delta y_{\texttt{corr}}|$ più in alto. L'angolo approssimato di puntamento del cannone si può valutare dunque come

$$\tan\theta' \simeq \frac{h-\Delta y_{\texttt{corr}}}{a} = \frac{h}{a} + \frac{g(h^2+a^2)}{2av_0^2} = 40.2^\circ \neq 38.7^\circ$$

Ma questa è solo una soluzione approssimata.
La bomba lasciata cadere dal bombardiere immediatamente prima di essere colpito ha equazioni del moto:

$$x_b(t) = -vt + a \qquad \text{la stessa del bombardiere} \quad ,$$

$$y_b(t) = h - \frac{1}{2}gt^2 \qquad \text{supponendo } v_y(t=0) = 0 \quad .$$

La bomba arriva a terra dopo un tempo $\Delta t_1 = \sqrt{2h/g} = 18.1$ s e si trova a $x_b = -v\sqrt{2h/g} + a = -0.508$ km, oltre la postazione della contraerea che quindi non è al sicuro nelle condizioni date potendo essere colpita da una bomba lanciata dal bombardiere prima che questo sia abbattuto.
Il calcolo corretto della traiettoria, senza trascurare l'effetto della forza di gravità, procede come segue. Le equazioni del moto diventano:

$$\begin{aligned} x_a(t) &= -vt + a \quad , \\ y_a(t) &= h \quad , \\ x_p(t) &= (t-t_0)v_0\cos\theta \quad , \\ y_p(t) &= (t-t_0)v_0\sin\theta - \frac{1}{2}g(t-t_0)^2 \quad . \end{aligned}$$

Si noti che solo la quarta equazione si è modificata. Le incognite sono t_0, il tempo a cui si deve sparare, e θ, l'alzo del cannone per colpire, al tempo $t = 0$ il bombardiere nel punto di coordinate $x = a$ e $y = h$. Si ottengono quindi le equazioni

$$x_p(t=0) = a = (-t_0)v_0\cos\theta \quad ,$$

$$y_p(t=0) = h = (-t_0)v_0\sin\theta - \frac{1}{2}g(-t_0)^2 \quad .$$

che risolte rispetto a t_0 e $\tan\theta$ forniscono

$$t_0 = -\frac{a}{v_0\cos\theta} \qquad \text{come prima ma ora } \theta \text{ è incognito} \quad ,$$

$$\frac{ga^2}{2v_0^2}\tan^2\theta - a\tan\theta + h + \frac{ga^2}{2v_0^2} = 0 \quad .$$

CC BY NC ND

Le due soluzioni per $\tan\theta$ sono:

$$\tan\theta = \frac{v_0^2\left(1 \pm \sqrt{1 - \frac{g}{v_0^2}\left(2h + \frac{ga^2}{v_0^2}\right)}\right)}{ga} = \begin{cases} \theta_1 = 40.3^\circ \implies t_{0\,1} = -4.37\ \mathrm{s} \\ \theta_2 = 88.4^\circ \implies t_{0\,2} = -120.\ \mathrm{s} \end{cases},$$

→ 1264

La soluzione che interessa sarà quella con il minore valore di $\tan\theta$ perché corrisponde a colpire l'aereo direttamente e quindi in minore tempo, anziché nella fase di ricaduta del proiettile. Questo è confermato dalla soluzione per t_0 che per il minore valore di $\tan\theta$ fornisce il minore valore del tempo di volo $|t_0|$. Si ha, come deve, che nel limite $g \to 0$, $\tan\theta_1 \to h/a$ e $t_0 \to -\sqrt{a^2+h^2}/v_0$, che è la soluzione trovata nel caso in cui si è trascurata la gravità. Lo sviluppo al primo ordine in g della soluzione per $\tan\theta_1$ usando lo sviluppo del binomio

$$\sqrt{1+x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \mathcal{O}(x^3) \qquad -1 < x \leq +1 \tag{23.09.09}$$

→ 1264

fornisce

$$\tan\theta_1 \simeq \frac{h}{a}\left[1 + \frac{g}{2hv_0^2}\left(a^2+h^2\right)\right] = 40.2^\circ \simeq \tan\theta$$

ed è, come ovvio, maggiore di h/a per compensare la caduta del proiettile sotto l'effetto della forza di gravità. L'angolo θ_1 così calcolato coincide con l'angolo θ' calcolato precedentemente. Nello sviluppo del binomio occorre utilizzare anche il termine di secondo grado nella formula (23.09.09) in quanto il g a denominatore della (23-037) semplifica il termine di primo ordine in g al numeratore. Si noti che il termine da sviluppare nella (23-037) include sia g che g^2 per cui il termine di ordine x^2 nella (23.09.09) fornisce anche un contributo di ordine g^2.
Nel caso del cacciatore e la lepre si ha $a = 0$ e l'applicazione della formula per α fornisce il risultato

$$\text{angolo di anticipo} \equiv 90^\circ - \alpha = 1.43^\circ$$

WORKED SOLUTION

1) $b = 2.59$ km; 2) Errore sulla quota del proiettile $\Delta y_{\mathtt{corr}} = -89.4$ m; 3) 0.508 km oltre la postazione.

This § is referenced at pages:
[1266, 1267]

Sia dato un cannone che spara proiettili con velocità iniziale $v_0 = 500$ ms ad un angolo θ dal suolo. 1) Determinare l'equazione della traiettoria del proiettile e l'angolo a cui deve essere puntato il cannone per ottenere la gittata massima trascurando la resistenza dell'aria. 2) Nel caso il cannone si trovi alla base di un pendio rettilineo che forma un angolo α con l'orizzontale determinare la gittata lungo il pendio. 3) Nel caso di sparo in pianura determinare l'angolo di lancio per cui la massima altezza raggiunta dal proiettile è uguale alla gittata.

WORKED SOLUTION

Scelto un sistema di coordinate con origine nel cannone, asse x orizzontale e asse y verticale, le equazioni del moto del proiettile sono

$$x(t) = v_0 t \cos\theta \quad ,$$
$$y(t) = v_0 t \sin\theta - \frac{1}{2} g t^2 \quad .$$

L'equazione della traiettoria si ottiene eliminando la variabile tempo dalle equazioni del moto:

$$\boxed{y = x\tan\theta - \frac{g}{2v_0^2}\left(1+\tan^2\theta\right)x^2} \qquad (23.09.10)$$

→ 1266

Il punto di caduta del proiettile, cioè la gittata G del cannone, sarà dunque

$$\boxed{G = \frac{v_0^2 \sin 2\theta}{g}}$$

Da cui segue per la massima gittata:

$$\theta_{\max} = \pi/4 \quad ,$$
$$G_{\max} = \frac{v_0^2}{g} = 25.5 \text{ km} \quad .$$

Nel caso il cannone si trovi alla base di un pendio che forma un angolo α con l'orizzontale il punto di caduta si determina dal sistema

$$y = x\tan\theta - \frac{g}{2v_0^2}\left(1+\tan^2\theta\right)x^2 \quad ,$$
$$y = x\tan\alpha \quad .$$

che fornisce

$$x = \frac{2v_0^2\cos^2\theta}{g}(\tan\theta - \tan\alpha)$$

da cui segue la gittata lungo il pendio G

$$\boxed{G = \frac{2v_0^2\cos^2\theta}{g\cos\alpha}(\tan\theta - \tan\alpha)}$$

WORKED SOLUTION

2) $G = 2v_0^2\cos^2\theta\,(\tan\theta - \tan\alpha)\,/\,(g\cos\alpha)$.

23-040 Parabola Di Sicurezza

©|BBM, , ..., ..., ...Ed., ...|2.1.6||

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.20||

Dato un cannone che spara colpi con una velocità iniziale di v_0 1) determinare il luogo dei punti che non sono raggiungibili dai proiettili sparati dal cannone; 2) determinare l'altezza massima raggiunta dal proiettile.

WORKED SOLUTION

Si scelga un sistema di coordinate con origine nel cannone, asse x parallelo al suolo e asse y verticale.

L'equazione della traiettoria del proiettile è (equazione (23.09.10)):

$$y = x\tan\theta - \frac{g}{2v_0^2}\left(1+\tan^2\theta\right)x^2$$

dove θ è l'alzo del cannone. Siano x' e y' le coordinate di un generico punto bersaglio. Determiniamo l'alzo che deve avere il cannone per colpire il bersaglio posto in (x', y'). Ciò si ottiene risolvendo l'equazione

$$y' = x'\tan\theta - \frac{g}{2v_0^2}\left(1+\tan^2\theta\right)x'^2$$

nell'incognita θ. Si trova

$$\tan\theta = \frac{x' \pm \sqrt{x'^2 - 4kx'^2\left(y'+kx'^2\right)}}{2kx'^2} \qquad \text{con } k \equiv \frac{g}{2v_0^2}$$

Tale equazione ha due soluzioni reali per $\tan\theta$ (eventualmente coincidenti) se e solo se

$$x'^2 - 4kx'^2\left(y'+kx'^2\right) \geq 0 \qquad \Leftrightarrow \qquad \boxed{y' \leq \frac{1}{4k} - kx'^2}$$

che rappresenta una parabola (detta di sicurezza). I punti sulla parabola possono essere colpiti dal cannone scegliendo opportunamente l'alzo. I punti all'interno della parabola possono essere colpiti con due alzi diversi del cannone, uno colpisce il bersaglio nella fase di salita, l'altro nella fase di discesa. Il vertice della parabola si trova alla quota $y'_{\max} = 1/(4k) = v_0^2/2g$, la massima quota raggiungibile dal cannone con $\theta = \pi/2$. La gittata massima si ha per $|x'_{\max}| = 1/(2k) = v_0^2/g$

23-041 Salto in Lungo

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.24 - 4.32||

Nelle Olimpiadi del 1968 a Città del Messico Bob Beamon stabilì il record mondiale con un salto in lungo di $l = 8.90$ m. Supponendo che la velocità iniziale al momento del salto sia stata pari a $v_0 = 9.50$ ms, pari circa a quella di un corridore dei 100 metri, e sapendo che l'accelerazione di gravità a Città del Messico vale $g = 9.78\ \mathrm{m/s^2}$ quale è la differenza tra il record e la massima gittata ottenibile in assenza di aria? Se Beamon avesse compiuto lo stesso salto a Berlino ($g = 9.81\ \mathrm{m/s^2}$), mantenendo gli stessi valori di θ e v_0, quanto avrebbe saltato?

WORKED SOLUTION

Si usino i risultati del problema § 23-039 e sia G la gittata del cannone.

$$G = \frac{v_0^2\sin 2\theta}{g} \quad ,$$
$$\theta_{\max} = \pi/4 \quad ,$$
$$G_{\max} = \frac{v_0^2}{g} \quad .$$

Nel caso di Beamon si ottiene $G_{\max} = 9.23$ m. Se si fosse incluso l'effetto della resistenza dell'aria tale valore sarebbe risultato ancora più basso. La dipendenza da g, a parità di v_0 e θ, si determina come segue:

$$\Delta G = \Delta\left(\frac{v_0^2\sin 2\theta}{g}\right) \quad ,$$
$$\Longrightarrow \frac{\Delta G}{G} = -\frac{\Delta g}{g} \quad .$$

da cui si ricava $\Delta G = -2.7$ cm

23-042 Il Cannone Sulla Collina

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.46||

23-043 Aggiustamento Del Tiro Del Cannone

©|H.C.Ohanian, , ..., ..., ...Ed., ...|4.33||

In artiglieria è pratica abituale sparare una successione di colpi di prova prima di iniziare a sparare per ottenere l'effetto voluto. L'artigliere prima spara prima un colpo al di qua del bersaglio, poi un colpo al di là e apporta le necessarie correzioni al tiro in base ai risultati dei due colpi in modo da colpire il bersaglio. Si supponga che il primo colpo, sparato con alzo $7°20''$, atterri $180\ \mathrm{m}$ al di qua del bersaglio mentre il secondo, sparato con angolo di tiro $7°35''$, atterri $120\ \mathrm{m}$ oltre il bersaglio. Quanto vale l'angolo di proiezione corretto per colpire il bersaglio?

WORKED SOLUTION

Nel problema dato v_0, la velocità con cui i proiettili sono sparati dal cannone, è fissata ed ignota. Dal problema § 23-039 si ha

$$\Delta G = \left.\frac{dG}{d\alpha}\right|_{\alpha=\alpha_0} \Delta\alpha = \frac{2v_0^2 \cos 2\alpha}{g}\Delta\alpha$$

e quindi

$$\Delta G_1 = \left.\frac{dG}{d\alpha}\right|_{\alpha=\alpha_0} \Delta\alpha_1 = -180\ \mathrm{m} \quad ,$$

$$\Delta G_2 = \left.\frac{dG}{d\alpha}\right|_{\alpha=\alpha_0} \Delta\alpha_2 = +120\ \mathrm{m} \quad .$$

da cui segue

$$\frac{\Delta G_1}{\Delta G_2} = \frac{\Delta\alpha_1}{\Delta\alpha_2} = \frac{\alpha-\alpha_1}{\alpha-\alpha_2} \equiv k \qquad \alpha \text{ incognita, } k \text{ nota}$$

Si ricava

$$\alpha = \frac{\alpha_1 - k\alpha_2}{1-k}$$

Tale relazione ha i limiti corretti nei casi $\Delta G_1 = 0$ ($\alpha = \alpha_1$), $\Delta G_2 = 0$ ($\alpha = \alpha_2$), $\Delta G_1 = -\Delta G_2$ ($\alpha = (\alpha_1 + \alpha_2)/2$). Usando i dati del problema si ottiene che l'angolo corretto di puntamento vale $\alpha = 7°29''$.

23-046 Distanza Minima Tra Due Aereoplani

Le equazioni del moto di due aereoplani, in un Coordinate System in cui l'origine coincide con l'aereoporto, gli assi x e y sono paralleli al suolo e l'asse z è verticale e orientato verso l'alto, sono

$$\mathbf{x}_1(t) = a_1 t \mathbf{e}_x + b_1 t \mathbf{e}_y + c_1 t^2 \mathbf{e}_z \quad ,$$
$$\mathbf{x}_2(t) = (a_2 t + a_{20})\,\mathbf{e}_x + (b_2 t + b_{20})\,\mathbf{e}_y + \left(c_{20} - c_2 t^2\right)\mathbf{e}_z \quad .$$

Il primo aereoplano è in fase di decollo mentre il secondo è in fase di atterraggio. Determinare a quale istante i due aereoplani si trovano alla distanza minima e il valore della distanza minima tra i due aereoplani supponendo che le varie costanti, tutte espresse in unità del Sistema Internazionale, valgano $a_1 = 1$, $b_1 = 2$, $c_1 = +3$, $a_2 = 0$, $b_2 = 2$, $c_2 = -3$, $a_{20} = 1$, $b_{20} = 1$, $c_{20} = 10$.

WORKED SOLUTION

La distanza è stazionaria rispetto al tempo se e solo se

$$(\mathbf{x}_1 - \mathbf{x}_2)\cdot(\mathbf{v}_1 - \mathbf{v}_2)$$

WORKED SOLUTION

$t_0 = 1$ s, $d = 101$.

23-047 Distanza Minima Tra Due Oggetti in Moto Arbitrario

Un punto materiale si muove nello spazio con equazione del moto generica

$$\mathbf{x}(t) = x_1(t)\mathbf{e}_1 + x_2(t)\mathbf{e}_2 + x_3(t)\mathbf{e}_3 \tag{23.09.11}$$

1) Dimostrare che condizione sufficiente affinché la distanza del punto dall'origine abbia un minimo relativo è

$$\mathbf{x}\cdot\mathbf{v} = 0 \qquad v^2 + \mathbf{x}\cdot\mathbf{a} > 0 \tag{23.09.12}$$

→ 1268

2) Si generalizzi il risultato per determinare la condizione sufficiente affinché la distanza tra due punti materiali, in moto con equazione del moto $\mathbf{x}_1(t)$ e $\mathbf{x}_2(t)$, un minimo relativo.

WORKED SOLUTION

Si studi la condizione di minimo del quadrato della distanza del punto dall'origine in funzione del tempo: $d^2 = \mathbf{x}\cdot\mathbf{x}$.

WORKED SOLUTION

2) La condizione (23.09.12) viene espressa in termini della posizione e velocità relative $\mathbf{x}_R \equiv \mathbf{x}_1 - \mathbf{x}_2$ e $\mathbf{v}_R \equiv \mathbf{v}_1 - \mathbf{v}_2$.

DRAFT - Proof

23-048 Oggetti Super-Luminali

Gli astronomi hanno scoperto oggetti che emettono getti di materia ad altissima velocità. Se la distanza dell'oggetto dalla Terra è nota (sia d) la misura della velocità angolare alla quale si vede il getto muoversi sulla sfera celeste permette di determinare la velocità con cui il getto di materia è emesso dal nucleo centrale. In alcuni casi sono stati osservati getti in moto con velocità apparente superiore alla velocità della luce, fatto in apparente contraddizione con la teoria della relatività speciale. Mostrare come sia possibile ottenere velocità apparenti superiori a quella della luce e come ciò non contrasti con la relatività speciale considerando l'emissione del getto ad un angolo θ rispetto alla linea di vista dell'osservatore terrestre. 1) Determinare la relazione tra velocità apparente e quella reale del getto di materia. 2) Determinare la velocità apparente di un sistema in cui la direzione di emissione del getto forma un angolo $\theta = 9.2°$ con la direzione di vista supponendo la velocità di emissione pari a $v = 0.987c$ (questa si può determinare dallo studio dello spostamento **Doppler** delle linee spettrali). 3) Determinare il valore dell'angolo θ per cui la velocità apparente del getto sulla sfera celeste è massima e il valore di tale velocità massima.

DRAFT

WORKED SOLUTION

Sia t_0 l'istante di emissione del getto di materia in direzione θ rispetto alla linea di vista. L'emissione del getto viene osservata da Terra al tempo t_1:

$$t_1 = t_0 + d/c$$

Il getto viene osservato da Terra, dopo che ha percorso la distanza $v\Delta t$, all'istante

$$t_2 = t_0 + \Delta t + \frac{d - v\Delta t\cos\theta}{c}$$

L'intervallo di tempo Δt tra le due osservazioni da Terra è

$$t_2 - t_1 = \Delta t(1 - \frac{v\cos\theta}{c}) < \Delta t \qquad (\text{se } \cos\theta > 0)$$

L'astronomo conosce la distanza d dell'oggetto e misura uno spostamento angolare $\Delta\theta$ sulla sfera celeste da cui deduce uno spostamento apparente Δx del getto. Lo spostamento apparente Δx sulla sfera celeste vale

$$\Delta x \equiv \Delta\theta d = \frac{v\Delta t\sin\theta}{d}d = v\Delta t\sin\theta$$

è da notare il fatto che la relazione precedente è esatta essendo $d \gg v\Delta t$ per cui non è necessario distinguere fra la distanza dell'oggetto che emette il getto, d, e la distanza del getto al tempo t_2 che vale $\simeq d - v\Delta t\cos\theta$. La velocità apparente osservata risulta dunque:

$$v_{\text{app}}(\theta) = \frac{\Delta x}{t_2 - t_1} = \frac{d\Delta\theta}{t_2 - t_1} = \frac{v\sin\theta}{1 - (v/c)\cos\theta}$$

che può essere maggiore di c.
Il massimo della velocità al variare dell'angolo di emissione θ si trova derivando rispetto a θ e ponendo la derivata uguale a zero:

$$\frac{dv_{\text{app}}(\theta)}{d\theta} = \frac{v\cos\theta - v^2/c}{(1 - v/c\cos\theta)^2} = 0$$

da cui segue che l'angolo a cui si ottiene la velocità apparente massima e la velocità apparente massima valgono

$$\cos\theta_{\text{max}} = v/c \qquad v_{\text{app}}\Big|_{\text{max}} = \frac{v}{\sqrt{1 - v^2/c^2}}$$

Con i dati del problema si ottiene $v_{\text{app}} = 6.14c$.

CC BY NC ND

WORKED SOLUTION

1) $v_{\text{app}}(\theta) = v\sin\theta/\left(1-(v/c)\cos\theta\right)$; 2) $v_{\text{app}} = 6.14c$; 3) $\cos\theta_{\text{max}} = v/c$.

23-049 Raggio Di Curvatura Della Traiettoria Di Un Grave

Si consideri il moto di un proiettile sparato da un cannone con velocità iniziale $v_0 = 450\,\text{ms}$ con un alzo pari a $\theta = 31°$. Si determini in quale punto della traiettoria l'accelerazione normale è massima, quanto vale, il raggio di curvatura e il valore dell'accelerazione tangenziale in quel punto. Si determini inoltre l'andamento del raggio di curvatura della traiettoria in funzione del tempo.

WORKED SOLUTION

Si utilizzi la rappresentazione intrinseca dell'accelerazione

WORKED SOLUTION

Scegliendo un sistema di assi cartesiani con origine nel cannone, asse x diretto parallelamente al suolo e asse y verticale orientato verso l'alto l'equazione del moto del proiettile è:

$$\begin{aligned} x(t) &= x_0 + v_0 t\cos\theta \quad , \\ y(t) &= y_0 + v_0 t\sin\theta - \frac{1}{2}gt^2 \quad . \end{aligned}$$

l'andamento della velocità e dell'accelerazione sono

$$\begin{aligned} \dot{x}(t) &= v_0\cos\theta \quad , \\ \dot{y}(t) &= v_0\sin\theta - gt \quad . \\ \dot{v}_x(t) &= 0 \quad , \\ \dot{v}_y(t) &= -g \quad . \end{aligned}$$

L'accelerazione durante il moto può essere scomposta nelle due componenti normale e tangenziale la cui somma da sempre g. All'istante in cui il proiettile raggiunge la quota massima la velocità è diretta orizzontalmente e quindi l'accelerazione normale è diretta verticalmente verso il basso. Il verso si deduce dal fatto che l'accelerazione normale punta sempre verso il centro del cerchio osculatore. In tale posizione l'accelerazione è dunque tutta normale e il suo modulo vale g. Dalla (23.03.09) si ha allora

$$\rho = \frac{v^2}{g} = \frac{v_0^2\cos^2\theta}{g} = 15.2\ \text{km}$$

dove si è tenuto conto che nel punto di massima altezza della traiettoria si ha $v_y = 0$ e $v = v_x = v_0\cos\theta$.
L'accelerazione normale nel punto di massima altezza della traiettoria vale dunque g e quella tangenziale vale zero (infatti il modulo della velocità ha un minimo in queste condizioni).
L'andamento del raggio di curvatura in funzione del tempo si può dedurre dalla relazione (23.03.04) usando le equazioni del moto date sopra. Si trova

$$\frac{1}{\rho} = \frac{v_0 g|\cos\theta|}{\left|v_0^2 + g^2t^2 - 2gv_0 t\sin\theta\right|^{3/2}}$$

che calcolato al punto di massimo della traiettoria ($t = v_0\sin\theta/g$) si riduce al valore calcolato sopra. Il calcolo può essere effettuato in modo più generale. Il modulo della velocità può essere calcolato dalle relazioni ricavate sopra

$$v = \sqrt{v_0^2 + g^2t^2 - 2gv_0 t\sin\theta}$$

Se ne deduce

$$a_T = \frac{dv}{dt} = \frac{g}{v}(gt - v_0\sin\theta)$$

CC BY NC ND

L'accelerazione tangenziale vale zero per $t = v_0 \sin\theta/g$, coerentemente con quanto ricavato sopra, in quanto questo è l'istante al quale il grave si trova alla quota massima. L'accelerazione del grave è sempre g per cui si può dedurre l'accelerazione normale in ogni punto delle traiettoria

$$a_N = \sqrt{g^2 - a_T^2} = \frac{g}{v} v_0 |\cos\theta| = \frac{v^2}{\rho}$$

ed è massima nel punto in cui v è minima che è il punto in cui la quota è massima essendo v_x costante e $|v_y|$ zero in quel punto. In tali circostanze vale (essendo $v = v_0|\cos\theta|$) $a_N\big|_{\max} = g$ come deve. Tale metodo permette di calcolare l'accelerazione normale e tangenziale (e di conseguenza le componenti tangenziale e normale della forza) senza calcolare il raggio di curvatura della traiettoria che ora può invece essere dedotto dall'espressione di a_N

$$\frac{1}{\rho} = \frac{g v_0 |cos\theta|}{v^3}$$

in accordo con quanto ricavato sopra.

23-050 Accelerazione Tangenziale Ed Accelerazione Normale

This § is referenced at pages:
[Never referenced.]

Dato un punto materiale in moto con equazione del moto $\mathbf{x}(t)$ determinare le componenti tangenziale e normale dell'accelerazione.

WORKED SOLUTION

Dalle formule (23.03.01), (23.03.02), (23.03.03).

$$\frac{1}{\rho} = \left|\frac{d\widehat{\mathbf{T}}}{dt}\right| \frac{1}{v}$$

si ricava

$$\mathbf{v} \equiv \frac{d\mathbf{x}}{dt} \equiv v\widehat{\mathbf{T}}$$

Il vettore $d\widehat{\mathbf{T}}/ds$ è ortogonale al versore $\widehat{\mathbf{T}}$ perché

$$0 = \frac{d}{ds}1 = \frac{d}{ds}\mathbf{T}\cdot\mathbf{T} = 2\frac{d\widehat{\mathbf{T}}}{ds}\cdot\widehat{\mathbf{T}}$$

Derivando

$$\frac{d\mathbf{v}}{dt} = v\widehat{\mathbf{T}} = \frac{dv}{dt}\widehat{\mathbf{T}} + v\frac{d\widehat{\mathbf{T}}}{dt}$$

$$\mathbf{a} = \frac{d\mathbf{v}}{dt} = \frac{dv}{dt}\widehat{\mathbf{T}} + \frac{v^2}{\rho}\widehat{\mathbf{N}}$$

Il vettore accelerazione giace dunque nel piano definito dai versori $\widehat{\mathbf{T}}$ e $\widehat{\mathbf{N}}$ Dalla relazione sopra si deduce che l'accelerazione tangenziale è legata al cambiamento del modulo della velocità mentre quella radiale non influisce sul modulo ma solo sulla direzione. Infatti $\mathbf{a}_T$ esiste se e solo se $dv/dt \neq 0$; mentre $\mathbf{a}_N$ esiste se e solo se $1/\rho \neq 0$ cioè se e solo se $d\widehat{\mathbf{T}}/dt \neq 0$ cioè se e solo se cambia la direzione di $\mathbf{v}$. Si ha

$$\frac{1}{\rho} = \frac{|\mathbf{x}'\wedge\mathbf{x}''|}{|\mathbf{x}'|^3} = \frac{|\mathbf{v}\wedge\mathbf{a}|}{v^3} \qquad (23.09.13)$$

$$\frac{1}{\tau} = \frac{|\mathbf{x}\wedge\mathbf{x}''|}{\mathbf{x}'\cdot(\mathbf{x}''\wedge\mathbf{x}''')} \qquad (23.09.14)$$

CC BY NC ND

Si hanno inoltre le proprietà seguenti:

$$\frac{1}{\rho} = 0 \Leftrightarrow \qquad \text{retta} \quad ,$$
$$\frac{1}{\tau} = 0 \Leftrightarrow \qquad \text{curva piana} \quad .$$

La conoscenza di ρ e τ caratterizza completamente la curva a meno di uno spostamento rigido. Cioè due curve che hanno gli stessi ρ e τ sono sovrapponibili.
In termini dell'ascissa curvilinea si hanno le formule di Frenet:

$$\frac{d\widehat{\mathbf{T}}}{ds} = \frac{1}{\rho}\widehat{\mathbf{N}} \quad ,$$
$$\frac{d\widehat{\mathbf{N}}}{ds} = -\frac{1}{\rho}\widehat{\mathbf{T}} - \frac{1}{\tau}\widehat{\mathbf{B}} \quad ,$$
$$\frac{d\widehat{\mathbf{B}}}{ds} = \frac{1}{\tau}\widehat{\mathbf{N}} \quad .$$

EN-PROGRESS

23-058 La Battaglia Navale

Una nave da battaglia è sul lato ovest di una piccola isola montuosa, la cui vetta è a $h = 1800\ \mathrm{m}$. Una nave nemica può avvicinarsi fino a $D = 2500\ \mathrm{m}$ dal lato est dell'isola e può sparare proiettili con una velocità iniziale di $v_0 = 250\ \mathrm{m/s}$. Se la costa orientale è, in orizzontale, a $d = 300\ \mathrm{m}$ dall vetta, quali sono le distanze dalla riva orientale in cui la nave può essere al sicuro da bombardamento della nave nemica?

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|2.P33||

Al National Physical Laboratory in Gran Bretagna hanno eseguito una misurazione di g lanciando verticalmente in alto una sfera di vetro in un tubo a vuoto e lasciandola ricadere.

Sia Δt_I l'intervallo di tempo fra i due passaggi della sfera a un livello inferiore, Δt_S l'intervallo di tempo fra i due passaggi a un livello superiore. Posta H la distanza tra i due livelli, si dimostri che:

$$g = \frac{8H}{\Delta t_I^2 - \Delta t_S^2} \quad .$$

WORKED SOLUTION

$$\Delta t = \frac{4v_0}{g} \qquad v_S^2 - v_I^2 = -2gH$$

23-066 Periodo Sinodico Dei Pianeti

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|11.22||

This § is referenced at pages:
[Never referenced.]

Si supponga che il moto della Terra, di Marte e di Venere attorno al Sole sia un moto circolare uniforme con centro nel Sole, che le orbite siano tutte coplanari e che il periodo di rivoluzione (periodo siderale) dei tre pianeti, sia rispettivamente $T_T = 365.26$ giorni, $T_M = 687$ giorni e $T_V = 224.7$ giorni. Determinare il periodo sinodico di Marte e Venere, cioè il periodo di tempo tra due successive congiunzioni o due successive opposizioni del pianeta. Per un pianeta interno, quale Venere, la congiunzione è definita come la circostanza in cui il pianeta, la Terra e il Sole sono allineati. Si distingue tra congiunzione inferiore, quando il pianeta è tra il Sole e la Terra, e congiunzione superiore quando il pianeta e la Terra si trovano da parti opposte rispetto al Sole. Anche per un pianeta esterno, quale Marte, sono possibili due circostanze in cui il pianeta, la Terra e il Sole sono allineati. Quando il pianeta e la Terra si trovano da parti opposte rispetto al Sole si parla di congiunzione mentre se la Terra si trova tra il Sole e il pianeta si parla di opposizione.

WORKED SOLUTION

Fissiamoci sul caso di opposizione del pianeta (gli altri casi procedono in modo del tutto analogo). Al tempo $t = 0$ il pianeta sia in opposizione. Allora detti θ_1 e θ_2 gli angoli sotto cui la Terra e il pianeta sono visti dal Sole, si ha

$$\theta_1(t = 0) = \theta_2(t = 0) = 0$$

Le equazioni del moto sono

$$\theta_1(t) = \omega_1 t \quad ,$$
$$\theta_2(t) = \omega_2 t \quad .$$

In generale si ha opposizione all'istante t tale che

$$\theta_1(t) = \theta_2(t) + 2\pi k \qquad k \text{ intero qualunque}$$

la prima opposizione si ha allora per

$$\theta_1(t) - \theta_2(t) = 2\pi \qquad (\text{supponendo } \omega_1 > \omega_2)$$

Cioè, detto t_0 il tempo al quale avviene la opposizione, per

$$(\omega_1 - \omega_2)t_0 = 2\pi \implies t_0 = \frac{2\pi}{\omega_1 - \omega_2}$$

Ne segue

$$\boxed{\frac{1}{t_0} = \frac{1}{T_1} - \frac{1}{T_2} \qquad (\text{per } T_1 < T_2)}$$

La relazione ha i limiti corretti nel caso $T_2 \gg T_1$ ($t_0 = T_1$) e nel caso $T_2 \simeq T_1$ ($t_0 \to \infty$). Con i dati del problema si trovano, per Marte e Venere, i periodi sinodici $T'_M = 2.135$ anni e $T'_V = 584$ giorni.

WORKED SOLUTION

$T'_V = 584$ giorni; $T'_M = 2.135$ anni.

23-074 Misura Della Velocità Della Luce Con Il Metodo Di Fizeau

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|8.P9||

Uno dei primi metodi per la misura della velocità della luce è il cosiddetto interferometro di Fizeau. Un fascio di luce attraversa una fenditura del bordo esterno di una ruota dentata, viaggia verso uno uno specchio e, riflesso da questo, torna sulla ruota dentata per passare attraverso una fenditura successiva della ruota dentata.

Si supponga che la ruota abbia raggio di $R = 5.0$ cm e che sul suo bordo siano stati ricavati $n = 500$ denti. Misurando la velocità della luce con lo specchio posto a $L = 500$ m dalla ruota si è ottenuto $c = 3.0 \cdot 10^8$ m/s.

- Si calcoli la velocità, angolare, supposta costante, della ruota dentata.

DRAFT - IN PROGRESS

WORKED SOLUTION

$$\omega = \frac{\pi c}{nL} = 3770 \text{ rad/s}$$

23-075 L'auto Sotto La Pioggia

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.70||

Si supponga che la pioggia cada verticalmente con velocità $v = 7.8\,\text{ms}$ rispetto al suolo. Un'auto si muove in linea retta con velocità $V = 55$ km/h. 1) Quale angolo formano con la verticale le tracce delle gocce di pioggia sul finestrino dell'auto? 2) Quale è la velocità delle gocce di pioggia osservata dall'auto.

WORKED SOLUTION

Detta $\mathbf{v'}$ la velocità delle gocce di pioggia nel Reference Frame dell'auto si ha:

$$\mathbf{v'} = \mathbf{v} - \mathbf{V}$$

Detto θ l'angolo con la verticale, considerato positivo per una traiettoria orientata all'indietro rispetto alla velocità dell'auto, ne segue:

$$\tan\theta = \frac{V}{v}$$

Se il lunotto posteriore di un auto ha un angolo di inclinazione θ_0 con la verticale questo non si bagnerà se e solo se la velocità dell'auto è sufficientemente grande che:

$$V > v \tan\theta_0$$

Si noti che la velocità della pioggia che si potrebbe calcolare usando questo problema risulterebbe inferiore della velocità vera. Infatti l'auto trascina parzialmente attorno a sé l'aria circostante.

23-076 L'aereo E Il Vento

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.73||

Un pilota vola verso est da A a B e quindi torna verso ovest in A. Sia $\mathbf{v}$ la velocità dell'aereo rispetto all'aria, $\mathbf{u}$ quella dell'aria rispetto la suolo e l la distanza tra A e B. Si supponga che l'aereo si muova a velocità costante. Se $u = 0$ mostrare che la durata del viaggio è $t_0 = 2l/v$. Supponendo che l'aria si muova verso est (o ovest) mostrare che la durata del viaggio è

$$t_E = \frac{t_0}{1 - u^2/v^2}$$

Supponendo che l'aria si muova verso nord (o sud) mostrare che la durata del viaggio è

$$t_N = \frac{t_0}{\sqrt{1 - u^2/v^2}}$$

WORKED SOLUTION

Nel caso il vento soffi verso est il modulo della velocità dell'aereo relativa al suolo vale $v'_1 = v + u$ all'andata e $v'_2 = v - u$ al ritorno. Ne segue

$$t_E = \frac{l}{v+u} + \frac{l}{v-u} = \frac{t_0}{1 - u^2/v^2} > t_0 \qquad \text{per } u < v$$

Si noti che deve essere $u < v$ perché altrimenti l'aereo non riesce a ritornare al punto A.
Nel caso il vento soffi verso nord l'aereo, per volare lungo la congiungente $A - B$, deve dirigersi, rispetto all'aria, ad una direzione che forma un angolo α verso sud rispetto alla direzione originaria

CC BY NC ND

$A-B$, per compensare la traslazione verso nord dell'aria rispetto alla quale la sua velocità è $\mathbf{v}$. L'angolo α è determinato dalla relazione

$$v_\perp + u = -v\sin\alpha + u = 0$$

In tal modo l'aereo si muove lungo la direzione $A-B$ puntando sempre la prua ad un angolo α verso sud. In altri termini il vettore velocità dell'aereo è diretto lungo la congiungente $A-B$ mentre la direzione dell'aereo (della sua prua) punta costantemente ad un angolo α rispetto a tale congiungente. La componente della velocità lungo la direzione della congiungente $A-B$ vale

$$v_\parallel = v\cos\alpha$$

Ne segue:

$$t_N = \frac{2l}{v\cos\alpha} = \frac{2l}{v\sqrt{1-u^2/v^2}} = \frac{t_0}{\sqrt{1-u^2/v^2}} > t_0 \qquad \text{per } u < v$$

Si noti che deve essere $u < v$ perché altrimenti l'aereo non riesce a raggiungere il punto B dal punto A. Infatti non esiste un angolo α che soddisfi la condizione $-v\sin\alpha + u = 0$ se $u > v$ e per $u = v$ si ha $v_\parallel = v\cos\alpha = 0$.

23-077 Moto Di Un Grave Dentro Un Ascensore

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.76||

Un ascensore sale con un'accelerazione $a = 1.22\ \mathrm{m/s^2}$ diretta verso l'alto. Nell'istante in cui la sua velocità vale $v_0 = 2.44\,\mathrm{ms}$ un bullone mal fissato cade dal soffitto posto ad un'altezza $h = 2.74\ \mathrm{m}$ dal suolo dell'ascensore. Calcolare il tempo che impiega il bullone ad arrivare al suolo dell'ascensore e la distanza percorsa dal bullone rispetto alla tromba dell'ascensore. Calcolare la velocità del bullone quando tocca il pavimento dell'ascensore sia rispetto al Reference Frame dell'ascensore che a quello fisso a terra. Si risolva il problema sia nel Reference Frame dell'ascensore che in quello fisso a terra e si confrontino i risultati.

WORKED SOLUTION

Si scelga l'asse x orientato verso l'alto e si scelga come origine la posizione del pavimento dell'ascensore al tempo $t = 0$ in cui il bullone si stacca. Le equazioni del moto del pavimento dell'ascensore e del bullone sono allora:

$$x_{\mathtt{asc}}(t) = v_0 t + \frac{1}{2}at^2 \tag{23.09.15}$$

→ 1278

$$x_B(t) = h + v_0 t - \frac{1}{2}gt^2 \tag{23.09.16}$$

→ 1278

Il bullone arriva la suolo all'istante t_0 in cui $x_{\mathtt{asc}}(t_0) = x_B(t_0)$:

$$h = \frac{1}{2}(g+a)t_0^2 \implies t_0 = \pm\sqrt{\frac{2h}{a+g}} = \pm 0.705\ \mathrm{s}$$

La soluzione corretta per questo problema è quella positiva. Si noti che nelle formule ricavate sopra per h e t_0 tutto va come se l'accelerazione effettiva del bullone fosse $a+g$. Il cambiamento di posizione rispetto al Reference Frame a terra vale:

$$\Delta x_B = x_B(t_0) - x_B(0) = v_0 t_0 - \frac{1}{2}gt_0^2 = -0.717\ \mathrm{m} < 0$$

Nel Reference Frame solidale con l'ascensore per l'accelerazione del bullone si ha, essendo $\mathbf{a}_T = \mathbf{a}$ e $\mathbf{a}_A = \mathbf{g}$,

$$\mathbf{a}_A = \mathbf{a}_R + \mathbf{a}_T + \mathbf{a}_C \implies \mathbf{g} = \mathbf{a}_R + \mathbf{a} \implies \mathbf{a}_R = \mathbf{g} - \mathbf{a}$$

Passando alle componenti sull'asse x si ha

$$a_R = -(g+a)$$

CC BY NC ND

L'osservatore nell'ascensore allora, essendo nulla la velocità iniziale del bullone nel Reference Frame solidale con l'ascensore, attribuirà al bullone l'equazione del moto

$$x'_B(t) = h + \frac{1}{2}a_R t^2 = h - \frac{1}{2}(g+a)t^2 \tag{23.09.17}$$

→ 1278

e calcolerà il tempo di caduta come

$$t_0 = \sqrt{\frac{-2h}{a_R}} = \sqrt{\frac{2h}{a+g}}$$

in accordo con l'osservatore a terra. Il segno meno davanti a $2h$ nella formula precedente deriva dalla scelta dell'orientazione verso l'alto dell'asse x che rende $a_R < 0$. Per il cambiamento di posizione si ha dalle equazioni del moto (23.09.15), (23.09.16), (23.09.17):

$$\Delta x'_B = x'_B(t_0) - x'_B(0) = -h \quad ,$$

$$\Delta x_{\mathsf{asc}} = v_0 t_0 + \frac{1}{2}a t_0^2 \quad ,$$

$$\Delta x_B = v_0 t_0 - \frac{1}{2}g t_0^2 \quad .$$

che soddisfano come deve alla

$$\Delta x_B = \Delta x'_B + \Delta x_{\mathsf{asc}}$$

Il calcolo della velocità si può effettuare usando la relazione

$$\boxed{v^2 = v_0^2 + 2a(x - x_0)}$$

Applicando la relazione sopra all'osservatore solidale con l'ascensore si ottiene:

$$v'^2 = 0 - 2(a+g)(\Delta x'_B) = 2h(a+g) = \left(\frac{2h}{t_0}\right)^2 \implies v' = -\frac{2h}{t_0} = -7.77\,\mathrm{ms}$$

Mentre applicandola al Reference Frame solidale con il suolo si ha:

$$v^2 = v_0^2 - 2(g)(\Delta x_B) = (v_0 - g t_0)^2 \implies v = v_0 - g t_0 = -4.47\,\mathrm{ms}$$

In entrambi i casi si è scelto il segno corretto estraendo la radice quadrata. La legge di composizione delle velocità

$$\boxed{\mathbf{v} = \mathbf{v}' + \mathbf{v}_T} \tag{23.09.18}$$

→ 1250

se si usa la relazione

$$v_T = v_0 + a t_0 = 3.30\,\mathrm{ms}$$

diventa

$$v = v' + v_T = v' + v_0 + a t_0$$

che è correttamente verificata usando i valori calcolati di v, v_T e v'.

23-078 La Barca Che Attraversa Il Fiume

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|4.79||

Una barca può muoversi alla velocità di $6.44\ \mathrm{km/h}$, rispetto all'acqua, e la corrente del fiume ha velocità di $3.22\ \mathrm{km/h}$. 1) In quale direzione deve vogare se vuole raggiungere la riva opposta nel punto di fronte a quello di partenza? 2) Se il fiume è largo $6.44\ \mathrm{km}$ quanto tempo impiega ad attraversarlo? 3) Quanto tempo impiega a remare $3.22\ \mathrm{km}$ più a valle e quindi nuovamente verso il punto di partenza? 4) Quanto tempo impiega a remare $3.22\ \mathrm{km}$ più a monte e quindi nuovamente verso il punto di partenza? 5) In quel direzione deve vogare per raggiungere la riva opposta nel minor tempo possibile e quanto vale questo tempo?

23-079 Aberrazione Non Relativistica Della Luce Stellare (Di Bradley)

La direzione di provenienza della luce stellare è soggetta al fenomeno dell'aberrazione (scoperta da Bradley nel 1727) a seguito del quale la direzione apparente della stella cambia durante l'anno a causa del moto della Terra attorno al Sole. Supponendo che la velocità della luce rispetto al Reference Frame in cui il Sole è in quiete sia $\mathbf{c}$ e che la Terra ruoti attorno al Sole con velocità $\mathbf{v}_T$ determinare l'angolo di aberrazione, cioè l'angolo tra la direzione vera della stella e quella in cui viene osservata per effetto del moto della Terra. Sapendo che il valore massimo dell'angolo di aberrazione misurato dagli astronomi vale $\Delta\alpha = 20.5''$ determinare la velocità media della Terra nella sua orbita e il raggio dell'orbita sapendo che il periodo siderale della Terra vale $T = 365.26$ giorni

WORKED SOLUTION

Applicando la legge di composizione delle velocità alla luce della stella si ottiene

$$\mathbf{c} = \mathbf{v}_T + \mathbf{c}' \tag{23.09.19}$$

→ 1279

Sia α l'angolo tra $\mathbf{c}$ e $-\mathbf{v}_T$ e sia α' l'angolo tra $\mathbf{c}'$ e $-\mathbf{v}_T$. Moltiplicando scalarmente e vettorialmente entrambi i membri dell'equazione (23.09.19) per il vettore $-\mathbf{v}_T$ e tenendo conto delle definizioni degli angoli α e α' si ottengono le relazioni

$$\begin{aligned} c\cos\alpha &= c'\cos\alpha' - v_T \quad , \\ c\sin\alpha &= c'\sin\alpha' \end{aligned}$$

da cui si deduce:

$$\boxed{\tan\alpha' = \frac{c\sin\alpha}{c\cos\alpha + v_T}}$$

Nel caso $v_T \to 0$ la formula si riduce correttamente a $\alpha' = \alpha$ (nessuna aberrazione). In pratica la condizione è soddisfatta per $v_T \ll c|\cos\alpha|$. Ma $\cos\alpha$ varia durante l'anno per cui la condizione risulta $v_T \ll c\min|\cos\alpha|$

Sia $\Delta\alpha \equiv \alpha - \alpha'$. Dal teorema di Carnot si ha:

$$c'^2 = c^2 + v_T^2 + 2cv_T\cos\alpha \qquad \text{e} \qquad \left|\frac{v_T}{c}\right| \ll 1 \implies c' \simeq c$$

Dal teorema dei seni si ha:

$$\frac{\sin\Delta\alpha}{v_T} = \frac{\sin\alpha'}{c} = \frac{\sin\alpha}{c'} \implies \sin\Delta\alpha = \frac{v_T}{c'}\sin\alpha \simeq \frac{v_T}{c}\sin\alpha$$

Da cui il valore massimo dell'aberrazione $\Delta\alpha$ misurato dagli astronomi (per $\alpha \simeq 90°$) vale

$$\sin\Delta\alpha\Big|_{\max} = \frac{v_T}{c}$$

Ne segue $v_T = 29.8$ km/s per la Terra. Per il raggio dell'orbita terrestre si ha

$$R = \frac{v_T T}{2\pi} = 1.496{\cdot}10^{11}\ \text{m}$$

23-080 Moto Libero Osservato Da Un Reference Frame Ruotante

Un punto materiale si muove con velocità costante $\mathbf{v_0}$ rispetto al Reference Frame del Laboratorio xyz. Il punto materiale viene osservato da un Reference Frame costituito da un disco orizzontale di raggio $R = 30$ cm che ruota con velocità angolare $\omega_0 = 3$ giri/s attorno all'asse z del Reference Frame del Laboratorio. All'istante iniziale il punto si trova a distanza $r_0 = 7$ cm dall'asse ed ha velocità $v_0 = 15$ ms diretta perpendicolarmente al vettore $\mathbf{r_0}$. Determinare il modulo della velocità del punto rispetto al Reference Frame solidale col disco ruotante quando questo raggiunge il bordo del disco. Determinare l'andamento in funzione del tempo delle componenti radiali della velocità del punto materiale rispetto al Reference Frame del Laboratorio.

WORKED SOLUTION

L'equazione del moto del punto rispetto al Reference Frame del Laboratorio, con una scelta opportuna dell'orientamento degli assi xy, è:

$$x(t) = r_0 \quad ,$$
$$y(t) = v_0 t \quad .$$

Dalla relazione generale che lega le velocità di due Reference Frame xyz e $x'y'z'$, detta O l'origine del Reference Frame $x'y'z'$, si ha

$$\mathbf{v} = \mathbf{v'} + \mathbf{v}_O + \boldsymbol{\omega} \wedge \mathbf{x'}$$

si trova

$$\mathbf{v'} = \mathbf{v_0} - \boldsymbol{\omega} \wedge \mathbf{x'}$$

Detto ϕ l'angolo tra l'asse x e la posizione del punto materiale quando questo raggiunge il bordo si ha $\cos\phi = r_0/R$. Le componenti radiale e tangenziale di $\mathbf{v'}$ valgono

$$\mathbf{v}'_R = v_0 \sin\phi \quad ,$$
$$\mathbf{v}'_T = v_0 \cos\phi - \omega R \quad .$$

Ne segue il modulo della velocità $\mathbf{v'}$

$$v'^2 = v_0^2 + \omega^2 R^2 - 2\omega v_0 r_0$$

Sostituendo i valori dati, dopo aver osservato che $\omega = 2\pi\omega_0$, si trova $v' = 14.7\,\mathrm{ms}$.
Studiamo il moto del punto materiale nel Reference Frame del Laboratorio in coordinate polari. Dalle equazioni del moto in coordinate cartesiane si ricavano quelle in coordinate polari:

$$r(t) \equiv \sqrt{x^2(t) + y^2(t)} = \sqrt{r_0^2 + v_0^2 t^2} \quad ,$$

$$\theta(t) \equiv \arctan\frac{y}{x} = \arctan\frac{v_0 t}{r_0}$$

Ne seguono le espressioni

$$\dot{r}(t) = \frac{v_0^2 t}{r} \quad ,$$

$$\dot{\theta}(t) = \frac{v_0 r_0}{r^2}$$

Il modulo della velocità, calcolato usando le componenti in coordinate polari, vale

$$v^2 = \dot{r}^2(t) + r^2\dot{\theta}(t)$$

ed è uguale a v_0^2 come deve.

23-081 Il Cannoncino Sulla Giostra

Su una giostra di raggio R che ruota attorno al suo asse con velocità angolare costante Ω è sistemato un cannoncino, la cui bocca è situata esattamente sull'asse della giostra, che spara un proiettile con velocità v_0 parallela al suolo. Descrivere il moto del proiettile, dallo sparo al suo arrivo al bordo della giostra, dal punto di vista dell'osservatore solidale con la giostra e mostrare che i risultati che si ottengono sono equivalenti a quelli dell'osservatore solidale con il suolo.

WORKED SOLUTION

Si consideri il Reference Frame $\mathcal{A}$ solidale con il suolo (convenzionalmente il Reference Frame assoluto) e il Reference Frame $\mathcal{R}$ solidale con la giostra (convenzionalmente il Reference Frame relativo). Si fissino per i due Sistemi di Riferimento $\mathcal{A}$ e $\mathcal{R}$ i sistemi di coordinate xyz e $x'y'z'$, rispettivamente solidali con il suolo e con la giostra, e sia O l'origine del sistema di coordinate $x'y'z'$. I due sistemi di coordinate abbiano origine nel centro della giostra, gli assi z e z' coincidenti tra loro e con l'asse della giostra e gli assi x e x' coincidenti tra loro e con la direzione e verso del cannoncino all'istante dello sparo $t = 0$. Sia Ω la velocità angolare del Reference Frame $\mathcal{R}$ rispetto al Reference

Frame $\mathcal{A}$. Per l'osservatore solidale con il suolo il moto del proiettile è rettilineo e uniforme lungo l'asse x e il proiettile arriva dopo un tempo $\Delta t_B = R/v_0$ al bordo della giostra ($x_B = R$ e $y_B = 0$). Dal punto di vista dell'osservatore solidale con la giostra la velocità e l'accelerazione si esprimono come

$$\boxed{\mathbf{v}_A = \mathbf{v}_R + \mathbf{v}_T \implies \mathbf{v} = \{\mathbf{v}'\} + \{\mathbf{v}_O + \boldsymbol{\Omega}\wedge\mathbf{r}'\}}$$

$$\boxed{\mathbf{a}_A = \mathbf{a}_R + \mathbf{a}_T + \mathbf{a}_C \implies \mathbf{a} = \{\mathbf{a}'\} + \left\{\mathbf{a}_O + \dot{\boldsymbol{\Omega}}\wedge\mathbf{x}' + \boldsymbol{\Omega}\wedge\left(\boldsymbol{\Omega}\wedge\mathbf{x}'\right)\right\} + \{2\,\boldsymbol{\Omega}\wedge\mathbf{v}'\}} \qquad (23.09.20)$$

da cui segue

$$\begin{aligned} \mathbf{v}' &= \mathbf{v}_0 - \boldsymbol{\Omega}\wedge\mathbf{r}' \qquad \mathbf{v} = \mathbf{v}_0 \quad , \\ \mathbf{a}' &= -\,\boldsymbol{\Omega}\wedge\left(\boldsymbol{\Omega}\wedge\mathbf{r}'\right) - 2\,\boldsymbol{\Omega}\wedge\mathbf{v}' \qquad \mathbf{a} = \mathbf{0} \end{aligned}$$

La velocità angolare della giostra si esprime come

$$\boldsymbol{\Omega} = \Omega\mathbf{e}_3 = \Omega\mathbf{e}_3'$$

L'accelerazione di Coriolis diventa dunque

$$\mathbf{a}_C = 2\,\boldsymbol{\Omega}\wedge\mathbf{v}' = 2\Omega\left[\dot{r}\widehat{\mathbf{e}}_\theta - r\dot{\theta}\widehat{\mathbf{e}}_r\right]$$

Si noti che la componente radiale dell'accelerazione di Coriolis deriva da v_θ' mentre quella tangenziale deriva da v_r'
mentre l'accelerazione di trascinamento (che ha solo la componente dell'accelerazione centripeta) diventa

$$\mathbf{a}_T = \boldsymbol{\Omega}\wedge\left(\boldsymbol{\Omega}\wedge\mathbf{r}'\right) = \boldsymbol{\Omega}\left(\boldsymbol{\Omega}\cdot\mathbf{r}'\right) - \mathbf{r}'\Omega^2 = -r\Omega^2\widehat{\mathbf{e}}_r$$

Ne seguono le componenti radiale e tangenziale dell'accelerazione:

$$\mathbf{a}_r' = \left(r\Omega^2 + 2\Omega r\dot{\theta}\right)\widehat{\mathbf{e}}_r = \left(\ddot{r} - r\dot{\theta}^2\right)\widehat{\mathbf{e}}_r$$

$$\mathbf{a}_\theta' = \left(-2\Omega\dot{r}\right)\widehat{\mathbf{e}}_\theta = \left(2\dot{\theta}\dot{r} + r\ddot{\theta}\right)\widehat{\mathbf{e}}_\theta$$

L'equazione per le componenti tangenziali può essere integrata, dopo aver moltiplicato per r, ottenendo

$$r^2\dot{\theta} + r^2\Omega = cost \equiv 0 \qquad \text{vale zero per le condizioni iniziali a } t = 0$$

Ne segue, essendo r non identicamente nullo,

$$\dot{\theta} = -\Omega$$

Cioè la velocità angolare del proiettile nel Reference Frame solidale con la giostra è uguale e opposta alla velocità angolare della giostra. Lo spostamento angolare nell'intervallo di tempo Δt si trova allora dalla

$$\Delta\theta = -\Omega\Delta t$$

Usando il risultato trovato si può ricavare l'accelerazione radiale:

$$\mathbf{a}_r' = -r\Omega^2\widehat{\mathbf{e}}_r = \left(\ddot{r} - r\Omega^2\right)\widehat{\mathbf{e}}_r$$

da cui si deduce l'equazione del moto radiale $\ddot{r} = 0$. Le condizioni iniziali sono $r(t=0) = 0$ e $\dot{r}(t=0) = v_0$ (segue dalla espressione ricavata $\mathbf{v}' = \mathbf{v}_0 - \boldsymbol{\Omega}\wedge\mathbf{r}'$ quando $\mathbf{r}' = 0$). La legge del moto nel Reference Frame solidale con la giostra è dunque

$$r(t) = v_0 t$$

Anche per l'osservatore sulla giostra il proiettile raggiunge dunque il bordo della giostra dopo un intervallo di tempo $\Delta t_B = R/v_0$. Il Δt_B è lo stesso per i due Reference Frame in quanto nella Meccanica Classica gli intervalli di tempo sono assoluti e uguali per tutti gli osservatori. Lo spostamento angolare del proiettile mentre raggiunge il bordo vale dunque $\Delta\theta = -\Omega\Delta t_B = -\Omega R/v_0 < 0$ che è uguale ed opposto allo spostamento angolare della giostra nello stesso intervallo di tempo. A questo corrisponde uno spostamento ΔL misurato lungo il bordo della giostra pari a $\Delta L = R\Delta\theta = -v_b\Delta t_B < 0$ dove $v_b = \Omega R$ indica la velocità del bordo della giostra. Tale risultato

CC BY NC ND

è consistente con la descrizione dell'osservatore solidale con il suolo che vede il bordo della giostra ruotare in modo tale che, durante il tragitto del proiettile, il bordo ruota di una quantità pari a ΔL. L'analisi ha mostrato che la velocità radiale del proiettile misurata dai due osservatori è la stessa. Ciò è ovvio perché le coordinate radiali dei due Reference Frame coincidono sempre. Il valore assoluto della velocità vale costantemente v_0 per l'osservatore al suolo mentre aumenta nel tempo per l'osservatore solidale con la giostra

$$V = \sqrt{v_0^2 + r^2\Omega^2}$$

Infatti dall'equazione per $\mathbf{a}_\theta$ si ha che il proiettile è soggetto ad un'accelerazione tangenziale costante e con $\ddot{\theta} = 0$. Questo implica che $\theta(t)$ cresce linearmente col tempo. Poiché però anche $r(t)$ aumenta col tempo la componente tangenziale della velocità ($v'_\theta = r\dot{\theta}$) cresce. Si noti che $\mathbf{a}'_\theta$ deriva da v'_r ed è quindi costante, mentre $\mathbf{a}'_r$ deriva dall'accelerazione di trascinamento $\mathbf{a}_T$ e da v'_θ.

24.01 Introduction

© - QUOTE

Robert Weinstock: Am.J.Phys, , ..., ..., ...Ed., ... 29, 698 (1961); doi: 10.1119/1.1937555
We assume means for measuring time and length, and thus for measuring velocity and acceleration, as known; in brief, the kinematics of a particle relative to any given coordinate system stands available for use.
We accept the notion of a particle as a body whose linear dimensions are negligible compared with lengths we ordinarily measure; **as such it will be called point-particle**.
Our space is assumed to be euclidean, our relativity Galilean.

We assume tools and methods for measuring time and lengths, and thus for measuring velocity and acceleration, as known: the kinematics of a point-particle relative to any given Coordinate System in any given Reference Frame is known.

Space is euclidean.

Time is a universal parameter.

Galilean relativity is at work,

A **point-particle is a body whose linear dimensions are negligible compared with relevant dimensions** of our phenomena/models. we ordinarily measure; **as such it will be called point-particle**.

Except when stated otherwise, the systems will be assumed to be closed, that is contain a fixed set of particles.

- I use the term **Classical Mechanics** for the non-relativistic and non-quantum mechanics; also, the terms **Newtonian Mechanics** and|or **Galilean Mechanics** will be used as synonyms or as **Galilei-Newton Mechanics** .
- Relativistic mechanics will be normally mentioned as: **Relativistic Mechanics**.
- Quantum mechanics will be normally mentioned as: **Quantum Mechanics**.
- The term **mass** will normally mean **inertial mass**; when referring to gravitational mass the term **gravitational mass** will be normally used.
- Whenever the momentum of any vector is written without putting any subscript to indicate the pole, it is assumed that the momentum is independent on the pole.
- Tentatively, the following nomenclature will be used. Assume mass-points.

WIP - Work In Progress

- Force|Torque.
  - Force: $\mathbf{f}$, an applied vector in P.
  - Torque: $\tilde{\gamma}$, a momentum of forces independent from the pole; it is not necessarily built from a set of forces, but it may be elementary, as for ideal **Electric Dipoles** | **Magnetic Dipoles** .
  - Orbital momentum of forces with respect to the pole O: $\gamma_0 = (P-O)\wedge\mathbf{f}$.
  - Total momentum of the forces (or Total Torque) with respect to the pole O: $\gamma_0 = (P-O)\wedge\mathbf{f} + \tilde{\gamma}$.
- Linear momentum and angular momentum.
  - Linear momentum: $\mathbf{p}$, an applied vector in P.
  - Intrinsic Angular momentum or spin: $\mathbf{s}$, an intrinsic angular momentum independent from the pole; it is not necessarily built from a set of linear momenta, but it may be elementary.
  - Orbital angular momentum with respect to the pole O: $\ell_0 = (P-O)\wedge\mathbf{p}$.
  - Total angular momentum with respect to the pole O: $\ell_P = (P-O)\wedge\mathbf{p} + \mathbf{s}$.
- Force, torque and total torque as well as linear momentum, spin, and total angular momentum, form a **screw/torseur**, respectively in English/French, the object of screw theory [a].
- For a vector field:
  - sources|sinks are points where the divergence is different from zero;
  - vortexes are points where the rotor is different from zero.
- For ElectroMagnetic fields:
  - positive|negative charges are sources|sinks for electric fields;
  - currents are vortexes, as well as points where $\partial_t\mathbf{E} \neq 0$ or $\partial_t\mathbf{B} \neq 0$ are vortexes as well.
- To avoid a sloppy language, **the term *generator* will be tentatively used for sources|sinks|vortexes**.
- Beware, all this is not a universal nomenclature, as many different naming schemes and tastes do exist.

24.03 Modeling of mechanical systems and their evolution

- Define the **system**, read § 24.03.01.
- Determine the expressions for the **kinematical/dynamical quantities** of the system, read § 24.03.02.
- Determine the expressions for the **interactions of the system**, both internal and with the universe, read § 24.03.03.
- Determine how the system exchanges dynamical quantities with the universe: the **law of physics**.

Read § 24.03.04 for more details.

24.03.01 Systems

This § is referenced at pages:
[1289]

The definition of the **system** in physics is arbitrary, but a crucial one.

A system is well-defined whenever, for any entity, it can be unambiguously stated whether it belongs to the system or not. The complement of the system is generically called **universe**. Read also § 64.06.

It is very easy, in physics, to get things wrong due to a insufficiently precise definition/characterization of **the system**.

... since Dirac's natural introduction of the spin and derivation of the correct value for the **gyromagnetic ratio** in relativistic quantum mechanics, it is often believed that relativity is necessarily involved in these issue. In fact, spin has specifically nothing to do with relativity or quantum mechanics, but arises from the representations of the rotation group, which already plays a role in **Galilei-Newton Mechanics** . Furthermore, the expression for the **gyromagnetic ratio** , namely, the electron charge divided by its mass, does not contain the speed of light nor Planck's constant,

DRAFT - NEW - 1

so it probably has a non-relativistic, non-quantum origin.

A mass point is a geometrical point endowed with mass. It is the basic building block of all mechanics and physics. As such the mechanical concepts related to mass points are introduced at first.

The mass point, in the modern view of particle physics, corresponds to a spin-less particle.

However, for more generality, it is necessary to extend the concept.

© - QUOTE

©|H.C.Corben and P.Stehle|Classical Mechanics|*§ 78*|

...
In the definition of a particle given in Section 2, the only part of the description of a particle which could depend upon the time was taken to be its position. We now want to relax this restriction and consider a particle with an "intrinsic" angular momentum or spin, independent of the orbital motion of the particle but which may be subjected to torques and forces. In particular, we are interested in a spin of constant magnitude with which is associated a magnetic moment ...
... This particular system is interesting because it is a reasonable classical analogue to the quantum-mechanical electron of the Dirac theory. There the electron has a spin $\hbar/2$ which vanishes in the classical limit so that the analogy is not exact in the sense of the correspondence principle, but nonetheless certain features of interest emerge from a classical model.
...

24.03.02.01 Mass Points

This § is referenced at pages:
[2396]

The minimal and simplest system in **Galilei-Newton Mechanics** is the mass point, a geometrical point with an associated intrinsic property, the inertial mass, $m > 0$. In fact, in **Galilei-Newton Mechanics** massless particles do not exist, or, more precisely, even if they exist, they do not interact in any way with the rest of the universe.

Mass points are defined to only interact with the rest of the universe through forces: no torques, no other multiple interactions...

Mass points are endowed with another intrinsic property, the gravitational mass, describing the gravitational forces among particles.

It is a fundamental axiom that inertial mass and gravitational mass are coincident.

Mass points can be endowed with other intrinsic properties, generally called charges. A charged mass point (aka a point electric charge) is a mass point endowed with an additional intrinsic property, electric charge, describing electric forces. other charges, in the language of modern particle physics do exist, such as color charges, flavour charges, ... Note that the gravitational mass is one charge.

The Center-Of-Mass of any system is exactly a mass point.

L.D.Landau *et al.*, *Mechanics*, ..., ..., ...Ed., WEB - URL - ISBN: 978-0-7506-2896-9.
One of the fundamental concepts of mechanics is that of a particle. By this we mean a body whose dimensions may be neglected in describing its motion. The possibility of so doing depends, of course, on the conditions of the problem concerned. For example, the planets may be regarded as particles in considering their motion about the Sun, but not in considering their rotation about their axes.

© - QUOTE

©|S.Forte - Spin in Quantum Field theory|WEB - URL ||

Both in non-relativistic and relativistic theories, spin is one of the quantum numbers that classify elementary excitations.

© - QUOTE

©|E.Castellani - Galilean Particles|WEB - URL ||

Both in the non-quantum and quantum case, the characteristic invariant quantities one obtain by constructing the irreducible (projective) representations of the Galilei group are the mass m (as can be seen also from the relations representing the Lie brackets for the Galilei group generators), the internal energy (that is, the energy in the rest system) and a quantity which can be interpreted as an internal angular momentum or spin. It is known that the internal energy of an isolated particle is an arbitrary parameter.

Un punto materiale in **Galilei-Newton Mechanics** è un oggetto grande abbastanza da non essere un oggetto quantistico, ma piccolo abbastanza da poter essere trattato geometricamente come puntiforme, nell'ambito della sensibilità dell'esperimento. Da questo punto di vista può avere, come per un corpo rigido piccolo, una struttura interna: momento angolare intrinseco, dipolo, quadrupolo ...

In the modern view of particle physics, this amounts to generalize Newton spinless particle to particles with any spin.

It can be shown that, in all generality, particles can be classified according to their mass, internal energy and spin, according to the properties of the irreducible representations of the Galilei group.

Tale modello di un sistema è utile se e solo se le dimensioni del sistema sono trascurabili rispetto alle altre dimensioni in gioco e se gli eventuali gradi di libertà interni del sistema, ad eccezione dello spin, non intervengono in modo rilevante.

Si assume quindi che ogni particella sia caratterizzata da una massa e da un momento angolare di spin, il momento angolare della particella invariante per scelta del polo.

Tale definizione generalizza quella di punto materiale ed è utile, per esempio, per descrivere la fisica di un dipolo elettrico o magnetico ideali nonché dal fatto che le particelle elementari (pur non descrivibili, a rigore, attraverso la fisica classica) sono caratterizzate di un momento angolare intrinseco oltre che di una massa.

In ogni caso specifico occorre poi determinare:

1. il legame tra lo spin e le eventuali proprietà della particella, quali momento di dipolo elettrico o magnetico, o momenti di ordine superiore;
2. il legame cinematico (vincolo costitutivo) tra velocità e impulso;
3. il legame cinematico (vincolo costitutivo) tra velocità angolare e momento angolare, se ha senso, altrimenti si studia semplicemente la dinamica del vettore di spin;
4. la legge della Force|Torque che definiscono, per lo specifico sistema, la Force|Torque che agiscono sulla particella.

© - QUOTE

©|M.Rivas|kinematic theory of spinning particles: classical and quantum formalism||

In **Galilei-Newton Mechanics** the simplest geometrical object is a point of mass m. Starting with massive points we can construct arbitrary systems of any mass and shape, and thus any distribution of matter. The massive point can be considered as the elementary particle of **Galilei-Newton Mechanics** . In the modern view of particle physics it corresponds to a spin-less particle. We know that there exist **spinning objects** like electrons, muons, photons, neutrinos, quarks and perhaps many others, that can be considered as elementary particles in the sense that they cannot be considered as compound systems of other objects. Even more, we do not find in Nature any spin-less elementary particles (except for the Higgs boson, as of today). It is clear that the **Galilei-Newton Mechanics** point mass does not give account of the spin structure of particles and the existence of spin is a fundamental intrinsic attribute of an elementary particle, which is lacking in **Galilei-Newton Mechanics** , but it has to be accounted for.
In quantum mechanics, Wigner work on the representations of the non-homogeneous Lorentz group provides a very precise mathematical definition of the concept of elementary particle. An elementary particle is a quantum mechanical system whose Hilbert space of pure states is the representation space of a projective unitary irreducible representation of the Poincaré group. Irreducible representations of the Poincaré group are characterized by two invariant parameters m and $\mathfrak{s}$, the mass and the spin of the system, respectively. By finding the different irreducible representations, we can obtain the quantum description of massless and massive particles of any spin.

© - QUOTE

©|J.M.Lévy-Leblond|Non-Relativistic particles and wave equations|*WEB - URL*; *Comm. Math. Phys. 6 (1967)*, ...

This paper is devoted to a detailed study of non-relativistic particles and their properties, as described by Galilei invariant wave equations, in order to obtain a precise distinction between the specifically relativistic properties of elementary quantum mechanical systems and those which are also shared by non-relativistic systems. After having emphasized that spin, for instance, is not such a specifically relativistic effect, we construct wave equations for non-relativistic particles with any spin.

Spin is an intrinsic property of any particle. It was discovered by the Stern-Gerlach experiment. It appeared like a spinning electric charge, but nothing is actually spinning.
Also, spin is a conserved quantity, it is an intrinsic property.

© - QUOTE

©|S.Forte - Spin in Quantum Field Theory|WEB - URL ||

We see that spin is one of the three numbers which classify non-relativistic elementary excitations, along with mass and internal energy.
...
Summarizing, both in non-relativistic and relativistic theories, spin is one of the quantum numbers that classify elementary excitations. In quantum mechanics, the state vectors of physical systems are expanded on a basis of irreducible representations of the rotation group (in the non-relativistic case) or the Lorentz group (in the relativistic case). In quantum field theory, one-particle states are, respectively, Galilei or Poincaré irreducible representations. In the relativistic case, rotations are implicitly defined by the Pauli-Lubanski vector as the subgroup of the Lorentz group which leaves the Four-Momentum invariant.

© - QUOTE

©|R.J.Gould|The intrinsic magnetic moment of elementary particles|*WEB - URL; Am.J.Phys, , ..., ..., ...Ed., ...*

In fact, spin has specifically nothing to do with relativity or quantum mechanics, but arises from the representations of the rotation group, which already play a role in **Galilei-Newton Mechanics** . Furthermore, the expression for the **gyromagnetic ratio** , namely, the electron charge divided by its mass, does not contain the speed of light nor Planck constant, so it probably has a non relativistic, non quantum origin.

Starting with mass points one can construct arbitrary systems, of any mass, shape, properties, that is any distribution of matter. Other kinds of systems, defined as geometrical points with mass, may have additional properties, such as: electric charge, electric or magnetic **Dipole** moment, spin, electric or magnetic **Quadrupole** moments, ... (all in all generically called **particles**).

In general, a system is treated as a geometrical point whenever there is no experimental indication of a size larger than zero, within the present experimental capabilities (for instance, as of today, the electron). Moreover, whenever the system is known to be an extended system but its size is very much smaller than all other lengths relevant to the problem, it can be modeled as a point system. In general, it is possible whenever the internal structure and details are not relevant.

Many different models for physical systems do exist, some of the most common are listed below.

- A mass point, which is implicitly assumed to have no size (that is it is a geometrical point) and to be isotropic (it has zero spin). This is the mass point of **Galilei-Newton Mechanics** .
- A point charge, that is a mass point carrying a property (the electric charge) such that it is subject to the ElectroMagnetic force; it is implicitly assumed to have no size and to be isotropic (zero spin).
- A **spinning** mass point, which is a mass point with intrinsic angular momentum, that is it has no size but it is not intrinsically isotropic (spin greater than zero). No real **spinning** is implied by the definition!
- A **Dipole** : a mass point endowed with some intrinsic property defined by a vector, such as an electric or **Magnetic Dipole** moment, which is implicitly assumed to have no size and to be not isotropic; eventually it might have an electric charge and|or other charges.
- An elementary particle: a mass point with an intrinsic angular momentum whose module cannot change (as in quantum physics), which is implicitly assumed to have no size and to be not isotropic; eventually it might have an electric charge and|or other charges.
- A classical particle: a mass point endowed with an intrinsic angular momentum whose module can change, which is implicitly assumed to have no size and to be not isotropic.
- A particle: in its most general and generic sense this name will be used to refer to a point-like

cc BY NC ND

massive object, possibly with some other properties to be specified; it might possibly have an internal structure which is not taken into account, as discussed in section § 65.05.04. Particles are the recognizable units composing a system at any time. Therefore a particle can be either a point-like object or an extended object studied from distances much larger than its dimensions and whose internal structure is either ignored or modeled on top of the point-like object.

- ...

24.03.02.03 What Is Spin?

Spin is an internal degree of freedom of any particle.

24.03.02.04 Other Model Systems

- **A discrete system made of points**: mass points, **Dipoles** or particles, or others.
- A continuous system made of of mass points, **Dipoles** or particles, or others.
- A continuous fluid system made of mass points, **Dipoles** or particles, or others.
- A continuous solid system made of of mass points, **Dipoles** or particles, or others.
- A continuous elastic solid system made of of mass points, **Dipoles** or particles, or others.
- The so-called micro-polar media, solids or fluids
- A rigid-body.
- ...

When studying any system, a suitable model must be chosen. Some examples follow.

- An atom, as long as its internal state does not change, can be considered as a mass point endowed with (a possibly null) spin, that is as a particle.
- A ion can be modeled as an atom plus an electric charge.
- The Earth, in its motion around the Sun, can be considered, to a first approximation, as a rigid-body of negligible size, and modeled as a particle, that is a mass point endowed with an intrinsic angular momentum which may eventually change. When a more refined analysis is carried on one realizes that the Earth shape is deformed by tides such that the gravitational interaction between Earth and Sun cannot be simply described as the interaction of two point masses.

The mass point is a model which perfectly fits the Center-Of-Mass concept.

24.03.03 Modeling Interactions and Dynamical Quantities

This § is referenced at pages:
[1289]

Many complex systems can be modeled as made of a large number of point systems, regardless the specific model of point system one uses (such as mass points, point **Dipoles** , point particles or any others): the elementary constituents.

The laws of mechanics for the complex systems may then be often deduced from the laws of the elementary constituents. However, as a more general approach, one can assume the validity of the cardinal equations of mechanics as postulates, and use them to describe the mechanics of any system. The equations for the elementary constituents can be deduced, in any case, as particular cases of the general systems.

The two essential and preliminary steps, in order to study any system, are as follows.

- The definition of the dynamical quantities relevant to the description of the system: kinetic energy, linear momentum, angular momentum.
- The modeling of the interactions which can affect the physical system and originated by the universe, that is the definition of the mathematical form of the interaction with the universe, such as force and torque. Many systems can be described interacting via a force and|or torque only; However, other systems might require more complex interactions, such as a **Quadrupole** moment interaction. Work/power and potential energy are thus also defined.

DRAFT - INTERNAL USE ONLY

CC BY NC ND

Note that, in general, fields also are typically present, which need to be accounted for in the modeling of the systems (interactions and dynamical quantities).

24.03.03.01 Superposition Principle of Interactions

This § is referenced at pages:
[1033]

The superposition principle of the interactions is assumed to hold: whenever any system is subject to any external Force|Torque|Interaction, the resulting interaction can be found by summing (typically a vector sum) the different Force|Torque|Interaction.

That is, Force|Torque (and other interactions) belong to a vector space, that is they add linearly according to a vector sum.

24.03.04 Synopsis - the Logical Structure of Mechanics

This § is referenced at pages:
[1289]

- Definition of the system: define which objects belongs to the systems and which of the objects do not; clearly and unambiguously define the boundary surface separating the system from the rest of the universe.
- Decide the model for the system: simple enough and detailed enough for the problems under study. Simple enough to be tractable; complex enough to be sensitive to what is of interest. Do understand which effects need to be included and which can be excluded.
  - Define the model.
    - Any point particle has strictly positive mass and greater or equal zero spin.
    - Discrete/continuous systems: always built with point particles.
  - Define the mechanical quantities for the model system: mass, linear momentum, angular momentum (including spin, if any), kinetic energy, work and potential energy. Use general properties:
    - additivity over subsystems;
    - the Center-Of-Mass;
    - general properties such as **Koënig theorem** ;
    - ....
  - Define the interactions for the model system: forces, torques, others, ... Which interactions are relevant for the problem? Which interactions can be neglected, given the task?
  - Choose a suitable Reference Frame and, in the Reference Frame, a suitable Coordinate System. Time is an absolute parameter, the same for all observers. Each observer lives in a euclidean 3D space.
  - Use general properties: the **superposition principle** , **Galilei-Invarian*** , ...
- Implement the axioms: the law of inertia and the three **Cardinal Equations** .
  - Put into the laws the mechanical quantities and the interactions and do predictions to falsify the theory.
  - Once a result is found, that is a prediction can be made, make sure it is not manifestly wrong: check dimensions, limiting cases of the parameters, plausibility of numerical results.
  - Experiments are the only check for physics.

24.04 Dynamical Quantities

24.04.01 Properties of Dynamical Quantities

© - QUOTE

L.D.Landau *et al.*, *Mechanics*, ..., ..., ...Ed., WEB - URL - ISBN: 978-0-7506-2896-9.
Not all integrals of the motion, however, are of equal importance in mechanics. There are some whose constancy is of profound significance, deriving from the fundamental homogeneity and isotropy of space and time. The quantities represented by such integrals of the motion are said to be conserved, and have an important common property of being additive: their values for a system composed of several parts whose interaction is negligible are equal to the sums of their values for the individual parts. - It is to this additivity that the quantities concerned owe their especial importance in mechanics. Let us suppose, for example, that two bodies interact during a certain interval of time. Since each of the additive integrals of the whole system is, both before and after the interaction, equal to the sum of its values for the two bodies separately, the conservation laws for these quantities immediately make possible various conclusions regarding the state of the bodies after the interaction, if their states before the interaction are known.

24.04.01.01 Mass

©|https://arxiv.org/abs/1501.07489|mass additivity||

Mass is an intrinsic property in **Galilei-Newton Mechanics** .
Mass of any system is, by definition, a quantity additive over sub-systems. That is, additivity of mass is the good way to define mass such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.
In **Galilei-Newton Mechanics** mass for and isolated system is a conserved quantity if and only if the total linear momentum for an isolated system is conserved; this follows from Galilei invariance, read § 24.10.04.
The principle of mass additivity states that the mass of a composite object is the sum of the masses of its elementary components.
Mass additivity is true in **Galilei-Newton Mechanics** , but false in relativistic physics.
That mass is additive is an empirical fact, in **Galilei-Newton Mechanics** , which we use without question in constructing our physical and mathematical models of the universe.

24.04.01.02 Linear Momentum

linear momentum of any system, is, by definition, a quantity additive over sub-systems. That is, additivity of linear momentum is the good way to define linear momentum such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.
In **Galilei-Newton Mechanics** the total linear momentum for and isolated system is a conserved quantity if and only if mass for an isolated system is conserved; this follows from Galilei invariance, read § 24.10.04.
linear momentum, **P**, is, by definition, a quantity additive over sub-systems. That is, additivity of linear momentum is the good way to define linear momentum such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.

D.-N.-PROGRESS

Galilei Transformation

Given two Inertial Reference Frame , $\mathcal{I}$ and $\mathcal{I}'$, such that the velocity of $\mathcal{I}'$ with respect to $\mathcal{I}$ is $\mathbf{V}$, the linear momentum of any (sub-)system transform as:

$$\boxed{\mathbf{P} = \mathbf{P}' + M\mathbf{V} \qquad \textbf{Galilei Transformation}} \quad .$$

24.04.01.03 Angular Momentum

Angular momentum of any system is, by definition, a quantity additive over sub-systems. That is, additivity of angular momentum is the good way to define angular momentum such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.

Total angular momentum with respect to any pole is given, in general, by an orbital angular momentum $\mathbf{L}$, plus an intrinsic, or spin, angular momentum, $\mathbf{S}$:

$$\boxed{\mathbf{J} = \mathbf{L} + \mathbf{S}} \quad .$$

Orbital angular momentum changes according to the usual law of change of momentum when changing the pole:

$$\boxed{\mathbf{L}_B = \mathbf{L}_A + \mathbf{x}_{AB} \wedge \mathbf{P} = \mathbf{L}_A + (\mathbf{x}_A - \mathbf{x}_B) \wedge \mathbf{P} = \mathbf{L}_A + (A - B) \wedge \mathbf{P}} \quad , \qquad (24.04.01)$$

→ 1394

dove $\mathbf{x}_{AB} \equiv \mathbf{x}_A - \mathbf{x}_B \equiv A - B$ è il vettore posizione del polo A rispetto al polo B.

It is seen from this formula that the angular momentum depends on the choice of origin except when the system is at rest as a whole $\mathbf{P} = 0$.

Spin is the part of the angular momentum which is invariant with respect to the choice of the pole.

Angular Momentum is, by definition, a quantity additive over sub-systems That is, additivity of angular momentum is the good way to define angular momentum such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.

Galilei Transformation

GO TO AFTER included File

We may also derive a relation between the angular momenta in two inertial frames of reference K and K', of which the latter moves with velocity $\mathbf{V}$ relative to the former. We shall suppose that the origins in the frames K and K' coincide at a given instant. Then the radius vectors of the particles are the same in the two frames, while their velocities are related by $\mathbf{v}_a = \mathbf{v}_a' + \mathbf{V}$. Hence we have

$$\mathbf{M} = \sum_a m_a \mathbf{r}_a \times \mathbf{v}_a = \sum_a m_a \mathbf{r}_a \times \mathbf{v}_a' + \sum_a m_a \mathbf{r}_a \times \mathbf{V}.$$

The first sum on the right-hand side is the angular momentum $\mathbf{M}'$ in the frame K'; using in the second sum the radius vector of the centre of mass (8.3), we obtain

$$\mathbf{M} = \mathbf{M}' + \mu \mathbf{R} \times \mathbf{V}. \tag{9.5}$$

This formula gives the law of transformation of angular momentum from one frame to another, corresponding to formula (8.1) for momentum and (8.5) for energy.

If the frame K' is that in which the system considered is at rest as a whole, then $\mathbf{V}$ is the velocity of its centre of mass, $\mu\mathbf{V}$ its total momentum $\mathbf{P}$ relative to K, and

$$\mathbf{M} = \mathbf{M}' + \mathbf{R} \times \mathbf{P}. \tag{9.6}$$

In other words, the angular momentum $\mathbf{M}$ of a mechanical system consists of its "intrinsic angular momentum" in a frame in which it is at rest, and the angular momentum $\mathbf{R} \times \mathbf{P}$ due to its motion as a whole.

GO TO BEFORE included File

Given two Inertial Reference Frame , $\mathcal{I}$ and $\mathcal{I}'$, such that the position of the origin of $\mathcal{I}'$, $\mathcal{O}'$, with respect to the origin of $\mathcal{I}$, $O \equiv \mathcal{O}$, is $\mathbf{R}$ and the velocity of $\mathcal{I}'$ with respect to $\mathcal{I}$ is $\mathbf{V} \equiv \dot{\mathbf{R}}$, the orbital angular momentum with respect to the pole $O \equiv \mathcal{O}$ of any (sub-)system transforms as:

$$\boxed{\mathbf{L}_0 = \mathbf{L}_0{}' + \mathbf{R}\wedge\mathbf{P} \qquad \textbf{Galilei Transformation}} \quad .$$

In fact:

$$\mathbf{r} = \mathbf{r}' + \mathbf{R} \equiv P - O \quad ,$$
$$\mathbf{v} = \mathbf{v}' + \mathbf{V} \quad ,$$
$$\mathbf{L}_0 \equiv \sum_a \mathbf{r}_a\wedge\mathbf{p}_a = \sum_a \mathbf{r}_a\wedge m_a\left(\mathbf{v}'_a + \mathbf{V}\right) = \sum_a m_a\mathbf{r}_a\wedge\mathbf{v}'_a + \sum_a m_a\mathbf{r}_a\wedge\mathbf{V} = \mathbf{L}_0{}' + M\,\mathbf{R}\wedge\mathbf{V} = \mathbf{L}_0{}' + \mathbf{R}\wedge\mathbf{P} \quad .$$

Note: $\mathbf{L}_0{}'$ is the same orbital angular momentum with respect to the same pole as $\mathbf{L}_0$, as seen from another Reference Frame.

24.04.01.04 Work

The work done on any system, $\mathcal{W}$, is, by definition, a quantity additive over sub-systems. That is, additivity of work is the good way to define work such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.

24.04.01.05 Kinetic Energy

Kinetic energy of any system, $\mathcal{K}$, is, by definition, a quantity additive over sub-systems. That is, additivity of kinetic energy is the good way to define kinetic energy such that it is a useful quantity in the formulation of **Cardinal Equations** . This is an experimental fact.

24.04.01.06 Energy

©|L.D.Landau *et al.*, *Mechanics*, ..., ..., ...Ed., WEB - URL - ISBN: 978-0-7506-2896-9.|||

The energy of a mechanical system which is at rest as a whole is usually called its internal energy, $\mathcal{U}$. This includes the kinetic energy of the relative motion of the particles in the system and the potential energy of their interactions plus the rest masses of the constituents, read § 65.05.

Galilei Transformation of Energy

The total energy of a system moving as a whole with velocity $\mathbf{V}$ can be written as:

$$\mathcal{E} = \frac{1}{2}mV^2 + \mathcal{U} \quad . \tag{24.04.02}$$

→ 1299

Although his formula is fairly obvious, we may give a direct proof of it. Given two Inertial Reference Frame , $\mathcal{I}$ and $\mathcal{I}'$, such that the velocity of $\mathcal{I}'$ with respect to $\mathcal{I}$ is $\mathbf{V}$, the energy of any mechanical (sub-)system transform as:

$$\boxed{\mathcal{E} = \mathcal{E}' + \mathbf{V}\cdot\mathbf{P}' + \frac{1}{2}mu^2 \qquad \textbf{Galilei Transformation}} \quad .$$

If the Center-Of-Mass of the system is at rest in $\mathcal{I}'$, then: $\mathcal{E}' = \mathcal{U}' = \mathcal{U}$ and $\mathbf{P}' = 0$; therefore one finds equation (24.04.02). Note the invariance of the internal energy:

$$\boxed{\mathcal{U}' = \mathcal{U}} \quad .$$

DRAFT IN PROGRESS

24.04.02
Dynamical Quantities for Point Particles

Common meaningful definitions for point particles are recalled here.

The definition of the dynamical quantities relevant to the description of other systems - linear momentum, angular momentum, kinetic energy - depend on the model system.

Point-particles, defined by a mass and a spin, $\mathbf{s}$, and located at $\mathbf{r}$, subject to forces and torques are considered in this section:

$$\boxed{\mathbf{f}[\mathbf{r}] \qquad \boldsymbol{\gamma}_0[\mathbf{r}] = \mathbf{r}\wedge f[\mathbf{r}] + \tilde{\boldsymbol{\gamma}}[\mathbf{s}] \equiv (P-O)\wedge\mathbf{f}[\mathbf{r}] + \tilde{\boldsymbol{\gamma}}[\mathbf{s}]} \quad .$$

24.04.02.01 Linear Momentum

$$\boxed{\mathbf{p} \equiv m\mathbf{v}} \quad .$$

24.04.02.02 Angular Momentum

$$\boxed{\mathbf{j}_O \equiv \boldsymbol{\ell}_O + \mathbf{s} \equiv (\mathbf{r}-\mathbf{r}_O)\wedge\mathbf{p} + \mathbf{s} \qquad \text{with respect to pole O}} \quad .$$

24.04.02.03 Work

Work Due to Displacement of the Point of Application of the Force for a mass-point

Il lavoro compiuto nello spostamento di un point particle da una configurazione posizionale iniziale $\mathbf{x}_1$ ad una configurazione posizionale finale $\mathbf{x}_2$, lungo una curva C_x, nello spazio della configurazione di posizione, da parte di una forza $\mathbf{f}$ è dato da:

$$\boxed{w \equiv \int_{C_x} \mathbf{f}\cdot \mathrm{d}\mathbf{x}} \quad ,$$

e la potenza sviluppata

$$\boxed{\pi \equiv \frac{\mathrm{d}w}{\mathrm{d}t} = \mathbf{f}\cdot\mathbf{v}} \quad .$$

Consider a force, $\mathbf{f}$, applied in P, and a fixed axis, $\hat{\mathbf{n}}$ passing by the pole O; let $\parallel$ and $\perp$ refer to the plane defined by P, O and $\hat{\mathbf{n}}$; let $\mathbf{x} = P - O$.

$$\mathrm{d}\mathbf{x} = \mathrm{d}\mathbf{x}_{\parallel} + \mathrm{d}\mathbf{x}_{\perp} \quad ,$$

$$\mathbf{f}\cdot\mathrm{d}\mathbf{x} = \mathbf{f}\cdot\mathrm{d}\mathbf{x}_{\parallel} + \mathbf{f}\cdot\mathrm{d}\mathbf{x}_{\perp} \quad ,$$

$$\mathbf{f}\cdot\mathrm{d}\mathbf{x} = \mathbf{f}\cdot\mathrm{d}\mathbf{x}_{\parallel} + \mathbf{f}\cdot(\mathrm{d}\boldsymbol{\theta}\wedge\mathbf{x}) = \mathbf{f}\cdot\mathrm{d}\mathbf{x}_{\parallel} + \mathrm{d}\boldsymbol{\theta}\cdot(\mathbf{x}\wedge\mathbf{f}) = \mathbf{f}\cdot\mathrm{d}\mathbf{x}_{\parallel} + \boldsymbol{\gamma}_0\cdot\mathrm{d}\boldsymbol{\theta} \quad .$$

So the **arm** part of the total torque on the particle is described by the $\mathbf{f}\cdot\mathrm{d}\mathbf{x}$ term.

Note that, here, $\mathrm{d}\boldsymbol{\theta}$ is the rotation around the external axis, $\hat{\mathbf{n}}$, of the point-particle, described by the external degree of freedom $\boldsymbol{\theta}$.

DRAFT - IN PROGRESS

Work Due to Intrinsic Rotation Caused by the Torque for a mass-point

Il lavoro compiuto nella rotazione intrinseca di un point particle dotata di una proprietà intrinseca direzionale (come un momento di dipolo), da una configurazione angolare iniziale $\tilde{\boldsymbol{\theta}}_1$ ad una configurazione angolare finale $\tilde{\boldsymbol{\theta}}_2$ (dove i $\tilde{\boldsymbol{\theta}}$ non sono vettori), lungo una curva $C_{\tilde{\theta}}$, da parte di un torque, $\tilde{\boldsymbol{\gamma}}$, indipendente dal polo, è dato da:

$$\boxed{w \equiv \int_{C_{\tilde{\theta}}} \tilde{\boldsymbol{\gamma}} \cdot \mathrm{d}\tilde{\boldsymbol{\theta}}} \quad ,$$

e la potenza sviluppata

$$\boxed{\pi \equiv \frac{\mathrm{d}w}{\mathrm{d}t} = \tilde{\boldsymbol{\gamma}} \cdot \tilde{\boldsymbol{\omega}}} \quad .$$

So the $\tilde{\boldsymbol{\gamma}} \cdot \mathrm{d}\tilde{\boldsymbol{\theta}}$ only includes the **intrinsic** (torque) part of the total torque on the particle.

Note that, here, $\mathrm{d}\tilde{\boldsymbol{\theta}}$ is the intrinsic rotation, described by the internal degree of freedom $\tilde{\boldsymbol{\theta}}$.

General mass-point

In generale il lavoro dipende dal cammino percorso C_x e $C_{\tilde{\theta}}$ e:

$$\boxed{\pi \equiv \frac{\mathrm{d}w}{\mathrm{d}t} = \mathbf{f} \cdot \mathbf{v} + \tilde{\boldsymbol{\gamma}} \cdot \tilde{\boldsymbol{\omega}}}$$

Se su un point particle agiscono più Force|Torque il lavoro totale compito sul point particle è, per definizione, la somma dei lavori compiuti dalle Force|Torque.

Per sistemi composti da più punti materiali, il lavoro è definito come la somma dei lavori compiuti su tutte i punti materiali.

General Work

In general, for every system, the correct and specific expression of work has to be defined.

24.04.02.04 Kinetic Energy

L'energia cinetica di una point particle è definita, in tutta generalità, dalla relazione

$$\boxed{k \equiv \frac{1}{2} m v v} \quad ,$$

in termini della velocità, v, e della massa, scalare positivo.

L'energia cinetica di una point particle dotata di una proprietà intrinseca direzionale (come un momento di dipolo), in tutta generalità, dalla relazione

$$\boxed{k \equiv \frac{1}{2} \mathbb{I}_{rs} \omega_r \omega_s} \quad ,$$

in termni della velocità angolare, $\boldsymbol{\omega}$, e del tensore simmetrico di inerzia, $\mathbb{I}$, positivo definito.

24.04.02.05 Potential Energy

Per una point particle dotata di una proprietà intrinseca direzionale (come un momento di dipolo), in un campo di Force|Torque conservative si può definire in tutta generalità, la differenza di energia potenziale tra due configurazioni (2) ed (1)

$$\boxed{-\mathrm{d}u[\mathbf{x}; \tilde{\boldsymbol{\theta}}] = \mathbf{f} \cdot \mathrm{d}\mathbf{x} + \tilde{\boldsymbol{\gamma}} \cdot \mathrm{d}\tilde{\boldsymbol{\theta}}} \quad . \tag{24.04.03}$$

→ 1302

In termini dell'energia potenziale la Force|Torque si esprime come

$$\boxed{\mathbf{f} = -\mathbf{grad}_{\mathbf{x}} u \qquad \tilde{\boldsymbol{\gamma}} = -\mathbf{grad}_{\tilde{\theta}} u}$$

DRAFT IN PROGRESS

La funzione scalare energia potenziale è definita a meno di una costante additiva arbitraria in quanto in base alla (24.04.03) solo la differenza di energia potenziale è definita.

Il bilancio dell'energia meccanica, $e \equiv k + u$, è

$$\boxed{\Delta e = \Delta k + \Delta u = w_{\text{NC}}} \quad . \tag{24.04.04}$$

→ 1349

dove w_{NC} è il lavoro delle Force|Torque non conservative o, in generale, di tutte le forze il cui contributo non è incluso nell'energia potenziale u.

Per una mass point tale che $w_{\text{NC}} = 0$ si conserva l'energia meccanica

$$e \equiv k + u \quad .$$

24.04.03
Dynamical Quantities for General Systems

Start from a generic system made of n particles, in the continuum limit. Here the word particle must be interpreted with the general meaning of physical system with certain known physical properties and modeled as a geometrical point.

La massa, la quantità di moto, il momento angolare e l'energia cinetica del sistema sono definite come la somma delle rispettive quantità di tutte le particelle che compongono il sistema:

$$M \equiv \sum_{j=1}^{n} \mathbf{m}_j \to \int \mathbb{d}m \qquad \mathbf{P} \equiv \sum_{j=1}^{n} \mathbf{p}_j \to \int \mathbb{d}\mathbf{p} \qquad \mathbf{J} \equiv \sum_{j=1}^{n} (\mathbf{s}_j + \mathbf{l}_j) \to \int (\mathbb{d}\mathbf{s} + \mathbb{d}\mathbf{l}) \qquad \mathcal{K} \equiv \sum_{j=1}^{n} k_j \to \int \mathbb{d}k \quad .$$

Il lavoro compiuto sul sistema da un sistema di forze è definito come la somma dei lavori fatti su tutte le particelle, e la variazione di energia potenziale del sistema è definita come la variazione delle energie potenziali di tutte le particelle:

$$W[A\Gamma B] = \sum_{j=1}^{n} w_j[A\Gamma B] \qquad \Delta\Phi[AB] = \sum_{j=1}^{n} \Delta u_j[AB] \quad .$$

Note that fields also are typically present, which need to be accounted for in the modeling of the systems as they can carry dynamical quantities.

24.04.04
Center-Of-Mass

24.04.04.01 Definition

Si dice centro di massa di un sistema di particelle il punto:

$$\mathbf{X}_{\text{CM}} = \frac{\sum_j m_j \mathbf{x}_j}{M} \quad .$$

Dalla definizione segue:

$$\mathbf{V}_{\text{CM}} = \frac{\sum_j m_j \mathbf{v}_j}{M} \qquad \mathbf{A}_{\text{CM}} = \frac{\sum_j m_j \mathbf{a}_j}{M} \qquad \mathbf{P} = M\mathbf{V}_{\text{CM}} \quad .$$

The center of mass is a geometrical point which can be external to the body.

An equivalent definition for the Reference Frame of the Center-Of-Mass, which results a better one beyond **Galilei-Newton Mechanics** , is: the translating Reference Frame such that the sum of the momenta is zero.

DRAFT-IN-PROGRESS

24.04.04.02 Some Properties

Proprietà Distributiva Del Center-Of-Mass

Dalla definizione stessa segue che il centro di massa di un sistema si può calcolare suddividendo il sistema in due sottosistemi arbitrari, la cui intersezione è nulla e la cui unione è il sistema originale, e calcolando i centri di massa dei due sottosistemi.

Il centro di massa del sistema complessivo si trova come la media pesata dei centri di massa dei due sottosistemi, usando come pesi le masse dei due sottosistemi stessi (cioè è il centro di massa dei due centri di massa assumendo la massa dei due sottositei concentrata nei due centri di massa).

Tale proprietà può essere usata anche per calcolare il centro di massa di un sistema per sottrazione, in presenza di buchi.

The demonstration is trivial from the definition of Center-Of-Mass.

I Teoremi Di Pappo-Guldino Sul Center-Of-Mass

©|T.M.Apostol, *Calculus Vol. 1,2*, 1967/1969, J.Wiley & Sons, ...Ed., ...|Vol. 2, 11.17 , 2nd edition||

Consider any homogeneous solid; the following results, being purely geometrical, are only true for homogeneous solids.

La superficie di un solido di rotazione, generato dalla rotazione di una linea piana attorno ad un asse che giace nel piano della linea e che non interseca la linea stessa, è data dal prodotto della lunghezza della linea per la lunghezza della circonferenza percorsa nella rotazione dal centro di massa della linea.

Il volume di un solido di rotazione, generato dalla rotazione di una superficie piana attorno ad un asse che giace nel piano della superficie e che non interseca la superficie stessa, è dato dal prodotto dell'area della superficie per la lunghezza della circonferenza percorsa nella rotazione dal centro di massa della superficie.

WORK - IN - PROGRESS

24.05

Axiom 1 - the Inertia Principle

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|||

There exists a class of Reference Frame, the Inertial Reference Frames , with respect to which a free mass-point moves with uniform rectilinear motion.

A free mass-point is a point far enough from all others objects with which it can interact. In fact, it is assumed that interactions are always produced by the **presence of others nearby objects** and that the **intensity of all interactions decreases when increasing the distance** away from such objects.

Obviously the concept of a free mass-point is an abstraction, but there are methods to verify the inertiality of a Reference Frame (for instance the **Focault Pendulum** , read § 24.21.15). Consequently, the concept of Reference Frame is also an abstraction.

The principle of inertia therefore defines the Reference Frames where the principles of mechanics apply.

Note that inertial frames need not have existed at all, and **the fact that they do exist is the real physical content of the First Law.**

DRAFT - IN-PROGRESS

24.06 Axiom 2 - the Cardinal Equations

The Cardinal equations characterizes how a system interact with the universe.
Consider any system made of arbitrary objects.
Assume any interaction satisfies the **superposition principle** .

DRAFT IN PROGRESS

24.06.01
Second Newton Law

Per una particella puntiforme dotata di quantità di moto $\mathbf{p}$ e momento angolare intrinseco $\mathbf{s}$, lo spin, se $\mathbf{f}$ è la forza totale che agisce sulla particella, e $\boldsymbol{\gamma}$ il momento totale che agisce sulla particella, con polo la posizione, P, della particella stessa, si ha:

$$\boxed{\mathbf{f} = \frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} \qquad \boldsymbol{\gamma} = \frac{\mathrm{d}\mathbf{s}}{\mathrm{d}t}} \quad . \tag{24.06.01}$$

→ 1305

Tale enunciato generalizza la seconda legge della dinamica al caso in cui la particella puntiforme oltre ad essere dotata di quantità di moto è dotata anche di un momento angolare intrinseco, lo spin. Tale contributo è fondamentale, ad esempio, nella trattazione dei dipoli elettrici e magnetici o nella trattazione delle particelle elementari.

From the conceptual point of view, equation (24.06.01) defines the total Force|Torque acting on the point particle. Using a suitable Force|Torque law predictions and Falsifiability are possible.

Dalla relazione (24.06.01), fissato un polo arbitrario O, e detto P il punto in cui è posizionata la particella, si deduce la relazione equivalente

$$\boxed{\boldsymbol{\gamma}_O = \frac{\mathrm{d}\mathbf{j}_O}{\mathrm{d}t}} \quad . \tag{24.06.02}$$

In fact,

$$\mathbf{r} \equiv (P - O) \qquad \mathbf{j}_O \equiv \boldsymbol{\ell}_O + \mathbf{s} \qquad \boldsymbol{\gamma}_P = \frac{\mathrm{d}\mathbf{s}}{\mathrm{d}t} \qquad \mathbf{r} \wedge \mathbf{f} = \frac{\mathrm{d}\boldsymbol{\ell}_O}{\mathrm{d}t} \qquad \boldsymbol{\gamma}_O = \boldsymbol{\gamma}_P + \mathbf{r} \wedge \mathbf{f} \quad .$$

24.06.02
First Cardinal Equation (Principle of Linear Momentum)

Let $\mathbf{F}^{(\mathrm{E})}$ be the resultant of external forces and $\mathbf{P}$ the total linear momentum of the system.

The first **Cardinal Equation** of mechanics (a postulate, in fact) reads:

$$\boxed{\mathbf{F}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{P}}{\mathrm{d}t}} \quad , \tag{24.06.03}$$

→ 1306 1327

that is:

$$\boxed{\mathbf{F}^{(\mathrm{E})} = 0 \qquad \Leftrightarrow \qquad \mathbf{P} = \text{constant}} \quad .$$

The total force on a system is a frame-independent quantity.

The first **Cardinal Equation** of mechanics, for closed systems, can be also written in terms of Center-Of-Mass kinematics:

$$\boxed{\mathbf{F}^{(\mathrm{E})} = M\mathbf{A}_{\mathrm{CM}}} \quad , \tag{24.06.04}$$

if and only if M is constant.

Thus, the Center-Of-Mass of any system moves as a mass point with mass equal to the total mass of the system and subject to the resultant of external forces. Equivalently, the motion of the Center-Of-Mass is only affected by the resultant of external forces.

CC BY NC ND

24.06.03
Second Cardinal Equation (Principle of Angular Momentum)

Let $\mathbf{\Gamma}_O^{(\mathrm{E})}$ be the resultant of the momenta of the external Force|Torque with respect to the pole O and and $\mathbf{J}_O^{(\mathrm{E})}$ the total angular momentum of the system with respect to the pole O.

The second **Cardinal Equation** of mechanics (a postulate, in fact) reads:

$$\boxed{\mathbf{\Gamma}_O^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{J}_O}{\mathrm{d}t} + \mathbf{v}_O \wedge \mathbf{P}} \quad . \tag{24.06.05}$$

→ 1327 1339

The equation reduces to the simpler form

$$\mathbf{\Gamma}_O^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{J}_O}{\mathrm{d}t}$$

in the case the pole is fixed in the chosen Reference Frame ($\mathbf{v}_O = 0$), in case the pole is at the Center-Of-Mass ($O = \mathrm{CM}$), or when $\mathbf{v}_O \parallel \mathbf{P}$. In all these cases, when $\mathbf{v}_O \wedge \mathbf{P} = 0$, one has:

$$\boxed{\mathbf{v}_O \wedge \mathbf{P} = 0 \implies \left\{ \mathbf{\Gamma}_O^{(\mathrm{E})} = 0 \qquad \Leftrightarrow \qquad \mathbf{J}_O = \text{constant} \right\}} \quad .$$

The total torque on a system is a frame-independent quantity.

It should be emphasized that, in the most general case, the total torque about any pole is given by the sum of the momenta of the single forces plus the sum of the momenta of all torques, schematically:

$$\boxed{\mathbf{\Gamma}_O = (\mathbf{x}_P - \mathbf{x}_O) \wedge \mathbf{f} + \tilde{\gamma}} \quad .$$

When using the Center-Of-Mass as the pole one has the second **Cardinal Equation** in the form resembling equation (24.06.03) as:

$$\boxed{\mathbf{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{J}_{\mathrm{CM}}}{\mathrm{d}t}} \quad . \tag{24.06.06}$$

→ 1457

That is, the motion of any system about its Center-Of-Mass is only affected by the resultant of external Force|Torque.

24.06.04
Third Cardinal Equation (Principle of Energy)

The third **Cardinal Equation** (a postulate, in fact) is the work-energy theorem, which also includes, at variance from the first two equations, the contribution from internal interactions:

$$\boxed{\frac{\mathrm{d}W^{(\mathrm{E})}}{\mathrm{d}t} + \frac{\mathrm{d}W^{(\mathrm{I})}}{\mathrm{d}t} = \frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} \qquad \Leftrightarrow \qquad W^{(\mathrm{E})} + W^{(\mathrm{I})} = \Delta\mathcal{K}} \quad . \tag{24.06.07}$$

→ 1328 1330

In principle, both internal and external forces can be conservative or not. Any conservative interaction can be described either as work or as potential energy; of course one and only one of the two must be included. The third **Cardinal Equation** thus can be written as an energy balance:

$$\boxed{\Delta\mathcal{K} + \Delta\mathcal{U}^{(\mathrm{E})} + \Delta\mathcal{U}^{(\mathrm{I})} = W_{\mathrm{NC}}^{(\mathrm{E})} + W_{\mathrm{NC}}^{(\mathrm{I})} + W_{\mathrm{CNU}}^{(\mathrm{E})} + W_{\mathrm{CNU}}^{(\mathrm{I})}} \quad . \tag{24.06.08}$$

→ 1330

where NC means **non conservative** and CNU means **conservative interactions not included in potential energy**.

DRAFT IN PROGRESS

24.06.05
Cardinal Equations of a Generic System

Note that the **Cardinal Equations** , seven scalar equations in total, are not, in general, equivalent to the set of all equations of motion of all particles. In general, they are a consequence of all the equations of motion of all particles, but the vice versa is not true.

It can be observed that while in some particular cases of simple systems some of the seven equations may be dependent on each other, in the case of generic systems the **Cardinal Equation** are, in general, among themselves independent. Simple cases such that less than the seven equations are are sufficient: a material point, a rigid body and any flat system.

In general, **Cardinal Equations** can be applied not only to any system but to any sub-system, while taking into account the **superposition principle** .

24.06.06
Conserved Quantities for Isolated Systems

This § is referenced at pages:
[Never referenced.]

©|WEB - URL |||

From the first **Cardinal Equations** for isolated system one finds two constants of motion:

$$\boxed{\mathbf{A}_{CM} = 0 \implies \mathbf{X}_{CM}[t] = \mathbf{X}^0_{CM} + t\mathbf{V}_{CM} \qquad \mathbf{X}^0_{CM} = \text{constant} \qquad \mathbf{V}_{CM} = \text{constant}} \quad , \tag{24.06.09}$$

$$\boxed{\frac{\mathrm{d}\mathbf{P}}{\mathrm{d}t} = 0 \implies \mathbf{P} = \text{constant}} \quad , \tag{24.06.10}$$

$\boxed{M = \text{constant}}$ from the above and from **Galilei-Invarian*** as in equation , (24.06.11)

$$\boxed{\mathbf{K} \equiv M\mathbf{X}^0_{CM} = M\mathbf{X}_{CM}[t] - t\mathbf{P} = \text{constant}} \quad . \tag{24.06.12}$$

that gives two usual constants of motion: $\mathbf{P}$ and $\mathbf{K} \propto \mathbf{X}^0_{CM}$, the sometimes called *dynamic mass moment*.

From the second **Cardinal Equations** for isolated system, whenever $\mathbf{v}_A \wedge \mathbf{P} = 0$ one finds:

$$\boxed{\frac{\mathrm{d}\mathbf{L}_A}{\mathrm{d}t} = 0 \implies \mathbf{L}_A = \text{constant}}$$

that gives the constant of motion: $\mathbf{L}_A$ for any pole such that $\mathbf{v}_A \wedge \mathbf{P} = 0$. Note that, in this second case, there is no quantity similar to $\mathbf{X}^0_{CM}$, because there is no angular variable analogous to $\mathbf{X}$. That is, **angular momentum is not the velocity of something**.

From the third **Cardinal Equation** for conservative systems one finds

$$\boxed{E = \text{constant}}$$

that gives the constant of motion mechanical energy: E. In fact, at a fundamental level, all fundamental interactions are conservative.

This gives in total the ten classical constants of motion for isolated systems:

$$\boxed{\mathbf{X}^0_{CM} \qquad \mathbf{P} \qquad \mathbf{L}_A \qquad E} \quad .$$

24.07 Axiom 3 - the Action-Reaction Principle

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|18||
©|E.Gerjuoy|On Newton Third Law and the Conservation of Momentum, Am.J.Phys, , ..., ..., ...Ed., ... 17, 477-482 (1949)||

the Action-Reaction Principle characterizes the internal forces/torques/interactions.

An Isolated System is one system such that the internal interactions dominate the dynamics with respect to the interactions with the rest of the universe.

© - QUOTE

E. Gerjuoy, On Newton Third Law and the Conservation of Momentum, Am.J.Phys, , ..., ..., ...Ed., ... 17, 477-482 (1949).
For this reason it is of interest to note that the conservation laws of linear and angular momentum can be justified by an argument which does not depend on special assumptions regarding the nature of the forces between the elementary particles composing material bodies. In particular, it is not necessary specifically to invoke Newton third law. Naturally this argument also involves a physical assumption. It is sufficient to assume that the internal forces in material bodies do no work in any virtual displacement which is merely an infinitesimal translation or rotation. This assumption is in many respects more in keeping with our present understanding of the nature of matter than is the assumption that material bodies consist of **Galilei-Newton Mechanics** particles.

Denote by $T_O \equiv \{\mathbf{F}, \mathbf{\Gamma}_0\}$ the set made of the total force and the total torque, with respect to the arbitrary pole O, of a system of forces.

For any system one can write the first two **Cardinal Equations** :

$$\mathbb{T}_O^{(E)} \equiv \left\{\mathbf{F}^{(E)}, \mathbf{\Gamma}_O^{(E)}\right\} = \left\{\frac{\mathrm{d}\mathbf{P}}{\mathrm{d}t},\ \mathbf{v}_0 \wedge \mathbf{P} + \frac{\mathrm{d}\mathbf{J}_O}{\mathrm{d}t}\right\} \quad ,$$

in terms of the external forces.

24.07.01 Nullity of the System of Internal Interactions

Consider a generic system and divide it conceptually into two parts, a and b.

Apply the first two **Cardinal Equations** either to the entire system and to both parts. Using the **superposition principle** one finds:

$$\left\{\mathbf{F}^{(E)}[A \oplus B], \mathbf{\Gamma}_O^{(E)}[A \oplus B]\right\} = \quad ,$$

$$\left\{\mathbf{F}^{(E)}[A], \mathbf{\Gamma}_O^{(E)}[A]\right\} + \left\{\mathbf{F}^{(E)}[B], \mathbf{\Gamma}_O^{(E)}[B]\right\} = \quad ,$$

$$= \left\{\frac{\mathrm{d}\mathbf{P}[A \oplus B]}{\mathrm{d}t},\ \mathbf{v}_0 \wedge \mathbf{P}[A \oplus B] + \frac{\mathrm{d}\mathbf{J}_O[A \oplus B]}{\mathrm{d}t}\right\} \quad ,$$

$$= \left\{\frac{\mathrm{d}\mathbf{P}[A]}{\mathrm{d}t} + \frac{\mathrm{d}\mathbf{P}[B]}{\mathrm{d}t},\ \mathbf{v}_0 \wedge \mathbf{P}[A] + \mathbf{P}[B] + \frac{\mathrm{d}\mathbf{J}_O[A] + \mathbf{J}_O[B]}{\mathrm{d}t}\right\} \quad ,$$

$$\left\{\mathbf{F}^{(E)}[A] + \mathbf{F}[B \to A], \mathbf{\Gamma}_O^{(E)}[A] + \mathbf{\Gamma}_0[B \to A]\right\} = \left\{\frac{\mathrm{d}\mathbf{P}[A]}{\mathrm{d}t},\ \mathbf{v}_0 \wedge \mathbf{P}[A] + \frac{\mathrm{d}\mathbf{J}_O[A]}{\mathrm{d}t}\right\} \quad ,$$

$$\left\{\mathbf{F}^{(E)}[B] + \mathbf{F}[A \to B], \mathbf{\Gamma}_O^{(E)}[B] + \mathbf{\Gamma}_0[A \to B]\right\} = \left\{\frac{\mathrm{d}\mathbf{P}[B]}{\mathrm{d}t},\ \mathbf{v}_0 \wedge \mathbf{P}[B] + \frac{\mathrm{d}\mathbf{J}_O[B]}{\mathrm{d}t}\right\} \quad .$$

DRAFT - IN PROGRESS

The generalized form of the **Action-Reaction Principle** follows:

$$\mathbb{T}^{a\to b}_{O} + \mathbb{T}^{b\to a}_{O} = 0 \quad . \tag{24.07.01}$$

This is assumed as a postulate for the mutual interaction of any pair of systems.

The generalized **Action-Reaction Principle** is equivalent to the fact that the resultant of internal forces and the resultant of internal torques is zero for any system:

$$\mathbf{F}^{(\mathtt{I})} = 0 \qquad \mathbf{\Gamma}^{(\mathtt{I})}_{\mathtt{0}} = 0 \quad . \tag{24.07.02}$$

Note that all terms like $\mathbf{\Gamma}^{\mathtt{0}}_{(\mathtt{E})}[Z]$, $\mathbf{\Gamma}^{\mathtt{0}}_{(\mathtt{I})}[Z]$ and $\mathbf{\Gamma}^{\mathtt{0}}[X \to Y]$ may include, in general, both terms of type $(\mathbf{x}_{\mathtt{P}} - \mathbf{x}_{\mathtt{0}}) \wedge \mathbf{f}$ and intrinsic torques.

Simple and neat examples in section § 36.20.10, § 36.20.11.

24.07.02
Nullity of the Virtual Work in Any Rigid Translation/Rotation

An equivalent formulation of the **Action-Reaction Principle** is the Generalized Newton third law, which assumes the homogeneity and isotropy of space.

Consider a **rigid** translation/rotation of any system made of point particles. By this we mean not only that the distance among any pair of particles does not change, but also that the angle between any vector describing physical properties of the system does not change. Thus, for instance, if there are **Dipoles** , they shall be rotated; same for **Quadrupoles** or other properties; and for the spins.

The system of internal interactions (forces, torques, interaction on higher **Multipoles** , ...) of any system is such that it does not perform any virtual work in any rigid translation or rotation of the whole system.

This statement generalizes Newton's third law and is of general validity being equivalent to the conservation of the quantity of momentum and total angular momentum of an isolated system.

Simple and neat examples in section § 36.20.10, § 36.20.11.

DRAFT-IN-PROGRESS

24.08 Consequences of the Axioms

24.08.01
Meaning of Cardinal Equations

For a many-body system, the Cardinal equations only represent a sort of summary of the system mechanics.

In fact, in principle, the Cardinal equations might be applied to any sub-system, so that the number of possible independent equations is roughly of the order of the number of the number of degrees of freedom of the system.

They represent a useful summary, providing the motion of the Center-Of-Mass and the motion about the Center-Of-Mass. In general, they provide little information about the details of the motion, except for the overall translation and rotation.

The virial theorem, § 30.07, is another summary relation similar to the cardinal equations, providing the dynamics of the overall size of the system via the polar momentum of inertia.

24.08.02
Teorema Dello Pseudo-Lavoro

Dalla prima **Cardinal Equation** si deduce il teorema dello pseudo-lavoro:

$$\int \mathbf{F}^{(\mathrm{E})} \cdot \mathrm{d}\mathbf{X}_{\mathrm{CM}} = \frac{1}{2} M \Delta V_{\mathrm{CM}}^2 \quad ,$$

in cui la quantità a primo membro è detta pseudo-lavoro.

24.08.03
Invariance of the Power of Internal Force|Torque

Thanks to the **Action-Reaction Principle** it can be shown that the power of internal forces is invariant for changes of Reference Frame in arbitrary relative motion.

It becomes a postulate.

It is of fundamental importance in thermodynamics.

DRAFT - IN PROGRESS

24.08.04
Statics

Condizione necessaria, ma non sufficiente, affinché un sistema sia in equilibrio è che la forza risultante esterna e il momento risultante delle forze esterne siano nulli.

A system is in equilibrium if and only if all its sub-systems are in equilibrium.

24.08.05
Impulso Lineare E Impulso Angolare

Dalle **Cardinal Equation** si definisce l'impulso lineare:

$$\mathbf{I}_P \equiv \int_{t_0}^{t} \mathbf{F}^{(E)} \, \mathrm{d}t = \Delta\mathbf{P} = \mathbf{P}[t] - \mathbf{P}[t_0] \quad . \tag{24.08.01}$$

Dalle **Cardinal Equation** si definisce l'impulso angolare, rispetto ad un polo O, supposto in quiete:

$$\mathbf{I}_{L_O} \equiv \int_{t_0}^{t} \mathbf{\Gamma}_O^{(E)} \, \mathrm{d}t = \Delta\mathbf{L}_O = \mathbf{L}_O[t] - \mathbf{L}_O[t_0] \qquad (\text{nel caso} \quad \mathbf{v}_0 \wedge \mathbf{P} = 0) \quad . \tag{24.08.02}$$

→ 1311

Si osservi che se la relazione (24.08.02) è applicata ad un fenomeno di urto, nel quale agisce una forza molto intensa per un intervallo di tempo molto breve, non è necessario imporre la condizione $\mathbf{v}_0 \wedge \mathbf{P} = 0$ per la validità della (24.08.02) stessa. In tal caso infatti, per la definizione stessa di fenomeno impulsivo, l'integrale temporale, durante l'urto, di $\mathbf{v}_0 \wedge \mathbf{P}$ è trascurabile rispetto all'integrale temporale di $\mathbf{\Gamma}_O^{(E)}$.

In generale, l'integrale temporale va esteso dall'istante di inizio dell'urto a quello di termine dell'urto in quanto in un fenomeno di urto interessa solitamente la variazione di $\mathbf{P}$ e di $\mathbf{\Gamma}_0$ tra un istante precedente e un istante seguente l'urto.

DRAFT IN PROGRESS

24.09 Two-Body Three-Body and N-Body Interactions

Physics has been remarkably successful in describing complex phenomena of many-particle systems by summing two-body interactions. However, not all complex systems can be satisfactorily described by two-body interactions.

A three-body Force|Torque|Interaction is a Force|Torque|Interaction that does not exist in a system of two objects but appears in a three-body system. In general, if the behavior of a system of more than two objects cannot be described by the two-body interactions between all possible pairs of objects, as a first approximation, the deviation is mainly due to a three-body (n-body) Force|Torque|Interaction. It is known that in some cases there must exist special Force|Torque|Interaction effects when many systems are present, effects which are not there in two-body systems.

Suppose that objects A and B are subject to a two-body Force|Torque|Interaction, $\mathbf{i}_{AB}$, in absence of any other object. If, in the presence of a third object C, the Force|Torque|Interaction between A and B cannot be described anymore by the same expression, $\mathbf{i}_{AB}$, we are in presence of a three-body Force|Torque|Interaction, triggered by the third body C. One should assume that the presence of C changes some properties of A and|or B which change the Force|Torque|Interaction between A and B.

In other words: we have a three-body Force|Torque|Interaction whenever the Force|Torque|Interaction between A and B, in the presence of a third body C, also depends on the coordinates of C: $\mathbf{i}_{AB} \to \mathbf{i}_{AB|C}$

The generalisation to n-body Force|Torque|Interaction is straightforward.

Examples

- A non elementary and simple example of a three-body force can be found in the Earth-Moon-Satellite system. The position of the satellite can be calculated from the sum of the potentials between the individual objects. However, the result of this calculation does not agree with the observed position of the satellite. This is due to the presence of a three-body force: the gravitational force between the Moon and the Earth changes the shape of the Earth creating tides, which, consequently, alters the force between the Earth and the Satellite.
- A number of experimental observations seem to indicate that three-body forces exist inside atomic nuclei. Nuclei are built of nucleons (protons and neutrons), which are composite objects. When two nucleons interact, they are modified, so that they are no longer identical to a free particle. When a third nucleon is interacting with this two-nucleon system, the system can therefore not be described by summing two-body forces between free objects.
- Consider three Polarizable molecules: the force on each one depends on the coordinates of all three molecules (three-body force) because each molecules polarises the other two.

Note that the **superposition principle** is not violated by n-body forces! The force on any object is still the superposition of the forces generated by all the other objects but this same force cannot be described by the same expression one uses in absence of other objects.

24.10 Galilei-Invarian*

©|J.M.Lévy-Leblond - Galilei Group And Galilean Invariance|WEB - URL ||

©|J.M.Lévy-Leblond - Galilei Group and Non-Relativistic Quantum Mechanics|WEB - URL ||

It is a postulate that the law of interactions, forces and torques, are Galilei-Invarian* . Note that for the case of Lorentz force, which depends on the velocity, this implies that the ElectroMagnetic fields must change when changing Reference Frame.

24.10.01 Inertial Reference Frame

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|||

Nowadays we interpret the first Newton law as defining an Inertial Reference Frame :

Inertial Reference Frames are all and only the Reference Frames such that the principle of inertia applies, that is an object not subject to any force moves with constant velocity.

As a corollary:

Inertial Reference Frames do exist.

When is an object subject to no force? Experience shows that all known real forces are due to the existence of something which is the source of the force and that the intensity of all real forces decreases when increasing the distance from the source. In fact, if the forces did not fall off rapidly we could never isolate the interactions of two bodies among those of all other bodies in the universe. Therefore:

An object is subject to no force when it is far enough from any other body source of interactions.

How can one decide whether its own Reference Frame is a inertial one? Operatively: throw force-free massive objects in various directions and observe their motion; if they move at constant speed: then the Reference Frame is an inertial one; if they do not: use their motion to correct.

© - QUOTE

©|P.W. Bridgman|Am.J.Phys, , ..., ..., ...Ed., ... 29 (1961) 32|*Excellent; several excerpts below.*|

A system of three rigid orthogonal axes fixes a Galilean frame if three force-free massive particles projected along the three axes with arbitrary velocities continue to move along the axes with uniform velocities. Our terrestrial laboratories do not constitute such a frame, but we may construct such a frame in our laboratories by measuring how three arbitrarily projected masses deviate from the requirement ... and incorporating these deviations as negative corrections into our specifications for the Galilean frame. There need be no reference to the stars, but the behavior of bodies can be relevantly described in terms of such immediately observable things as the rotation of the plane of the Foucault pendulum with respect to the earth or the deviation of a falling body from the perpendicular. Even if the rocket operator who is trying to put a satellite into orbit finds it convenient to make some of his specifications in terms of observations on the pole star, it is obvious that his apparatus must eventually be described in terrestrial terms. ... In a Galilean frame a rotating body, after it has been set into rotation and the forces disconnected, preserves the orientation of its plane of rotation in the frame and, consequently, preserves the direction of its axis of rotation.

DRAFT

24.10.02
Galilei Transformation of Space-Time Coordinates

This § is referenced at pages:
[2396]

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|||

Galilei Transformation are those transformations mapping one Inertial Reference Frame into another Inertial Reference Frame .

Galilei relativity principle: the law of physics must be the same for all inertial observers linked by **Galilei Transformation** ; that is all inertial observers are equivalent.

Consider two Inertial Reference Frames , $\mathcal{I}$ and $\mathcal{I}'$ with origins at O and O'. Let $\mathbf{X}$ the position of the origin O' with respect to the Inertial Reference Frame $\mathcal{I}$. Assume that $\mathcal{I}'$ is moving, with respect to $\mathcal{I}$, with a velocity $\mathbf{U}$. Assume that a orthonormal Cartesian Coordinates Coordinate System and a time coordinate are defined in both Inertial Reference Frames . For simplicity always use a orthonormal Cartesian Coordinates Coordinate System. Assume that the rotation matrix between the two orthonormal Cartesian Coordinates Coordinate System is $\mathbb{R}$. The rotation between the two Coordinate System, if any, is time independent and therefore the rotation matrix $\mathbb{R}$, a special orthogonal matrix in three dimensions, if any, is time independent. The spatial translation of the origins of the two Coordinate System at $t = t' = 0$ is: $\mathbf{X}_0$. The time translation of the origins of the two time scales is: t_0.

Galilei Transformation in their most general form, read:

$$\begin{cases} \boxed{\mathbf{x}' = \mathbb{R}\mathbf{x} - \mathbf{X} = \mathbb{R}\mathbf{x} - \mathbf{U}t - \mathbf{X}_0} \ , \\ \boxed{t' = t - t_0} \quad \text{different time-zones are equivalent for physics} \end{cases} \ , \quad \rightarrow 2406$$

$$\begin{cases} \boxed{\mathbf{v}' = \mathbb{R}\mathbf{v} - \mathbf{U}} \ , \quad \text{if no rotation:} \quad \mathbf{v}' = \mathbf{v} - \mathbf{U} \ , \\ \boxed{\mathbf{a}' = \mathbb{R}\mathbf{a}} \ , \quad \text{if no rotation:} \quad \mathbf{a}' = \mathbf{a} \end{cases} .$$

Galilei Transformation form a group with ten parameters:

$$\boxed{\mathbf{U} \quad \mathbf{X}_0 \quad \mathbb{R}(\text{three parameters}) \quad t_0} \ .$$

ElectroMagnetism and Galilei Transformation

This § is referenced at pages:
[2396, 2488]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|||

Only consider ElectroMagnetism in vacuum, in order to avoid a privileged Reference Frame given by matter.

ElectroMagnetism is not invariant with respect to **Galilei Transformation** , because **Maxwell Equations** for ElectroMagnetic waves implies that ElectroMagnetic waves have a fixed speed, $c \equiv 1/\sqrt{\varepsilon_0 \mu_0}$, unequivocally determined. So they cannot be valid in any Reference Frame if **Galilei Transformation** (in particular the law of addiction of velocities) are valid.

Therefore the following possibilities arise:

- c is measured with respect to some privileged Reference Frame: the so-called **ether frame**;
- ElectroMagnetism is wrong or, at least, is only valid in the ether Reference Frame;
- **Galilei-Newton Mechanics** is wrong.

To the physicists of the end of XIX century: the latter could be hardly accepted after centuries of successes for **Galilei-Newton Mechanics** : remember, for instance, the prediction of the existence of

DRAFT - IN PRODUCTION

Neptune and its discovery as predicted. The second option seemed to be, anyway false, due to the many correct predictions of ElectroMagnetism.

It should be noted that at the end of the XIX century all known waves had a medium to propagate on as traveling oscillations in the material medium. It was therefore natural to think of Electric|Magnetic fields as strains in an invisible jelly-like unknown medium: the **ether**.

Therefore people started to look for the ether frame, trying to detect the **ether wind**.

See section § 58.04.01, § 61.03.05.

24.10.04
Linear Momentum and Mass Conservation With Galilei-Invarian*

This § is referenced at pages:
[1296, 1296, 1600, 1600]

It can be shown that, if linear momentum is conserved for an isolated system in some Inertial Reference Frame , it is also conserved in any other Inertial Reference Frame if and only if mass is also conserved.

See, for a deeper discussion, § 60.01.03.03, after the introduction of relativistic physics.

24.10.05
Other Transformation Laws

Kinetic energy: **Koënig theorem** (24.11.05) shows that only the Center-Of-Mass term changes.

DRAFT - IN-PROGRESS

24.11 Dynamical Quantities With Respect to the SdRCM

The Center-Of-Mass Reference Frame, say $\mathcal{I}'$, for any system is defined as the Reference Frame translating with the Center-Of-Mass without rotation. With no loss of generality it can be assumed that the axes of the Laboratory system and the Center-Of-Mass system are parallel and the origin is at the Center-Of-Mass. In general it is a non-Inertial Reference Frame , unless the Center-Of-Mass moves with constant velocity.

In general:

$$\boxed{\mathbf{V}'_{\text{CM}} = 0 \qquad \boldsymbol{\omega} = 0} \quad .$$

More specifically:

$$\boxed{\mathbf{X}'_{\text{CM}} = 0 \qquad \boldsymbol{\omega} = 0 \qquad \mathbf{e}'_k \parallel \mathbf{e}_k} \quad .$$

Koënig theorems express the dynamical quantities of a system as the sum of two quantities: one associated to the Center-Of-Mass as a mass point having the mass of the full system; the other associated to the motion relative to the Center-Of-Mass.

In the Center-Of-Mass Reference Frame, by definition, one has:

$$\mathbf{x}' \equiv \mathbf{x} - \mathbf{X}_{\text{CM}} \quad ,$$

$$\mathbf{v}' \equiv \mathbf{v} - \mathbf{V}_{\text{CM}} \qquad \text{pure translation} \quad ,$$

$$\sum_k^{\dots} \mathbf{p}'_k = 0 \qquad \text{definition of the [glo:CMRF]Center-of-Momenta Reference Frame} \quad ,$$

$$\sum_k^{\dots} m_k \mathbf{x}'_k = 0 \qquad \text{origin of } \mathcal{I}' \text{ at the Center-Of-Mass} \quad ,$$

$$\sum_k^{\dots} m_k \mathbf{x}'_k = ...M \qquad \text{position of the Center-Of-Mass with respect to } \mathcal{I}' \quad .$$

24.11.01 Koënig Theorem for Linear Momentum

Koënig theorem for Linear Momentum is just the well-known statement that the linear momentum relative to the Center-Of-Mass is, by definition, zero:

$$\boxed{\mathbf{P} = \mathbf{P}_{\text{CM}} + \mathbf{P}' = M\mathbf{V}_{\text{CM}} + 0 \qquad \mathbf{P}' = 0} \quad , \tag{24.11.01}$$

and the total linear momentum corresponds to the Center-Of-Mass linear momentum.

24.11.02 Koënig Theorem for Angular Momentum

This § is referenced at pages:
[1321, 1326, 1609]

Koënig theorem for Angular Momentum states that il momento angolare di un sistema rispetto ad un polo arbitrario O [1] può essere decomposto in una parte legata al moto del centro di massa, $\mathbf{L}_{\text{CM}}$, (momento angolare orbitale) e una parte legata al moto relativo al centro di massa con polo il Center-Of-Mass stesso,

[1] There are two conventions for the definition of angular momentum. The first convention uses the relative velocity between the particle and the pole while the second convention uses the absolute velocity of the particle. This second convention is more in line with the general treatment of the topic of system of applied vectors. Either conventions is perfectly valid, but some results differ, depending on the definition used. Examples of books that define angular momentum using the relative velocity convention include Greenwood (1977; 1988) while examples of books that define angular momentum using the absolute velocity convention include Synge and Griffith (1959), O'Reilly (2001) and Thornton and Marion (2004).

DRAFT–IN–PROGRESS

$\mathbf{L}'$, (momento angolare intrinseco o di spin).

$$\boxed{\mathbf{L}_O = \mathbf{L}_{CM} + \mathbf{L}' = (\mathbf{X}_{CM} - \mathbf{x}_O)\wedge\mathbf{P} + \mathbf{L}'} \quad . \tag{24.11.02}$$

→ 1317 1442 1604

Note that, if any particle has spin, this does not enter the theorem, as the spin is independent of the pole.

La decomposizione esprime il fatto che il momento angolare rispetto ad un polo arbitrario può essere espresso come somma del momento angolare che il sistema avrebbe se fosse concentrato nel centro di massa più il momento angolare rispetto al centro di massa.

24.11.02.01 Theorems on Angular Momentum

Il momento angolare intrinseco può essere espresso in modo diversi, ma equivalenti, tramite la posizione relativa al centro di massa e la velocità relativa al centro di massa, assumendo che il polo e origine of the moving frame coincidano entrambi con il Center-Of-Mass:

$$\boxed{\mathbf{L}' = \sum_k \mathbf{x}'_k\wedge\mathbf{p}_k = \sum_k \mathbf{x}_k\wedge\mathbf{p}'_k = \sum_k \mathbf{x}'_k\wedge\mathbf{p}'_k \qquad \text{CM} \equiv \text{pole} \equiv \mathcal{O}'} \quad . \tag{24.11.03}$$

Comunque, dalla relazione (24.11.02) discende il fatto fondamentale che il momento angolare nel Reference Frame del Center-Of-Mass non dipende dalla scelta del polo in quanto in tale Reference Frame, per definizione, $\mathbf{P}' = 0$:

$$\boxed{\mathbf{L}_{\mathcal{O}'} = \mathbf{L}' \qquad \text{in the [glo:CMRF]Center-of-Momenta Reference Frame, for any pole } \mathcal{O}' \text{ fixed in the moving frame}} \quad , \tag{24.11.04}$$

so that there is no ambiguity in the notation $\mathbf{L}'$ as the angular momentum in the [glo:CMRF]Center-of-Momenta Reference Fr regardless of the pole fixed in the moving [glo:CMRF]Center-of-Momenta Reference Frame. Obviously it is convenient to place the pole at the Center-Of-Mass.

24.11.03 Koënig Theorem for Kinetic Energy

This § is referenced at pages:
[1609, 2576]

Koënig theorem for Kinetic Energy states that l'energia cinetica di un sistema di particelle può essere decomposta in una parte legata al moto del centro di massa e una parte legata al moto relativo al centro di massa. Si consideri la velocità relativa al centro di massa di ogni particella, $\mathbf{v}'_k \equiv \mathbf{v}_k - \mathbf{V}_{CM}$. Si osservi che tale velocità è la velocità della particella vista da un Reference Frame solidale con il centro di massa e con gli assi paralleli a quelli del Reference Frame originale. Si ha allora

$$\boxed{\mathcal{K} = \frac{1}{2}MV_{CM}^2 + \frac{1}{2}\sum_k m_k {\mathbf{v}'_k}^2} \quad . \tag{24.11.05}$$

→ 1315 1443 1604

The above decomposition, is often said to decompose the total kinetic energy into the sum of a translational part plus a rotational part.

La decomposizione esprime il fatto che l'energia cinetica può essere espressa come la somma dell'energia cinetica che il sistema avrebbe se fosse concentrato nel centro di massa più l'energia cinetica rispetto al centro di massa.

DRAFT - NEW - PROGRESS

24.11.03.01 Theorems on Kinetic Energy

Per un sistema di n particelle con massa m_k, l'energia cinetica relativa al centro di massa, $\mathcal{K}'$, può essere espressa tramite la relazione

$$\mathcal{K}' = \frac{1}{2}\sum_{k=1}^{n} m_k v_k'^{\,2} = \frac{1}{2}\sum_{i,j=1;i\neq j}^{n} \frac{m_i m_j v_{ij}^2}{2M} \quad . \tag{24.11.06}$$

dove $\mathbf{v}_{ij} \equiv \mathbf{v}_i - \mathbf{v}_j$ è la velocità della particella i relativa alla particella j e il fattore due a denominatore corregge per il doppio conteggio nella doppia sommatoria.

24.11.04
Separation of Rotational Motion Around the Center-Of-Mass

©|J.Jellinek and D. H. Li, Phys. Rev. Lett., 1989, 62 241||*Very clear explanation.*|

©|H.Essén|Eur. J. Phys., 1993, Vol. 14, Issue 5, Article number 002, Pages 201-205|*WEB - URL* |

The separation of rotational motion around the Center-Of-Mass is not trivial. See the references for the formulation of a general prescription for separation of the energy of the overall rotation from that of the **internal/vibrational** motion in any isolated N-body (mass points) system, without imposing any restriction on the degree of its floppiness or making any assumption regarding its symmetry.

By defining a **rigid-body** instantaneous angular velocity, a vector $\boldsymbol{\omega}^{\mathrm{rb}}[t]$, satisfying the equation

$$\boxed{\mathbf{L} \equiv \mathbb{I}[t]\cdot\boldsymbol{\omega}^{\mathrm{rb}}[t]} \quad .$$

The meaning of $\boldsymbol{\omega}^{\mathrm{rb}}[t]$, which is defined by the above equation uniquely, is easily understood: it is the angular velocity with which the non-rigid system of total angular momentum $\mathbf{L}$ and tensor of inertia $\mathbb{I}[t]$ would rotate if at instant t it were a true rigid-body. Or in other words, at any time t we can associate with the non-rigid system a rigid-body rotating with angular velocity $\boldsymbol{\omega}^{\mathrm{rb}}[t]$ and having the same $\mathbf{L}$ and $\boldsymbol{\omega}^{\mathrm{rb}}[t]$ as the non-rigid system; the motion of this rigid-body represents the instantaneous overall rotation of the non-rigid system. Thus by assigning $\boldsymbol{\omega}^{\mathrm{rb}}[t]$ to a non-rigid system we separate out its overall or **rigid-body** part rotation. This means that a different rigid-body corresponds to our non-rigid system at different times. The kinetic energy is then:

$$\boxed{\mathcal{K} = \frac{1}{2}\boldsymbol{\omega}^{\mathrm{rb}}[t]\cdot\mathbf{L}} \quad .$$

24.12 Mechanics of a Two-Particle System

This § is referenced at pages:
[Never referenced.]

24.12.01 Reduction of the Two-Particle Problem

Suppose that two particles are subject to two-body forces. Ignore torques, if any, and only consider forces.

Il moto relativo al centro di massa può essere separato da quello del centro di massa. Il moto del centro di massa è descritto dalla prima equazione cardinale in termini delle sole forze esterne. Detta $\mathbf{f}_{12}$ la forza che la particella 1 esercita sulla particella 2, e $\mathbf{f}_{21}$ la forza che la particella 2 esercita sulla particella 1 il moto interno del sistema, cioè, il moto relativo delle due particelle, può essere separato dal moto del Centro di Massa. Infatti:

$$m_1\ddot{\mathbf{r}}_1 = \mathbf{f}_{21} + \mathbf{F}_1^{\mathrm{E}} \Longrightarrow m_2 m_1 \ddot{\mathbf{r}}_1 = m_2\mathbf{f}_{21} + m_2\mathbf{F}_1^{\mathrm{E}} \quad ,$$
$$m_2\ddot{\mathbf{r}}_2 = \mathbf{f}_{12} + \mathbf{F}_2^{\mathrm{E}} \Longrightarrow m_1 m_2 \ddot{\mathbf{r}}_2 = m_1\mathbf{f}_{12} + m_1\mathbf{F}_2^{\mathrm{E}} \quad .$$

The first **Cardinal Equation** follows by summing the two equations on the left side. The equation of the relative motion follows by subtracting the equations on the right side:

$$\boxed{\mu\left(\ddot{\mathbf{r}}_2 - \ddot{\mathbf{r}}_1\right) \equiv \mu\left(\mathbf{a}_2 - \mathbf{a}_1\right) \equiv \mu\mathbf{a} = \mathbf{f}_{12} + \mu\left(\frac{\mathbf{F}_2^{\mathrm{E}}}{m_2} - \frac{\mathbf{F}_1^{\mathrm{E}}}{m_1}\right)} \quad , \qquad (24.12.01)$$

→ 1635

dove μ,

$$\boxed{\frac{1}{\mu} \equiv \frac{1}{m_1} + \frac{1}{m_2}}$$

indica la massa ridotta della coppia.

The results for a two-body problem can be obtained by considering the motion of a fictitious particle, of mass equal to the reduced mass, whose position is to be interpreted as the relative position of the two original particles and the force is the force between the two particles. In this way the problem of two particles is reduced to two independent problems for one particle, that is the two equations of motions have been decoupled into two independent equations for two different fictitious particles: the Center-Of-Mass and the **reduced particle** with mass equal to the reduced mass, position vector given by the relative position of one particle with respect to the other and force equal to the internal force between the two particles. In general, this reduction is not possible when more than two particles are present, even if the Center-Of-Mass can be always separated.

Note that, whenever $\mathbf{F}_1^{\mathrm{E}} = \mathbf{F}_2^{\mathrm{E}} = 0$ the system is isolated, but the system be isolated $\mathbf{F}_1^{\mathrm{E}} = -\mathbf{F}_2^{\mathrm{E}} \neq 0$.

Read § 24.13 for the basics of the three-body dynamics.

PRELIMINARY PROOFS

24.12.02
Jacobi Coordinates for a Two-Particle System

This § is referenced at pages:
[Never referenced.]

The Jacobi coordinates for a two-particle system are usually defined as:

$$\boldsymbol{\rho}_1 \equiv \mathbf{R}_{\text{CM}} \equiv \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2} \quad ,$$
$$\boldsymbol{\rho}_2 \equiv \mathbf{r} \equiv (\mathbf{r}_2 - \mathbf{r}_1) \quad . \tag{24.12.02}$$

Sometimes the definition is made more general by introducing the factor k_2 to be chosen in the most appropriate way:

$$\boldsymbol{\rho}_1 \equiv \mathbf{R}_{\text{CM}} \equiv \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2} \quad ,$$
$$\boldsymbol{\rho}_2 \equiv \mathbf{r} \equiv \frac{(\mathbf{r}_2 - \mathbf{r}_1)}{k_2} \quad . \tag{24.12.03}$$

→ 1320

Unless stated otherwise the choice $k_2 = 1$ will be made.

The conjugate momenta can be calculated in the usual way from the kinetic energy which will be assumed to contain only a quadratic part and assuming that the potential energy in velocity independent. Read § **??**.

The inverse transformations of (24.12.03) are:

$$\mathbf{r}_1 = \mathbf{R}_{\text{CM}} - k_2\frac{m_2\mathbf{r}}{m_1 + m_2} \quad ,$$
$$\mathbf{r}_2 = \mathbf{R}_{\text{CM}} + k_2\frac{m_1\mathbf{r}}{m_1 + m_2} \quad . \tag{24.12.04}$$

→ 1320

From equations (24.12.04) one can also find the position and velocity with respect to the [glo:CMRF]Center-of-Momenta Refe

$$\mathbf{r}'_1 \equiv \mathbf{r}_1 - \mathbf{R}_{\text{CM}} = -k_2\frac{m_2\mathbf{r}}{m_1 + m_2} \quad ,$$
$$\mathbf{r}'_2 \equiv \mathbf{r}_2 - \mathbf{R}_{\text{CM}} = +k_2\frac{m_1\mathbf{r}}{m_1 + m_2} \quad , \tag{24.12.05}$$

→ 1321

and velocities

$$\mathbf{v}'_1 \equiv \mathbf{v}_1 - \mathbf{V}_{\text{CM}} = -k_2\frac{m_2\dot{\mathbf{r}}}{m_1 + m_2} \quad ,$$
$$\mathbf{v}'_2 \equiv \mathbf{v}_2 - \mathbf{V}_{\text{CM}} = +k_2\frac{m_1\dot{\mathbf{r}}}{m_1 + m_2} \quad . \tag{24.12.06}$$

→ 1321

24.12.03
Momenta of Two Point Particles

Using the methods presented in section § **??** one finds:

$$\mathbf{P} \equiv \frac{\partial\mathcal{L}}{\partial\mathbf{V}_{\text{CM}}} = (m_1 + m_2)\,\mathbf{V}_{\text{CM}} \quad ,$$
$$\mathbf{p}_r \equiv \frac{\partial\mathcal{L}}{\partial\mathbf{v}_r} = k_2^2\frac{m_1 m_2}{m_1 + m_2}\mathbf{v}_r \qquad \mathbf{v}_r \equiv \dot{\mathbf{r}} \quad . \tag{24.12.07}$$

→ 1321

Note that in the above relations, the mass coefficients multiplying the velocities are, respectively, the total mass and the reduced mass of the (2|1) pair.

DRAFT IN PROGRESS

24.12.04
Angular Momenta of Two Point Particles

The angular momentum calculated in [glo:CMRF] Center-of-Momenta Reference Frame is independent from the choice of the pole. The concept of intrinsic angular momentum is therefore meaningful.

By using the Jacobi variables one can write the orbital part of the intrinsic angular momentum of a two particle system as:

$$\boxed{\mathbf{L}' = \mathbf{L}_{2|1}} \quad .$$

In fact an observer fixed on the [glo:CMRF] Center-of-Momenta Reference Frame, such that $\mathbf{P}_{\text{CM}} = \mathbf{p}'_1 + \mathbf{p}'_2 = 0$, will write:

$$\boxed{\mathbf{L}' = \sum_{k=1}^{2} \mathbf{r}'_k \wedge \mathbf{p}'_k = \mathbf{r} \wedge \mathbf{p}_r} \quad ,$$

the latter equality coming from the relations (24.12.05), (24.12.06), , (24.12.07) with $k_2 = 1$.

Therefore, the pair of variables $\{\mathbf{r}, \mathbf{p}_r\}$ provide the same form of the angular momentum with respect to the [glo:CMRF] Center-of-Momenta Reference Frame as the standard definition.

In summary, from equation § 24.11.02:

$$\boxed{\mathbf{L} = \mathbf{L}_{\text{CM}} + \mathbf{L}' = \mathbf{L}_{\text{CM}} + \mathbf{L}_{2|1}} \quad .$$

24.12.05
Kinetic Energy of Two Point Particles

Per un sistema di due particelle con massa m_1, m_2 l'energia cinetica relativa al centro di massa, che appare nel teorema di Koënig, può essere espressa tramite la relazione

$$\boxed{\mathcal{K}' = \frac{1}{2}\mu v_{\text{R}}^2} \quad ,$$

dove $\mathbf{v}_{\text{R}} \equiv \mathbf{v}_2 - \mathbf{v}_1$ è la velocità relativa delle due particelle. Quindi il teorema di Koënig si può riscrivere nella forma

$$\boxed{\mathcal{K} = \frac{1}{2}MV_{\text{CM}}^2 + \frac{1}{2}\mu v_{\text{R}}^2} \quad , \qquad (24.12.08)$$

→ 1321

dove $M = m_1 + m_2$, $\mathbf{V}_{\text{CM}}$ è la velocità del centro di massa e $\mathbf{v}_{\text{R}} \equiv \mathbf{v}_2 - \mathbf{v}_1$ la velocità relativa delle due particelle.

Dalla relazione (24.12.08) si deduce che per due particelle isolate che compiono un urto elastico la velocità relativa è invariante.

An equivalent equation is given by:

$$\boxed{\mathcal{K} = \frac{\mathbf{P}^2}{2M} + \frac{\mathbf{p}_r^2}{2\mu}} \quad .$$

Therefore, the pair of variables $\{\mathbf{r}, \mathbf{p}_r\}$ provide the same form of the angular momentum with respect to the [glo:CMRF] Center-of-Momenta Reference Frame as the standard definition.

DRAFT-IN-PROGRESS

24.13 Mechanics of a Three-Particle System

This § is referenced at pages:
[1319]

24.13.01 Reduction of the Three-Particle Problem

Suppose that three particles are subject to two-body forces. Ignore torques, if any, and only consider forces.

The separation of the relative and Center-Of-Mass motion in a two-particle system cannot be in general extended to more than two particles. While the Center-Of-Mass motion can be always separated, the internal motions cannot, in general.

24.13.02 Jacobi Coordinates for a Three-Particle System

This § is referenced at pages:
[Never referenced.]

The Jacobi coordinates for a three-particle system are usually defined as:

$$\begin{aligned} \boldsymbol{\rho}_1 \equiv \mathbf{R}_{\text{CM}} &\equiv \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2 + m_3\mathbf{r}_3}{m_1 + m_2 + m_3} \\ \boldsymbol{\rho}_2 \equiv \mathbf{r} &\equiv (\mathbf{r}_2 - \mathbf{r}_1) \quad , \\ \boldsymbol{\rho}_3 \equiv \boldsymbol{\rho} &\equiv \left(\mathbf{r}_3 - \left(\frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2}\right)\right) \quad . \end{aligned} \tag{24.13.01}$$

Sometimes the definition is made more general by introducing the factors k_2 and k_3 to be chosen in the most appropriate way:

$$\begin{aligned} \boldsymbol{\rho}_1 \equiv \mathbf{R}_{\text{CM}} &\equiv \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2 + m_3\mathbf{r}_3}{m_1 + m_2 + m_3} \quad , \\ \boldsymbol{\rho}_2 \equiv \mathbf{r} &\equiv \frac{(\mathbf{r}_2 - \mathbf{r}_1)}{k_2} \quad , \\ \boldsymbol{\rho}_3 \equiv \boldsymbol{\rho} &\equiv k_3\left(\mathbf{r}_3 - \left(\frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2}\right)\right) \quad . \end{aligned} \tag{24.13.02}$$

→ 1325

Unless stated otherwise the choice $k_2 = 1$ and $k_3 = 1$ will be made. Another used choice is:

$$k_2^2 = k_3^2 \equiv \frac{m_3}{\mu}\left(\frac{m_1 + m_2}{m_1 + m_2 + m_3}\right) \qquad \text{and} \qquad \mu^2 \equiv \frac{m_1 m_2 m_3}{m_1 + m_2 + m_3}$$

The conjugate momenta can be calculated in the usual way from the kinetic energy which will be assumed to contain only a quadratic part and assuming that the potential energy in velocity independent. Read **§ ??**.

DRAFT - IN PROGRESS

The inverse transformations of (24.13.02) are:

$$\begin{aligned}
\mathbf{r}_1 &= \mathbf{R}_{\text{CM}} - k_2 \frac{m_2 \mathbf{r}}{m_1 + m_2} - \frac{m_3 \boldsymbol{\rho}}{k_3 (m_1 + m_2 + m_3)} \\
\mathbf{r}_2 &= \mathbf{R}_{\text{CM}} + k_2 \frac{m_1 \mathbf{r}}{m_1 + m_2} - \frac{m_3 \boldsymbol{\rho}}{k_3 (m_1 + m_2 + m_3)} \\
\mathbf{r}_3 &= \mathbf{R}_{\text{CM}} + \frac{\boldsymbol{\rho} (m_1 + m_2)}{k_3 (m_1 + m_2 + m_3)} \quad .
\end{aligned} \tag{24.13.03}$$

→ 1325

From equations (24.13.03) one can also find the position and velocity with respect to the [glo:CMRF]Center-of-Momenta Refe positions

$$\begin{aligned}
\mathbf{r}'_1 &\equiv \mathbf{r}_1 - \mathbf{R}_{\text{CM}} = -k_2 \frac{m_2 \mathbf{r}}{m_1 + m_2} - \frac{m_3 \boldsymbol{\rho}}{k_3 (m_1 + m_2 + m_3)} \quad , \\
\mathbf{r}'_2 &\equiv \mathbf{r}_2 - \mathbf{R}_{\text{CM}} = +k_2 \frac{m_1 \mathbf{r}}{m_1 + m_2} - \frac{m_3 \boldsymbol{\rho}}{k_3 (m_1 + m_2 + m_3)} \quad , \\
\mathbf{r}'_3 &\equiv \mathbf{r}_3 - \mathbf{R}_{\text{CM}} = +\frac{\boldsymbol{\rho} (m_1 + m_2)}{k_3 (m_1 + m_2 + m_3)} \quad ,
\end{aligned} \tag{24.13.04}$$

→ 1326

and velocities

$$\begin{aligned}
\mathbf{v}'_1 &\equiv \mathbf{v}_1 - \mathbf{V}_{\text{CM}} = -k_2 \frac{m_2 \dot{\mathbf{r}}}{m_1 + m_2} - \frac{m_3 \dot{\boldsymbol{\rho}}}{k_3 (m_1 + m_2 + m_3)} \quad , \\
\mathbf{v}'_2 &\equiv \mathbf{v}_2 - \mathbf{V}_{\text{CM}} = +k_2 \frac{m_1 \dot{\mathbf{r}}}{m_1 + m_2} - \frac{m_3 \dot{\boldsymbol{\rho}}}{k_3 (m_1 + m_2 + m_3)} \quad , \\
\mathbf{v}'_3 &\equiv \mathbf{v}_3 - \mathbf{V}_{\text{CM}} = +\frac{\dot{\boldsymbol{\rho}} (m_1 + m_2)}{k_3 (m_1 + m_2 + m_3)} \quad .
\end{aligned} \tag{24.13.05}$$

→ 1326

24.13.03
Momenta of Three Point Particles

Using the methods presented in section § ?? one finds:

$$\begin{aligned}
\mathbf{P} &\equiv \frac{\partial \mathcal{L}}{\partial \mathbf{V}_{\text{CM}}} = (m_1 + m_2 + m_3)\, \mathbf{V}_{\text{CM}} \\
\mathbf{p}_r &\equiv \frac{\partial \mathcal{L}}{\partial \mathbf{v}_r} = k_2^2 \frac{m_1 m_2}{m_1 + m_2} \mathbf{v}_r \qquad \mathbf{v}_r \equiv \dot{\mathbf{r}} \\
\mathbf{p}_\rho &\equiv \frac{\partial \mathcal{L}}{\partial \mathbf{v}_\rho} = \frac{m_3 (m_1 + m_2)}{k_3^2 (m_1 + m_2 + m_3)} \mathbf{v}_\rho \qquad \mathbf{v}_\rho \equiv \dot{\boldsymbol{\rho}} \quad .
\end{aligned} \tag{24.13.06}$$

→ 1326

Note that in the above relations, the mass coefficients multiplying the velocities are, respectively, the total mass, the reduced mass of the (2|1) pair, $\mu_{(2|1)}$, and the reduced mass of the (3|(1+2)) mass, $\mu_{(3|(1+2))}$.

24.13.04
Angular Momentum of Three Point Particles

The angular momentum calculated in [glo:CMRF]Center-of-Momenta Reference Frame is independent from the choice of the pole. The concept of intrinsic angular momentum is therefore meaningful.

By using the Jacobi variables one can write the orbital part of the intrinsic angular momentum of a three particle system as:

$$\boxed{\mathbf{L}' = \mathbf{L}_{2|1} + \mathbf{L}_{3|12}} \quad .$$

In fact an observer fixed on the [glo:CMRF]Center-of-Momenta Reference Frame, such that $\mathbf{P}_{\text{CM}} = \mathbf{p}'_1 + \mathbf{p}'_2 + \mathbf{p}'_3 = 0$, will write:

$$\boxed{\mathbf{L}' = \sum_{k=1}^{3} \mathbf{r}'_k \wedge \mathbf{p}'_k = \mathbf{r} \wedge \mathbf{p}_r + \boldsymbol{\rho} \wedge \mathbf{p}_\rho} \quad ,$$

DRAFT - In-PROGRESS

the latter equality coming from the relations (24.13.04), (24.13.05), , (24.13.06) with $k_2 = 1$ and $k_3 = 1$.

Therefore, the pair of variables $\{\mathbf{r}, \mathbf{p}_r\}$ and $\{\boldsymbol{\rho}, \mathbf{p}_\rho\}$ provide the same form of the angular momentum with respect to the [glo:CMRF]Center-of-Momenta Reference Frame as the standard definition.

In summary, from equation § 24.11.02:

$$\boxed{\mathbf{L} = \mathbf{L}_{\text{CM}} + \mathbf{L}' = \mathbf{L}_{\text{CM}} + \mathbf{L}_{2|1} + \mathbf{L}_{3|12}} \quad .$$

24.13.05

Kinetic Energy of Three Point Particles

Per un sistema di tre particelle con massa m_1, m_2, m_3 l'energia cinetica relativa al centro di massa, che appare nel teorema di Koënig, può essere espressa tramite la relazione

$$\mathcal{K}' = \frac{1}{2}\sum_{k=1}^{3} m_k v_k'^{\,2} = \frac{1}{2}\left[\frac{m_1 m_2 v_{12}^2 + m_2 m_3 v_{23}^2 + m_3 m_1 v_{31}^2}{m_1 + m_2 + m_3}\right] \quad . \tag{24.13.07}$$

An equivalent equation is given by:

$$\boxed{\mathcal{K} = \frac{\mathbf{P}^2}{2M} + \frac{\mathbf{p}_r^2}{2\mu_{(2|1)}} + \frac{\mathbf{p}_\rho^2}{2\mu_{(3|(1+2))}}} \quad .$$

Therefore, the pair of variables $\{\mathbf{r}, \mathbf{p}_r\}$ and $\{\boldsymbol{\rho}, \mathbf{p}_\rho\}$ provide the same form of the angular momentum with respect to the [glo:CMRF]Center-of-Momenta Reference Frame as the standard definition.

DRAFT-IN-PROGRESS

24.14 Variable Mass - Open Systems

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|Mécanique: fondements et applications - 7e édition|*§ 22*|
©|WEB - URL |Irschik, Hans and Humer, Alexander. (2014). in: 10.1007/978-3-7091-1809-2.|*Full treatment*|

Variable Mass Systems (open systems) refer to systems with mass entering/exiting the system, that is crossing its - well defined - boundary. Read also § 65.05.08.

Consider an open system with some mass entering, $\left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} > 0\right)$, and|or exiting, $\left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} < 0\right)$, the system, at various places, P, located at $\mathbf{x}_{\mathrm{P}}$, with velocities $\mathbf{v}_{\mathrm{P}}$, with respect to the given Reference Frame (absolute velocity), and velocities $\mathbf{u}_{\mathrm{P}}$, with respect to the (absolute) velocity $\mathbf{V}$ of the point P where mass enters/exits the system:

$$\boxed{\mathbf{v}_{\mathrm{P}} \equiv \mathbf{u}_{\mathrm{P}} + \mathbf{V}} \quad .$$

Note that it is assumed that the absolute Reference Frame is a inertial one and that the control surface defining the variable mass system is fixed and non deformable in this Reference Frame. In case the Reference Frame is not a inertial one, inertial forces must be added.

24.14.01 Theorem of Linear Momentum for Open Systems

The first **Cardinal Equation** (24.06.03) reads:

$$\boxed{\frac{\mathrm{d}\mathbf{P}}{\mathrm{d}t} = \mathbf{F}^{(\mathrm{E})} + \sum_P \left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} \mathbf{v}_{\mathrm{P}}\right)} \quad . \tag{24.14.01}$$

→ 1327

Note that the velocity $\mathbf{v}_{\mathrm{P}}$ is the absolute velocity and the correctness of the sign of the last term to be a thrust.

For a stationary system (which includes the notable case of isolated systems):

$$\boxed{\frac{\mathrm{d}\mathbf{P}}{\mathrm{d}t} = 0 \implies \mathbf{F}^{(\mathrm{E})} + \sum_P \left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} \mathbf{v}_{\mathrm{P}}\right) = 0} \quad .$$

The equation (24.14.01) can be cast in the equivalent form:

$$\boxed{M[t]\frac{\mathrm{d}\mathbf{V}}{\mathrm{d}t} = \mathbf{F}^{(\mathrm{E})} + \sum_P \left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} \mathbf{u}_{\mathrm{P}}\right)} \quad , \tag{24.14.02}$$

in terms of the relative velocity of the entering/exiting mass.

24.14.02 Theorem of Angular Momentum for Open Systems

Assume the case of a fixed pole, $\mathbf{v}_0 \wedge \mathbf{P} = \mathbf{0}$.

The second **Cardinal Equation** (24.06.05) reads:

$$\boxed{\frac{\mathrm{d}\mathbf{L}_0}{\mathrm{d}t} = \mathbf{\Gamma}_0^{(\mathrm{E})} + \sum_P \left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} (\mathbf{x}_{\mathrm{P}} - \mathbf{x}_0) \wedge \mathbf{v}_{\mathrm{P}}\right)} \quad . \tag{24.14.03}$$

Note that the velocity $\mathbf{v}_{\mathrm{P}}$ is the absolute velocity and the correctness of the sign of the last term to be a thrust.

For a stationary system (which includes the notable case of isolated systems):

$$\boxed{\frac{\mathrm{d}\mathbf{L}_0}{\mathrm{d}t} = 0 \implies \mathbf{\Gamma}_0^{(\mathrm{E})} + \sum_P \left(\left.\frac{\mathrm{d}M}{\mathrm{d}t}\right|_{\mathrm{P}} (\mathbf{x}_{\mathrm{P}} - \mathbf{x}_0) \wedge \mathbf{v}_{\mathrm{P}}\right) = 0} \quad .$$

DRAFT IN PROGRESS

24.14.03
Theorem of Kinetic Energy for Open Systems

The third **Cardinal Equation** (24.06.07) reads:

$$\boxed{\frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} = \Pi^{(\mathrm{E})} + \Pi^{(\mathrm{I})} + \frac{1}{2}\sum_P \left(\frac{\mathrm{d}M}{\mathrm{d}t}\bigg|_{\mathrm{P}} \mathbf{v}_{\mathrm{P}}^2 \right)} \quad . \tag{24.14.04}$$

Note that the velocity is the absolute velocity.

For a stationary system:

$$\boxed{\frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} = 0 \implies \Pi^{(\mathrm{E})} + \Pi^{(\mathrm{I})} + \frac{1}{2}\sum_P \left(\frac{\mathrm{d}M}{\mathrm{d}t}\bigg|_{\mathrm{P}} \mathbf{v}_{\mathrm{P}}^2 \right) = 0} \quad .$$

DRAFT-IN-PROGRESS

24.15 Mechanics of a Point Particle in a non-Inertial Reference Frame

24.15.01 Inertial Reference Frame and non-Inertial Reference Frame

©|Berkeley Physics Course, in 5 Vol., , ..., McGraw-Hill, ...Ed., ...|||

24.15.02 Dynamics

Dalle leggi della dinamica e dalla legge di composizione delle accelerazioni (23.07.03) si possono ricavare le leggi della dinamica in un Reference Frame non inerziale. Se $\mathbf{f}_0$ è la forza fisica cui è soggetta una particella, la forza totale $\mathbf{f}$ di cui risente la particella in n Reference Frame non inerziale include anche i contributi delle forze inerziali: la forza di trascinamento e quella di Coriolis

$$\mathbf{f}_0 = \frac{\mathrm{d}\mathbf{p}}{\mathrm{d}t} = m\mathbf{a} \quad .$$

Le forze inerziali (o fittizie) non sono legate alla presenza di corpi nelle vicinanze della particella, non soddisfano alla terza legge di Newton e non diminuiscono al crescere della distanza, diversamente da tutte le forze fisiche reali note. Dipendono in modo essenziale dal moto del Reference Frame non inerziale rispetto ad un Reference Frame inerziale.

Similarly, for a particle subject to an elementary torque, γ^0, the relative dynamics can be found from the law of transformation of angular velocities and accelerations, sections § 23.06.02.05, § 23.06.02.06, starting from **Cardinal Equations** :

$$\gamma_0 = \frac{\mathrm{d}\mathbf{s}}{\mathrm{d}t} = \{\mathbb{I}\}\cdot\boldsymbol{\omega} \quad ,$$

where the pole in the equation above is the location of the point particle.

DRAFT - IN - PROGRESS

24.16 Equilibrium and Stability

24.17 Some Properties of the Equation of Motion

DRAFT - IN PROGRESS

24.17.01 Determinism of Galilei-Newton Mechanics

The first two **Cardinal Equations** are, in general, systems of second-order differential equations in normal form; therefore their solution exists and is unique with Cauchy initial conditions.

The third **Cardinal Equation**, depending on whether it is expressed in either form (24.06.07) or (24.06.08), can be of either second-order of first order. Whenever it can be cast in the form (24.06.07) with zero right-hand side, that is, $0 = W^{(\mathrm{E})}_{\mathrm{NC}} = W^{(\mathrm{I})}_{\mathrm{NC}} = W^{(\mathrm{E})}_{\mathrm{CNU}} = W^{(\mathrm{I})}_{\mathrm{CNU}}$, it is first-order, thus greatly simplifying the mathematical solution, which is the great advantage of energy conservation from the computational point of view.

24.17.02 Mathematical Properties of the Equations of Motion

Consider mass-points subject to Force|Torque only.

24.17.02.01 Finite Force|Torque

Assume that Force|Torque are limited functions, as a function of time, but possibly with discontinuities of the first kind. Thus, impulsive phenomena are excluded here.

Consider the first **Cardinal Equation**; integration with respect to time provides continuous velocity functions and thus also continuous position functions.

Consider the second **Cardinal Equation**; integration with respect to time provides continuous angular momentum functions, assuming that the velocity of the pole is a limited function of time.

Similar considerations apply to the third equation, which can be either a second-order or a first-order system of differential equations.

24.17.02.02 Infinite Force|Torque (Impulsive Dynamics)

Assume possible impulsive phenomena on the first two **Cardinal Equations**.

Momenta and angular momenta can have discontinuities of the first-kind, in presence of impulsive forces. Positions are still continuous functions of time. Angles can be integrated from angular momenta/velocities, in general only locally; in this case they are continuous functions of time.

Read § 29.06.20, § 26.07.10, § 26.07.11.

24.18 Continuous Systems

24.18.01 Homogeneity and Isotropy

A medium is homogeneous when its physical properties do not depend on the position inside the medium.

A medium is isotropic when its physical properties at any point do not depend on the direction around that point.

For example: a liquid under hydrostatic pressure in a gravity field is isotropic but not necessarily homogeneous, because pressure and density, for instance, might depend on the height; a non-cubic crystal, is homogeneous but, possibly, not isotropic.

24.18.02 Nomenclature for Force|Torque Inside a Continuous Medium

This § is referenced at pages:
[1455]

Consider a three-dimensional material medium, with an ideal plane surface inside the medium and an ideal straight line perpendicular to the plane.

- The component of the force per unit area perpendicular to the surface is called the **normal stress** (also called pressure or tension).
- The components of the forces per unit area parallel to the surface are called **shear stresses**.
- The component of the torque along the axis is called **twisting torque**.
- The components of the torques perpendicular to the axis are called **bending torques**.

Read also § 27.

24.18.02.01 Volume Force|Torque

Le forze e i momenti delle forze agenti su un oggetto continuo (fluido o solido) possono essere classificate come Force|Torque di volume e Force|Torque di superficie, a seconda che l'intensità sia proprozionale al volume (il punto di applicazione delle forze è distribuito nell'intero volume) o alla superficie (il punto di applicazione delle forze è distribuito nell'intera superficie che forma il bordo del volume), della porizione di sistema continuo.

Supponiamo, per semplicità, di usare un Coordinate System cartesiano nel Reference Frame prescelto. Si consideri un elemento infinitesimo di volume, macroscopicamente piccolo e microscopicamente grande.

Le Force|Torque di volume sono proporzionali al volume della porzione di oggetto considerato:

$$\boxed{\mathrm{d}\mathbf{F}^{\mathrm{V}}[\mathbf{x}] \equiv \mathbf{f}^{\mathrm{V}}[\mathbf{x}]\ \mathrm{d}V} \quad ,$$

$$\boxed{\mathrm{d}\boldsymbol{\Gamma}^{\mathrm{V}}[\mathbf{x}] \equiv \boldsymbol{\gamma}^{\mathrm{V}}[\mathbf{x}]\ \mathrm{d}V = \left(\mathbf{x}\wedge\mathbf{f}^{\mathrm{V}}[\mathbf{x}] + \boldsymbol{\tau}^{\mathrm{V}}[\mathbf{x}]\right)\ \mathrm{d}V} \quad ,$$

where the fixed but arbitrary pole is not explicitly written and total torque is divided into the pole dependent/independent parts.

Instead of unit volume one can use the density per unit mass:

$$\boxed{\mathrm{d}\mathbf{F}^{\mathrm{V}} \equiv \mathbf{f}^{\mathrm{M}}\,\mathrm{d}M \equiv \rho\mathbf{f}^{\mathrm{M}}\,\mathrm{d}V \equiv \mathbf{f}^{\mathrm{V}}\,\mathrm{d}V \qquad \mathrm{d}\boldsymbol{\Gamma}^{\mathrm{V}} \equiv \boldsymbol{\gamma}^{\mathrm{M}}\,\mathrm{d}M \equiv \rho\boldsymbol{\gamma}^{\mathrm{M}}\,\mathrm{d}V \equiv \boldsymbol{\gamma}^{\mathrm{V}}\,\mathrm{d}V \qquad \mathrm{d}\mathbf{T}^{\mathrm{V}} \equiv \boldsymbol{\tau}^{\mathrm{M}}\,\mathrm{d}M \equiv \rho\boldsymbol{\tau}^{\mathrm{M}}\,\mathrm{d}V \equiv \boldsymbol{\tau}^{\mathrm{V}}\,\mathrm{d}V} \quad .$$

Volume Force|Torque include inertial forces in non-Inertial Reference Frame .

DRAFT-IN-PROGRESS

24.18.02.02 Force|Torque Di Superficie

Le Force|Torque di superficie, che agiscono su una superficie infinitesima della frotniera del volume, hanno in generale una componente perpendicolare, normal stress e normal (twisting) torque-stress, ed una parallela alla superficie, shear stress e shear (bending) torque-stress.

La componente k della Force|Torque di superficie che agisce su una superficie infinitesima ideale di area $\mathbb{d}\mathbf{S}$ e orientata perpendicolarmente al unit vector $\widehat{\mathbf{n}}$, $\mathbb{d}\mathbf{S} \equiv \widehat{\mathbf{n}}\, \mathbb{d}\mathbf{S}$, si può esprimere come:

$$\boxed{\mathbb{d}F^{\mathsf{S}}_k[\mathbf{x}] = \mathcal{S}^{\cdot\cdot}_{kj}[\mathbf{x}]\, \mathbb{d}\mathbf{S}_j[\mathbf{x}]} \quad ,$$

$$\boxed{\mathbb{d}\Gamma^{\mathsf{S}}_k[\mathbf{x}] = \mathcal{M}^{\cdot\cdot}_{kj}[\mathbf{x}]\, \mathbb{d}\mathbf{S}_j[\mathbf{x}]} \quad ,$$

dove $\mathbb{d}\mathbf{S}_j[\mathbf{x}]$ è l'area della proiezione sull'asse j della superficie $\mathbb{d}\mathbf{S}[\mathbf{x}]$ ad $[\mathbf{x}]$.

La grandezza $\mathcal{S}^{\cdot\cdot}_{kj}$ è il **force-stress tensor** e descrive la forza per unità di superficie in direzione k che agisce su una superficie infinitesima perpendicolare alla direzione j.

La grandezza $\mathcal{M}^{\cdot\cdot}_{kj}$ è il **torque-stress tensor** e descrive la coppia per unità di superficie in direzione k che agisce su una superficie infinitesima perpendicolare alla direzione j.

Surface forces include forces due pressure and forces due to rigid-bodies in contact wit the fluid.

DRAFT - IN-PROGRESS

24.19 Modeling Forces and Torques on Particles/Systems

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|12.7||

Le interazioni (forze e momenti) che agiscono su un sistema sono in generale schematizzabili in tre categorie:

1. interazioni a contatto;
2. interazioni a distanza;
3. interazioni inerziali.

As far as their dependence important cases arise:

- Force|Torque dependent on position.
- Force|Torque dependent on time.
- Force|Torque dependent on velocity.

24.19.01 Some Force|Torque Laws for Point Particles

24.19.01.01 Gravitational Force

This is one of the fundamental laws of Nature.

La forza gravitazionale attrattiva che una mass point (1) di massa gravitazionale m_1 esercita su una mass point (2) di massa gravitazionale m_2 posta ad $\mathbf{r} \equiv \mathbf{r}_2 - \mathbf{r}_1$ vale:

$$\mathbf{f}_{12} = -G\frac{m_1 m_2}{r^2}\widehat{\mathbf{e}}_r \quad ,$$

dove $\widehat{\mathbf{e}}_r$ il unit vector diretto dalla mass point (1) verso la mass point (2).

È un assioma fondamentale della fisica relativistica che massa inerziale e massa gravitazionale siano identiche. Read § 24.20.

24.19.01.02 Reazioni Vincolari

Quando un sistema è vincolato i vincoli esercitano sul sistema delle forze, dette reazioni vincolari, necessarie a mantenere il sistema vincolato.

Le reazioni vincolari non sono, in generale, note a priori ma vanno determinate tramite le equazioni del moto; sono sempre incognite del problema.

Una point particle può essere vincolata a muoversi lungo una linea oppure una superficie; i vincoli possono essere bi-laterali (definiti da una eguaglianza) o uni-laterali (definiti da una diseguaglianza).

La reazione vincolare a cui è soggetto una point particle vincolata ad una curva si può sempre scomporre in una componente perpendicolare alla curva (componente normale) e in una componente tangente alla curva (forza di attrito).

La reazione vincolare a cui è soggetto una point particle vincolata ad una superficie si può sempre scomporre in una componente perpendicolare alla superficie (componente normale) e in una componente tangente alla superficie (forza di attrito).

Nei casi reali, qualora la reazione vincolare fornita dalla soluzione del problema con la configurazione prevista o ipotizzata, sia eccessiva rispetto alla capacità meccaniche del vincolo, il vincolo può deformarsi, permanentemente o no, o rompersi e il problema deve essere reimpostato.

Nel caso di attrito statico, la eventualmente ipotizzata condizione di staticità non può essere soddisfatta, e il problema deve essere reimpostato con la point particle in movimento.

DRAFT - IN PROGRESS

24.19.01.03 Reazioni Vincolari Normali - Vincoli Ideali

Normal constraints cannot do any work whenever they are fixed. On the other hand, moving normal constraints can do work: see, for instance, § 24-038.

24.19.01.04 Reazioni Vincolari Tangenti: Attrito Radente

La forza di attrito statico, $\mathbf{f}_s$, presente nel caso il point particle sia in quiete a contatto con una superficie, è diretta tangenzialmente alla superficie e, detto $N = |\mathbf{N}|$ il modulo della reazione normale, soddisfa alla relazione

$$\boxed{|\mathbf{f}_s| \leq \mu_s N \qquad \mathbf{f}_s \propto -\mathbf{v}} \quad . \tag{24.19.01}$$

→ 1334 1363

In generale la forza di attrito statico si oppone al moto (cioè alla velocità) che ci sarebbe se l'attrito statico non ci fosse.

La forza di attrito cinetico $\mathbf{f}_c$, presente nel caso il point particle sia in movimento rispetto alla superficie, è tale che

$$\boxed{\mathbf{f}_c = -\mu_c N \frac{\mathbf{v}}{v}} \tag{24.19.02}$$

→ 1334 1363

ed è quindi sempre diretta in senso opposto alla velocità relativa alla superficie.

Le relazioni (24.19.01), (24.19.02) sono relazioni tra i moduli dei vettori $\mathbf{f}_s$, $\mathbf{f}_c$ e $\mathbf{N}$, essendo le direzioni dei vettori diverse tra loro. Infatti $\mathbf{N}$ è sempre normale alla superficie del vincolo mentre $\mathbf{f}_s$ e $\mathbf{f}_c$ sono sempre tangenziali alla superficie.

Il coefficiente di attrito non dipende dall'estensione della superficie di contatto. Questo perché la superficie di contatto effettiva, a causa delle deformazioni della superficie, è in prima approssimazione indipendente dalla superficie di contatto e proporzionale alla pressione.

La forza di attrito statico è determinata dalle condizioni di equilibrio. Si suppone il sistema in equilibrio, si determina il valore della forza di attrito statico necessaria per l'equilibrio e si confronta con la relazione (24.19.01) per verificare se l'attrito statico può fornire o meno la forza richiesta affinché il point particle sia in equilibrio. Il fatto che la forza di attrito statico così determinata soddisfi alla relazione (24.19.01) è condizione necessaria e sufficiente all'equilibrio. Nel caso la relazione non sia verificata si deve reimpostare il problema tenendo conto che il sistema si mette in moto ed usare, eventualmente, la relazione (24.19.02).

Le proprietà descritte dell'attrito, sia statico che cinetico, giustificano il principio in base al quale se si trascura l'attrito in un problema di statica si agisce in favore della sicurezza in quanto l'attrito si oppone sempre al moto attuale del sistema (attrito cinetico) oppure al moto che ci sarebbe in assenza di attrito (attrito statico).

In generale deve essere

$$\boxed{\mu_c \leq \mu_s} \quad ,$$

come si dimostra per assurdo.

DRAFT IN PROGRESS

24.19.01.05 Kinematic Constraints

A kinematic constrain is a constraint on the kinematics of the system to its possible motions and/ot motion of its parts. Read § 24-038, § 24-019.

24.19.01.06 Legge Di Hooke

Per deformazioni elastiche attorno ad una posizione di equilibrio si applica la legge di Hooke

$$\mathbf{f} = -k\,(\mathbf{r} - \mathbf{r}_0) = -k\Delta\mathbf{r} \quad , \tag{24.19.03}$$

dove k è la costante elastica e $\Delta\mathbf{r}$ lo spostamento dalla posizione di equilibrio.

24.19.01.07 Resistenza Del Mezzo

La resistenza al moto che incontra un point particle che si muove entro un fluido dipende dalla velcità.
A piccole velocità la resistenza del mezzo tende ad essere proporzionale alla velocità:

$$\mathbf{f} = -a\mathbf{v} \qquad a \text{ costante} \quad .$$

A grandi velocità la resistenza del mezzo tende ad essere proporzionale al quadrato della velocità:

$$\mathbf{f} = -b\hat{\mathbf{v}}v^2 = -bv\mathbf{v} \qquad \text{con } b \text{ costante} \quad .$$

24.19.01.08 ElectroStatic Coulomb Force)

La forza coulombiana che un charged mass point (1) di carica elettrica q_1 esercita su un charged mass point (2) di carica elettrica q_2 posta ad $\mathbf{r} \equiv \mathbf{r}_2 - \mathbf{r}_1$ vale:

$$\mathbf{f}_{12} = +\frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2}\hat{\mathbf{e}}_r \quad ,$$

dove $\hat{\mathbf{e}}_r$ il unit vector diretto dal charged mass point (1) verso il charged mass point (2).
See equation (36.06).

24.19.01.09 MagnetoStatic Biot-Savart Force)

See equation (36.06).

24.19.01.10 Lorentz Force

Lorentz force, equation (36.05.01) is actually the definition of the Electric|Magnetic fields.
Note that Lorentz force violates Newton third law, read § 58.03.04.

[16]The charged particles in a rigid body are presumably held together by electromagnetic forces, but the magnetic part of the **Lorentz** force law does not obey Newton's 3rd law, with the violation being of order v^2/c^2, where v is the velocity of the charges and c is the speed of light in vacuum. That is, for electric charges q_i at positions $\mathbf{x}_i$ with velocities $\mathbf{v}_i$ with $v_i \ll c$, the Lorentz force is, in Gaussian units,

$$\begin{aligned}
\mathbf{F}_{1,2} &= q_1\mathbf{E_2} + q_1\frac{\mathbf{v}_1}{c}\times\mathbf{B}_2 = q_1 q_2\frac{\mathbf{x}_{12}}{x_{12}^3} + q_1\frac{\mathbf{v}_1}{c}\times\left(q_2\frac{\mathbf{v}_2}{c}\times\frac{\mathbf{x}_{12}}{x_{12}^3}\right) \\
&= q_1 q_2\left[\frac{\mathbf{x}_{12}}{x_{12}^3}\left(1 - \frac{\mathbf{v}_1\cdot\mathbf{v}_2}{c^2}\right) + \frac{\mathbf{v}_1\cdot\mathbf{x}_{12}}{x_{12}^3}\mathbf{v}_2\right], \qquad (20) \\
\mathbf{F}_{2,1} &= q_1 q_2\left[\frac{\mathbf{x}_{21}}{x_{21}^3}\left(1 - \frac{\mathbf{v}_1\cdot\mathbf{v}_2}{c^2}\right) + \frac{\mathbf{v}_2\cdot\mathbf{x}_{21}}{x_{21}^3}\mathbf{v}_1\right] = -q_1 q_2\left[\frac{\mathbf{x}_{12}}{x_{12}^3}\left(1 - \frac{\mathbf{v}_1\cdot\mathbf{v}_2}{c^2}\right) + \frac{\mathbf{v}_2\cdot\mathbf{x}_{12}}{x_{12}^3}\mathbf{v}_1\right] \\
&= -\mathbf{F}_{1,2} + q_1 q_2\frac{(\mathbf{v}_2\cdot\mathbf{x}_{12})\mathbf{v}_1 - (\mathbf{v}_1\cdot\mathbf{x}_{12})\mathbf{v}_2}{x_{12}^3}, \qquad (21)
\end{aligned}$$

where $\mathbf{x}_{12} = \mathbf{x}_1 - \mathbf{x_2} = -\mathbf{x}_{21}$. Thus, when $\mathbf{v}_1$ is different from $\mathbf{v}_2$ and neither is along the line of centers $\mathbf{x}_{12}$, we have that $\mathbf{F}_{12} \neq -\mathbf{F}_{12}$.

DRAFT - IN - PROGRESS

24.19.02
Other Examples of Force|Torque

©|WEB - URL |||

In general the **Cardinal Equations** of mechanics can be applied to any system after a description of the forces, torques and work on the components of the system are modeled. The kind of interaction any component has is part of the characteristics of the system.

Typical examples follows.

- A point electric fixed **Dipole** , which is affected by a force, in any non-homogeneous external electric field, plus a pole-independent torque in any external electric field. Read § 36.05.01, § 41.02.02, § 36.05.04.
- A point magnetic fixed **Dipole** , which is affected by a force, in any non-homogeneous external magnetic field, plus a pole-independent torque in any external magnetic field. Read § 36.05.01, § 41.02.02, § 36.05.04.
- A point electric induced **Dipole** .
- A point magnetic induced **Dipole** .
- The **Dipole -Dipole** force, which is a non-central force. However, the resultant moment of internal interactions sums to zero.
- Darwin interaction Lagrangian gives the lowest order relativistic correction to the interaction of point charge particles. It neglects radiation of ElectroMagnetic waves. It gives a non-central force.

$$L_{\text{int}} = \frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2}\left(-1+\frac{1}{2c^2}\left(\mathbf{v}_1\cdot\mathbf{v}_2+\frac{(\mathbf{v}_1\cdot\mathbf{r})(\mathbf{v}_2\cdot\mathbf{r})}{r^2}\right)\right) \quad .$$

- The tensor force is found in systems of nucleons: it is given by an interaction Hamiltonian depending on the relative position, $\mathbf{r}$, and spins, $\boldsymbol{\sigma}_1$ and $\boldsymbol{\sigma}_2$, of the two particles:

$$H_{\text{int}} \propto \boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2 - \frac{3(\boldsymbol{\sigma}_1\cdot\mathbf{r})(\boldsymbol{\sigma}_2\cdot\mathbf{r})}{r^2} \quad .$$

  It gives a non-central force.
- A spin-orbit coupling is found in many systems: it is given by an Hamiltonian like:

$$H_{\text{int}} \propto \mathbf{L}\cdot\mathbf{S} \quad .$$

Note that any vector linked to some of the properties of the particles, such as **Electric Dipole** | **Magnetic Dipole** moments, spin or velocity, can be used to provide a non-central force without breaking the space isotropy.

24.19.03
Interactions in Macroscopic Systems

Interactions in macroscopic systems arise from microscopic interactions summed on large number of particles.

- Static and dynamic sliding friction.
- Normal reaction forces.
- Elastic forces, in one, two and three dimensions.

24.21 Examples and Physical Applications

24.21.01
Second Cardinal Equation and law of transformation of momenta

Suppose one has derived the second cardinal equation (24.06.05) without the term $\mathbf{v}_0 \wedge \mathbf{P}$. Show, by applying it to two different poles, that the missing term makes it incompatible with the law of transformation of momenta for force and angular momentum.

24.21.02
Arnold Proposition 1.7

Show that:

$$L^2 \leq 2I\mathcal{K} \quad .$$

24.21.03
Internal Torque Between Two Particles

The force of attraction/repulsion between two particles is given by:

$$\mathbf{f}_{21} = k\left(\mathbf{r}_2 - \mathbf{r}_1 + \frac{r}{v_0}(\mathbf{v}_2 - \mathbf{v}_1)\right) \quad ,$$

where k is a constant, v_0 is a constant velocity, and $r = |\mathbf{r}_2 - \mathbf{r}_1|$. Calculate the internal torque for the system; why does this quantity not vanish? Is the system conservative?

24.21.04
On the Cardinal Equations

Show that if the second **Cardinal Equation** is valid with respect to two different poles, then it implies the first **Cardinal Equation** .

24.21.05
System of Forces

Consider a system of applied Force|Torque.

- Resultant external force: it affects the Center-Of-Mass motion.
- Resultant external torque: it affects motion about the Center-Of-Mass.
- A force: ...
- A pure torque: the resultant is zero; many cases may arise:
  - a couple;
  - a n-couple: any set of identical vectors, applied in a circle, tangentially with the same handedness and applied at equi-distant points.
  - ... infinite other cases....
- a zero force and zero torque system; many cases may arise:
  - any two opposite torques;
  - any number of identical vectors applied on a circle, at equi-distant points, radially pointing; they provoke a dilatation/compression; the virial is non-zero;
  - four identical forces, applied at the vertexes of a square in a **Quadrupole** -like arrangement.

Si supponga che il Reference Frame solidale con il Sole sia un Reference Frame inerziale e si considerino i moti di rivoluzione e di rotazione della Terra supponendo l'orbita del moto di rivoluzione circolare con centro nel Sole ed entrambi i moti di rivoluzione e rotazione uniformi. Introducendo un Reference Frame $Oxyz$ solidale con la Terra e avente origine nel suo centro discutere i vari contributi dell'accelerazione di trascinamento del Reference Frame. Si supponga la Terra di forma sferica e con una distribuzione interna di massa a simmetria sferica e si supponga inoltre che la forza peso che agisce su un punto materiale di massa m alla superficie della Terra valga

$$\mathbf{F}_p = -\frac{GM_T m}{r^3}\mathbf{r}$$

dove $M_T = 5.98{\cdot}10^{24}$ kg è la massa della Terra, $G = 6.67{\cdot}10^{-11}$ $\mathrm{m^3 s^{-2} kg^{-1}}$ è la costante di gravitazione universale, e $\mathbf{r}$ è il vettore posizione del punto materiale rispetto al centro della Terra, supponendo $r < R_T$ e sapendo che $R_T = 6.38{\cdot}10^3$ km. Determinare la direzione della verticale apparente alla superficie della Terra e il valore del peso apparente alla latitudine di 45°. Si assuma il periodo di rivoluzione della Terra $T_{\mathtt{riv}} = 365.25$ giorni (periodo siderale), il periodo di rotazione della Terra $T_{\mathtt{rot}} = 23.93$ ore (giorno siderale pari a 86160 s, diverso dal giorno solare medio) e il raggio dell'orbita terrestre pari a $R = 1.496{\cdot}10^{11}$ m.

WORKED SOLUTION

Si denoti con $\mathbf{R}$ il vettore posizione della Terra rispetto al Reference Frame inerziale solidale con il Sole e avente origine nel centro del Sole e con $\mathbf{r}$ il vettore posizione del punto materiale rispetto al Reference Frame solidale con la Terra e avente origine nel centro della Terra. Sia Ω la velocità angolare, supposta costante, di rivoluzione attorno al Sole e ω la velocità angolare, supposta costante, di rotazione della Terra su sé stessa. L'accelerazione di trascinamento ha, per le ipotesi fatte, le due componenti di modulo

$$\left|\frac{d^2\mathbf{R}}{dt^2}\right| = \left|-\Omega^2\mathbf{R}\right| = \Omega^2 R \quad ,$$

$$|\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{r})| \approx \omega^2 R_T \qquad \text{vale esattamente } \omega^2 R_T \text{ all'equatore}$$

Le velocità angolari di rivoluzione e di rotazione della Terra sono

$$\Omega = 1.99{\cdot}10^{-7} \text{ rad/s} \quad ,$$
$$\omega = 7.29{\cdot}10^{-5} \text{ rad/s} \quad .$$

Da queste si deducono le accelerazioni centripete

$$\Omega^2 R = 5.93{\cdot}10^{-3} \text{ m/s}^2 \quad ,$$
$$\omega^2 R_T = 3.39{\cdot}10^{-2} \text{ m/s}^2 \qquad \text{all'equatore}$$

da cui risulta che l'accelerazione legata al moto di rivoluzione è un ordine di grandezza inferiore a quella legata al moto di rotazione e può essere trascurata in prima approssimazione. Per confronto l'accelerazione centripeta legata al moto del Sole attorno al centro della galassia può essere stimata pari a

$$\Omega_G^2 R_G \approx 3{\cdot}10^{-10} \text{ m/s}^2$$

ed è quindi di molto inferiore alle due precedenti.

Nel Reference Frame non inerziale solidale con la Terra la direzione della verticale apparente si determina dalla risultante delle forze agenti su un punto materiale in quiete (peso e forza centrifuga, senza la forza di Coriolis):

$$\mathbf{F} = \mathbf{F}_p + \mathbf{F}_c = -\frac{GM_T m}{r^3}\mathbf{r} - m\,\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{r}) = +m\mathbf{g} + m\omega^2\,[\mathbf{r} - \widehat{\mathbf{n}}\,(\mathbf{n}\cdot\mathbf{r})]$$

dove, essendo alla superficie della Terra, si è introdotta l'accelerazione di gravità $g = GM_T/R_T^2$ e la forza centrifuga è stata decomposta nelle componenti radiale e parallela ad $\boldsymbol{\omega}$ introducendo il unit vector $\widehat{\mathbf{n}} \equiv \boldsymbol{\omega}/\omega$. La forza centrifuga risulta dunque diretta perpendicolarmente all'asse di rotazione terrestre e diretta radialmente verso l'esterno. Il modulo della forza centrifuga è, detta λ la latitudine,

$$|\mathbf{F}_c| = m\omega^2 R_T \cos[\lambda] = (3.39{\cdot}10^{-2}\ \mathrm{m/s^2})m\cos[\lambda]$$

La relazione sopra permette di introdurre una accelerazione di gravità efficace alla superficie della Terra definita da

$$\mathbf{g}_{\mathtt{eff}} \equiv \mathbf{g} - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{r}) \tag{24.21.01}$$

Una relazione approssimata per $g_{\mathtt{eff}}$ si può ricavare applicando il teorema di Carnot e sviluppando al primo ordine in $\omega^2 R_T/g = 3.46{\cdot}10^{-3} \ll 1$

$$g_{\mathtt{eff}} \simeq g - \omega^2 R_T \cos^2\lambda \tag{24.21.02}$$

che si riduce a $g_{\mathtt{eff}} = g - \omega^2 R_T$ (valore esatto) per $\lambda = 0$ e $g_{\mathtt{eff}} = g$ (valore esatto) per $\lambda = \pm 90°$. Si noti che il parametro di sviluppo, $\omega^2 R_T/g$ altro non è che il rapporto F_c/F_p tra la forza centrifuga e la forza peso.

Detta $\Delta\theta$ la deviazione dalla direzione radiale, cioè dalla direzione di $\mathbf{r}$, si ha dal teorema dei seni

$$\frac{\sin[\Delta\theta]}{F_c} = \frac{\sin[(\Delta\theta+\lambda)]}{F_p}$$

da cui si deduce

$$\sin[\Delta\theta] = \frac{\omega^2 R_T}{g}\left[\sin[\lambda]\cos[\lambda]\cos[\Delta\theta] + \cos^2\lambda\sin[\Delta\theta]\right] \ll 1 \tag{24.21.03}$$

→ 1341 1342

essendo $\omega^2 R_T/g \ll 1$ (forza centrifuga molto minore della forza peso). Raccogliendo nella (24.21.03) a fattore comune $\sin[\Delta\theta]$ si può scrivere

$$\sin[\Delta\theta]\left[1 - \frac{\omega^2 R_T}{g}\cos^2\lambda\sin[\Delta\theta]\right] = \frac{\omega^2 R_T}{g}\sin[\lambda]\cos[\lambda]\cos[\Delta\theta]$$

da cui segue

$$\sin[\Delta\theta] \simeq \frac{\omega^2 R_T}{g}\sin[\lambda]\cos[\lambda]\cos[\Delta\theta] \ll 1$$

Si ha allora $\sin[\Delta\theta] \simeq \Delta\theta \ll 1$ e $\cos[\Delta\theta] \simeq 1$ e la relazione precedente si può approssimare a

$$\Delta\theta \simeq \frac{\omega^2 R_T}{2g}\sin[2\lambda] = 1.73{\cdot}10^{-3}\ \mathrm{rad} \simeq 0.1°$$

che fornisce la deviazione voluta con il segno corretto se si conviene di misurare l'angolo $\Delta\theta$ a partire da $\mathbf{g}$ verso $\mathbf{g}_{\mathtt{eff}}$ e positivo se in senso antiorario. Tale deviazione è nulla al polo (dove $F_c = 0$), è nulla all'equatore (dove $\mathbf{F}_c \parallel \mathbf{F}_p$) ed è massima alla latitudine di $\pm 45°$. Il calcolo dell'angolo $\Delta\theta$ poteva anche essere effettuato osservando che $\Delta\theta$ è l'angolo fra il vettore forza risultante, $\mathbf{F}$, e il vettore $-\mathbf{r}$. Ne segue, usando l'approssimazione $|\mathbf{F}| \simeq |\mathbf{F}_p| = mg$ (giustificata da $\omega^2 R_T/g \ll 1$)

$$|\sin[\Delta\theta]| = \frac{|-\mathbf{r}\wedge\mathbf{F}|}{|\mathbf{F}||\mathbf{r}|} \simeq \frac{\omega^2 R_T}{2g}|\sin[2\lambda]|$$

La relazione esatta per $\Delta\theta$ è

$$\tan[\Delta\theta] = \frac{\omega^2 R_T \sin[\lambda]\cos[\lambda]}{g - \omega^2 R_T\cos^2\lambda} \tag{24.21.04}$$

CC BY NC ND

che si riduce alla (24.21.03) nel caso $\omega^2 R_T/g \ll 1$.

24.21.07
Deviazione Verso Est/Ovest Della Caduta Dei Gravi Alla Superficie Della Terra

This § is referenced at pages:
[1375]

©|Alonso & Finn, , ..., ..., ...Ed., ...|E6.3||

©|M.R.Spiegel, *Theory And Problems Of Theoretical Mechanics*, 1967, McGraw-Hill, ...Ed., ...|6.15 6.16 6.17||

Si stimi approssimativamente l'entità della deviazione verso est in una (breve) caduta libera di un grave che parte da fermo alla superficie terrestre nell'emisfero nord. Si assuma la terra a simmetria sferica e ruotante con velocità angolare costante, $\boldsymbol{\omega}$ e che la zona alla superficie della Terra in cui avviene uil moto del proiettile sia piccola rispetto alla distanza della zona stessa dall'asse di rotazione terrestre.

Di quanto devia verso est un grave lasciato cadere da un'altezza $h = 100$ m alla latitudine di $45°$?

WORKED SOLUTION

Si consideri, come da ipotesi, la zona di caduta così piccola da poter trascurare le variazioni di accelerazione di gravità e le variazioni della forza centrifuga durante la caduta.

Sia $\mathbf{x}$ la posizione relativa al Reference Frame terrestre e la posizione iniziale del grave sia: $\mathbf{x}[t=0] = \mathbf{x}_S$.

L'accelerazione relativa al Reference Frame terrestre, non inerziale, è data da

$$\mathbf{a}[\mathbf{x},\mathbf{v}] = \mathbf{g}[\mathbf{x}] - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}) - 2\,\boldsymbol{\omega}\wedge\mathbf{v} \simeq \mathbf{g}[\mathbf{x}_0] - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_0) - 2\,\boldsymbol{\omega}\wedge\mathbf{v} \equiv \mathbf{g}_E[\mathbf{x}_0] - 2\,\boldsymbol{\omega}\wedge\mathbf{v} \quad ,$$

dove $\mathbf{g}_E[\mathbf{x}_0]$ è l'accelerazione efficace alla superficie della Terra, nelle vicinanze del posto dove si muove il corpo, che include il contributo della forza centrifuga come discusso nel problema § 24.21.06.

L'accelerazione $\mathbf{g}_E$ giace nel piano meridiano della Terra e quindi una deviazione trasversale può solo derivare dal termine di Coriolis: $-2\,\boldsymbol{\omega}\wedge\mathbf{v}$.

Possiamo supporre, approssimativamente, che sia $\mathbf{g}_{\mathtt{eff}} \parallel \mathbf{g} \parallel \mathbf{r}$, trascurando sia il fatto che la Terra non ha una distribuzione di massa a simmetria sferica, per cui in generale $\mathbf{g}$ non è parallelo ad $\mathbf{r}$, sia l'effetto della forza centrifiga, per cui in generale $\mathbf{g}_{\mathtt{eff}}$ non è paralelo a $\mathbf{g}$ (e quindi ad $\mathbf{r}$).

In fact in the usual case, at the Earth surface, $|\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_S)| \ll |\mathbf{g}|$ and therefore the centrifugal force can be neglected with respect to the weight. The driving parameter is $R\omega^2/g \approx 3\cdot 10^{-3}$. Note that in the generic case of a rotating object it might be nont possible to neglect the effect of centrifugal forces, if the object is rotating with a large angular velocity.

Adottiamo un metodo approssimato che consiste nel considerare l'effetto della forza di Coriolis come una piccola perturbazione al moto (imperturbato) che si avrebbe in assenza di forza di Coriolis. Si determina quindi prima il moto imperturbato in assenza di forza di Coriolis e poi si valuta l'effetto della forza di Coriolis usando l'equazione oraria del moto imperturbato.

Detta v_M la componente della velocità del grave nel piano meridiano l'accelerazione trasversale a tale piano, diretta verso est nell'emisfero nord, ha modulo

$$|a_T| = 2\omega|v_M\cos[\lambda]| \qquad \text{avendo assunto } \mathbf{g}_{\mathtt{eff}} \parallel \mathbf{r} \quad , \tag{24.21.05}$$

e indicando con λ la latitudine, perchè, per ipotesi, il proiettile cade radialmente nel moto imperturbato con l'approssiamzione fatta $\mathbf{g}_{\mathtt{eff}} \parallel \mathbf{r}$.

Il moto imperturbato è una caduta libera radiale verso il centro della Terra con accelerazione costante. In base all'approccio che si vuole usare, si osserva che, in prima approssimazione, per un tragitto breve cosicché v_M resta sufficientemente piccola in modulo, si può sostituire v_M con il valore della velocità che si calcolerebbe trascurando l'effetto della forza di Coriolis (moto imperturbato).

Ciò è giustificato dal fatto che, nelle ipotesi fatte, l'accelerazione di Coriolis rappresenta solo una piccola correzione alla $\mathbf{g}_{\mathrm{E}}$, essendo $2\omega|v_{\mathrm{M}}\cos[\lambda]| \ll g$ per $|\mathbf{v}_{\mathrm{M}}|$ abbastanza piccolo.
Si scelga un Coordinate System cartesiane ortoginali con l'asse z radiale uscente dalla Terra, l'asse x tangente al meridiano terrestre e orientato da nord a sud (corentemente con il fatto che l'angolo polare si intende contato a partire dal polo nord, e l'asse y orinetato di conseguenza (risulta orientato da ovest verso est).
Note that the Coriolis force for a falling body is oriented, in the northern hemisphere, from west to east.
Si può allora porre, essendo $v = -gt$,

$$a_{\mathrm{T}} \equiv \ddot{y} \simeq 2\omega v\cos[\lambda] \simeq 2\omega g t\cos[\lambda] \quad ,$$

con il segno corretto per l'emisfero nord perchè l'asse y è orientato verso est.
L'equazione, integrata con la condizione iniziale $\dot{y}(t=0)=0$, essendo la velocità trasversa iniziale nulla, fornisce

$$\boxed{\Delta y = \frac{1}{3}g\omega\cos[\lambda]\,t^3} \quad . \tag{24.21.06}$$

Nelle approssimazioni fatte la deviazione si calcola usando la relazione

$$h = \frac{g}{2}t^2 \quad ,$$

e risulta

$$\boxed{\Delta y \simeq \frac{2}{3}h\omega\cos[\lambda]\sqrt{\frac{2h}{g}}} = 1.55\ \mathrm{cm} \quad .$$

Si noti che la velocità trasversale da origine, tramite la forza di Coriolis, ad una correzione alla velocità nel piano meridiano che è però una correzione di secondo ordine.

24.21.08
Motion Relative to the Earth

©|M.S. Tiersten and H. Soodak|Am.J.Phys, , ..., ..., ...Ed., ..., Vol 68, No 2, February 2000, p. 129||

Show that the motion of a particle of mass m relative to the Earth is described by the equation

$$\ddot{\mathbf{x}} + 2\,\boldsymbol{\omega}\wedge\dot{\mathbf{x}} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}) = \mathbf{g}[\mathbf{x}] + \frac{\mathbf{F}[\mathbf{x}]}{m} \equiv \hat{\mathbf{g}}[\mathbf{x}] \quad , \tag{24.21.07}$$

→ 1344 1345

where $\mathbf{x}$ is the position of the particle relative to the Center of the Earth, $|\boldsymbol{\omega}| = 7.3{\cdot}10^{-5}$ rad/s is the angular velocity of the Earth, assumed to be constant, $\mathbf{g}[\mathbf{x}]$ is the acceleration of gravity and $\mathbf{F}[\mathbf{x}]$ is any other positional force acting on the particle.

Use the method of successive approximation to show that when the particle starts at $\mathbf{x}[t=0] \equiv \mathbf{x}_{\mathrm{S}}$ with velocity $\mathbf{v}[t=0] \equiv \mathbf{v}_{\mathrm{S}}$, in a neighboring of $\mathbf{x}_{\mathrm{S}}$ such that both $\mathbf{g}[\mathbf{x}]$ and $\mathbf{F}[\mathbf{x}]$ can be considered as uniform, the position as a function of time, to third order in time, is given by:

$$\mathbf{x}[t] = \mathbf{x}_{\mathrm{S}} + \mathbf{v}_{\mathrm{S}}t + \frac{t^2}{2}(\hat{\mathbf{g}} - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_{\mathrm{S}}) - 2\,\omega\wedge\mathbf{v}_{\mathrm{S}}) - \frac{1}{3}(\boldsymbol{\omega}\wedge\hat{\mathbf{g}})\,t^3 \quad , \tag{24.21.08}$$

→ 1344

where

$$\hat{\mathbf{g}}[\mathbf{x}] \equiv \mathbf{g}[\mathbf{x}] + \frac{\mathbf{F}[\mathbf{x}]}{m} \qquad \text{and} \qquad \hat{\mathbf{g}} \equiv \hat{\mathbf{g}}[\mathbf{x}_{\mathrm{S}}] \quad .$$

If either $\mathbf{g}[\mathbf{x}]$ or $\mathbf{F}[\mathbf{x}]$ cannot be considered uniform then the method must be applied by taking into account $\mathbf{g}[\mathbf{x}[t]]$ or $\mathbf{F}[\mathbf{x}[t]]$.

Note that if the object is not a point particle one must interpret the motion as the motion of the Center-Of-Mass and the forces as the resultant of ecternal forces. In this case the object might also have an internal motion.

PROGRESS

WORKED SOLUTION

Note that the solution (24.21.08) includes a constant acceleration part, with acceleration given by

$$\hat{\mathbf{g}} - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_S) - 2\,\omega\wedge\mathbf{v}_S \quad ,$$

plus a corrective term, depending of the third power of t.

To solve the problem first note that, according to the hypothesis that both $\mathbf{g}[\mathbf{x}]$ and $\mathbf{F}[\mathbf{x}]$ can be considered as uniform in the region of motion, the effect of $\mathbf{F}[\mathbf{x}]$ can be trivially accounted for by defining an effective gravity field:

$$\hat{\mathbf{g}}[\mathbf{x}] \equiv \mathbf{g}[\mathbf{x}] + \frac{\mathbf{F}[\mathbf{x}]}{m} \equiv \hat{\mathbf{g}} \quad .$$

Assume therefore that it is possible to neglect the variations of $\hat{\mathbf{g}}[\mathbf{x}]$ in the region of motion.

Solve the differential equation by means of Picard method of successive approximations. Note that the series development is a series development in t, the independent variabile of the differential equation. Even better, from a physical point of view, one should think of a series development in the dimensionless parameter $|\boldsymbol{\omega}|t$.

The zero-order approximation is obtained by replacing in equation (24.21.07), written in normal form

$$\ddot{\mathbf{x}} = \hat{\mathbf{g}} - 2\,\boldsymbol{\omega}\wedge\dot{\mathbf{x}} - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}) \quad , \tag{24.21.09}$$

→ 1344

the initial conditions

$$\mathbf{x}[t] \equiv \mathbf{x}_S = \mathbf{x}[t=0] \equiv \mathbf{x}_S \qquad \mathbf{v}[t] \equiv \mathbf{v}_S = \mathbf{v}[t=0] \equiv \mathbf{v}_S \quad . \tag{24.21.10}$$

→ 1344

Note that the method of successive approximations (Picard method) is normally used with first-order systems of differential equations. However, the single second-order equation of motion (24.21.09) can be reduced in a standard fashion to a first-order systems of differential equations by defining the new variable:

$$\mathbf{y} \equiv \dot{\mathbf{x}} \quad .$$

After doing that the two variables, $\mathbf{x}$ and $\mathbf{y}$, must be considered as independent variables, and the relation $\mathbf{y} \equiv \dot{\mathbf{x}}$ emerging only as a result of the solution of the system. Therefore the method of successive approximations implies that one chooses as zero order approximation the initial value of the two variables, that is equation (24.21.10). This explains the apparently inconsistent initial conditions (24.21.10) with a non-zero constant velocity corresponding to a constant position.

This gives:

$$\ddot{\mathbf{x}} = \hat{\mathbf{g}} - 2\,\omega\wedge\mathbf{v}_S - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_S) \equiv \mathbf{G} = \text{constant} \tag{24.21.11}$$

$$\Longrightarrow \mathbf{x}_0[t] = \mathbf{x}_S + \mathbf{v}_S t + \frac{t^2}{2}\mathbf{G} \quad .$$

The zero-order approximation is then replaced into the right-hand side of the full equation (24.21.09) to get the first-order approximation:

$$\ddot{\mathbf{x}} = \hat{\mathbf{g}} - 2\,\omega\wedge\mathbf{v}_S - \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_S) - t\,(2\,\boldsymbol{\omega}\wedge\mathbf{G} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S)) - \frac{t^2}{2}\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{G}) \quad ,$$

$$= \mathbf{G} - t\,(2\,\boldsymbol{\omega}\wedge\mathbf{G} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S)) - \frac{t^2}{2}\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{G}) \quad ,$$

$$\Longrightarrow \mathbf{x}_1[t] = \mathbf{x}_S + \mathbf{v}_S t + \frac{t^2}{2}\mathbf{G} - \frac{t^3}{6}(2\,\boldsymbol{\omega}\wedge\mathbf{G} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S)) - \frac{t^4}{24}\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{G}) \quad .$$

Note that the second-order term of the first-order solution $\mathbf{x}_1[t]$ is the same as the second-order term of the zero-order solution $\mathbf{x}_0[t]$. Therefore one might expect that it will not change in higher-order approximations.

The third-order coefficient gives, in its exact expression and the truncated expression to second-order in ω,

$$2\,\boldsymbol{\omega}\wedge\mathbf{G} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S) = 2\,\boldsymbol{\omega}\wedge\mathbf{g} - 3\,\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S) + 2\omega^2\,\boldsymbol{\omega}\wedge\mathbf{x}_S \quad ,$$

$$2\,\boldsymbol{\omega}\wedge\mathbf{G} + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S) = 2\,\boldsymbol{\omega}\wedge\mathbf{g} - 3\,\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{v}_S) + \mathcal{O}\,(\omega)^3 \quad .$$

CC BY NC ND

It is expected that the third-order coefficient will not change in higher-order approximations, while the fourth-order term will change. This can be indeed verified by carrying on the next iteration.
In the usual case, at the Earth surface, $|\boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge\mathbf{x}_S)| \ll |\hat{\mathbf{g}}|$ and therefore the centrifugal force can be neglected with respect to the weight. The driving parameter is $R\omega^2/g \approx 3.5\cdot 10^{-5}$.
By using this simplification the first-order approximation is simplified by $\mathbf{G} \simeq \hat{\mathbf{g}} - 2\,\boldsymbol{\omega}\wedge\mathbf{v}_S$, showing that, for small times, the acceleration of the particle is given by the acceleration of gravity corrected by the term $-2\,\boldsymbol{\omega}\wedge\mathbf{v}_S$, whose direction is, a priori, arbitrary. In the case of an object starting with zero velocity the initial velocity is directed along $\mathbf{g}$ and therefore the corrective term to the acceleration of gravity is perpendicular to both $\boldsymbol{\omega}$ and $\mathbf{g}$, that is eastwards/westwards.
Note that the corrective term to the acceleration of gravity given by the Coriolis force is of the same order in ω as the acceleration of gravity, because $v \approx gt$. As a matter of fact the Coriolis acceleration is small with respect to the acceleration of gravity as long a the velocity of the object is $v \lesssim 10^5$ m/s.
The result is a development in series of time, or better, in the dimensionless variable $|\boldsymbol{\omega}|t$. Therefore it applies, for small centrifugal and Coriolis force, for small enough times.
Note finally that the equation (24.21.07) can actually be solved exactly, as it is a linear system.
Note that the Coriolis force is of first-order in $\boldsymbol{\omega}$ while the centrifugal force is of second-order in $\boldsymbol{\omega}$. Therefore, as long as the angular velocity is small enough, the centrifugal force can be neglected with respect to the Coriolis force. Actually the balance of the two terms is given by the relative magnitude of the two quantities ωR and v, in term of the distance R of the object from the Earth axis and the velocity v of the object. Note, however, that when the velocity of the body is zero with respect to the non inertial system the Coriolis force is zero. This happens, in particular, when the object starts with zero velocity. Therefore, due to the latter two arguments, it is not possible to ignore the centrifugal force with respect to the Coriolis force only in the grounds that the former is of second-order with respect to the small angular velocity.
Note that the centrifugal force at the Earth surface is always small, in module, with respect to the force of gravity, as long as the body is close to the Earth surface (not too far from the Earth rotation axis). Therefor, under the latter conditions, one might just neglect it with respect to the weight as long as the body does not move so much that the position dependence of the weight and centrifugal force is negligible.
The eastwards deviation for an object falling from $h = 100$ m with zero start velocity at a latitude of λ 45 °, is found to be: $\Delta y = 1.5$ cm.
The final formula for an object falling starting with zero velocity ($\mathbf{v}_S = 0$) can be obtained as follows. Let us neglect in the formula the centrifugal force with respcet to the force of gravity, as it is appropriate at the surface of the Earth. Then:

$$\mathbf{G} \simeq \mathbf{g} \quad .$$

Therefore the first approximation $\mathbf{x}_1[t]$ does not carry any effect of the Earth rotation, under the current hypotesis.
The third order term becomes, to first-order in ω:

$$2\,\boldsymbol{\omega}\wedge\mathbf{g} + \mathcal{O}\left(\omega\right)^2 \quad .$$

The (eastwards) deviation of the real motion with respect to the case of no roation of the Earth is thus:

$$-\frac{t^3}{6}\left(2\,\boldsymbol{\omega}\wedge\mathbf{g}\right) = -\frac{t^3}{3}\boldsymbol{\omega}\wedge\mathbf{g} \quad .$$

Compare with problem § 24-050.

Oggetto Fermo a Terra Visto Da Una Giostra in Moto

Un bambino si trova fermo al centro di una giostra che ruota con velocità angolare costante Ω. Egli osserva i suoi genitori che sono fermi a terra ma che, dal suo punto di vista, si muovono di moto circolare uniforme rispetto al centro della giostra. Nella descrizione del bambino chi fornisce la forza centripeta necessaria per mantenere i genitori in moto circolare uniforme?

WORKED SOLUTION

Si considerino le sole forze agenti sul piano orizzontale. Sui genitori non agisce alcuna forza reale con componenti nel piano orizzontale. Dal punto di vista del bambino, osservatore non inerziale, sui genitori agiscono però le forze (fittizie) centrifuga e di Coriolis. La loro risultante fornisce la forze centripeta richiesta.

[1369]

Risolvere il problema § 24-038 utilizzando le equazioni cardinali della meccanica dei sistemi.

WORKED SOLUTION

Si usino le notazioni del problema § 24-038. Consideriamo come sistema l'insieme del blocco e del piano inclinato. Il sistema è conservativo e inoltre, poiché il tavolo è liscio, la risultante delle forze esterne sul sistema è nulla lungo la direzione orizzontale. L'accelerazione del centro di massa è dunque nulla nella direzione orizzontale. Ne segue

$$MA_x + ma_x = 0 \implies MV_x + mv_x = costante = 0 \tag{24.21.12}$$

→ 1346 1347

in cui il valore della costante è stato posto uguale a zero grazie alle condizioni iniziali. Introduciamo la coordinata s che misura la posizione del blocco rispetto alla cima del piano inclinato. La relazione tra la coordinata s e le coordinate cartesiane x' e y' che individuano la posizione del blocco relativa al piano inclinato è

$$\begin{aligned} x' &= +s\cos[\theta] \quad , \\ y' &= -s\sin[\theta] \end{aligned}$$

La relazione tra le velocità è

$$v_x = V_x + \dot{x}' = V_x + \dot{s}\cos[\theta] \tag{24.21.13}$$

→ 1346 1347

$$v_y = V_y + \dot{y}' = -\dot{s}\sin[\theta] \tag{24.21.14}$$

→ 1346 1347

essendo $V_y = 0$. Il principio di conservazione dell'energia meccanica applicato al sistema fornisce allora l'equazione

$$0 = \frac{1}{2}m\left(v_x^2 + v_y^2\right) + \frac{1}{2}MV_x^2 - mgs\sin[\theta] \tag{24.21.15}$$

→ 1346

avendo scelto come riferimento per l'energia potenziale gravitazionale la configurazione in cui il blocco è al vertice del piano inclinato. Si noti che l'energia potenziale gravitazionale del piano inclinato non cambia. Le equazioni (24.21.12), (24.21.13), (24.21.14) permettono di esprimere le velocità v_x, v_y e V_x in termini di $s(t)$ e delle sue derivate. Sostituendo tali espressioni in (24.21.15)

si perviene ad una equazione differenziale per $s(t)$:

$$\dot{s}^2 = \frac{2g\sin[\theta]\,(M+m)}{M+m\sin^2\theta}s \tag{24.21.16}$$

→ 1347

Integrando l'equazione differenziale per $s(t)$, avendo scelto il segno positivo per $\dot{s}(t)$ in quanto s è positiva nel problema, ed osservando che $\dot{s}$ non è identicamente nulla, si ottiene

$$s(t) = \frac{k}{4}t^2$$

con

$$k = \frac{2g\sin[\theta]\,(M+m)}{M+m\sin^2\theta}$$

L'espressione per $s(t)$ non dipende dalla posizione iniziale e dalle velocità iniziali perché si è posto in partenza velocità iniziali nulle e posizione iniziale $s_0 = 0$. da cui segue l'accelerazione lungo il piano inclinato

$$\ddot{s} = \frac{g\sin[\theta]\,(M+m)}{M+m\sin^2\theta}$$

Alternativamente l'accelerazione può essere determinata dalla (24.21.16) derivando entrambi i membri rispetto al tempo e semplificando la velocità, cosa possibile in quanto la velocità non è identicamente nulla come risulta evidente dalla (24.21.16) stessa. Un ulteriore metodo per derivare l'accelerazione dalla (24.21.16) è l'uso della (23.03.09.02) dato che il moto è un moto rettilineo uniformemente accelerato. Le componenti cartesiane dell'accelerazione possono essere ricavate dalle equazioni (24.21.12), (24.21.13), (24.21.14), derivate rispetto la tempo, e si ottiene

$$\begin{aligned} a_x &= \frac{M}{M+m}\cos[\theta]\,\ddot{s} \quad , \\ a_y &= -\ddot{s}\sin[\theta] \quad , \\ A_x &= -\frac{m}{M+m}\cos[\theta]\,\ddot{s} \end{aligned}$$

Si osservi che dalle stesse equazioni (24.21.12), (24.21.13), (24.21.14), si può ricavare il vincolo cinematico:

$$-a_y = a_x\left(1+\frac{m}{M}\right)\tan[\theta]$$

Si noti che in questo problema la coppia di reazioni vincolari tra il blocco e il piano inclinato, $\mathbf{N}$ e $-\mathbf{N}$, coppia di azione e reazione, compiono lavoro, nel giudizio dell'osservatore a terra. Infatti è la forza che il blocco esercita sul piano che accelera il piano inclinato e il suo ruolo è dunque quello di far in modo che una parte dell'energia potenziale gravitazionale del blocco vada in energia cinetica del piano inclinato anziché tutta in energia cinetica del blocco. La coppia di reazioni vincolari tra il blocco e il piano inclinato, $\mathbf{N}$ e $-\mathbf{N}$, coppia di azione e reazione, è una coppia di forze interne al sistema blocco-piano che compie lavoro. Il lavoro totale delle due forze è però nullo in quanto le forze sono uguali ed opposte ed hanno lo stesso punto di applicazione (sono forze a contatto). Quindi non contribuiscono al bilancio globale del sistema (teorema lavoro-energia). Infatti sul blocco agiscono due forze che compiono lavoro, la forza di gravità e la reazione normale, e si ha

$$\begin{aligned} \mathrm{d}L_B^{\mathtt{peso}} &= m\mathbf{g}\cdot\,\mathrm{d}\mathbf{X} + m\mathbf{g}\cdot\,\mathrm{d}\mathbf{x}' = m\mathbf{g}\cdot\,\mathrm{d}\mathbf{x}' \quad , \\ \mathrm{d}L_B^{\mathtt{normale}} &= \mathbf{N}\cdot\,\mathrm{d}\mathbf{X} + \mathbf{N}\cdot\,\mathrm{d}\mathbf{x}' = +\mathbf{N}\cdot\,\mathrm{d}\mathbf{x}' \end{aligned}$$

mentre sul piano inclinato la sola reazione normale $-\mathbf{N}$ compie lavoro

$$\mathrm{d}L_P^{\mathtt{normale}} = -\,\mathbf{N}\cdot\,\mathrm{d}\mathbf{X} - \mathbf{N}\cdot\,\mathrm{d}\mathbf{x}' = -\mathbf{N}\cdot\,\mathrm{d}\mathbf{x}' > 0 \quad .$$

Infatti il vettore $\mathbf{N}$ è perpendicolare allo spostamento relativo al piano inclinato $\mathrm{d}x'$. I due contributi, uguali ed opposti, $\mathrm{d}L_B^{\mathtt{normale}}$ e $\mathrm{d}L_P^{\mathtt{normale}}$, esistono se e solo se il piano inclinato si muove.
Si confronti con il problema § 24-038.

Si riconsideri il moto della puleggia del problema § 24-019 nel caso in cui la puleggia abbia massa M non trascurabile rispetto alle masse in gioco, momento di inerzia I e raggio R. si supponga che la fune, ideale e priva di massa, non strisci sulla carrucola.

1. Determinare l'accelerazione delle due masse.
2. Determinare il moto del centro di massa delle due masse. Risolvere il problema sia usando le **Cardinal Equation** che considerazioni energetiche.

WORKED SOLUTION

Poiché la massa della puleggia non è trascurabile la tensione della fune non è uguale ai due capi della stessa. La caduta di tensione serve a fornire un'accelerazione angolare alla carrucola. Le equazioni del moto per i due oggetti e per la carrucola si scrivono, avendo scelto un sistema di coordinate con asse x rivolto verso l'alto e scelto per l'angolo di rotazione della carrucola come positivo il verso antiorario,

$$\begin{aligned} T_1 - m_1 g &= m_1 a_1 \quad , \\ T_2 - m_2 g &= m_2 a_2 \quad , \\ F - T_1 - T_2 - M g &= 0 \quad , \\ R\,(T_1 - T_2) &= I\alpha \quad . \end{aligned}$$

ed avendo scelto la tensione T_1, corrispondente alla massa m_1 come quella che tende a far ruotare la carrucola in senso antiorario, $\Delta\theta > 0$. Il vincolo cinematico che i due oggetti sono legati ai due capi della corda impone le condizioni

$$\Delta x_1 = -\Delta x_2 \implies a \equiv a_1 = -a_2$$

Il vincolo di non strisciamento della corda sulla carrucola impone la condizione

$$\Delta x \equiv \Delta x_1 = -\Delta x_2 = -R\Delta\theta \implies v = -\omega R$$

i cui segni sono dettati dalle condizioni sui versi di x e θ scelti in precedenza. Le due relazioni ricavate costituiscono due vincoli cinematici per il sistema. Ne risulta un sistema di sei equazioni

DRAFT

nelle sei incognite a_1, a_2, T_1, T_2, F e α che risolto da

$$
\begin{aligned}
a_1 = -\, a_2 = -R\alpha = g\left[\frac{m_2 - m_1}{m_2 + m_1 + I/R^2}\right] \quad , \\
T_1 = m_1 g\left[\frac{2m_2 + I/R^2}{m_1 + m_2 + I/R^2}\right] \quad , \\
T_2 = m_2 g\left[\frac{2m_1 + I/R^2}{m_1 + m_2 + I/R^2}\right] \quad , \\
F = g\left[\frac{4m_1 m_2 + (m_1 + m_2) I/R^2}{m_1 + m_2 + I/R^2}\right] + Mg \quad .
\end{aligned}
$$

Ne risulta che il modulo dell'accelerazione delle due masse è inferiore rispetto al caso in cui $I = 0$. Parte dell'energia potenziale gravitazionale delle due masse è convertita infatti in energia cinetica di rotazione della carrucola tramite la forza di attrito statico tra la carrucola e la fune.
Il problema può pure essere risolto applicando il bilancio dell'energia meccanica alle due masse e alla carrucola. Il bilancio dell'energia meccanica, equazione (24.04.04), è

$$\boxed{\Delta E = \Delta \mathcal{K} + \Delta \Phi = L_{\text{NC}}}$$

dove L_{NC} è il lavoro delle forze non conservative o, in generale, di tutte le forze il cui contributo non è incluso nell'energia potenziale Φ. Partendo da una configurazione iniziale di quiete e applicando il bilancio dell'energia meccanica (24.04.04) rispettivamente alla massa m_1, alla massa m_2 e alla carrucola si ottengono le tre equazioni

$$
\begin{aligned}
\frac{1}{2} m_1 v^2 + m_1 g \Delta x_1 = \frac{1}{2} m_1 v^2 + m_1 g \Delta x = T_1 \Delta x_1 = +T_1 \Delta x \quad , \\
\frac{1}{2} m_2 v^2 + m_2 g \Delta x_2 = \frac{1}{2} m_2 v^2 - m_2 g \Delta x = T_2 \Delta x_2 = -T_2 \Delta x \quad , \\
\frac{1}{2} I \left[\frac{v}{R}\right]^2 = \Gamma \Delta\theta = (T_2 - T_1)\, \Delta x = R\,(T_1 - T_2)\, \frac{\Delta x}{R}
\end{aligned}
$$

Il secondo membro della terza equazione è semplicemente il lavoro fatto sulla carrucola dalle forze esterne, $\Gamma\Delta\theta$. Il suo segno può anche essere determinato dal fatto che, in base alle convenzioni fatte, $\Delta x_1 = \Delta x$ per cui se $\Delta x > 0$ si ha che $T_2 > T_1$ e questo capita se e solo se $m_2 > m_1$. Il sistema di tre equazioni permette di ricavare T_1, T_2 e v in funzione di Δx. Il bilancio dell'energia meccanica (24.04.04) può pure essere applicato al sistema complessivo delle due masse più la carrucola e si ottiene la relazione

$$\frac{1}{2}(m_1 + m_2)\, v^2 + g\Delta x\,(m_1 - m_2) + \frac{I v^2}{R^2} = \Delta E = 0$$

→ 1349

da cui si ricava

$$v^2 = 2\Delta x \left(\frac{g\,(m_2 - m_1)}{m_1 + m_2 + I/R^2}\right)$$

Notare che nel bilancio energetico globale non compare il contributo delle tensioni T_1 e T_2, forze interne, in quanto il lavoro complessivo di tutte le forze di tensione è nullo. Questo approccio è sufficiente a determinare la dinamica ma se si vogliono ricavare le tensioni della fune bisogna ricorrere al bilancio energetico dei tre sottosistemi ricavato sopra mentre per determinare la forza di reazione che tiene sospesa la carrucola bisogna ricorrere alle **Cardinal Equation** . Infatti il bilancio globale elimina le tensioni interne T_1 e T_2 (forze interne che compiono lavoro complessivo nullo). Per determinare tali tensioni occorre allora usare il bilancio separato delle due masse e della carrucola (24.21.12) in cui le tensioni appaiono.

WORKED SOLUTION

1) $a_1 = -a_2 = -R\alpha = g\,[m_2 - m_1]\,/\,[m_2 + m_1 + I/R^2]$; 2) $a_{CM} = -g\,[m_2 - m_1]^2\,/\,[m_2 + m_1]^2$.

La Corsa Sul Vagone Ferroviario

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|9.31||

This § is referenced at pages:
[1391, 1391, 1391]

Un vagone ferroviario di massa M si muove su un binario rettilineo con velocità costante u_0 in assenza di attrito apprezzabile. Sul vagone si trova un uomo, inizialmente fermo rispetto al vagone. L'uomo si mette a correre lungo il vagone in verso opposto a quello del moto del vagone e quando salta giú dalla coda del vagone la sua velocità rispetto al vagone ha modulo v_R.

1. Determinare, subito dopo che l'uomo è saltato giú, la velocità del vagone, V, e dell'uomo, v, rispetto al suolo.

WORKED SOLUTION

Sul sistema vagone più uomo non agiscono forze esterne con componente orizzontale quindi la componente della quantità di moto del sistema nella direzione orizzontale si conserva. Denotando con v e V rispettivamente le componenti delle velocità finali dell'uomo e del vagone, rispetto al Reference Frame solidale con il suolo, e con v_R il modulo della velocità relativa, per la legge di trasformazione delle velocità si ha $v = V - v_R$, in cui il segno meno davanti a v_R è dovuto la fatto che v_R ha verso opposto ad u_0 e che con v_R si è indicato il modulo della velocità relativa dell'uomo rispetto al vagone. La conservazione della quantità di moto fornisce allora

$$(m + M)\,u_0 = P_{0x} = P_x = MV + m\,(V - v_R)$$

Ne segue

$$V = u_0 + \frac{m}{m + M} v_R \quad ,$$

$$v = u_0 - \frac{m}{m + M} v_R \quad .$$

Il risultato ottenuto è del tutto indipendente dai dettagli della corsa dell'uomo sul vagone. La sola cosa che conta è la sua velocità finale.

WORKED SOLUTION

1) $V = u_0 + m/\,(m + M)\,v_R$; $v = u_0 - m/\,(m + M)\,v_R$.

Simple Toy Model for Bike Braking

Simple 2D model. Bike going in the negative x (horizontal) direction with velocity, at time t_0, $\mathbf{V}_0$ and $V_{x0} < 0$. Assume the wheels are blocked while braking, so that they are slipping without rolling. Assume that the trailing wheel is attached to the road. Start solving the problem in the Inertial Reference Frame of the ground.

1. Solve the problem with pole for the 2nd Cardinal Equation at the Center-Of-Mass.
2. Solve the problem with pole for the 2nd Cardinal Equation at the two contact points.
3. Solve the problem with pole for the 2nd Cardinal Equation at any point on the road.
4. Write the expression for the angular momentum of the bike with respect to both the two moving contact points of the wheels with the road; note that they are moving poles.
5. Extend the problem to the case of rotating without slipping wheels.
6. Solve the problem in the non-Inertial Reference Frame attached to the bike.

This § is referenced at pages:
[1357]

Una fune inestensibile e omogenea di lunghezza L e massa m è appesa al soffitto e sorregge un peso di massa M.

1. Determinare, in condizioni di equilibrio, l'andamento della tensione lungo la fune.
2. Determinare la condizione sotto la quale si può trascurare la variazione della tensione della fune e il valore della tensione costante in tale caso.
3. Si supponga di avere a che fare con una catena costituita da 5 anelli di massa $100\ \mathrm{g}$ sollevata con un'accelerazione costante pari ad $a = 2.50\ \mathrm{m/s^2}$ Si determini la forza risultante agente su ciascun anello e la forza esterna che agisce sul primo anello.

WORKED SOLUTION

La densità lineare di massa della fune vale $\lambda = m/L$. Si scelga un sistema di coordinate con asse x verticale, orientato verso il basso e con origine nel punto in cui la fune è attaccata al soffitto. Sia $T(x)$ il modulo della tensione della fune all'ascissa x. La condizione di equilibrio per l'elemento Δx della fune si scrive:

$$T(x + \Delta x) + \lambda g \Delta x = T(x)$$

da cui segue, nel limite $\Delta x \to 0$,

$$\boxed{\frac{dT(x)}{dx} = -\lambda g}$$

che integrata fornisce

$$T(x) = -\lambda g x + c$$

La condizione di equilibrio applicata alla massa M fornisce l'equazione

$$Mg - T(L) = 0$$

da cui si determina la costante c che interviene in $T(x)$. Risulta:

$$T(x) = Mg + \lambda g(L - x)$$

che fornisce la tensione della corda in ogni punto e determina, in particolare, la tensione massima della corda nel punto di attaccamento al soffitto $T(0) = g(M + m)$.
Si noti che se la fune è supposta senza massa ($\lambda = 0$) l'equazione differenziale trovata per $T(x)$ si riduce a $T(x)$ costante, indipendente da x e $T(x) = Mg$, dalla condizione di equilibrio della massa appesa.
La condizione di tensione costante lungo la fune si può determinare osservando che

$$\boxed{\frac{|T(L) - T(0)|}{T(L)} = \frac{m}{M}}$$

Tensione costante lungo la fune significa allora massa della fune trascurabile rispetto alla massa del corpo appeso. Si noti che la variazione di tensione ai due capi della fune, $|T(L) - T(0)|$, conseguenza della massa non nulla della fune, è stata confrontata con il valore della tensione che la fune assume nel caso in cui se ne trascura la massa, $T = Mg$.

La condizione di tensione costante lungo la fune si può determinare alternativamente imponendo la condizione

$$\frac{|T(L)-T(0)|}{T(0)}=\frac{m}{M+m}\ll 1$$

che può essere risolta nel modo seguente

$$\frac{|T(L)-T(0)|}{T(0)}=\frac{m}{M+m}\equiv\epsilon\ll 1\implies\frac{m}{M}=\frac{\epsilon}{1-\epsilon}\simeq\epsilon\ll 1$$

ottenendo la stessa condizione $m/M\ll 1$ con l'approssimazione fatta nell'ultima equazione giustificata dal fatto che $\epsilon\ll 1$.

This § is referenced at pages:
[1334, 1348]

Una forza **F** diretta verso l'alto è applicata all'asse di una puleggia. Si supponga che la carrucola e la fune siano di massa trascurabile, che la fune sia perfettamente flessibile e inestensibile e che non ci siano attriti. Agli estremi della fune, passante sulla carrucola, sono appesi due corpi di massa $m_1=1.2\ \mathrm{kg}$ e $m_2=1.9\ \mathrm{kg}$.

1. Determinare l'accelerazione delle due masse e la tensione della fune nel caso la forza **F** sia quella necessaria a sorreggere la carrucola (ad esempio nel caso che la carrucola sia appesa al soffitto). Si supponga poi che l'oggetto di massa m_2 sia a contatto col suolo.
2. Determinare quale è il valore massimo del modulo della forza **F** che consente all'oggetto di restare attaccato al suolo senza sollevarsi.
3. Quale è la tensione della fune se $F=110\ \mathrm{N}$ e quanto vale l'accelerazione delle due masse?
4. Se è data l'accelerazione verso l'alto della carrucola, **A**, quale è l'accelerazione massima che consente alla massa m_2 di non sollevarsi dal suolo ?

WORKED SOLUTION

Essendo le masse della fune e della puleggia trascurabili la tensione della fune è la stessa in ogni punto (problema § 24-016). Le equazioni del moto per i due oggetti si scrivono, avendo scelto un sistema di coordinate con asse x rivolto verso l'alto

$$\begin{aligned}T_1-m_1g&=m_1a_1\quad,\\ T_2-m_2g&=m_2a_2\quad,\\ F-T_1-T_2&=0\quad,\\ T_1-T_2&=0\quad.\end{aligned}$$

Il vincolo cinematico che i due oggetti sono legati ai due capi della corda impone le condizioni

$$\Delta x_1=-\Delta x_2\implies a\equiv a_1=-a_2$$

A.I.T.-T.W. - PROGRE

che fornisce la quinta equazione necessaria a risolvere il sistema nelle cinque incognite a_1, a_2, T_1, T_2 ed F. La soluzione del sistema fornisce

$$\begin{aligned} a = a_1 = -a_2 &= g\frac{m_2 - m_1}{m_2 + m_1} \quad , \\ T_1 = T_2 = T &= \frac{2m_1 m_2}{m_1 + m_2} g \quad , \\ F &= \frac{4m_1 m_2}{m_1 + m_2} g \quad . \end{aligned}$$

L'accelerazione del corpo di massa m_1 è positiva (cioè diretta verso l'alto) nel caso $m_2 > m_1$. Si noti che si ha

$$F = \frac{4m_1 m_2}{m_1 + m_2} g < (m_1 + m_2) g \qquad \text{se } m_1 \neq m_2$$

cioè in tutti i casi in cui $a \neq 0$ la forza che si deve esercitare per sorreggere la carrucola è minore della somma dei pesi dei due oggetti che è la forza che si deve esercitare nel caso la carrucola sia in equilibrio ($m_2 = m_1$). Inoltre, essendo $m_1 < m_2$, si ha sempre

$$m_1 g < T = \frac{2m_1 m_2}{m_1 + m_2} g < m_2 g$$

come deve essere in quanto la massa m_1 è sollevata dalla fune mentre il peso della massa m_2 è maggiore della tensione della fune stessa. Nei casi limite $m_1 \ll m_2$ oppure $m_1 \gg m_2$ l'accelerazione ha modulo pari a g.

Nel caso alla carrucola sia applicata una forza $\mathbf{F}$ diretta verso l'alto di valore assegnato le equazioni del moto sono ancora (la massa della carrucola è supposta trascurabile)

$$\begin{aligned} T_1 - m_1 g &= m_1 a_1 \quad , \\ T_2 - m_2 g &= m_2 a_2 \quad , \\ F - T_1 - T_2 &= 0 \quad , \\ T_1 - T_2 &= 0 \quad . \end{aligned}$$

ma adesso F è assegnata anziché incognita e le accelerazioni a_1 e a_2 non sono più legate dal vincolo cinematico $a_1 = -a_2$ in quanto le due masse oltre a cadere lungo la carrucola partecipano del moto di insieme della stessa. La soluzione del sistema fornisce ora

$$\begin{aligned} a_1 &= \frac{F}{2m_1} - g \quad , \\ a_2 &= \frac{F}{2m_2} - g \quad , \\ T_1 = T_2 &= F/2 \quad . \end{aligned}$$

Si osservi che, denotando con $\Delta x_1'$ e $\Delta x_2'$ gli spostamenti dei corpi relativi alla puleggia e con Δx lo spostamento della puleggia, si ha

$$\Delta x_1 = \Delta x_1' + \Delta x \qquad \Delta x_2 = \Delta x_2' + \Delta x \tag{24.22.01}$$

→ 1359

da cui si deduce

$$\begin{aligned} a_1 &= a_1' + a \quad , \\ a_2 &= a_2' + a \quad . \end{aligned}$$

e il vincolo cinematico diventa ora

$$\Delta x_1' = -\Delta x_2' \implies a_1' = -a_2' \tag{24.22.02}$$

In questa forma il vincolo cinematico è di validità generale, qualunque sia lo stato di moto della carrucola. Nel Reference Frame solidale con la carrucola, in moto con accelerazione a, le due masse hanno accelerazioni a_1' e a_2' e risentono delle forze inerziali $-m_1 a$ e $-m_2 a$. Le accelerazioni incognite a_1 e a_2 potrebbero essere sostituite, come variabili dinamiche, dall'accelerazione della

CC BY NC ND

carrucola a e dalle accelerazioni interne $a'_1 = -a'_2$. Si ricava dalle equazioni del moto

$$a = \frac{F}{4}\left(\frac{m_1 + m_2}{m_1 m_2}\right) - g \quad ,$$

$$a'_1 = -a'_2 = \frac{F}{4}\left(\frac{m_2 - m_1}{m_1 m_2}\right) \quad .$$

Supponiamo ora che la massa m_2 sia appoggiata. Le equazioni del moto diventano (imponendo subito $T_1 = T_2 = T$)

$$\begin{aligned} T - m_1 g &= m_1 a_1 \quad , \\ T - m_2 g + N_x &= 0 \quad , \\ F - 2T &= 0 \quad . \end{aligned}$$

dove si è indicato con N_x la componente della reazione vincolare del tavolo. Le incognite sono ora T, a ed N_x. La reazione vincolare $\mathbf{N}$ si determina dalle equazioni del moto. Il problema ha ora una incognita in più, $\mathbf{N}$, ma la presenza del vincolo stesso ha eliminato l'incognita $\mathbf{a}_2$. In generale i vincoli aggiungono incognite ma eliminano gradi di libertà. Per la sua caratteristica di vincolo unilatero la componente di $\mathbf{N}$ lungo l'asse x deve essere non negativa: $N_x \geq 0$. Si deduce

$$\begin{aligned} N_x &= m_2 g - F/2 \quad , \\ a_1 &= \frac{F}{2m_1} - g \quad , \\ T &= \frac{F}{2} \quad . \end{aligned}$$

Il corpo resta appoggiato in equilibrio sul tavolo se e solo se

$$N_x > 0 \qquad \Leftrightarrow \qquad F < 2m_2 g = 37.3 \text{ N}$$

Lo stacco dal tavolo avviene per $N_x = 0$. Il risultato $F < 2m_2 g$ mette in chiaro come solo metà della forza applicata $\mathbf{F}$ viene usata per sollevare la massa m_2. Una condizione equivalente che poteva essere applicata per determinare a quale forza avviene lo stacco dal tavolo era imporre che l'accelerazione a_2, determinata nel caso libero, fosse uguale a zero. Infatti, dal confronto dei due sistemi di equazioni del moto nel caso libero e in presenza del tavolo si osserva che la sola equazione che cambia è quella relativa alla massa m_2 in cui $m_2 a_2$ a secondo membro viene rimpiazzato da N_x a primo membro. Porre $N_x = 0$ equivale allora a porre $a_2 = 0$ nel caso libero.
Nel caso richiesto, $F = 110$ N la massa m_2 si solleva e si ha:

$$\begin{aligned} T &= F/2 = 55 \text{ N} \quad , \\ a_1 &= \frac{F}{2m_1} - g = 36.0 \text{ m/s}^2 \quad , \\ a_2 &= \frac{F}{2m_2} - g = 19.1 \text{ m/s}^2 \quad . \end{aligned}$$

Dalle equazioni (24.22.01) e dal vincolo cinematico (24.22.04) si deduce ora

$$\Delta x_1 = 2\Delta x \implies a_1 = 2a$$

da cui si deduce

$$N = g\,(m_2 - m_1) - 2m_1 A \geq 0$$

da cui la condizione di sollevamento del blocco

$$a \geq \frac{g}{2m_1}(m_2 - m_1)$$

Si osservi che il risultato fornisce, come deve, la condizione che, se $m_2 < m_1$ la massa m_2 si stacca anche per $a = 0$ Tale risultato è coerente con quello ottenuto sopra in termini della forza $\mathbf{F}$.

WORKED SOLUTION

1) $a_1 = -a_2 = g\dfrac{m_2 - m_1}{m_2 + m_1}$, $T_1 = T_2 = T = \dfrac{2m_1 m_2}{m_1 + m_2}g$, $F = \dfrac{4m_1 m_2}{m_1 + m_2}g$; 2) $F < 2m_2 g = 37.3$ N; 3) $T = F/2 = 55$ N; $a_1 = \dfrac{F}{2m_1} - g = 36.0\ \mathrm{m/s^2}$, $a_2 = \dfrac{F}{2m_2} - g = 19.1\ \mathrm{m/s^2}$.

Una sbarra orizzontale è usata per sostenere tra due muri un peso di massa $75\ \mathrm{kg}$ appeso al centro della sbarra. Le due forze, di uguale modulo, che la sbarra esercita contro i due muri possono essere variate cambiando la lunghezza della sbarra tramite un sistema di vite e molla. Solo l'attrito tra le estremità della sbarra e i muri sorregge la sbarra e il coefficiente di attrito statico vale 0.41. Quale è il minimo valore della forza che la sbarra deve esercitare contro il muro affinché si abbia equilibrio?

©|H.C.Ohanian, , ..., ..., ...Ed., ...|6.39||

Una forza orizzontale $F = 53.4\ \mathrm{N}$ spinge un blocco di massa $m = 2.27\ \mathrm{kg}$ contro un muro verticale. Il coefficiente di attrito statico tra il muro ed il blocco vale $\mu_s = 0.60$ e quello di attrito cinetico vale 0.40. Il blocco è inizialmente fermo.

1. Il blocco inizierà a muoversi?
2. Quale è la forza esercitata sul blocco dal muro? Si cambia la direzione della forza esercitata sul libro in modo da formare un angolo θ rispetto alla parete (misurato a partire dall'alto).
3. Quale è il modulo della forza minimo affinché il libro non cada?
4. Per quale valore dell'angolo θ il modulo di tale forza assume il valore minimo possibile e quanto vale tale valore minimo?
5. Se l'angolo θ è maggiore dell'angolo retto (cioè se la forza spinge verso il basso) occorrerà esercitare una forza notevole per impedire al libro di cadere. Per quale valore dell'angolo θ risulta comunque impossibile sostenere il libro?

24-026 Il Piano Inclinato Sulla Bilancia

Un blocco di massa m è appoggiato senza attrito su un piano inclinato di angolo θ e massa M che appoggia su una bilancia orizzontale. Il coefficiente di attrito statico tra il piano inclinato e la bilancia vale μ_s.

1. A quale condizione deve soddisfare μ_s affinché il piano inclinato non scivoli durante la discesa del blocco?
2. Quale è il peso R letto della bilancia?

WORKED SOLUTION

Supponiamo che il piano inclinato non scivoli e sia quindi fermo. Si scelga un Coordinate System con asse x parallelo al piano inclinato. Le equazioni del moto del blocco sono

$$mg\sin[\theta] = ma \quad ,$$
$$N - mg\cos[\theta] = 0 \quad .$$

Si scelga un secondo Coordinate System con asse x' parallelo al piano orizzontale della bilancia per descrivere il moto (in questo caso la condizione di equilibrio) del piano inclinato. Le equazioni di equilibrio del piano inclinato sono

$$-N\sin[\theta] + f_s = 0 \quad ,$$
$$R - Mg - N\cos[\theta] = 0 \quad .$$

Ne segue

$$f_s = mg\sin[\theta]\cos[\theta] \quad ,$$
$$R = Mg + mg\cos^2\theta$$

Il blocco resta allora fermo se e solo se

$$m\sin[\theta]\cos[\theta] \le \mu_s(M + m\cos^2\theta)$$

essendo $\sin[\theta] \ge 0$ e $\cos[\theta] \ge 0$. Il peso letto dalla bilancia vale

$$R = Mg + mg\cos^2\theta \le g(M + m)$$

ed è massimo, $R = g(M + m)$, per $\theta = 0$. La forza di attrito statico richiesta per mantenere fermo il piano inclinato è massima per $\theta = \pi/4$.

WORKED SOLUTION

1) $m\sin[\theta]\cos[\theta] \le \mu_s(M + m\cos^2\theta)$; 2) $R = Mg + mg\cos^2\theta \le g(M + m)$.

24-027 Due Blocchi Che Scivolano Dal Pendio

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|6.25||

Una cassa è appoggiata sul pianale scabro di un autocarro. Il coefficiente di attrito statico tra la cassa e il pianale è μ_s. Se l'autocarro frena bruscamente la cassa scivola in avanti. Quanto vale la decelerazione massima che l'autocarro può avere in frenata se la cassa deve restare ferma?

24-028 Moto Di Un Oggetto Soggetto a Forza Crescente in Presenza Di Attrito

Un punto materiale di massa m è fermo su un piano orizzontale. I coefficienti di attrito statico e cinetico sono rispettivamente μ_s e μ_c. Il punto materiale è soggetto ad una forza orizzontale, dipendente dal tempo, $F = kt$. Descrivere il moto del punto materiale.

1. A quale istante t_0 inizia a muoversi?
2. Quale è l'andamento dell'accelerazione in funzione del tempo?

WORKED SOLUTION

1) $t_0 = \mu_s mg/k$; 2) $a(t) = 0$ per $t < t_0$, $a(t) = kt/m - \mu_c g$ per $t > t_0$.

24-029 Blocco Lanciato Su per Un Piano Inclinato Con Attrito

Un blocco di massa m viene lanciato su per un piano inclinato di angolo θ con velocità iniziale v_0. Se i coefficienti di attrito statico e cinetico tra il piano inclinato e il blocco sono rispettivamente μ_s e μ_c (con $\mu_s \geq \mu_c$) si determini il moto del blocco.

WORKED SOLUTION

Scegliamo un sistema di coordinate con asse x parallelo al piano inclinato e diretto verso il basso, asse y uscente dal piano inclinato e origine nel punto più basso del piano inclinato. Si noti che essendo $0 \leq \theta \leq 90°$ si ha $\cos[\theta] \geq 0$ e $\sin[\theta] \geq 0$. Le forze agenti sul blocco sono la forza peso $m\mathbf{g}$, la reazione normale del piano $\mathbf{N}$ e la forza di attrito. L'equazione del moto si scrive

$$m\mathbf{g} + \mathbf{N} + \mathbf{f} = m\mathbf{a}$$

Nella fase di salita si ha che la forza di attrito cinetico è diretta verso il basso, opposta alla velocità. Proiettando l'equazione si ha dunque

$$\begin{aligned} mg\sin[\theta] + f_c &= ma_x^S \quad , \\ N - mg\cos[\theta] &= ma_y = 0 \quad . \end{aligned}$$

con

$$f_c = \mu_c N > 0$$

Ne segue per l'accelerazione nella fase di salita

$$a_x^S = g\left(\sin[\theta] + \mu_c \cos[\theta]\right)$$

Durante la fase di salita l'effetto della forza di attrito cinetico si somma all'accelerazione di gravità nel rallentare il moto. Nel caso $\mu_c = 0$ si riduce correttamente all'accelerazione per un piano inclinato senza attrito, $g\sin[\theta]$. Nel caso $\theta = 0$ si riduce correttamente all'accelerazione sul piano in presenza di attrito, $g\mu_c$. Data l'accelerazione costante del blocco lo spazio percorso prima di fermarsi si deduce dalla relazione (23.03.09.02)

$$v^2 = v_0^2 + 2a(x - x_0)$$

imponendo $v = 0$ e data la condizione iniziale $x_0 = 0$ si determina la coordinata x_f a cui il blocco si ferma:

$$0 = v_0^2 + 2a(x_f - x_0) \implies x_f = -\frac{v_0^2}{2a_x^S} < 0$$

Occorre ora stabilire se il blocco, dopo essersi fermato, ridiscende oppure se l'attrito statico è sufficiente a mantenerlo fermo. Nel caso il blocco resti in equilibrio si hanno le equazioni

$$\begin{aligned} mg\sin[\theta] + f_s &= 0 \quad , \\ N - mg\cos[\theta] &= 0 \quad . \end{aligned}$$

da cui si deduce il valore della componente f_s, ora incognita, della forza di attrito statico necessario a mantenere il blocco in equilibrio

$$f_s = -mg\sin[\theta] < 0$$

negativa in quanto deve opporsi alla forza di gravità la cui componente lungo l'asse x è positiva. La forza di attrito statico può fornire la componente richiesta a mantenere l'equilibrio se e solo se, in base alla (24.19.01),

$$|f_s| = mg\sin[\theta] \leq \mu_s N = \mu_s mg\cos[\theta]$$

cioè se e solo se

$$\tan[\theta] \leq \mu_s$$

Questa relazione definisce l'angolo limite per un piano inclinato al di sopra del quale il blocco scende e può essere usata per misurare il coefficiente di attrito statico μ_s. Si noti che la forza di attrito statico è determinata dalle equazioni del moto.
Se la relazione sopra non è soddisfatta il blocco riprende a scendere. Le equazioni del moto sono ora

$$\begin{aligned} mg\sin[\theta] + f_c &= ma_x^D \quad , \\ N - mg\cos[\theta] &= ma_y = 0 \quad . \end{aligned}$$

ma ora la componente della forza di attrito cinetico f_c, essendo sempre opposta alla velocità risulta negativa:

$$f_c = -\mu_c N = -\mu_c mg\cos[\theta] < 0$$

Ne segue per l'accelerazione nella fase di discesa

$$a_x^D = g(\sin[\theta] - \mu_c\cos[\theta]) > 0$$

Si ha che $a_x^D \geq 0$ perché il blocco ridiscende se e solo se $\tan[\theta] > \mu_s \geq \mu_c$. In modulo l'accelerazione nella discesa risulta minore a quella durante la salita perché questa volta la forza di attrito cinetico ha verso opposto alla componente della forza di gravità lungo l'asse x coerentemente con la relazione (24.19.02) per cui la forza di attrito cinetico è sempre opposta al moto.

24-031 trascinare una cassa su un piano con attrito

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|6.20 6.22||

©|H.C.Ohanian, , ..., ..., ...Ed., ...|6.40||

©|I.E.Irodov, *Problems In General Physics*, 1988, MIR publishers Moscow, ...Ed., ...|1.67||

Si supponga di dover trascinare una cassa al suolo tramite una fune. La massa della cassa vale m e il coefficiente di attrito cinetico tra cassa e suolo vale $\mu_c = 0.25$. Si schematizzi la cassa come un punto materiale.

1. Determinare la direzione ottimale a cui bisogna dirigere la fune per trascinare la cassa di moto rettilineo uniforme applicando la forza minima e il valore di tale forza minima. Se la fune ha una tensione di rottura pari a $T_{\max} = 1.22\cdot 10^3$ N e se il coefficiente di attrito statico tra la cassa e il suolo vale $\mu_s = 0.35$ quale è il valore massimo della massa della cassa che si può trascinare?

cc BY NC ND

WORKED SOLUTION

Si scelga un sistema di coordinate con asse x orizzontale e asse y verticale. Sia $\mathbf{F}$ la forza che bisogna applicare ad un angolo θ con l'orizzontale e sia $\mathbf{f}$ la forza di attrito e $\mathbf{N}$ la reazione normale del piano. Le equazioni del moto sono

$$F\cos[\theta] - f = 0 \quad ,$$
$$F\sin[\theta] + N - mg = 0 \quad .$$

con $0 \leq \theta \leq 90°$. Si ricava il valore della forza $\mathbf{F}$ necessaria in funzione dell'angolo θ a cui è applicata:

$$\boxed{F = \frac{\mu_c mg}{\cos[\theta] + \mu_c \sin[\theta]}}$$

che è una funzione crescente di μ_c. Nel caso limite $\theta = 0$ si riduce a $F = \mu_c mg$, come deve. Nel caso limite $\theta = 90°$ si riduce a $F = mg$, come deve perché in tal caso solo la forza di attrito cinetico ha una componente orizzontale che non può essere equilibrata da $\mathbf{F}$ per cui la forza di attrito cinetico va azzerata cosa possibile se e solo se $\mathbf{N} = 0$ che implica $\mathbf{F} = -m\mathbf{g}$
Il valore minimo di $|\mathbf{F}|$ al variare di θ si ha per

$$\tan[\theta] = \mu_c$$

e risulta

$$F = \frac{\mu_c mg}{\sqrt{1+\mu_c^2}}$$

che è una funzione crescente del coefficiente di attrito cinetico.
Essendo il coefficiente di attrito statico maggiore o uguale di quello di attrito cinetico il momento critico si ha alla partenza quando è necessario applicare la massima forza. Le relazioni che si applicano sono le stesse determinate sopra pur di sostituire il coefficiente cinetico con quello statico. Applicando la forza all'angolo ottimale, dato dalla relazione $\tan[\theta] = \mu_s$, si ottiene il valore massimo del peso trasportabile come

$$mg \leq \frac{\sqrt{1+\mu_s^2}}{\mu_s} T_{\max}$$

Mantenendo la stessa direzione e la stessa intensità della forza $T_{\max}$ applicata all'istante iniziale il moto della cassa sarà uniformemente accelerato in quanto la forza di attrito diminuisce subito dopo la partenza. Volendo proseguire in modo ottimale si potrà, una volta che la cassa è in moto, riaggiustare l'angolo, in base alla $\tan[\theta] = \mu_c$, e diminuire l'intensità della forza.
Questo problema mostra che per trascinare con la minor forza possibile una cassa in presenza di attrito occorre applicare una componente della forza verso l'alto in modo da diminuire il valore della reazione normale. Questo spiega anche perché sia più semplice trascinare una cassa invece che spingerla. Nel primo caso è infatti relativamente semplice applicare una componente verticale della forza, mentre nel secondo lo è meno, anzi si rischia di applicare una componente verso il basso che aumenta la forza di attrito.

WORKED SOLUTION

1. $\tan[\theta] = \mu_c$; $F = \mu_c mg/\sqrt{1+\mu_c^2}$;
2. $mg \leq T_{\max}\sqrt{1+\mu_s^2}/\mu_s$.

CC BY NC ND

24-032 Problema Del Ristagno in Presenza Di Attrito Statico

Un blocco di massa m è posizionato su un piano inclinato di angolo θ. Il coefficiente di attrito statico tra il piano e il blocco vale μ_s. Una molla di costante elastica k e lunghezza a riposo x_0 è disposta parallelamente alla superficie del piano inclinato e collega il blocco al vertice superiore del piano inclinato. Determinare per quale intervallo di posizioni il blocco resta in equilibrio.

WORKED SOLUTION

Si scelga un sistema di coordinate con asse x parallelo al piano inclinato, orientato verso il basso e avente origine alla sommità del blocco e asse y diretto perpendicolarmente al piano e verso l'alto. Detta $\mathbf{N}$ la reazione normale del piano, $\mathbf{f}$ la forza di attrito statico tra il blocco e il piano e $\mathbf{F}$ la forza che la molla esercita sul blocco la condizione di equilibrio si scrive

$$m\mathbf{g} + \mathbf{F} + \mathbf{N} + \mathbf{f} = \mathbf{0}$$

Proiettando sugli assi x e y si ottengono le equazioni scalari

$$mg\sin[\theta] + f_x + F_x = 0 \quad ,$$
$$N - mg\cos[\theta] = 0 \quad .$$

avendo denotato f_x e F_x rispettivamente le componenti lungo l'asse x delle due forze $\mathbf{f}$ e $\mathbf{F}$. Si ha inoltre, dalla legge di Hooke,

$$\boxed{F_x = -k(x - x_0) \equiv -k\Delta x}$$

Ne segue

$$N = mg\cos[\theta] \quad ,$$
$$f_x = k\Delta x - mg\sin[\theta]$$

La condizione di equilibrio può essere soddisfatta se e solo se

$$|f_x| \leq \mu_s N$$

relazione che coinvolge il valore assoluto della componente f_x, e che equivale a

$$|k\Delta x - mg\sin[\theta]| \leq \mu_s mg\cos[\theta]$$

che risolta da

$$mg\left(\sin[\theta] - \mu_s\cos[\theta]\right) \leq k\Delta x \leq mg\left(\sin[\theta] + \mu_s\cos[\theta]\right)$$

Nel caso $\mu_s = 0$ la diseguaglianza sopra fornisce la condizione di equilibrio $k\Delta x = mg\sin[\theta]$, da cui risulta pure $\Delta x > 0$. Nel caso $\theta = 0$ la condizione di equilibrio si riduce a $|k\Delta x| \leq \mu_s mg$, coerente con il fatto che in tal caso si ha $f \leq \mu_s N = \mu_s mg$. Nel caso $\theta = \pi/2$ si ha $k\Delta x = mg$, che esprime il fatto che in tal caso solo la molla può opporsi alla forza peso in quanto $\mathbf{N}$ (e quindi $\mathbf{f}$) deve valere zero perché non esistono altre forze nella direzione dell'asse y.

WORKED SOLUTION

$mg\left(\sin[\theta] - \mu_s\cos[\theta]\right) \leq k\Delta x \leq mg\left(\sin[\theta] + \mu_s\cos[\theta]\right)$.

CC BY NC ND

24-033 Le Due Masse Sul Piano Inclinato

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|6.29||

Due oggetti di massa $m_1 = 1.65$ kg e $m_2 = 3.22$ kg sono collegati da un'asta di massa trascurabile parallela al piano inclinato su cui i due oggetti scivolano con la massa m_2 posta in bassa rispetto alla massa m_1. L'angolo del piano inclinato è $\theta = 29.5\,^\circ$ e i coefficienti di attrito cinetico tra le due mese e il piano sono rispettivamente $\mu_1 = 0.226$ e $\mu_1 = 0.127$.

1. Calcolare la comune accelerazione dei due oggetti.
2. Calcolare la tensione della sbarra.
3. Come si modificano le due risposte precedenti se le posizioni delle due masse sono invertite?

24-034 Il Traino Della Slitta

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|6.30 6.31||

©|Alonso & Finn, , ..., ..., ...Ed., ...|7.75||

Si supponga di dover trascinare una slitta di massa M il cui coefficiente di attrito cinetico con il suolo sia μ_c. Sopra la slitta è appoggiata una cassa di massa m e il coefficiente di attrito statico tra la cassa e la slitta vale μ_s. Se alla slitta è applicata una forza orizzontale $\mathbf{F}$ determinare il valore massimo di tale forza affinché la cassa non scivoli sopra la slitta e l'accelerazione del sistema in questa condizione.

WORKED SOLUTION

Si scelga un Coordinate System con asse x orizzontale e concorde con il verso della forza $\mathbf{F}$ e asse y diretto verso l'alto. Le forze agenti sulla cassa sono il peso $m\mathbf{g}$, la forza di attrito statico tra cassa e slitta $\mathbf{f}$, diretta nello stesso verso della forza $\mathbf{F}$, e la reazione normale della slitta sulla cassa $\widehat{\mathbf{n}}$. Le forze che agiscono sulla slitta sono le forze corrispondenti alle coppie azione-reazione con la cassa, $-\mathbf{f}$ e $-\widehat{\mathbf{n}}$, la forza esterna $\mathbf{F}$, il peso $M\mathbf{g}$, la reazione normale del suolo $\mathbf{N}$ e la forza di attrito cinetico con il suolo $\mathbf{f}_0$. Supponendo che la cassa resti solidale con la slitta e chiamando $\mathbf{a}$ l'accelerazione del sistema slitta-cassa, e supponendo che la slitta si muova nella direzione della forza $\mathbf{F}$, le equazioni del moto di cassa e slitta, proiettate sugli assi x e y, si scrivono:

$$\begin{aligned} f &= ma \quad , \\ n &= mg \quad , \\ F - f_0 - f &= Ma \quad , \\ N - n - Mg &= 0 \quad , \\ f_0 &= \mu_c N \quad . \end{aligned}$$

dove le incognite sono a, f, f_0, n ed N. Risolvendo il sistema si trova

$$\begin{aligned} a &= \frac{F - \mu_c(M+m)g}{M+m} = \frac{F}{M+m} - g\mu_c \quad , \\ n &= mg \quad , \\ N &= g(M+m) \quad , \\ f &= m\frac{F - \mu_c(M+m)g}{M+m} \quad , \\ f_0 &= \mu_c(M+m)g \quad . \end{aligned}$$

Si osservi che l'accelerazione del sistema è quella che si calcolerebbe considerando solo le forze esterne, $m\mathbf{g}$, $M\mathbf{g}$, $\mathbf{F}$, $\mathbf{N}$ e $\mathbf{f}_0$, agenti sul sistema complessivo di massa $M+m$. Nel caso di assenza di attrito con il suolo, $\mu_c = 0$ l'accelerazione si riduce ad $a = F/(M+m)$ come deve. Si noti anche che si è supposto che il sistema si muova nella direzione della forza $\mathbf{F}$, cioè si è usato per la componente di $\mathbf{f}_0$ lungo l'asse x $-f_0 < 0$. Se la slitta si muovesse, ad un certo istante nella direzione negativa

DRAFT

dell'asse x, essendo decelerata dalla forza $\mathbf{F}$, si sarebbe dovuto usare per la componente di $\mathbf{f}_0$ lungo l'asse x $f_0 > 0$. Affinché la cassa resti solidale con la slitta occorre e basta che sia soddisfatta la condizione

$$0 \leq f = m\frac{F - \mu_c(M+m)g}{M+m} \leq \mu_s mg \implies F \leq g(M+m)(\mu_s + \mu_c)$$

Questo risultato sulla forza massima può essere applicato all'analogo problema di un foglio estratto velocemente da sotto un peso: se la forza è troppo elevata il peso resta fermo.

24-035 L'auto in Curva

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|6.34 6.35 6.42 6.47 ||

©|H.C.Ohanian, , ..., ..., ...Ed., ...|6.61||

©|Alonso & Finn, , ..., ..., ...Ed., ...|7.76||

Si deve progettare una strada con un tratto di curva circolare il cui raggio di curvatura è $R = 100$ m. Si determini l'angolo di inclinazione ottimale della strada nel tratto di curva affinché un'auto con velocità $v_0 = 70$ km/h possa percorrerla senza dipendere dall'aderenza dei pneumatici in modo cioè che la sola reazione normale della strada fornisca la forza centripeta necessaria. Supponendo che la curva sia costruita con questo angolo ottimale determinare la massima velocità che un auto può tenere senza perdere aderenza nel caso in cui il coefficiente di attrito statico tra i pneumatici e la strada vale $\mu_{aa} = 0.75$ (asfalto asciutto), $\mu_{ab} = 0.50$ (asfalto bagnato), $\mu_g = 0.25$ (ghiaccio).

WORKED SOLUTION

Si schematizzi l'auto come un punto materiale e si scelga un Coordinate System con asse x orizzontale diretto verso il centro di curvatura della strada e asse y verticale. La condizione affinché l'auto percorra il tratto di curva circolare è

$$m\mathbf{g} + \mathbf{N} + \mathbf{f} = m\mathbf{a}_c$$

che proiettata sulle componenti da il sistema

$$N\sin[\theta] + f\cos[\theta] = m\frac{v_0^2}{R} \quad ,$$
$$N\cos[\theta] - f\sin[\theta] - mg = 0 \quad .$$

dove si è supposto che la forza di attrito statico sia diretta verso l'interno della curva. Nel caso la forza di attrito statico necessaria sia diretta in verso opposto a quello convenzionalmente scelto (cioè verso l'esterno della curva) si otterrà un valore di f negativo. Volendo sempre interpretare f come il modulo del vettore $\mathbf{f}$, cioè un numero positivo, il segno meno andrebbe riassorbito nei coseni direttori del vettore $\mathbf{f}$. Le incognite sono dunque i moduli delle forze $N \equiv |\mathbf{N}|$ e $f \equiv |\mathbf{f}|$ tenendo conto della precisazione fatta sopra circa il caso in cui f risultasse negativo. Il problema non sussiste per N in quanto, essendo il vincolo unilatero, il verso di $\mathbf{N}$ è noto a priori. La soluzione del sistema fornisce

$$f = m\frac{v_0^2}{R}\cos[\theta] - mg\sin[\theta] \quad ,$$
$$N = mg\cos[\theta] + m\frac{v_0^2}{R}\sin[\theta]$$

La forza di attrito vale zero se e solo se

$$\boxed{\tan[\theta] = \frac{v_0^2}{Rg}} = 0.385 \implies \theta = 21.1^\circ$$

che fornisce, in funzione di R e θ l'angolo di cui occorre inclinare la curva affinché la sola reazione normale della strada fornisca la forza centripeta necessaria. Nel caso $\theta = 0$ la relazione fornisce correttamente $f = mv_0^2/R$ e $N = mg$. La relazione ricavata per f mostra che se v_0 cresce il modulo

di **f** cresce e f risulta positivo, concordemente con l'orientamento convenzionale scelto per il vettore **f**. Il caso in cui f, che é un modulo, diventa negativo (per v_0 piccola) va interpretato come il fatto che in tali condizioni il vettore **f** è diretto in verso opposto a quello convenzionalmente scelto. In tal caso il segno negativo di f potrebbe essere riassorbito nei $\cos[\theta]$ e $\sin[\theta]$ delle equazioni del moto proiettate.
La velocità massima, v, per un'auto sulla curva si determina dalla condizione

$$0 \le f \le \mu_s N \implies \frac{v^2}{gR}(\cos[\theta] - \mu_s \sin[\theta]) \le (\sin[\theta] + \mu_s \cos[\theta]) \qquad \text{per } f \ge 0$$

con **f** diretta verso l'interno della curva.
Nel caso particolare $\theta = 0$ la relazione diventa $v^2 \le \mu_s R g$.
Essendo sempre $\cos[\theta] \ge 0$ e $\sin[\theta] \ge 0$ si ha che nel caso in cui $\tan[\theta] > 1/\mu_s$ la condizione è sempre verificata cioè in tal caso la pendenza della curva e l'attrito statico sono in grado di impedire all'auto di uscire dalla curva verso l'esterno per quanto grande sia la sua velocità. Ciò è possibile in quanto più θ è grande e più la reazione normale **N** è inclinata verso l'orizzontale fornendo la forza centripeta necessaria.
Si noti che questa condizione limita l'uscita verso l'esterno dell'auto e non la possibile caduta verso l'interno nel caso in cui v è piccolo e/o θ è grande. Con i valori del problema si ottengono per le velocità massime nei tre casi

$$v_{aa} = 142 \text{ km/h} \qquad v_{ab} = 118 \text{ km/h} \qquad v_g = 94.5 \text{ km/h}$$

La relazione ricavata per $\theta = 0$ può essere invertita per ottenere la condizione su R data una certa velocità: $R > v_0^2/g\mu_s$ che da il raggio di curvatura minimo ottimale a cui può essere percorsa una curva circolare orizzontale ad una velocità fissata. Si osservi che tale raggio di curvatura è doppio della distanza ($v_0^2/2g\mu_s$) in cui l'auto potrebbe fermarsi se frenasse in condizioni ottimali.
La condizione affinché l'auto non cada verso l'interno della curva si determina imponendo che

$$0 \le -f \le \mu_s N \implies \frac{v^2}{gR}(\cos[\theta] + \mu_s \sin[\theta]) \ge (\sin[\theta] - \mu_s \cos[\theta]) \qquad \text{per } f \le 0$$

con **f** diretta verso l'esterno della curva.
Nel caso particolare $\theta = \pi/2$ la relazione diventa $v^2 \ge Rg/\mu_s$.
Essendo sempre $\cos[\theta] \ge 0$ e $\sin[\theta] \ge 0$ si ha che nel caso in cui $\tan[\theta] < \mu_s$ la condizione è sempre verificata cioè in tal caso l'attrito statico è in grado di impedire all'auto di uscire dalla curva verso l'interno.
Se la velocità è sufficientemente alta dunque l'auto potrebbe restare sulla curva circolare anche nel caso in cui questa sia verticale. Tale effetto è sfruttato anche in certi giochi da Luna-Park ("Il Rotore") § 24-047.
Si noti che se $\mu_s > 1$ si può avere, per un θ opportuno $1/\mu_s < \tan[\theta] < \mu_s$ e l'auto può restare in curva qualunque sia la sua velocità.

[1334, 1334, 1346, 1346, 1346]

Un piano inclinato di massa M e angolo θ è appoggiato su un tavolo e sorregge un blocco di massa m. Si supponga che tra il piano inclinato e il tavolo e tra il piano inclinato e il blocco non ci sia attrito. Il sistema viene lasciato libero con blocco e piano inclinato in quiete.

1. Quale è l'accelerazione del piano inclinato e quali sono le componenti orizzontale e verticale dell'accelerazione del blocco? Queste accelerazioni si riducono ai valori corretti nel caso in cui $M \gg m$? Quale accelerazione orizzontale del piano è necessaria, rispetto al tavolo, affinché il corpo resti fermo rispetto al piano? Quale forza orizzontale bisogna applicare al sistema per ottenere questo risultato?

WORKED SOLUTION

Si scelga un sistema di coordinate con asse x orizzontale e asse y verticale e origine sul vertice superiore del piano inclinato. Si supponga il piano inclinato orientato con l'angolo $\theta < 90°$ nel verso positivo dell'asse x e, di conseguenza, con l'angolo di $90°$ orientato nel verso negativo. Detta $\mathbf{N}$ la reazione vincolare del piano inclinato sul corpo e $\mathbf{R}$ quella del tavolo sul piano inclinato le equazioni del moto del sistema si scrivono come

$$\begin{aligned} -N\sin[\theta] &= MA_x \quad , \\ R - Mg - N\cos[\theta] &= MA_y = 0 \qquad \text{(il piano è vincolato sul tavolo)} \quad , \\ N\sin[\theta] &= ma_x \quad , \\ N\cos[\theta] - mg &= ma_y \quad . \end{aligned}$$

Le incognite sono R, N, A_x, a_x e a_y con sole quattro equazioni. Esiste tuttavia un vincolo cinematico. Detti infatti $\Delta x'$ e $\Delta y'$ gli spostamenti del blocco rispetto al piano inclinato, ΔX e ΔY gli spostamenti

cc BY NC ND

del piano rispetto al tavolo e Δx e Δy gli spostamenti del corpo rispetto al tavolo si ha la condizione cinematica:

$$-\Delta y' = \Delta x' \tan[\theta]$$

che lega i cambiamenti di coordinate del corpo sul piano inclinato. Dalle relazioni che legano il moto in due sistemi di coordinate diversi si ottiene:

$$\begin{aligned} x &= X + x' \implies \Delta x = \Delta X + \Delta x' \quad , \\ y &= y' \implies \Delta y = \Delta y' \end{aligned}$$

Ne segue per le accelerazioni

$$\begin{aligned} a_x &= A_x + a'_x \quad , \\ a_y &= a'_y \end{aligned} \tag{24.22.03}$$

da cui si ottiene il legame voluto

$$-a_y = \tan[\theta]\,(a_x - A_x)$$

che fornisce la quinta equazione necessaria per risolvere le equazioni del moto. Si noti che dal sistema (24-038) si deduce

$$-\frac{A_x}{a_x} = \frac{m}{M}$$

e quindi

$$-a_y = a_x\left(1 + \frac{m}{M}\right)\tan[\theta] \tag{24.22.04}$$

Notare che si ha

$$\begin{aligned} \frac{d}{dt}\Delta x &= \frac{dx}{dt} \quad , \\ \frac{d}{dt}\Delta x' &= \frac{dx'}{dt} \quad , \\ \frac{d}{dt}\Delta X &= \frac{dX}{dt} \end{aligned}$$

E che la derivata temporale nei due sistemi di coordinate coincide essendo questi animati da moto reciproco traslatorio ($\boldsymbol{\omega} = 0$). Notare che la seconda delle equazioni del sistema (24-038) è la sola che contiene R e sarà quindi usata solo per determinare tale reazione vincolare. La soluzione del sistema fornisce

$$\begin{aligned} a_x &= +\,g\left[\frac{M\tan[\theta]}{M(1+\tan^2\theta) + m\tan^2\theta}\right] = +g\left[\frac{M\sin[\theta]\cos[\theta]}{M + m\sin^2\theta}\right] \quad , \\ a_y &= -\,g\left[\frac{(M+m)\tan^2\theta}{M(1+\tan^2\theta) + m\tan^2\theta}\right] = -g\left[\frac{(M+m)\sin^2\theta}{M + m\sin^2\theta}\right] \quad , \\ A_x &= -\,g\left[\frac{m\tan[\theta]}{M(1+\tan^2\theta) + m\tan^2\theta}\right] = -g\left[\frac{m\sin[\theta]\cos[\theta]}{M + m\sin^2\theta}\right] \quad . \end{aligned}$$

Analizziamo alcuni casi limite.
Per $\theta = 0$ risulta $a_x = a_y = A_x = 0$.
Per $\theta = \pi/2$ risulta $a_x = A_x = 0$ e $a_y = -g$.
Per $M \gg m$ risulta $a_x = g\sin[\theta]\cos[\theta]$, $a_y = -g\sin^2\theta$ e $A_x = 0$.
Per $m \gg M$ risulta $a_x = 0$, $a_y = -g$ e $A_X = -g/\tan[\theta]$.
Si veda pure § 24.21.10.

24-039 Il Piano Oscillante Con La Massa Sopra

Un piano orizzontale può oscillare lungo la verticale con legge del moto armonico di pulsazione ω grazie ad un molla opportuna. Il piano parte da fermo dalla quota $x = -x_0 < 0$ rispetto alla posizione di riposo della molla, posta alla quota $x = 0$. Una massa m giace sul piano, in quiete rispetto allo stesso nel momento in cui il piano viene rilasciato.

1. Determinare sotto quali condizioni la massa si stacca dal piano e in quale posizione.
2. Determinare la velocità della massa all'istante dello stacco.

WORKED SOLUTION

1) Lo stacco si ha per $x(t)$ tale che $x(t)\omega^2 \geq g$. 2) $v = \omega x_0 \sqrt{1 - g^2/\omega^4 x_0^2}$ quando $x = g/\omega^2$.

24-040 Resistenza proporzionale alla velocità - Il cannone - La pioggia

This § is referenced at pages:
[1260]

Discutere il moto di un punto materiale soggetto ad una forza costante (per esempio la forza di gravità) e ad una resistenza del mezzo proporzionale alla velocità $\mathbf{F_R} = -k\mathbf{v}$ dove k è una costante positiva che dipende dalle caratteristiche dell'oggetto e del mezzo. Si consideri il moto di un proiettile sparato con velocità iniziale $\mathbf{v}_0$. Si introduca Coordinate System con asse x parallelo al suolo e nella direzione verso cui è sparato il proiettile e asse y verticale diretto verso l'alto. Si mostri che la legge oraria

$$x(t) - x_0(t) = \frac{v_{x0}}{b}[1 - \exp -b\Delta t] \quad ,$$

$$y(t) - y_0(t) = -\frac{g}{b}\Delta t + \frac{1}{b^2}(gv_{y0} + b)[1 - \exp -b\Delta t]$$

in cui $k \equiv mb$ e $\Delta t \equiv t - t_0$, soddisfa l'equazione del moto. Si mostri che la velocità è data dalle relazioni

$$v_x(t) = v_{x0} \exp -b\Delta t \quad ,$$

$$v_y(t) = -\frac{g}{b} + \frac{1}{b}(gv_{y0} + b) \exp -b\Delta t$$

WORKED SOLUTION

Sviluppando le (24-040) in serie di b con $b \simeq 0$, si ritrova l'equazione del moto senza resistenza dell'aria. L'equazione della traiettoria si può ricavare dalle (24-040) sostituendo la grandezza in parentesi quadra nella equazione della componente x nella equazione per la componente y e ricavando Δt dalla equazione della componente x e sostituendola nella equazione per la componente y. Si trova

$$y - y_0 = \frac{g}{b^2}\log 1 - \frac{b(x - x_0)}{v_{x0}} + \frac{1}{b}(gv_{y0} + b)\left(\frac{x - x_0}{v_{x0}}\right)$$

→ 1371

Per ottenere l'equazione della traiettoria occorre sviluppare per $b \simeq 0$ all'ordine b^2. Si riottiene così, per esempio, la formula per la gittata. Lo sviluppo all'ordine b^3 (o superiori) fornisce le correzioni dovute alla resistenza dell'aria.

24-041 Resistenza proporzionale al quadrato della velocità - Il paracadute

©|Alonso & Finn, , ..., ..., ...Ed., ...|7.59 7.86||
©|I.E.Irodov, *Problems In General Physics*, 1988, MIR publishers Moscow, ...Ed., ...|1.104||

Un oggetto si muove sotto l'azione di una forza costante $\mathbf{F}$ in un mezzo che presenta una forza resistente $\mathbf{F_R} = -bv\mathbf{v}$ dove b è una costante positiva che dipende dalle caratteristiche dell'oggetto e del mezzo. Supponendo che l'oggetto parta all'istante $t = 0$ dalla posizione $\mathbf{x} = \mathbf{x}_0 = 0$ con velocità $\mathbf{v}_0$ parallela a $\mathbf{F}$ dimostrare che la velocità limite è data da

$$v_L = \sqrt{F/b}$$

che l'andamento della velocità in funzione del tempo è dato da

$$v = v_L \frac{(v_0 + v_L)\exp bv_L t/m + (v_0 - v_L)\exp -bv_L t/m}{(v_0 + v_L)\exp bv_L t/m - (v_0 - v_L)\exp -bv_L t/m}$$

e che la relazione tra velocità e spazio percorso è

$$v^2 = F/b + \left[v_0^2 - F/b\right]\exp -2b(x - x_0)/m$$

PRELIM

WORKED SOLUTION

L'equazione del moto, supposto unidimensionale in quanto $\mathbf{F} \parallel \mathbf{v}_0$ implica $\mathbf{F} \parallel \mathbf{v}$, è

$$m\frac{d\mathbf{v}}{dt} = \mathbf{F} - bv\mathbf{v}$$

che proiettata sull'asse x fornisce (supponendo $\mathbf{F}\cdot\mathbf{v_0} > 0$)

$$m\frac{dv}{dt} = F - bv^2 \qquad (24.22.05)$$

→ 1372

Se $F - bv_0^2 > 0$ l'accelerazione è positiva e la velocità cresce fino ad una velocità limite, v_L,

$$\frac{dv}{dt} = 0 \implies v_L = \sqrt{F/b}$$

Se $F - bv_0^2 < 0$ l'accelerazione è negativa e la velocità decresce fino alla stessa velocità limite. Nel caso $F - bv_0^2 = 0$ l'accelerazione è nulla e la velocità resta costante e uguale alla velocità limite. L'equazione del moto può essere integrata per separazione delle variabili. Supponiamo $v_0 < v_L$.

$$\frac{dv}{1 - bv^2/F} = \frac{Fdt}{m}$$

Integrando e tenendo conto della condizione iniziale $v_0 < v_L$ si trova

$$\log\left(\frac{v_L + v}{v_L - v}\right) = \frac{2\sqrt{Fb}}{m}t + cost \quad ,$$

$$cost = \frac{v_L + v_0}{v_L - v_0}$$

da cui si deduce il risultato richiesto per $v(t)$.
Per ricavare la dipendenza della velocità dalla posizione, $v(x)$, si parte dalla stessa equazione (24.22.05) e la si riscrive come

$$mv\frac{dv}{dx} = F - bv^2$$

e procedendo per separazione delle variabili come sopra si ottiene, nel caso $v_0 < v_L$,

$$v^2 = F/b + \left[v_0^2 - F/b\right]\exp -2b(x - x_0)/m$$

come richiesto.

CC BY NC ND

24-042 La Catena Che Scivola Dal Bordo Del Tavolo

©|M.R.Spiegel, *Theory And Problems Of Theoretical Mechanics*, 1967, McGraw-Hill, ...Ed., ...|3.85 3.86 3.111||

Una catena ideale, perfettamente flessibile e inestensibile, di lunghezza L e densità per unità di lunghezza λ, scivola dal bordo di un tavolo.

1. Supponendo che non ci sia attrito, che la catena parta da ferma e che all'istante iniziale una parte lunga x_0 di essa penda dal bordo del tavolo dimostrare che il tempo occorrente alla catena per scivolare dalla tavola vale
$$\sqrt{\frac{L}{g x_0^2}} \log L + \sqrt{L^2 - x_0^2}$$
Si supponga ora che il coefficiente di attrito cinetico tra la catena e il piano del tavolo valga μ_c.
2. Determinare l'accelerazione della catena in funzione della lunghezza x della parte di catena che pende dal bordo del tavolo.
3. Dimostrare che in tal caso, supponendo che nella posizione iniziale la forza di attrito statico non sia in grado di tenere ferma la catena, il tempo occorrente alla catena per scivolare dalla tavola vale
$$\sqrt{\frac{L}{g\,(1+\mu)}} \log \left\{ \frac{L + \sqrt{L^2 - [x_0\,(1+\mu) - L\mu]^2}}{x_0\,(1+\mu) - L\mu} \right\}$$
4. Se il coefficiente di attrito statico vale μ_s dimostrare che la catena non cade dal tavolo se e solo se
$$x_0\,(1+\mu_s) \leq \mu_s L$$

WORKED SOLUTION

2) $a = (g/L)\,(x\,(1+\mu_c) - \mu_c L)$

Si stimi approssimativamente l'entità della deviazione verso est di un grave in una (breve) caduta libera da fermo alla superficie terrestre nell'emisfero nord. Di quanto devia verso est un grave lasciato cadere da un'altezza $h = 100$ m alla latitudine di $45°$?

Compare with problem § 24.21.07.

WORKED SOLUTION

L'accelerazione relativa al Reference Frame terrestre, non inerziale, è data da

$$\mathbf{a} = \mathbf{g}_{\mathtt{eff}} - 2\,\boldsymbol{\omega}\wedge\mathbf{v}$$

dove $\mathbf{g}_{\mathtt{eff}}$ è l'accelerazione effettiva alla superficie della Terra che include il contributo della forza centrifuga. L'accelerazione $\mathbf{g}_{\mathtt{eff}}$ giace nel piano meridiano della Terra e quindi una deviazione trasversale può solo derivare dal termine di Coriolis. Possiamo supporre, approssimativamente, che sia $\mathbf{g} = \mathbf{g}_{\mathtt{eff}}$ in modo che sia $\mathbf{g} \parallel \mathbf{r}$. Questo equivale a trascurare la forza centrifuga rispetto alla forza peso. Detta $\mathbf{v}_m$ la componente della velocità del grave nel piano meridiano l'accelerazione trasversale a tale piano, e diretta verso est nell'emisfero nord, ha modulo

$$a_{\mathtt{trasv}} = 2\omega v_m \cos[\lambda] \tag{24.22.06}$$

→ 1376

avendo indicato con λ la latitudine. In prima approssimazione, per un tragitto breve cosicché v_m resta sufficientemente piccola in modulo, si può sostituire v_m con il valore della velocità che si calcolerebbe trascurando l'effetto della forza di Coriolis. Ciò è giustificato dal fatto che nelle ipotesi fatte l'accelerazione di Coriolis rappresenta solo una piccola correzione alla $\mathbf{g}_{\mathtt{eff}}$ essendo $2\omega v_m \cos[\lambda] \ll g$ per v_m abbastanza piccolo. Allora si può porre, essendo $v = gt$,

$$\boxed{a_{\mathtt{trasv}} \equiv \ddot{y} \simeq 2\omega\cos[\lambda]\, v \simeq 2\omega\cos[\lambda]\, gt}$$

che integrata con la condizione iniziale $\dot{y}(t=0) = 0$, essendo la velocità trasversa iniziale nulla, fornisce

$$\boxed{\Delta y = \frac{1}{3} g\omega\cos[\lambda]\, t^3} \tag{24.22.07}$$

Nelle approssimazioni fatte la deviazione si calcola usando la relazione

$$h = \frac{g}{2}t^2$$

e risulta

$$\boxed{\Delta y \simeq \frac{2}{3} h\omega\cos[\lambda]\sqrt{\frac{2h}{g}}} = 1.55 \text{ cm}$$

Si noti che la velocità trasversale da origine, tramite la forza di Coriolis, ad una correzione alla velocità nel piano meridiano che è però una correzione di secondo ordine.

24-051 Deviazione Verso Ovest Di Un Oggetto Lanciato Verso L'alto

©|Alonso & Finn, , ..., ..., ...Ed., ...|6.33||

Un punto materiale è lanciato verticalmente verso l'alto con velocità v_0. Dimostrare che ricadrà in un punto spostato verso ovest di una distanza pari a

$$\Delta y = \frac{4}{3}\omega \cos[\lambda]\sqrt{\frac{8h^3}{g}}$$

dove h è l'altezza a cui sale il punto materiale.

WORKED SOLUTION

In generale, risolvendo l'equazione (24.22.06), si trova

$$\Delta y = \dot{y}(t=0)t + \omega v_0 \cos[\lambda]\, t^2 + \frac{1}{3}\omega a \cos[\lambda]\, t^3$$

dove a è l'accelerazione nel piano meridiano. Si noti che il segno della forza di Coriolis in salita ed in discesa è diverso.

24-052 Oggetto Fermo Visto Da Una Giostra in Moto

Un bambino si trova fermo al centro di una giostra che ruota con velocità angolare costante Ω. Egli osserva i suoi genitori che sono fermi a terra ma che, dal suo punto di vista, si muovono di moto circolare uniforme rispetto al centro della giostra. Nella descrizione del bambino chi fornisce la forza centripeta necessaria per mantenere i genitori in moto circolare uniforme?

WORKED SOLUTION

Si considerino le sole forze agenti sul piano orizzontale. Sui genitori non agisce alcuna forza con componenti nel piano orizzontale. Dal punto di vista del bambino, osservatore non inerziale, sui genitori agiscono però le forze (fittizie) centrifuga e di Coriolis. La loro risultante fornisce la forze centripeta richiesta.

24-056 Accelerazione Di Protoni

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|7.20||

Un protone (nucleo dell'isotopo più leggero dell'atomo di idrogeno) può essere accelerato da un acceleratore lineare lungo un tratto rettilineo con accelerazione $a = 3.60 \cdot 10^{15}\ \mathrm{m/s^2}$. Un protone entra in un tratto accelerante lungo $l = 3.50\ \mathrm{cm}$ con una velocità iniziale $v_0 = 2.40 \cdot 10^{7}$ ms.

1. Si calcoli la velocità del protone al termine dell'accelerazione.
2. Si calcoli il guadagno di energia cinetica del protone. La massa del protone vale $m = 1.67 \cdot 10^{-27}\ \mathrm{kg}$. Si ignorino gli effetti relativistici sul moto del protone.

24-057 Collisioni Tra Comete E La Terra E Crateri Prodotti

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|7.29||

Una cometa di massa $m = 8.30 \cdot 10^{11}\ \mathrm{kg}$ urta la Terra con velocità relativa $v = 30\ \mathrm{km/s}$.

1. Si calcoli l'energia cinetica della cometa espressa in megatoni di TNT. Un megatone di TNT corrisponde all'energia liberata nell'esplosione di un milione di tonnellate di tritolo ed è pari a $4.2 \cdot 10^{15}$ J. Il diametro del cratere prodotto da una grande esplosione è proporzionale alla radice cubica dell'energia sviluppata; con un megatone di TNT si produce un cratere di diametro circa pari a $D = 1\ \mathrm{km}$.
2. Quanto misura il diametro D del cratere prodotto dall'impatto della cometa sulla Terra?

WORKED SOLUTION

1) $\mathcal{K} = 9.0 \cdot 10^{4}$ megatoni di TNT; 2) $D = 45\ \mathrm{km}$.

This § is referenced at pages:
[1383, 1383]

Un ragazzo di massa m è seduto in cima ad una grande calotta di ghiaccio di forma semisferica con raggio R. Si supponga nullo l'attrito tra il ragazzo e il ghiaccio. Se il ragazzo incomincia a scivolare partendo da fermo in quale punto si stacca dalla calotta? Per quale valore della velocità iniziale $\mathbf{v}_0$, orizzontale, il ragazzo si stacca subito? Quale è la sua velocità all'istante dello stacco? Quale è la sua traiettoria dopo lo stacco?

WORKED SOLUTION

Si schematizzi il ragazzo come un punto materiale. Si introduca un Coordinate System polari, centrato al centro della semisfera di ghiaccio, che individua la posizione del ragazzo, e si misuri l'angolo θ a partire dal punto più alto della semisfera. In tal modo $\theta(t=0)=0$. Detto N il modulo della reazione normale ed $\mathbf{F}$ la risultante delle forze che agiscono sul ragazzo, le equazioni del moto del ragazzo si scrivono, in coordinate polari,

$$F_r = N - mg\cos[\theta] = m\left(\ddot{r} - r\dot{\theta}^2\right) \tag{24.22.08}$$

→ 1383

$$F_\theta = mg\sin[\theta] = m\left(2\dot{r}\dot{\theta} + r\ddot{\theta}\right) \tag{24.22.09}$$

→ 1383

L'equazione per F_θ è equivalente ad applicare la legge della variazione del momento angolare rispetto al polo fisso O coincidente con il centro della semisfera

$$\boxed{\boldsymbol{\gamma} = \frac{\mathrm{d}\mathbf{l}}{\mathrm{d}t} + \mathbf{v}_0 \wedge \mathbf{p}} \tag{24.22.10}$$

Finché il ragazzo resta a contatto con la semisfera le incognite sono $\theta(t)$ ed N, essendo $r(t)=R$ noto. Il vincolo cioè, finché è effettivo, aggiunge una incognita (il valore della reazione vincolare) ma elimina un grado di libertà (la coordinata radiale). Dopo che il ragazzo si è staccato N non è più una grandezza fisica del problema e le due incognite diventano $r(t)$ e $\theta(t)$. Finché il ragazzo resta a contatto con la semisfera la seconda equazione permette di determinare il moto $\theta(t)$ mentre la prima determina la reazione vincolare. In tale condizione la seconda equazione può essere integrata moltiplicando entrambi i membri per $\dot{\theta}$ e sostituendo $r(t)=R$. Questo è equivalente ad applicare il principio di conservazione dell'energia meccanica. Scegliendo il livello di riferimento dell'energia potenziale gravitazionale al livello del suolo si ha

$$mgR + \frac{m}{2}v_0^2 = mgR\cos[\theta] + \frac{m}{2}v^2 \equiv E$$

da cui si deduce

$$v = R\dot{\theta} = \sqrt{v_0^2 + 2gR\left(1-\cos[\theta]\right)}$$

che fornisce la velocità in funzione della posizione sulla semisfera. Ora il valore della reazione vincolare può essere ricavato sostituendo l'espressione di $\dot{\theta}$ nella prima equazione

$$N = mg\left(3\cos[\theta] - 2\right) - \frac{mv_0^2}{R}$$

CC BY NC ND

La reazione normale è effettiva finché $N > 0$ e si ha $N(\theta = 0) = mg - \frac{mv_0^2}{R}$. Se $v_0 = 0$ lo stacco avviene cioè per $\cos[\theta] = 2/3$.

Se la velocità iniziale è $v_0 \neq 0$ lo stacco avviene subito se e solo se $N(\theta = 0) = mg - \frac{mv_0^2}{R} \leq 0$ cioè se e solo se $v_0^2 \geq Rg$. Tale risultato può anche essere ricavato utilizzando le componenti intrinseche delle quantità cinematiche.
La velocità del ragazzo all'istante dello stacco si ricava dall'espressione per v e vale $v = R\dot{\theta} = \sqrt{2gR/3}$.
Dopo lo stacco il moto del ragazzo è quello di un grave in caduta libera. Introduciamo un Coordinate System cartesiane centrato nel centro della semisfera, con asse x orizzontale e asse y verticale. La posizione iniziale, $\mathbf{r}_0$, e la velocità iniziale, $\mathbf{v}_0$, sono date dalle relazioni

$$\begin{aligned}\mathbf{r}_0 &= R\sin[\theta]\,\widehat{\mathbf{e}}_1 + R\cos[\theta]\,\widehat{\mathbf{e}}_2 \quad ,\\ \mathbf{v}_0 &= v\cos[\theta]\,\widehat{\mathbf{e}}_1 - v\sin[\theta]\,\widehat{\mathbf{e}}_2 \quad .\end{aligned}$$

e l'equazione del moto del ragazzo dopo lo stacco, se lo stacco avviene al tempo t_0, è

$$\mathbf{r} = \mathbf{r}_0 + \mathbf{v}_0\,(t - t_0) - \frac{g}{2}\widehat{\mathbf{e}}_2(t - t_0)^2$$

Si veda la generalizzazione in section § 24-075
In presenza di attrito l'equazione per la componente radiale della forza (24.22.08) resta immutata mentre nell'equazione per la componente tangenziale (24.22.09) entra il contributo della forza di attrito. L'espressione della reazione normale che si ricava dalla prima equazione è dunque la stessa ma cambia la velocità che deve essere introdotta in tale equazione. L'energia meccanica non è più conservata ma occorre applicare il bilancio energetico. In ogni caso, per la presenza dell'attrito, la particella avrà, a parità di posizione, una velocità inferiore al caso senza attrito per cui lo stacco avverrà più tardi (cioè a θ maggiore).

24-075 Il Punto Materiale Che Cade Lungo Un Profilo Qualunque

©|BBM, , ..., ..., ...Ed., ...|2.3.7||

This § is referenced at pages:
[1382]

Si consideri una generalizzazione del problema § 24-074. Un punto materiale di massa m scivola lungo una guida piana posta in un piano verticale con la concavità rivolta verso il basso. La guida è descritta dalla funzione $g(x, y) = 0$ dove l'asse x è orizzontale e l'asse y è diretto verticalmente verso il basso. Il raggio di curvatura della guida, variabile, è la funzione $\rho(x, y)$.

1. Determinare in funzione di θ, v e ρ la condizione di distacco del punto dalla superficie.
2. Sapendo che il punto materiale viene lanciato dalla quota y_0 con velocità v_0 tangente alla guida determinare la quota y a cui avviene il distacco dalla guida in funzione di y, y_0, ρ, θ e v_0.

WORKED SOLUTION

Supponiamo $\partial g/\partial y \neq 0$. è possibile in tal caso scegliere il segno di $g(x, y)$ in modo tale che $\partial g/\partial y > 0$. In tal caso il versore normale è dato da

$$\widehat{\mathbf{n}} = \frac{\frac{\partial g}{\partial x}\widehat{\mathbf{e}}_1 + \frac{\partial g}{\partial y}\widehat{\mathbf{e}}_2}{\sqrt{\left(\frac{\partial g}{\partial x}\right)^2 + \left(\frac{\partial g}{\partial y}\right)^2}}$$

Conviene utilizzare il Coordinate System intrinseco al profilo della guida dato che, fino a che il punto non si stacca, il moto del punto materiale coincide con il profilo della stessa. Si denoti con θ l'angolo formato tra la forza peso (cioè il versore $\hat{\mathbf{e}}_2$) e il versore normale alla guida. Le equazioni del moto proiettate sulla terna intrinseca sono

$$-N + mg\cos[\theta] = m\frac{v^2}{\rho} \quad ,$$

$$mg\sin[\theta] = m\frac{dv}{dt}$$

Da cui si ricava il valore di N

$$N = m\left(g\cos[\theta] - \frac{v^2}{\rho}\right)$$

Il punto si stacca dalla guida quando $N = 0$. Di conseguenza il punto resta attaccato alla guida finché

$$g\cos[\theta] - \frac{v^2}{\rho} > 0$$

e si stacca allorché

$$g\cos[\theta] - \frac{v^2}{\rho} = 0$$

In particolare all'istante iniziale il punto resta attaccato o si stacca a seconda che le condizioni iniziali siano soddisfatte o no all'istante iniziale. L'energia è conservata per cui si può scrivere

$$mgy_0 + \frac{m}{2}v_0^2 = mgy + \frac{m}{2}v^2 \equiv E$$

e quindi la condizione di distacco diventa

$$\rho(x,y)g\cos[\theta] - v_0^2 + 2g(y - y_0) = 0$$

che permette, insieme all'equazione della curva $g(x,y) =$ di determinare le coordinate del punto di distacco. Dalla soluzione trovata si deduce che il distacco avviene sempre con $\cos[\theta] > 0$, cioè il punto materiale lascia sempre la guida prima che diventi verticale. La formula trovata può essere applicata al caso della semisfera discussa in section § 24-074.

WORKED SOLUTION

1) Il punto si stacca quando $g\cos[\theta] - v^2/\rho = 0$. 2) Il punto si stacca quando $\rho(x,y)g\cos[\theta] - v_0^2 + 2g(y - y_0) = 0$.

24-076 Il Pendolo Balistico

©|H.C.Ohanian, , ..., ..., ...Ed., ...|7.51 7.52||

Un punto materiale è appeso in quiete ad una fune ideale di lunghezza R (un pendolo). Si colpisce il punto materiale con una forza impulsiva in modo tale da fornirgli, all'istante iniziale, una velocità $\mathbf{v}_0$ in direzione orizzontale. Quale deve essere il valore minimo della velocità iniziale affinché il punto materiale compia tutta la circonferenza? Quanto vale il valore massimo della tensione assunto dalla fune?

WORKED SOLUTION

Si supponga di misurare la posizione del punto con l'angolo θ a partire dalla posizione più bassa. Supponiamo che il punto si muova lungo una circonferenza di raggio R. Ciò è possibile se e solo se la tensione della fune è diretta verso il centro della circonferenza in quanto la fune non può esercitare che una trazione sul punto materiale. L'equazione del moto del punto in coordinate

intrinseche diventa, in tale condizione,

$$-T + mg\cos[\theta] = -m\frac{v^2}{R} \quad ,$$
$$-mg\sin[\theta] = m\frac{\mathrm{d}v}{\mathrm{d}t}$$

che sono le equazioni del moto di un pendolo. Il principio di conservazione dell'energia meccanica si scrive, scegliendo come punto di riferimento per l'energia potenziale gravitazionale il punto più basso,

$$\frac{m}{2}v_0^2 = \frac{m}{2}v^2 + mgR(1-\cos[\theta])$$

da cui si ricava l'espressione per T

$$T = \frac{mv_0^2}{R} + mg(3\cos[\theta] - 2)$$

Finché $T > 0$ il pendolo si muove sulla circonferenza. Il valore minimo di T si ha per $\theta_{\mathtt{min}} = -\pi$ e si deve quindi avere

$$T_{\mathtt{min}} = \frac{mv_0^2}{R} - 5mg > 0 \implies v_0^2 > 5gR$$

affinché il pendolo percorra tutta la circonferenza.
La tensione della corda assume il suo valore massimo per $\theta_{\mathtt{max}} = 0$ e vale

$$T_{\mathtt{max}} = \frac{mv_0^2}{R} + mg$$

e con la velocità minima per percorrere tutta la circonferenza si ha $T_{\mathtt{max}} = 6mg$.

24-077 Il Giro Della Morte

This § is referenced at pages:
[1468]

Una particella di massa m si muove all'interno di una guida circolare di raggio R disposta nel piano verticale. La velocità della particella nel punto più basso della sua traiettoria vale v_0.

1. Quale è il valore minimo $v_{\mathtt{min}}$ della velocità v_0 che consente alla particella di effettuare un giro completo senza perdere contatto con la guida?
2. La velocità v_0 vale $v_0 = 0.775v_{\mathtt{min}}$. Sia θ l'angolo che descrive la posizione della particella entro la guida, a partire dalla posizione orizzontale. In tale modo la posizione iniziale della particella è $\theta_0 = -\pi/2$ rad. Per quale valore di θ la particella perde contatto con la guida?

WORKED SOLUTION

1) $v_{\mathtt{min}} = \sqrt{5gR}$; 2) $\sin[\theta] = 1/3$.

24-078 Punto Materiale Attaccato Alla Molla Ruotante

Un punto materiale di massa m ruota in una traiettoria circolare con velocità angolare costante ω attorno ad un punto cui è collegato da una molla di costante elastica k e lunghezza a riposo d. Determinare la distanza di equilibrio, r_0 sia usando le **Cardinal Equation** che considerazioni energetiche.

WORKED SOLUTION

Consideriamo la situazione dal punto di vista del Reference Frame ruotante solidalmente con il punto materiale. La condizione di equilibrio tra la forza reale della molla e la forza centrifuga fittizia si scrive

$$m\omega^2 r_0 - k(r_0 - d) = 0$$

da cui segue

$$r_0 = \frac{kd}{k - m\omega^2}$$

Esaminiamo alcuni casi limite. Nel caso $\omega = 0$ si ha $r_0 = d$ come deve (molla a riposo). Nel caso $\omega^2 < k/m$ e $\omega^2 \longrightarrow k/m$ si ha $r_0 \longrightarrow \infty$: se la velocità angolare cresce a sufficienza la posizione di equilibrio tende all'infinito in quanto la forza elastica della molla non è più sufficiente ad equilibrare la forza centrifuga. Naturalmente in tal caso una molla reale smetterà di comportarsi idealmente secondo la legge di Hooke. Nel caso $\omega^2 \geq k/m$ non è possibile equilibrio.
La posizione di equilibrio può essere pure determinata dal minimo dell'energia potenziale (nel Reference Frame ruotante)

$$\Phi(r) = \frac{k}{2}(r - d)^2 - \frac{m\omega^2}{2} r^2$$

WORKED SOLUTION

$r_0 = kd/\left(k - m\omega^2\right)$

24-079 Il Potenziale Di Yukawa

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|8.45||

Il cosidetto potenziale di Yukawa

$$\Phi(r) = \frac{r_0}{r}\Phi_0 \exp\left[-r/r_0\right] \tag{24.22.11}$$

fornisce una descrizione approssimata dell'interazione tra due nucleoni (cioè protoni e neutroni), i costituenti del nucleo atomico. La costante r_0 vale circa $r_0 \simeq 1.5{\cdot}10^{-15}$ m mentre la costante Φ_0 vale circa $\Phi_0 \simeq 50$ MeV.

1. Si determini la corrispondente espressione della forza $F(r)$ tra due nucleoni.
2. Per rendersi conto del suo corto raggio di azione si calcoli il rapporto del modulo di tale forze per $r = 2r_0, 4r_0, 10r_0$ con il valore $F(r = r_0)$.

WORKED SOLUTION

1) $F(r) = -\Phi_0\left(r_0 r^{-2} + r^{-1}\right)\exp -r/r_0$; 2) 0.14, 0.0078, $6.8{\cdot}10^{-6}$.

24-086 Accelerazione Angolare Che Accompagna La Contrazione

©|Alonso & Finn, , ..., ..., ...Ed., ...|8.43||

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|§ 6.4 § 6.5||

Un punto materiale di massa m si muove con velocità v_0 lungo una traiettoria circolare di raggio r_0 su un tavolo orizzontale privo di attrito. Il punto è mantenuto nella sua orbita circolare da una fune che passa attraverso un'apertura senza attrito al centro del tavolo e trattenuta all'altro capo da una forza costante $\mathbf{F}_0$. Determinare l'espressione di $\mathbf{F}_0$ in funzione dei parametri dati. Supponendo che la forza venga aumentata molto lentamente fino al valore $\mathbf{F}$ e che l'orbita finale sia circolare determinare le caratteristiche dell'orbita finale. Determinare il lavoro fatto dalla forza $\mathbf{F}$ per cambiare il raggio dell'orbita e il valore finale della velocità angolare.

WORKED SOLUTION

L'equazione del moto si scrive, nelle due situazioni iniziale e finale, essendo per ipotesi le orbite circolari,

$$F_0 = m\frac{v_0^2}{r_0} \quad ,$$
$$F = m\frac{v^2}{r}$$

Essendo la forza $\mathbf{F}$ sempre diretta lungo il raggio il suo momento rispetto al centro è nullo e quindi il momento angolare è conservato, per cui ne segue

$$mr_0v_0 = mrv$$

Usando tale relazione è possibile determinare il legame tra F_0 ed F, la forza che bisogna applicare affinché il punto materiale si muova sull'orbita circolare di raggio r in funzione dei parametri F_0 ed r_0,

$$F = F_0\left(\frac{r_0}{r}\right)^3$$

La variazione di energia cinetica è

$$\Delta\mathcal{K} = \mathcal{K} - \mathcal{K}_0 = \frac{m}{2}\left(v^2 - v_0^2\right) = \mathcal{K}_0\left[\left(\frac{r_0}{r}\right)^2 - 1\right]$$

e le due energie cinetiche sono legate da

$$\mathcal{K} = \mathcal{K}_0\left(\frac{r_0}{r}\right)^2$$

La variazione di energia cinetica risulta dunque positiva se $r < r_0$ per cui la forza fa lavoro positivo. Considerando che la forza aumenti molto lentamente in modo tale che il moto può essere considerato in ogni istante circolare uniforme con raggio lentamente variabile si può anche calcolare

direttamente il lavoro fatto dalla forza $\mathbf{F}$

$$\mathrm{d}L \equiv \mathbf{F} \cdot \mathrm{d}\mathbf{r} = -F(r)\hat{\mathbf{e}}_r \cdot \mathrm{d}r\hat{\mathbf{e}}_r = -F(r)\,\mathrm{d}r$$

che integrata da

$$L = \int_{r_0}^{r} -F(r)\,\mathrm{d}r = -F_0 \int_{r_0}^{r} \left(\frac{r_0}{r}\right)^3 \mathrm{d}r = \frac{F_0 r_0^3}{2}\left(\frac{1}{r^2} - \frac{1}{r_0^2}\right) = \frac{m v_0^2 r_0^2}{2}\left(\frac{1}{r^2} - \frac{1}{r_0^2}\right)$$

che coincide con l'espressione della variazione di energia cinetica calcolata sopra, come deve per il teorema lavoro energia.
La velocità angolare finale

$$\omega = \frac{v}{r} = \omega_0 \left(\frac{r_0}{r}\right)^2$$

La velocità angolare dunque aumenta se il raggio dell'orbita diminuisce.

24-100 Il Distacco Dell'ultimo Stadio Del Missile

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|9.35||

L'ultimo stadio di un missile viaggia a velocità $u_0 = 7600\ \text{km/s}$ ed è composto dalla sonda spaziale di massa $m = 150\ \text{kg}$ e dal serbatoio vuoto dell'ultimo stadio, di massa $M = 290\ \text{kg}$. Le due parti sono bloccate insieme da un fermo che mantiene compressa una molla. All'istante in cui si decide il distacco dell'ultimo stadio il fermo viene rimosso e la molla allontana così le due parti impartendo loro una velocità relativa $v_R = 910\ \text{km/s}$. Si supponga che tutte le velocità giacciano sulla stessa direzione.

1. Quali sono le velocità finali del serbatoio, V, e della capsula, v?
2. Quale è l'energia cinetica del sistema prima e dopo la separazione? Se sono diverse spiegare perché.

UNDER EDITORIAL REVIEW

WORKED SOLUTION

La soluzione è del tutto analoga al problema § 24.21.13. Supponendo, a differenza del problema § 24.21.13, che sia la sonda spaziale a muoversi con velocità $\mathbf{v}$ concorde ad $\mathbf{u}_0$ si ha

$$V = u_0 - \frac{m}{m+M} v_R = 7290 \text{ km/s} \quad ,$$
$$v = u_0 + \frac{M}{m+M} v_R = 8200 \text{ km/s} \quad .$$

in cui i segni sono opposti al quelli della soluzione del problema § 24.21.13.
Il calcolo dell'energia cinetica iniziale e finale fornisce

$$\mathcal{K}_0 = \frac{1}{2}(m+M)\, u_0^2 = 1.271 \cdot 10^{10} \text{ J} \quad ,$$
$$\mathcal{K}_f = \frac{1}{2} M V^2 + \frac{1}{2} m v^2 = 1.275 \cdot 10^{10} \text{ J} \quad .$$

L'aumento di energia cinetica del sistema è dovuto al lavoro delle forze interne che provocano lo sganciamento della capsula (la molla).

WORKED SOLUTION

1) $V = 7290$ km/s; $v = 8200$ km/s. 2) $\mathcal{K}_0 = 1.271 \cdot 10^{10}$ J; $\mathcal{K}_f = 1.275 \cdot 10^{10}$ J.

Dimostrare che, nel caso di due particelle di massa m_1 ed m_2, il teorema di Koenig si può riscrivere nella forma

$$\mathcal{K} = \frac{1}{2} M V_{\text{CM}}^2 + \frac{1}{2} \mu v_{\text{REL}}^2 \tag{24.22.16}$$

dove $M = m_1 + m_2$, V_{CM} è la velocità del centro di massa, μ indica la massa ridotta della coppia e v_{REL} è la velocità relativa delle due particelle.

WORK-IN-PROGRESS

24-104 Teorema Di Koënig per Tre O Più Particelle

©|M.R.Spiegel, *Theory And Problems Of Theoretical Mechanics*, 1967, McGraw-Hill, ...Ed., ...|7.97||

Dimostrare che per un sistema di tre particelle con massa m_1, m_2, m_3 l'energia cinetica relativa al centro di massa, come risulta dal teorema di Koenig, può essere espressa tramite la relazione

$$\frac{1}{2}\sum_{k=1}^{3} m_k {v'_k}^2 = \frac{1}{2}\left[\frac{m_1 m_2 v_{12}^2 + m_2 m_3 v_{23}^2 + m_3 m_1 v_{31}^2}{m_1 + m_2 + m_3}\right] \tag{24.22.17}$$

WORKED SOLUTION

Sia $M \equiv m_1 + m_2 + m_3$.

$$v'_1 = v_1 - V_{CM} = \frac{(m_2 + m_3)\, v_1 - m_2 v_2 - m_3 v_3}{M} \quad ,$$
$$v'_2 = v_2 - V_{CM} = \frac{(m_3 + m_1)\, v_2 - m_3 v_3 - m_1 v_1}{M} \quad ,$$
$$v'_3 = v_3 - V_{CM} = \frac{(m_1 + m_2)\, v_3 - m_1 v_1 - m_2 v_2}{M}$$

Ne segue

$$\frac{1}{2} m_1 {v'_1}^2 = \frac{m_1}{2M^2}\left[(m_2 + m_3)^2 v_1^2 + m_2^2 v_2^2 + m_3^2 v_3^2 - 2m_2 (m_2 + m_3) v_1 v_2 - 2m_3 (m_2 + m_3) v_1 v_3 + 2m_2 m_3 v_2 v_3\right] \quad ,$$
$$\frac{1}{2} m_2 {v'_2}^2 = \frac{m_2}{2M^2}\left[(m_3 + m_1)^2 v_2^2 + m_3^2 v_3^2 + m_1^2 v_1^2 - 2m_3 (m_3 + m_1) v_2 v_3 - 2m_1 (m_3 + m_1) v_2 v_1 + 2m_3 m_1 v_3 v_1\right] \quad ,$$
$$\frac{1}{2} m_3 {v'_3}^2 = \frac{m_3}{2M^2}\left[(m_1 + m_2)^2 v_3^2 + m_1^2 v_1^2 + m_2^2 v_2^2 - 2m_1 (m_1 + m_2) v_3 v_1 - 2m_2 (m_1 + m_2) v_3 v_2 + 2m_1 m_2 v_1 v_2\right]$$

Sviluppando poi v_{12}^2, v_{23}^2, v_{31}^2, a secondo membro e raccogliendo i termini analoghi si verifica l'uguaglianza.

24-105 Teorema Dello Pseudo-Lavoro

Il momento angolare totale di un sistema di particelle rispetto ad un polo O in un Reference Frame inerziale è definito da

$$\mathbf{L} = \sum_k \mathbf{r}_k\wedge\mathbf{p}_k \tag{24.22.19}$$

1. Si usino le relazioni
$$\begin{aligned}\mathbf{r}_k &= \mathbf{r}_{\text{CM}} + \mathbf{r'}_k \quad ,\\ \mathbf{p}_k &= m_k\mathbf{V}_{\text{CM}} + \mathbf{p'}_k \quad .\end{aligned}$$
per esprimere il momento angolare totale in termini delle grandezze $\mathbf{r'}_k$ e $\mathbf{p'}_k$ relative al centro di massa.
2. Si dimostri come il momento angolare totale può essere decomposto in una parte orbitale ed una parte di momento angolare rispetto al centro di massa, $\mathbf{L'}$, detta anche momento angolare di spin, tramite la relazione
$$\mathbf{L} = M\,\mathbf{r}_{\text{cm}}\wedge\mathbf{V}_{\text{CM}} + \mathbf{L'} \tag{24.22.20}$$

24-110 Momento Angolare Nel Reference Frame Del Centro Di Massa

©|Am.J.Phys, , ..., ..., ...Ed., ...|???||

Si consideri il momento angolare di un sistema di particelle relativo al Reference Frame del centro di massa, il Reference Frame che ha origine nel centro di massa del sistema e si muove solidalmente con esso senza ruotare rispetto al Reference Frame del Laboratorio. Si denotino, rispettivamente, con $\mathbf{r}_k$ e $\mathbf{p}_k$ posizione e quantità di moto della k-esima particella rispetto al Reference Frame del Laboratorio e $\mathbf{r'}_k$ e $\mathbf{p'}_k$ le stesse quantità rispetto al Reference Frame del centro di massa. Si dimostri che il momento angolare del sistema rispetto al Reference Frame del centro di massa si può esprimere con le tre espressioni equivalenti

$$\mathbf{L}_{CM} = \sum_k \mathbf{r}'_k \wedge \mathbf{p}_k \quad ,$$

$$\mathbf{L}_{CM} = \sum_k \mathbf{r}_k \wedge \mathbf{p}'_k \quad ,$$

$$\mathbf{L}_{CM} = \sum_k \mathbf{r}'_k \wedge \mathbf{p}'_k$$

Un disco cilindrico omogeneo, di massa $M = 80\ \mathrm{g}$ e raggio $R = 15\ \mathrm{cm}$, è imperniato su un asse orizzontale che passa per il suo centro O ed è inizialmente in quiete.

Un piccolo oggetto di massa $m = 5\ \mathrm{g}$, che viaggia in orizzontale con velocità $v_0 = 0.8\ \mathrm{m/s}$ perpendicolare all'asse del disco, urta contro il disco conficcandosi in esso al bordo, nella sua estremità inferiore. Tra l'asse ed il disco agisce una molla a di torsione avente costante di torsione $k = 2{\cdot}10^{-3}\ \mathrm{N \cdot m \cdot rad^{-1}}$ ed è anche presente è attrito radente con momento $\tau_a = 10^{-3}\ \mathrm{N \cdot m}$.

Si calcoli:

1. la velocità angolare del sistema dopo l'urto nonchè l'impulso sull'asse conseguente all'urto;
2. dove, ed a quale tempo, si arresta per la prima volta il sistema dopo l'urto;
3. come cambia la risposta al punto precedente se anziché l'attrito radente è presente l'attrito viscoso dell'aria proporzionale alla velocità angolare che genera un momento $\tau_v = -c\omega$ con $c = 10^{-3}\ \mathrm{N \cdot m \cdot s}$?

DRAFT IN PROGRESS

WORKED SOLUTION

DRAFT-IN-PROGRESS

- Nell'urto si conserva il momento angolare rispetto al centro del disco. Si ha quindi:

$$mv_0 R = I\Omega \qquad I = \frac{MR^2}{2} + mR^2 = 10^{-3} kg\, m^2$$

da cui

$$\Omega = \frac{mv_0}{(m + M/2)R} = 0.59\ rad\ s^{-1}.$$

Il CM del disco non si muove e quindi $\Delta P_x^{\texttt{disco}} = 0$. La conservazione della quantità di moto,

$$\Delta P_x^{\texttt{asse}} + \Delta P_x^{\texttt{sfera}} + \Delta P_x^{\texttt{disco}} = 0,$$

fornisce quindi:

$$\Delta P_x^{\texttt{asse}} = mv_0 - mR\Omega = 3.6 \times 10^{-3} N\ s^{-1}.$$

- La seconda **Cardinal Equation** è:

$$I\ddot{\theta} = -k\theta - mgR\sin\theta \pm \tau_a$$

(segno + se $\dot{\theta} < 0$), che nel limite di piccole oscillazioni diventa:

$$\ddot{\theta} = -\omega^2(\theta \mp \delta)$$

dove:

$$\omega = \sqrt{\frac{k + mgR}{I}} = 3.06\ rad\ s^{-1} \qquad \delta = \frac{\tau_a}{k + mgR} = 0.11\ rad$$

Con le condizioni iniziali :

$$\theta(0) = 0 \qquad \dot{\theta}(0) = \Omega$$

dalla soluzione generale

$$\theta(t) = A\cos(\omega t + \phi) \pm \delta$$

e tenendo conto che nella prima fase del moto abbiamo $\dot{\theta} > 0$, otteniamo:

$$\theta(t) = \sqrt{\frac{\Omega^2}{\omega^2} + \delta^2}\cos(\omega t + \phi) - \delta$$

con $\cos\phi = \dfrac{\delta}{\sqrt{\delta^2 + (\Omega/\omega)^2}}$ e $\tan\phi = -\Omega/(\delta\omega)$.
Abbiamo quindi l'arresto quando $\cos(\omega t + \phi) = 1$ e quindi:

$$\theta = \sqrt{\frac{\Omega^2}{\omega^2} + \delta^2} - \delta = 0.11\ rad$$

che si verifica al tempo

$$t = -\frac{1}{\omega}\arctan\left(-\frac{\Omega}{\omega\delta}\right) = 0.34\ s.$$

- L'attrito viscoso produce un momento $\tau_v = -c\dot{\theta}$. L'**Cardinal Equation** diventa quindi:

$$\ddot{\theta} + 2\gamma\dot{\theta} + \omega^2\theta = 0$$

con $\gamma = c/(2I) = 0.5 s^{-1}$.
Posto $\omega' = \sqrt{\omega^2 - \gamma^2} = 3.02\ rad\ s^{-1}$, le condizioni iniziali nella soluzione generale

$$\theta(t) = A\exp -\gamma t\cos(\omega' t + \phi)$$

forniscono:

$$\theta(t) = \frac{\Omega}{\omega'}\exp -\gamma t\sin(\omega' t).$$

Il sistema si arresta per la prima volta quando $\dot{\theta} = 0$, vale a dire:

$$\frac{\Omega}{\omega'}\exp -\gamma t(-\gamma\sin(\omega' t) + \omega'\cos(\omega' t)) = 0$$

e quindi:

$$t = \frac{1}{\omega'}\arctan\omega'/\gamma = 0.47\ s$$

Relativamente alla posizione

$$\theta = \frac{\Omega}{\omega'}\exp -\gamma t\sin(\omega' t) = 0.15\ rad$$

WORK-IN-PROGRESS

25.01 Overview

Oscillation is the name of a periodic or almost-periodic motion; almost-periodic motion is a motion which can be considered periodic over a small number of periods, that is whose period is changing slowly, over a large number of periods.

Many different systems and phenomena are described by the damped, forced harmonic oscillator equation. These include many kind of different systems including, in classical physics, many types of mechanical as well as electric systems. This explains the outermost importance of second-order linear systems in physics, deserving an accurate study of them.

In realistic cases one must almost always add a damping term, because damping almost always exists, even if it is sometimes negligible.

Moreover, in most real cases, one may have an external forcing, keeping the oscillations from fading away.

A damped, forced harmonic oscillator system/equation is a linear system. In real cases one must always check whether the system can be treated as a linear system ad what conditions need to be satisfied for that. In particular one must check what happens when the oscillations are big, and the usual small oscillations approximation breaks down. At some point, in fact, the restoring generalized force might stop to be linear.

It might be also possible that the damping force might stop to be linear. An important case, for instance, is the case of aero-dynamic drag when the viscous friction can be modeled as a force linear in the velocity at small velocities but must be modeled as a force quadratic in the velocities at higher velocities.

25.01.01 One Versus Many Degrees of Freedom - Normal Modes

One important point is the fundamental result that any un-damped mechanical system with an arbitrary number of degrees of freedom, near an equilibrium configuration, can be described, for sufficient small oscillations, in terms of **normal modes of oscillations** characterized by the fact that all coordinates oscillate with the same frequency and phases but possibly different amplitudes. The number of normal modes is exactly equal to the number of degrees of freedom of the system.

Therefore while studying the case of a single degree-of-freedom system one should keep in mind that many results can extended to an arbitrary number of degrees of freedom by simply considering the system having many frequencies of resonance, instead of a single one.

25.01.02 Small Oscillations Around a Stable Equilibrium Position

Si consideri, per concretezza, il caso di oscillazioni meccaniche. Per piccole oscillazioni attorno ad una posizione di equilibrio stabile, ξ_0, la Force|Torque di richiamo, σ, può essere sempre approssimata, tramite la formula di Taylor, con una forza armonica, proporzionale e di verso opposto allo spostamento dalla posizione di equilibrio, $\Delta\xi \equiv \xi - \xi_0$, schematicamente, per un solo grado di libertà:

$$\sigma[\xi] = -\alpha\,(\xi - \xi_0) + \mathcal{O}\left[(\xi - \xi_0)^2\right] \simeq -\alpha\Delta\xi \quad .$$

Starting from any stable equilibrium configuration of the system, let the system be described by the set of variables ξ_k and let $\xi_k[t] = \xi_{k|0}$ the equilibrium configuration.

Whatever the variable describing the system always use as a variable the **change with respect to the equilibrium configuration**:

$$\xi_k[t] \equiv \eta_k[t] - \eta_{k|0} \quad .$$

This choice is useful to remove constant terms from the equations, without changing the physics involved.

© - QUOTE

Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...
A good representation of the viscous damping force is also provided by a flat plate moving normal to its plane through a gas at very low pressure, as in Fig. 7.11, provided the speed of the plate V is much slower than the average speed of the molecules v of the gas. The pressure must be sufficiently low that we can neglect the collisions of the molecules with each other. The rate at which molecules strike the plate is proportional to the relative velocity of the incoming molecules and the plate. Suppose that the molecules move only in one dimension. On one side of the plate the relative velocity is $v + V$; on the other side it is $v - V$. The pressure is proportional to the rate at which molecules strike the plate times the average momentum transfer to the plate per molecule. The average momentum transfer is itself proportional to the relative velocity, so that the pressures p_1 and p_2 on the two sides of the plate are $p_1 \propto (v + V)^2$ and $p_2 \propto (v - V)^2$. The net pressure is the difference of the pressures on the opposite sides of the plate, $p_1 - p_2 = 4vV$, so that the drag (the net force on the moving plate) is directly proportional to the speed V of the plate. The direction of the drag can be seen to oppose the motion of the plate.

25.02 Harmonic Oscillations

Una grandezza fisica armonica function of a variable w and with period $\mathcal{P}$, è una grandezza fisica, $\xi = \xi[w]$, la cui dipendenza è Sinusoidal|Cosinusoidal :

$$\xi[w] = C\cos\left[\frac{2\pi}{\mathcal{P}}(w-w_0)-\delta\right] \equiv A\cos\left[\frac{2\pi}{\mathcal{P}}(w-w_0)\right] + B\sin\left[\frac{2\pi}{\mathcal{P}}(w-w_0)\right] \quad , \qquad (25.02.01)$$

→ 1407

dove le due coppie di costanti $\{C,\delta\}$ e $\{A,B\}$ sono due coppie alternative di costanti determinate dalle (condizioni iniziali)|(condizioni al contorno) e tra loro collegate tramite le relazioni:

$$A = \xi[w_0] \equiv \xi_0 \qquad \frac{2\pi}{\mathcal{P}}B = \frac{\mathrm{d}\xi}{\mathrm{d}w}[w_0] \equiv \left.\frac{\mathrm{d}\xi}{\mathrm{d}w}\right|_{w_0} \quad ,$$

$$A = C\cos[\delta] \qquad B = C\sin[\delta] \quad ,$$

$$\begin{cases} C = \sqrt{A^2+B^2} \geq 0 \quad , \\ \delta = \arctan(B/A) \qquad \text{se } A > 0 \quad , \\ \delta = \arctan(B/A) + \pi \qquad \text{se } A < 0 \quad , \\ \delta = -\pi/2 \qquad \text{se } A = 0 \text{ e } B > 0 \quad , \\ \delta = +\pi/2 \qquad \text{se } A = 0 \text{ e } B < 0 \end{cases} .$$

In the two most important cases, time and space oscillation, we have the following definitions.

$$T \quad \text{period of the oscillation} \quad \Leftrightarrow \quad \lambda \quad \text{wavelength of the oscillation} \quad ,$$

$$\omega_0 \equiv \frac{2\pi}{T} = 2\pi\nu \quad \text{angular frequency} \quad \Leftrightarrow \quad k_0 \equiv \frac{2\pi}{L} = 2\pi\sigma \quad \text{wave-number} \quad ,$$

$$C \quad \text{amplitude of the oscillation} \quad ,$$

$$\delta \quad \text{phase of the oscillation} \quad .$$

Also read § 18.02.

Read § 44.02.02.02 for the case of waves, doubly-periodic in time and space.

Read § 19.02 for the important and useful relations about the sum of harmonic functions with the same frequency.

In the rest of the chapter only the case of time dependence will be considered.

PRELIMINARY PROGRESS

25.03 Free Undamped Harmonic Oscillator

L'equazione differenziale che fornisce una dipendenza temporale armonica (equazione (25.02.01)) è:

$$\boxed{\ddot{\xi} + \omega_0^2 \xi = 0} \quad .$$

Note that the interpretation depends on the specific meaning of the involved physical quantity, ξ. It might be a real motion of a point, a current in an electric circuit, ... In what follows, for definiteness, when it is required to specify the system, we will always implicitly refer to a real motion of a point particle except when specified otherwise.

L'energia cinetica e potenziale, nel caso delle oscillazioni meccaniche di un oggetto di massa m, sono date dalle relazioni:

$$k = \frac{m}{2}\omega_0^2 C^2 \sin^2\left[\omega_0\left(t - t_0\right) - \delta\right] \Longrightarrow \langle k \rangle = \frac{m}{4}\omega_0^2 C^2 \quad ,$$

$$u = \frac{m}{2}\omega_0^2 C^2 \cos^2\left[\omega_0\left(t - t_0\right) - \delta\right] \Longrightarrow \langle u \rangle = \frac{m}{4}\omega_0^2 C^2 \quad .$$

L'energia totale è costante e pari a:

$$e = k + u = \frac{m}{2}\omega_0^2 C^2 = \langle k \rangle + \langle u \rangle \quad .$$

DRAFT - IN-PROGRESS

25.04 Free Damped Harmonic Oscillator

L'equazione del moto armonico smorzato libero è

$$\ddot{\xi} + 2\beta\dot{\xi} + \omega_0^2\xi = 0 \quad \Leftrightarrow \quad \ddot{\xi} + \Gamma\dot{\xi} + \omega_0^2\xi = 0 \quad . \tag{25.04.01}$$

→ 1411

As for every linear system the superposition of solutions apply (read § 19.01).

L'uso dell'uno o dell'altro dei due fattori (entrambi costanti e positivi, essendo il moto smorzato)

$$\Gamma \equiv 2\beta \geq 0 \quad ,$$

è dettato da pura semplicità delle espressioni per ovviare a vari fattori 2 (esatti) che intervengono in espressioni diverse.

Altra notazione usata:

$$\Gamma \equiv 2\beta \equiv \tau^{-1} \quad . \tag{25.04.02}$$

→ 1408

La soluzione dipende dal tipo di soluzioni dell'equazione caratteristica di secondo grado:

$$\lambda^2 + 2\beta\lambda + \omega_0^2 = 0 \implies \lambda = -\beta \pm \sqrt{\beta^2 - \omega_0^2}$$

che implica:

$\beta^2 - \omega_0^2 < 0 \quad \omega_1 \equiv \sqrt{\omega_0^2 - \beta^2} \quad \implies \xi[t] = C\exp[-\beta t]\cos[\omega_1 t - \delta]$ moto debolmente smorzato

(25.04.03) → 1408 1409 1410 1412

$\beta^2 - \omega_0^2 = 0 \quad \implies \xi[t] = (A + Bt)\exp[-\beta t]$ moto criticamente smorzato

(25.04.04) → 1408 1410 1412

$\beta^2 - \omega_0^2 > 0 \quad \alpha \equiv \sqrt{\beta^2 - \omega_0^2} \quad \implies \xi[t] = \exp[-\beta t]\,(c_1\exp[+\alpha t] + c_2\exp[-\alpha t])$ moto ultra-smorzato .

con $\{C, \delta\}$, $\{A, B\}$ e $\{c_1, c_2\}$ costanti determinate dalle condizioni iniziali.

Note that in the usual physical cases when $\beta > 0$, that is a system dissipating energy, the real part of λ is negative. In fact in the case of two distinct real roots the characteristic equation shows that the sum of the roots has to be negative ($\lambda_1 + \lambda_2 = -\beta < 0$) while their product has to be positive ($\lambda_1\lambda_2 = \omega_0^2 > 0$). In the case of two identical real roots one has $\lambda_0 = -\beta$; in the case of two complex conjugate solutions the real part of the roots is $-\beta$. Therefore in any case the exponential function goes to zero for large times.

The results, equations (25.04.03), (25.04.04), (25.04) show the meaning of the constant τ defined in equation (25.04.02): it is one-half the time constant for time decay of the amplitude of the oscillation as it is shown by equation:

$$\exp[-\beta t] = \exp\left[-\frac{t}{2\tau}\right] \quad .$$

→ 1408 1410 1412

La frequenza di oscillazione nel caso debolmente smorzato (25.04.03) vale

$$\omega_1 = \sqrt{\omega_0^2 - \beta^2} \leq \omega_0 \quad . \tag{25.04.05}$$

→ 1410

Il coefficiente α nel moto ultra-smorzato vale

$$\alpha = \sqrt{\beta^2 - \omega_0^2} \leq \beta \quad . \tag{25.04.06}$$

→ 1410

DRAFT - IN PROGRESS

25.04.01
Weakly Damped Oscillations

Consider a weakly damped oscillator: weakly damped means that the exponential factor is about constant during one oscillation period. Neglecting numerical factors of the order of the unity one can then deduce the following condition for weak damping:

$$\frac{1}{\beta} \gg \frac{2\pi}{\omega_1} \Longrightarrow \beta \ll \omega_0 \quad .$$

Energies are always quadratic functions of either coordinates or velocities. Therefore when averaging over one oscillation period a weakly damped oscillation, taking into account that the exponential factor might be considered about constant in the derivative, one has:

$$\xi[t] = C \exp[-\beta t] \cos[\omega_1 t - \delta] \quad \Longrightarrow \xi^2[t] \propto \exp[-2\beta t] \cos[\omega_1 t - \delta] \quad \Longrightarrow \langle \xi^2[t] \rangle \propto \exp[-2\beta t] \quad ,$$

$$\dot{\xi}[t] \simeq -C\omega_1 \exp[-\beta t] \sin[\omega_1 t - \delta] \quad \Longrightarrow \dot{\xi}^2[t] \propto \omega_1^2 \exp[-2\beta t] \sin[\omega_1 t - \delta] \quad \Longrightarrow \langle \dot{\xi}^2[t] \rangle \propto \omega_1^2 \exp[-2\beta t] \quad .$$

Therefore the time-averaged energies are:

$$\langle k \rangle = \langle k \rangle_0 \exp[-2\beta t] \quad ,$$
$$\langle u \rangle = \langle u \rangle_0 \exp[-2\beta t] \quad ,$$
$$\langle e \rangle = \langle e \rangle_0 \exp[-2\beta t] \quad .$$

25.04.02
Critically Damped and Over-Damped Oscillations

For a given set of initial conditions and a fixed ω_0, while varying β, the critically damped harmonic oscillator ($\beta = \omega_0$) is the one going fastest to zero.

In fact it is physically obvious that a weakly damped oscillator will not go to zero quickly and also that a strongly damped one will not go to zero quickly. There is, therefore, a certain value of β corresponding to the fastest settling to zero, for a fixed ω_0.

Start from a weakly damped oscillations: increasing β will give a faster settling to zero, due the presence of the $\exp[-\beta t]$ factor, until the critically damped, $\beta \equiv \beta_{\text{CR}} = \omega_0$, case is reached. Increasing β even more will not improve the settling to zero because the term $\exp[-\beta t] \exp[+\alpha t]$, which is the slowest of the two exponential terms of the over-damped case, will be slower than the critically damped case to settle to zero; in fact $\beta - \alpha < \omega_0 \equiv \beta_{\text{CR}}$, because $\beta > \omega_0$.

This fact is often used in finding the optimal damping when designing systems which must settle to zero as fast as possible after a perturbation.

25.04.03
Initial Constants and Full Solution

This § is referenced at pages:
[1046]

The explicit expression in terms of the initial constants for the motion (25.04.03) is:

$$\xi[t] = \exp[-\beta t] \left(\xi_0 \cos[\omega_1 t] + (v_0 + \beta \xi_0) \frac{\sin[\omega_1 t]}{\omega_1} \right) \quad . \qquad (25.04.07)$$

→ 1409 1410 1430

In the case of weak damping, $\beta \ll \omega_0$, the exponential in (25.04.07) can be considered about constant during one cycle. The velocity can thus be calculated by taking the exponential factor constant, to a good approximation. It turns out that the mechanical energy is about constant during one cycle and it decays exponentially over many cycles with time decay constant $\tau = \beta^{-1}$.

DRAFT LM-PDG-PRE-S1

The explicit expression in terms of the initial constants for the motion (25.04.04) is:

$$\boxed{\xi[t] = \exp\left[-\beta t\right]\left(\xi_0 + \left(v_0 + \beta\xi_0\right)t\right)} \quad . \tag{25.04.08}$$

→ 1430

The explicit expression in terms of the initial constants for the motion (25.04) is:

$$\boxed{\xi[t] = \exp\left[-\beta t\right]\left(\xi_0 \operatorname{coh}\left[\alpha t\right] + \left(v_0 + \beta\xi_0\right)\frac{\operatorname{sih}\left[\alpha t\right]}{\alpha}\right)} \quad . \tag{25.04.09}$$

→ 1410 1430

Note that the two equations (25.04.07), (25.04.09) can be actually considered as fully equivalent formulas, in any case, if one allows ω_1 and α to become pure imaginary numbers and takes into account the relations between circular and hyperbolic functions with pure imaginary arguments (equation (14.03.03)).

25.04.04
Q-Factor

This § is referenced at pages:
[1419, 1420]

The Q-factor for a free damped harmonic oscillator is defined by equation

$$\boxed{Q \equiv \frac{\omega_0}{2\beta} \equiv \frac{\omega_0}{\Gamma}} \quad . \tag{25.04.10}$$

→ 1419 1420

Weak damping, therefore, means $Q \gg 1$.

It can be shown that (see problem (25-002)), in the case of small damping ($Q \gg 1/2$), the evolution of the total energy is described by the relations:

$$\frac{\mathrm{d}\langle e\rangle}{\mathrm{d}t} = -m\Gamma\langle v^2\rangle \qquad \Longrightarrow \qquad \boxed{\frac{\mathrm{d}\langle e\rangle}{\mathrm{d}t} \simeq -\Gamma\langle e\rangle \equiv -\frac{\langle e\rangle}{\tau} \equiv -\omega_0\frac{\langle e\rangle}{Q}} \quad . \tag{25.04.11}$$

→ 1420

La frequenza di oscillazione nel caso debolmente smorzato (25.04.03) si può scrivere in termini del Q come (equazione (25.04.05)):

$$\boxed{\omega_1 = \sqrt{\omega_0^2 - \beta^2} = \omega_0\sqrt{1 - \frac{1}{4Q^2}} \leq \omega_0 \qquad \text{per } Q > \frac{1}{2}} \quad . \tag{25.04.12}$$

Il coefficiente α nel moto ultra-smorzato (25.04) si può scirvere in termini del Q come (equazione (25.04.06)):

$$\boxed{\alpha = \sqrt{\beta^2 - \omega_0^2} = \omega_0\sqrt{\frac{1}{4Q^2} - 1} \leq \beta \qquad \text{per } Q < \frac{1}{2}} \quad . \tag{25.04.13}$$

25.05 Forced Damped Harmonic Oscillator

This § is referenced at pages:
[1420]

All is already known from Calculus: just re-phrase in physical terms

We will consider a generic system described by the oscillating variable ξ. All the arguments can be applied to any system described by a second-order linear differential equation with constant coefficients when the equation after the appropriate equation has been written.

Si può supporre che la forza esterna vari sinusoidalmente con il tempo. Poiché il sistema è lineare, infatti, la risposta del sistema ad una generica forza esterna (periodica o non periodica) può essere ottenuta sovrapponendo le risposte alle singole componenti armoniche (principio di sovrapposizione delle sorgenti, read § 19.01). In generale:

$$F[t] = \sum_k G_k \cos\left[\omega_k t + \phi_k\right] \qquad F[t] = \int G[\omega] \cos\left[\omega t + \phi[\omega]\right] \, \mathrm{d}\omega \quad ,$$

dove la somma è una **Fourier Series** , nel caso di $F[t]$ periodica, mentre è un integrale di Fourier, nel caso di $F[t]$ non periodica.

25.05.01
General Solution

Let us consider the problem:

$$\ddot{\xi} + 2\beta\dot{\xi} + \omega_0^2\xi \equiv \ddot{\xi} + \Gamma\dot{\xi} + \omega_0^2\xi = G_0[\omega]\cos\left[\omega t + \phi_0\right] \qquad G_0[\omega] > 0 \quad . \tag{25.05.01}$$

→ 1411 1412

Common cases include:

$$G[\omega] = G_0 \quad ,$$
$$G[\omega] = G_0\omega^2 \quad .$$

Senza perdere di generalità si può considerare il problema di una forzante cosinusoidale di frequenza assegnata ω e fase nulla ($\phi_0 = 0$):

$$\ddot{\xi} + 2\beta\dot{\xi} + \omega_0^2\xi \equiv \ddot{\xi} + \Gamma\dot{\xi} + \omega_0^2\xi = G_0[\omega]\cos\left[\omega t\right] \qquad G_0[\omega] > 0 \quad , \tag{25.05.02}$$

→ 1421

where, in general, the amplitude of the external force might depend on its angular frequency: $G_0 = G_0[\omega]$.

Infatti, nel caso di forzante Sinusoidal | Cosinusoidal quando sia nota la soluzione del problema (25.05.01), $\xi[t]$, è sempre possibile ricavare la soluzione al problema in cui la forzante sia $G_0[\omega]\cos\left[\omega t + \phi_0\right]$ come $\xi[t + \phi_0/\omega]$. Ciò, infatti, equivale ad effettuare un cambio di variabile sui tempi: $t \longrightarrow t' = t + \phi_0/\omega$:

$$G_0[\omega]\cos\left[\omega t\right] \to G_0[\omega]\cos\left[\omega t + \phi_0\right] \quad ,$$
$$\xi[t] \to \xi[t'] \equiv \xi[t + \phi_0/\omega] \quad .$$

Ovviamente quando si sovrappongono forzanti diverse non è più possibile ignorare le fasi relative perchè non è più possibile, in generale, scegliere un tempo che annulla tutte le fasi contemporaneamente. A simple way to re-introduce in the formulas the phase ϕ_0 whenever necessary will be presented in section § 25.05.02:

$$\phi_0 = 0 \longleftrightarrow \delta \qquad \phi_0 \longleftrightarrow \delta + \phi_0$$

La soluzione generale è la somma della soluzione generale dell'equazione omogenea (25.04.01), ξ_{G}, più una soluzione particolare dell'equazione completa (25.05.01), ξ_{P}:

$$\xi[t] = \xi_{\mathrm{G}}[t] + \xi_{\mathrm{P}}[t] \quad .$$

DRAFT-IN-PROGRESS

CC BY NC ND

25.05.01.01 Steady Solution for the Position

The part of $\xi[t]$ surviving at very large times, when the exponential terms in the solution of the homogeneous equation have faded away, is called the steady solution.

Si ha:

$$\xi_{\mathrm{S}} = \frac{G_0[\omega]}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\cos\left[\omega t-\delta[\omega]\right] \quad , \tag{25.05.03}$$

→ 1416 1417

$$\cos\left[\delta[\omega]\right] = \frac{\omega_0^2-\omega^2}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}} \Longrightarrow \begin{cases} 0 \le \delta[\omega] < \pi/2 & \text{for } \omega < \omega_0 \\ \pi/2 < \delta[\omega] \le \pi & \text{for } \omega > \omega_0 \end{cases} \quad , \tag{25.05.04}$$

→ 1416

$$\sin\left[\delta[\omega]\right] = \frac{\Gamma\omega}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}} \geq 0 \Longrightarrow 0 \le \delta[\omega] \le \pi \quad . \tag{25.05.05}$$

→ 1416

The amplitude of the response is thus:

$$\max\left[|\xi_{\mathrm{P}}|\right] = \frac{G_0[\omega]}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}} \quad .$$

As $\sin\left[\delta[\omega]\right] \geq 0$ while $\cos\left[\delta[\omega]\right]$ can have both signs sign the solution can be written in terms of the $\arctan$, provided the solution is always chosen such that $0 \le \delta[\omega] \le \pi$:

$$\delta[\omega] = \arctan\left(\frac{\Gamma\omega}{\omega_0^2-\omega^2}\right) \qquad \text{the solution such that } 0 \le \delta[\omega] \le \pi \quad ,$$

and the only ambiguity from the formula, between $\delta = 0$ and $\delta = \pi$, might arise when the argument of the arc-tangent, $\Gamma\omega/\left(\omega_0^2-\omega^2\right)$, is zero.

Even better:

$$\delta[\omega] = \arccos\left(\frac{\omega_0^2-\omega^2}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\right) \quad .$$

Note that in the case $\phi_0 \neq 0$ the phase-angle $\delta[\omega]$ must be interpreted as the phase-angle with respect to the phase of the forcing term, ϕ_0.

La soluzione generale dell'equazione omogenea è una soluzione transiente in quanto in ogni caso è presente un esponenziale negativo che fa tendere la soluzione a zero per $t \longrightarrow \infty$, come mostrato dalle equazioni (25.04.03), (25.04.04), (25.04).

La soluzione stazionaria rappresenta il termine permanente per tempi grandi e per questo è solitamente detta soluzione stazionaria, ξ_{S}. La soluzione stazionaria si determina sottraendo da una soluzione particolare la eventuale parte che risolve l'omogenea. Infatti la derivata prima e seconda rispetto al tempo della soluzione generale, a causa della presenza dell'esponenziale decrescente, tendono a zero per $t \longrightarrow \infty$. è quindi chiaro dalla equazione (25.05.01) che, almeno nel caso di forzante Sinusoidal | Cosinusoidal , l'andamento per tempi grandi della soluzione deve avere la stessa dipendenza temporale della forzante estern e quindi oscillare con ampiezza costante.

25.05.01.02 Steady Solution for the Velocity

The steady-state solution for $\dot{\xi}$ is:

$$\dot{\xi}_{\mathrm{S}}[t] = \frac{-G_0[\omega]\omega}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\sin\left[\omega t-\delta[\omega]\right] = \frac{G_0[\omega]\omega}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\cos\left[\omega t-\delta[\omega]+\pi/2\right] \quad . \quad (25.05.06)$$

→ 1418

The velocity is out-of-phase by $\pi/2$, with respect to the position.

25.05.01.03 Steady Solution for the Acceleration

The steady-state solution for $\ddot{\xi}$ is:

$$\ddot{\xi}_{\mathrm{S}}[t] = \frac{-G_0[\omega]\omega^2}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\cos\left[\omega t-\delta[\omega]\right] = \frac{G_0[\omega]\omega^2}{\sqrt{\left(\omega^2-\omega_0^2\right)^2+\Gamma^2\omega^2}}\cos\left[\omega t-\delta[\omega]+\pi\right] \quad . \quad (25.05.07)$$

The acceleration is out-of-phase by π, with respect to the position.

25.05.01.04 Limiting Cases for the Response in Terms of the Position

- If $0 \leq \omega \ll \omega_0$:

$$\mathcal{H}[\omega] \simeq \frac{G_0[\omega]}{\omega_0^2} \qquad \delta[\omega] \simeq 0 \qquad \xi_{\mathrm{P}} \sim +\frac{G_0[\omega]}{\omega_0^2}\cos\left[\omega t\right] \quad . \quad (25.05.08)$$

→ 1419

  The response is in-phase with the forcing.
- If $\omega \approx \omega_0$ (it is equivalent to $\omega \approx \omega_{\mathrm{R}}$ if and only if the oscillations are weakly damped):

$$\mathcal{H}[\omega] \simeq \frac{G_0[\omega]}{\Gamma\omega_0} \qquad \delta[\omega] \simeq \frac{\pi}{2} \qquad \xi_{\mathrm{P}} \sim \frac{G_0[\omega]}{\Gamma\omega_0}\sin\left[\omega t\right] \quad . \quad (25.05.09)$$

→ 1419

  The response is in-quadrature with the forcing.
- If $\omega \gg \omega_0$:

$$\mathcal{H}[\omega] \simeq \frac{G_0[\omega]}{\omega^2} \qquad \delta[\omega] \simeq \pi \qquad \xi_{\mathrm{P}} \sim -\frac{G_0[\omega]}{\omega^2}\cos\left[\omega t\right] \quad . \quad (25.05.10)$$

→ 1419

  The response is out-of-phase by π rad with respect to the forcing.

25.05.01.05 Limiting Cases for the Response in Terms of the Velocity

25.05.01.06 Limiting Cases for the Response in Terms of the Acceleration

25.05.01.07 Graphs

Consider the common case when there is no dependence on the frequency in $G_0[\omega] = G_0$.

The amplitude and the phase of the response in position as a function of the frequency of the forcing are shown in figures 25.11, 25.12.

The amplitude and the phase of the response in velocity as a function of the frequency of the forcing are shown in figures 25.13, 25.14.

All the plots refer to a fixed ω_0 and different values of Γ, from $\omega_0/\Gamma = 0.1$ (strong damping) to $\omega_0/\Gamma = 10$ (weak damping).

25.05.02.01 Absorptive and Elastic Amplitudes for Zero Phase of the External Forcing

An alternative equivalent way to write the steady-state solution of equation (25.05.03) is based on the so-called **absorptive** and **elastic** (sometimes called **dispersive**) amplitudes:

$$\boxed{\xi_{\mathrm{S}}[t] = \mathcal{A}_{\mathrm{A}} \sin[\omega t] + \mathcal{A}_{\mathrm{E}} \cos[\omega t] \qquad \text{for } \phi_0 = 0} \quad , \quad ,$$

$$\boxed{\mathcal{A}_{\mathrm{E}} = G_0[\omega] \left(\frac{\omega_0^2 - \omega^2}{\left(\omega_0^2 - \omega^2\right)^2 + \Gamma^2 \omega^2} \right)} \quad , \quad ,$$

$$\boxed{\mathcal{A}_{\mathrm{A}} = G_0[\omega] \left(\frac{\Gamma \omega}{\left(\omega_0^2 - \omega^2\right)^2 + \Gamma^2 \omega^2} \right)} \quad , \quad ,$$

$$\mathcal{A}_{\mathrm{E}}^2 + \mathcal{A}_{\mathrm{A}}^2 = G_0^2[\omega] \left(\frac{1}{\left(\omega_0^2 - \omega^2\right)^2 + \Gamma^2 \omega^2} \right) \quad .$$

Note that the elastic and absorptive amplitudes are actually strictly related to the expressions (25.05.04), (25.05.05) for the sinus and cosinus of the phase-lag, as it is obvious from trigonometry.

The steady-state solution for $\dot{\xi}$ in terms of absorptive and elastic amplitudes is:

$$\boxed{\dot{\xi}[t] = \omega \mathcal{A}_{\mathrm{A}} \cos[\omega t] - \omega \mathcal{A}_{\mathrm{E}} \sin[\omega t]} \quad . \tag{25.05.11}$$

The names come from the fact that the time-averaged power given by the external force to the systems (and dissipated by the system in steady conditions) comes exclusively from the absorptive term $\mathcal{A}_{\mathrm{A}} \sin[\omega t]$. The term $\mathcal{A}_{\mathrm{E}} \cos[\omega t]$, on the other hand, only contributes to the instantaneous power, which, however, averages to zero over one full cycle of a steady-state oscillation. Note also that at the frequency $\omega = \omega_0$ the elastic part is zero showing that absorption is dominating.

In fact the instantaneous power is given by the external force times the velocity:

$$P[t] = m G_0[\omega] \cos[\omega t] \, \dot{\xi}[t] \quad ,$$

where a mechanical system of mass m has been assumed.

The instantaneous velocity has one component in phase and one component which is $\pi/2$ rad out of phase with respect to the external force. Only the velocity component in phase with the external force contributes to the time-averaged power. The in-phase component of the velocity is obviously produced by the out-of-phase component of the displacement.

25.05.02.02 Absorptive and Elastic Amplitudes for Arbitrary Phase of the External Forcing

The concepts of elastic and absorptive amplitudes allows to reintroduce the phase ϕ_0 of the external forcing very easily as:

$$\boxed{\xi_{\mathrm{S}}[t] = \mathcal{A}_{\mathrm{A}} \sin[\omega t + \phi_0] + \mathcal{A}_{\mathrm{E}} \cos[\omega t + \phi_0]} \quad .$$

DRAFT IN PROGRESS

25.05.03
Power and Energy

The time-averaged steady-state power is then:

$$\langle P\rangle = \frac{1}{2} m G_0[\omega]\omega \mathcal{A}_{\mathtt{A}} = \frac{1}{2}\left(\frac{m G_0^2[\omega]\Gamma\omega^2}{\left(\omega_0^2-\omega^2\right)^2+\Gamma^2\omega^2}\right) \quad , \tag{25.05.12}$$

→ 1417

from which the name absorptive amplitude follows.

As a cross-check one can calculate the time-averaged power dissipated into friction to find that it is identical to the above expression for P (equation (25.05.12)):

$$\langle P_{\mathtt{F}}\rangle = m\Gamma\langle \dot{\xi}_{\mathtt{S}}{}^2\rangle = \frac{1}{2} m\Gamma\omega^2\left(\mathcal{A}_{\mathtt{A}}^2+\mathcal{A}_{\mathtt{E}}^2\right) = \frac{1}{2}\left(\frac{m G_0^2[\omega]\Gamma\omega^2}{\left(\omega_0^2-\omega^2\right)^2+\Gamma^2\omega^2}\right) \quad . \tag{25.05.13}$$

In steady-state oscillation the time-averaged stored mechanical energy is given by:

$$\langle e\rangle = \langle k\rangle + \langle u\rangle = \frac{m}{2}\langle \dot{\xi}_{\mathtt{S}}{}^2\rangle + \frac{m\omega_0^2}{2}\langle \xi_{\mathtt{S}}{}^2\rangle = \frac{m}{4}\left(\omega^2+\omega_0^2\right)\left(\mathcal{A}_{\mathtt{A}}^2+\mathcal{A}_{\mathtt{E}}^2\right) = \frac{1}{4} m G_0^2[\omega]\left(\omega^2+\omega_0^2\right)\left(\frac{1}{\left(\omega_0^2-\omega^2\right)^2+\Gamma^2\omega^2}\right) \quad ,$$

in terms of the time-averaged kinetic and potential energies. The two terms, kinetic and potential energies, are equal if and only if $\omega = \omega_0$. This should be compared to the free damped harmonic oscillator, where the two terms are equal.

25.05.04
External Forcing Independent From the Frequency

This § is referenced at pages:
[Never referenced.]

Let us consider the common case when

$$G_0[\omega] = G_0 \quad ,$$

that is the amplitude of the external forcing is independent of the frequency.

Read § 25.05.05 for the case $G_0[\omega] = G_0\omega^2$.

25.05.04.01 Resonance Curves for the Position

Amplitude

La frequenza di risonanza è quella frequenza della forza esterna in corrispondenza della quale la risposta forzata del sistema ha l'ampiezza massima. Dalla (25.05.03) si ricava la frequenza di risonanza

$$\omega_{\mathtt{R}} = \sqrt{\omega_0^2-2\beta^2} = \sqrt{\omega_0^2-\frac{\Gamma^2}{2}} \qquad \text{for either } \omega_0^2-2\beta^2>0 \text{ or } \omega_0^2-\frac{\Gamma^2}{2}>0 \quad .$$

Se lo smorzamento β è così grande che la condizione non è soddisfatta l'ampiezza massima si ha per $\omega \longrightarrow 0$ con la forza esterna che tende a diventare costante così come la posizione $\xi[t]$. Il valore della ampiezza in condizione di risonanza vale ($\omega = \omega_{\mathtt{R}}$)

$$\xi[\omega=\omega_{\mathtt{R}}] \equiv \xi_{\mathtt{M}} = \frac{G_0}{2\beta\sqrt{\omega_0^2-\beta^2}} = \frac{2G_0}{\Gamma\sqrt{4\omega_0^2-\Gamma^2}} \quad .$$

L'ampiezza della risonanza nel caso di piccolo smorzamento vale

$$\xi[\omega=\omega_{\mathtt{R}}] \equiv \xi_{\mathtt{M}} = \frac{G_0}{2\omega_0\beta} = \frac{G_0}{\omega_0\Gamma} \quad .$$

PRELIMINARY PROGRESS

CC BY NC ND

Phase

The phase of the response is always $\pi/2$ rad at ω_0: $\delta[\omega = \omega_0] = \pi/2$

25.05.04.02 Resonance Curves for the Velocity

Amplitude

When one considers the response of the system in terms of the velocity, $\dot{\xi}$, instead of the coordinate, ξ, the response curve is different, as it is clearly shown by the fact that in equation (25.05.06) there is one more factor ω in the numerator.

This is particularly important in ElectroMagnetic oscillating circuits, for in that case one is often interested in the response in terms of the current, not charge.

Therefore, for instance, the maximum of the response of the system in terms of velocity is at the exact frequency ω_0 while the phase-angle is still $\pi/2$ rad at the exact frequency ω_0:

$$\dot{\xi}[\omega = \omega_0] = \frac{G_0}{\Gamma} \quad \text{value of the maximum} \quad , \quad \delta[\omega = \omega_0] = \pi/2 \quad .$$

Note, however, that the presence of the $-\sin[\ldots]$ function gives an additional phase of $+\pi/2$ of the velocity with respect to the external forcing, as shown from equation (25.05.06): the velocity is in advance of phase by $+\pi/2$ with respect to the coordinate and has a phase $-\delta[\omega] + \pi/2$ with respect to the external forcing.

The frequencies corresponding to $1/\sqrt{2}$ with respect to the maximum, ω_1 and ω_2, satisfy the following relations

$$\Delta\omega \equiv \omega_2 - \omega_1 = \Gamma \qquad \omega_1\omega_2 = \omega_0^2 \qquad \frac{\omega_1 + \omega_2}{2} = \sqrt{\omega_0^2 + \frac{\Gamma^2}{4}} \quad ,$$

$$\tan[\delta[\omega_1]] = +\pi/4 \qquad \tan[\delta[\omega_2]] = +3\pi/4 \quad .$$

Phase

25.05.05 External Forcing Proportional to the Square of the Frequency

This § is referenced at pages:
[1417]

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|11.1.4, 11.4.1||

A common case is when $G_0[\omega] \propto \omega^2$. In this case, amplitude and phase for the position response are shown in figures 25.13, 25.14.

The equation of motion of a mass point relative to a non-Inertial Reference Frame , $\mathcal{I}'$, moving in a straight line with time dependence $Z[t]$,

$$z \equiv Z + z' \quad ,$$

with $\bar{z}$ the displacement with respect to the relative equilibrium position,

$$\bar{z} \equiv z' - z'_0 \quad ,$$

gives:

$$\ddot{\bar{z}} + \Gamma\dot{\bar{z}} + \omega_0^2\bar{z} = -\ddot{Z} \quad .$$

Note that both the restoring force and the viscous force are in the relative coordinate system, as for a damped spring inside a box:

$$f_{\text{R}} = -m\omega^2\left(z' - z'_0\right) \equiv -m\omega^2\bar{z} \quad ,$$

$$f_{\text{V}} = -2m\beta\dot{z}' \equiv -2m\beta\dot{\bar{z}}$$

Preliminary Progress

Assume $Z[t] = Z_0 \cos[\omega t]$:

$$\ddot{\bar{z}} + \Gamma\dot{\bar{z}} + \omega_0^2 = +Z_0\omega^2 \cos[\omega t] \quad .$$

One would like a fast damping of the transient part of the solution, therefore choosing $\beta = \omega_0$. One then finds:

$$\mathcal{H}[\omega] = Z_0 \frac{\omega^2}{\omega^2 + \omega_0^2} \quad .$$

The expression

$$\frac{\bar{z}_{\text{MAX}}}{Z_0} = \frac{\omega^2}{\omega^2 + \omega_0^2} \quad ,$$

is thus the amplification of the instrument, that is the ratio between the amplitude of the oscillations of the mass, relative to $\mathcal{I}'$, with respect to the amplitude of the oscillations of the **box**.

25.05.05.01 Seismograph

Choose $\omega_0 \ll \omega$: then $\mathcal{H}[\omega] \simeq Z_0$.

The system responds to all frequencies with the same amplitude: faithful representation of different frequencies.

See equations (25.05.08), (25.05.09), (25.05.10).

25.05.05.02 Accelerometer Shock-Absorber and Insulation From Vibrations

Choose $\omega \ll \omega_0$: then $\mathcal{H}[\omega] \simeq Z_0\omega^2/\omega_0^2$

See equations (25.05.08), (25.05.09), (25.05.10).

- The system response is proportional to the acceleration of the non-inertial Reference Frame. It is then measuring the acceleration.
- The system has a vanishingly small response, that is its response damps the oscillations of the non-Inertial Reference Frame : it is a shock-absorber.
- Anther example include mechanical insulation from vibrations: when one assembly is attached to another assembly which can vibrate, transmitting the vibrations to the assembly, one should make sure that the amplification is small in the involved frequency range. One possibility is to make sure that the lowest frequency of the assembly, like ω_0, is much larger than the maximum frequency of the external excitation, thus working in a regime similar to the one of the shock-absorber, so that the system has a vanishingly small response.

25.05.06 Q-Factor in the Forced Case

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|1.24.1|*On the definition of ...*

The Q-factor was defined in equation (25.04.10) and discussed section § 25.04.04 for a free damped motion.

One must generalize the definition to the forced case. It should be noted that in the literature two different definitions might encountered, which are presented below.

It is worth remembering that the small damping condition reads:

$$Q \gg 1 \quad \Leftrightarrow \quad \Gamma \ll \omega_0 \quad \text{small-damping condition} \quad .$$

In the weak-damping case of a system near resonance the two definitions given below are basically the same. As the Q-factor is mostly useful when it is large, that is the system is weakly-damped, all the definitions are basically the same on practical grounds.

DRAFT-IN-PROGRESS

CC BY NC ND

25.05.06.01 Energetic-Based Definition

Equation (25.04.11) can be used to generalize the definition to the forced case as follows:

$$Q^{-1} \equiv -\frac{1}{\omega\langle e\rangle}\frac{\mathrm{d}\langle e\rangle}{\mathrm{d}t} \simeq -\frac{\Delta e}{e}\frac{1}{\omega T} = -\frac{1}{2\pi}\frac{\Delta e}{e} \qquad \text{for } Q > \frac{1}{2} \quad ,$$

in terms of Δe, the mechanical energy dissipated in one period of the external forcing entity, which equals the period of the oscillations.

This definition is expressed in terms of the external forcing frequency, because the steady-state solution will pulsate at the external oscillation frequency (read § 25.05). It measures the entity of the damping or, equivalently, the amount of energy required to keep the oscillations going on.

In the weak damping case it can be shown that

$$Q \simeq \frac{\omega_0}{\Delta\omega} \quad ,$$

where $\Delta\omega$ represents the width of the resonance curve at $1/\sqrt{2}$ height with respect to the maximum.

This definition, therefore, can be also written in the equivalent form

$$Q \equiv 2\pi\left(\frac{\text{Total Energy}}{\text{Energy dissipated in one oscillation}}\right) = \frac{\omega^2+\omega_0^2}{2\Gamma\omega} \quad .$$

This definition, therefore, emphasizes the energy balance of the system. When remaining near the proper frequency of the system, ω_0, one has:

$$Q = \frac{\omega^2+\omega_0^2}{2\Gamma\omega} \simeq \frac{\omega_0}{\Gamma} \qquad \text{for } \omega \simeq \omega_0 \quad .$$

25.05.06.02 Amplitude-Based Definition

In this case the same identical definition as for the free case, as discussed in section § 25.04.04, is used, equation (25.04.10):

$$Q \equiv \frac{\omega_0}{2\beta} \equiv \frac{\omega_0}{\Gamma} \quad . \tag{25.05.14}$$

This definition, therefore, emphasizes the amplitude response of the system, without considering the frequency of the actual forcing, that is the real period of the oscillations.

25.06 Complex Formalism

This § is referenced at pages:
[2018, 2067]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|1.22|*Excellent discussion*|
©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|§ 7 - MATHEMATICAL NOTES|*Excellent ...*

The calculations about linear second-order forced systems are often made easier by using complex numbers. Complex numbers have no real significance, but are just used as a tool for calculations. In fact we are dealing with sinusoids at fixed frequency characterized by an amplitude and a phase. A single complex number can keep both information, thus simplifying the formalism.

As all terms of the linear second-order forced system are real, if ξ_1 and ξ_2 are solutions of the homogeneous equation then also $\xi_1 \pm \mathtt{i}\xi_2$ are solutions of the homogeneous equation. Therefore it is possible to look for complex solutions of the homogeneous equation: two complex conjugate solutions will be found, from which two real solutions can be extracted by taking, for instance, the real and imaginary part.

Moreover, if one takes the forcing term to be complex and one finds a particular complex solution of the equation then the full complex equation can be separated into its two real and imaginary parts, both of them correct equations in terms of real numbers with a real forcing term. Therefore one can look for complex solutions with a complex forcing term, solve the equation and then take the real parts of both the solutions and the forcing term, to recover the physical quantities.

The previous two points are the basis for the complex formalism.

The convention will be assumed that the real physical entity is described by the real part of the complex number.

Consider a complex particular solution of the form:

$$\overline{\xi}[t] = \overline{\xi}0_{\exp}\left[\pm\mathtt{i}\omega t\right] \qquad \left(\longrightarrow \overline{\xi}0_{\exp}\left[-\mathtt{i}\omega t\right]\right) \quad .$$

The convention for the sign of the exponent varies in the literature. We will use the **minus sign** convention, because that is consistent with the standard choice in Quantum Physics:

$$\overline{\xi}[t] = \overline{\xi}_0 \exp\left[-\mathtt{i}\omega t\right] \qquad \Leftrightarrow \qquad , \qquad \rightarrow 1421$$

$$\boxed{\mathfrak{Re}\left[\overline{\xi}_0 \exp\left[-\mathtt{i}\omega t\right]\right] = \mathfrak{Re}\left[\overline{\xi}_0\right]\mathfrak{Re}\left[\exp\left[-\mathtt{i}\omega t\right]\right] - \mathfrak{Im}\left[\overline{\xi}_0\right]\mathfrak{Im}\left[\exp\left[-\mathtt{i}\omega t\right]\right] = \mathfrak{Re}\left[\overline{\xi}_0\right]\cos\left[\omega t\right] + \mathfrak{Im}\left[\overline{\xi}_0\right]\sin\left[\omega t\right]} \quad .$$

Let us use the trial solution (25.06) in equation (25.05.02) after making the forcing term a complex function:

$$G_0[\omega]\cos\left[\omega t + \phi_0\right] = G_0[\omega]\cos\left[-\omega t - \phi_0\right] \longrightarrow \boxed{G_0[\omega]\exp\left[-\mathtt{i}\left(\omega t + \phi_0\right)\right] \equiv \overline{G}_0[\omega]\exp\left[-\mathtt{i}\omega t\right]} \quad ,$$

$$\overline{G}_0[\omega] : \qquad \begin{cases} \text{module} : G_0[\omega] \quad , \\ \text{phase} : -\phi_0 \end{cases} \qquad ,$$

$$\boxed{\overline{\xi}_0 = \frac{\overline{G}_0[\omega]}{-\omega^2 - \mathtt{i}\Gamma\omega + \omega_0^2} \qquad \overline{\xi}[t] = \overline{\xi}_0 \exp\left[-\mathtt{i}\omega t\right]} \quad .$$

A common time dependence factor, $\exp\left[-\mathtt{i}\omega t\right]$, appears in all the terms as the derivative of an exponential is still an exponential. Therefore the use of complex numbers allows to factorize the time dependence leaving an algebraic expression only.

Moreover, it is clear that the complex formalism allows to account easily for a phase in the external forcing, ϕ_0.

WORK IN PROGRESS

25.07 Multi-Degrees of Freedom Free Undamped Coupled Harmonic Oscillators

©|H.C. Corben and P. Stehle|Classical Mechanics|*§ 45*|

Consider a conservative system with n degrees of freedom and any equilibrium configuration. As the gradient of the potential energy is zero, the potential energy can be developed in a Taylor series around the equilibrium configuration. The equation of motion then become a system of second-order linear differential equations with real and constant coefficients.

Normal modes of any oscillating system is a motion such that all degrees of freedom move sinusoidally with the same frequency and the same phase. The normal modes take place at the fixed frequencies.

It can be shown that any system with n degrees of freedom has n normal modes, that is n possible proper frequencies. The general small motion around an equilibrium configuration is a linear combination of the normal modes.

25.07.01
Normal Modes of Two Coupled Identical Oscillators

Consider two identical masses, of mass m connected by three springs, one with elastic constant K, the middle one which provides the coupling between the two identical oscillators, the other two with elastic constant k. The masses and springs form a linear chain whose extremes are kept fixed. See figure 25.15. Assume that the length at rest of the springs is equal to zero and that friction is negligible.

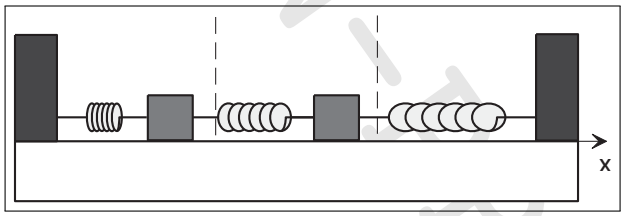

Figure 25.15: Two masses and three springs linear chain

Let $\overline{x}_1$ and $\overline{x}_2$ the position of the two masses, let $\overline{x}_0$ the position of the left-most extreme of the chain and let $\overline{x}_0 + L$ the position of the right-most extreme of the chain.

Equations:

$$m\ddot{\overline{x}}_1 = -k\left(\overline{x}_1 - \overline{x}_0\right) + K\left(\overline{x}_2 - \overline{x}_1\right) = -\overline{x}_1\left(k + K\right) + K\overline{x}_2 + k\overline{x}_0 \quad ,$$
$$m\ddot{\overline{x}}_2 = -K\left(\overline{x}_2 - \overline{x}_1\right) + k\left(\overline{x}_0 + L - \overline{x}_2\right) = +K\overline{x}_1 - \overline{x}_2\left(k + K\right) + k\left(\overline{x}_0 + L\right) \quad .$$

The middle spring, of constant K, couples two otherwise decoupled oscillators.

Transform to new variables describing the displacement with respect to the equilibrium position:

$$x_1^\star = \overline{x}_0 + \frac{KL}{k + 2K} \qquad \left(x_1^\star = \overline{x}_0 + \frac{1}{3}L \qquad \text{for } k = K\right) \quad ,$$
$$x_2^\star = \overline{x}_0 + \frac{(k + K)\,L}{k + 2K} \qquad \left(x_2^\star = \overline{x}_0 + \frac{2}{3}L \qquad \text{for } k = K\right) \quad ,$$

$$\overline{x}_1 \longrightarrow x_1 \equiv \overline{x}_1 - x_1^\star \qquad \overline{x}_2 \longrightarrow x_2 \equiv \overline{x}_2 - x_2^\star \quad .$$

In case the rest length of the spring is not zero there would be additional constant terms in the equations which would cancel in the final equations, after changing variables to the displacement with respect to the equilibrium position. Read also § 25.07.04.

The special motions of a system with many degrees of freedom when all degrees of freedom oscillate by harmonic motion with the same frequency and same phase (but possibly different amplitudes) are called normal modes.

DRAFT - IN PROGRESS

Let try to guess the normal modes: we look for solutions such that both x_1 and x_2 oscillate with the same frequency and phase, but allowing for different amplitudes:

$$x_1[t] = x_{1|0} \cos[\omega t + \phi] \quad ,$$
$$x_2[t] = x_{2|0} \cos[\omega t + \phi] \quad .$$

By substitution one can find the ratio of the amplitudes from both equations and equate them:

$$\frac{x_{1|0}}{x_{2|0}} = \frac{K}{k + K - m\omega^2} = \frac{k + K - m\omega^2}{K} \quad .$$

The characteristic equation then gives the two proper frequencies:

$$\left(k - m\omega^2\right)\left(k + 2K - m\omega^2\right) = 0 \qquad \Longrightarrow \left\{\omega_1^2 = \frac{k}{m} \qquad \omega_2^2 = \frac{k + 2K}{m}\right\} \quad .$$

It follows:

$$\omega_1^2 = \frac{k}{m} \Longrightarrow x_{1|0} = +x_{2|0} \quad ,$$
$$\omega_2^2 = \frac{k + 2K}{m} \Longrightarrow x_{1|0} = -x_{2|0} \quad .$$

The middle spring couples two otherwise decoupled oscillators and, as a consequence of that, the overall system has tow frequencies which, in general, are different from the original frequencies of the un-coupled system.

The first normal mode is such that the middle spring does not change its length. Therefore, in this mode, even if the middle spring is extended it applies just a constant force which does not change the proper frequency. Therefore the first proper frequency of the system is the same as the proper frequency of the single oscillators.

On the other hand the second normal mode is such that the middle spring changes its length, and changes the oscillation frequency.

The general solution is a superposition of the two modes:

$$x_1[t] = C_1 \cos[\omega_1 t + \phi_1] + C_2 \cos[\omega_2 t + \phi_2] \quad ,$$
$$x_2[t] = C_1 \cos[\omega_1 t + \phi_1] - C_2 \cos[\omega_2 t + \phi_2] \quad ,$$

where the constants of integration are the four constants: $\{C_1, C_2\}$ and $\{\phi_1, \phi_2\}$.

25.07.02
Normal Modes of Two Coupled Oscillators With the Same Mass

Generalize the previous system to arbitrary spring constants: k_1 and k_3 for the two oscillators, and k_2 as a coupling. Let the masses still be identical: $m_1 = m_2 = m$.

The proper frequencies turn out to be:

$$\Omega = \begin{pmatrix} \dfrac{-k_1 - k_2}{m} & \dfrac{k_2}{m} \\ \dfrac{k_2}{m} & \dfrac{-k_2 - k_3}{m} \end{pmatrix} \quad ,$$
$$\omega_1^2 = \frac{k_1 + 2k_2 + k_3 - \sqrt{4k_2^2 + (k_1 - k_3)^2}}{2m} \quad ,$$
$$\omega_2^2 = \frac{k_1 + 2k_2 + k_3 + \sqrt{4k_2^2 + (k_1 - k_3)^2}}{2m}$$

The general relation provides limiting cases for other simpler systems:

- No coupling: $k_2 \to 0$ implies $\omega^2 = \left\{\dfrac{k_1}{m}, \dfrac{k_3}{m}\right\}$;

DRAFT IN PROGRESS

- No spring at the left/right walls:

$$k_1 \to 0 \qquad \omega_L^2 = \left\{ \frac{2k_2 + k_3 + \sqrt{4k_2^2 + k_3^2}}{2m}, \frac{2k_2 + k_3 - \sqrt{4k_2^2 + k_3^2}}{2m} \right\} \quad ,$$

$$k_3 \to 0 \qquad \omega_R^2 = \left\{ \frac{k_1 + 2k_2 + \sqrt{k_1^2 + 4k_2^2}}{2m}, \frac{k_1 + 2k_2 - \sqrt{k_1^2 + 4k_2^2}}{2m} \right\}$$

- No walls: $k_1 \to 0$ and $k_3 \to 0$ implies $\omega^2 = \left\{ \frac{2k_2}{m}, 0 \right\}$;
- Rigidly fixed mass (1): $k_1 \to \infty$ implies $\omega^2 = \left\{ \frac{\infty}{m}, \frac{k_2 + k_3}{m} \right\}$;
- Rigidly fixed mass (2): $k_3 \to \infty$ implies $\omega^2 = \left\{ \frac{\infty}{m}, \frac{k_2 + k_1}{m} \right\}$.

25.07.03
Normal Modes of Two Coupled Different Oscillators

$$\Omega = \begin{pmatrix} \frac{-k_1 - k_2}{m_1} & \frac{k_2}{m_1} \\ \frac{k_2}{m_2} & \frac{-k_2 - k_3}{m_2} \end{pmatrix} \quad ,$$

$$\omega_1^2 = \frac{k_3 m_1 + k_1 m_2 + k_2 (m_1 + m_2) + \sqrt{((k_2 + k_3) m_1 + (k_1 + k_2) m_2)^2 - 4 (k_2 k_3 + k_1 (k_2 + k_3)) m_1 m_2}}{2 m_1 m_2} \quad ,$$

$$\omega_2^2 = \frac{k_3 m_1 + k_1 m_2 + k_2 (m_1 + m_2) - \sqrt{((k_2 + k_3) m_1 + (k_1 + k_2) m_2)^2 - 4 (k_2 k_3 + k_1 (k_2 + k_3)) m_1 m_2}}{2 m_1 m_2}$$

A linear mass-spring chain can be used as a very simplified model for a one-dimensional chain of atoms inside a solid. It is in fact a linear mass-spring chain of N coupled identical oscillators.

Consider a straight linear chain of N identical masses m forming a chain with $N + 1$ identical springs of elastic constant k and the rest length d. The two extremes are kept in a fixed position at a distance $L \equiv (N + 1)\, a$, where a is the distance between the masses at rest. The only external forces acting on the system (masses plus springs) is the constraint at the two extremes of the chain. Denote the absolute position of the i-mass as x_i and the position relative to equilibrium as ψ_i. The two fixed extreme points can be considered as a fictitious (0)-mass and (N+1)-mass, at positions, respectively, x_0 and $x_{N+1} = x_0 + L$. Then:

$$x_i = \psi_i + ia + x_0 \quad .$$

DRAFT - LIMITED PREVIEW

The force on the i-mass is:

$$\begin{aligned} m\ddot{x}_i &= -k\left((x_i - x_{i-1}) - d\right) + k\left((x_{i+1} - x_i) - d\right) \quad , \\ &= -k\left((\psi_i - \psi_{i-1}) + (a-d)\right) + k\left((\psi_{i+1} - \psi_i) + (a-d)\right) \quad , \\ &= k\left(\psi_{i+1} + \psi_{i-1} - 2\psi_i\right) \qquad \text{for } i = 1, \ldots N \quad . \end{aligned}$$

The latter equation shows that in terms of the displacements, ψ_i, the rest length of the springs and the distance between the masses at equilibrium do not show up in the final result.

The system is described by the set of coupled equations of motion:

$$m\ddot{\psi}_i = k\left(\psi_{i-1} - 2\psi_i + \psi_{i+1}\right) \qquad \text{for } i = 1, \ldots N \quad ,$$

or, equivalently, by the set:

$$\ddot{\psi}_i + 2\omega_0^2\psi_i = \omega_0^2\left(\psi_{i-1} + \psi_{i+1}\right) \qquad \text{for } i = 1, \ldots N \quad .$$

25.07.04.01 Solution

©|Berkeley Physics Course, Vol. 3, *Waves*, 1968, McGraw-Hill, ...Ed., ...|3.5|*Detailed discussion*|

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|27.5.3||

It can be shown that the proper frequency, ω_p, and wave-number, k_p, for the p-mode ($p = 1, \ldots N$), and the **Dispersion Relation** , $\omega_p[k_p]$ (read § 44.03.08) for the system of N coupled identical oscillators described in section § 25.07.04, with spring elastic constant k and mass m, on a linear chain with spacing a and length L, are:

$$\omega_p = 2\omega_0 \sin\left[\frac{p\pi}{2\left(N+1\right)}\right] \qquad (25.07.01) \quad \rightarrow \text{1426 2012}$$

$$k_p = \frac{p\pi}{\left(N+1\right)a} \qquad (25.07.02) \quad \rightarrow \text{2012}$$

$$\omega_p[k_p] = 2\omega_0 \sin\left[\frac{ak_p}{2}\right] \qquad (25.07.03) \quad \rightarrow \text{2012}$$

$$\text{for } p = 1, \ldots N \quad .$$

Due to the bounds for p the argument of the sinus is always strictly smaller than $\pi/2$, and therefore $0 < \omega_p < 2\omega_0$.

25.07.04.02 Continuum Limit for Infinite Masses/Springs

Suppose that we want to study the limiting case of infinitely many masses/springs. We then look for the limit when the number of masses and springs increases, $N \longrightarrow \infty$, by keeping the same total length, L, of the chain, (implies $a \longrightarrow 0$), the same total mass, $M \equiv Nm$, (implies $m \longrightarrow 0$), and the same total elastic constant of the whole chain, $K\left(N+1\right) \equiv k$.

In the limit for $a \longrightarrow 0$ the set of functions $\psi_i[t]$ is replaced by the interpolating function $\psi[x,t]$:

$$\psi_i[t] \longrightarrow \psi[x,t] \qquad \text{such that} \qquad \psi[x = x_0 + ia] \equiv \psi_i[t] \quad .$$

Therefore one can write the expressions:

$$\frac{\psi_{i+1} - \psi_i}{a} \simeq \frac{\partial\psi}{\partial x}[x = x_0 + (i + 1/2)\,a] \qquad \text{for } i = 1, \ldots N \quad ,$$

$$\frac{\psi_i - \psi_{i-1}}{a} \simeq \frac{\partial\psi}{\partial x}[x = x_0 + (i - 1/2)\,a] \qquad \text{for } i = 1, \ldots N \quad ,$$

$$\frac{\frac{\partial\psi}{\partial x}[x = x_0 + (i + 1/2)\,a] - \frac{\partial\psi}{\partial x}[x = x_0 + (i - 1/2)\,a]}{a} \simeq \frac{\partial^2\psi}{\partial x^2}[x = x_0 + ia] \qquad \text{for } i = 1, \ldots N \quad .$$

Moreover:

$$a^2\omega_0^2 = a^2\frac{k}{m} = a^2\frac{K\left(N+1\right)}{\frac{M}{N}} \longrightarrow \frac{L^2K}{M} \quad .$$

DRAFT IN PROGRESS

The system can then be transformed as:

$$\ddot{\psi}_i = \omega_0^2 \left((\psi_{i+1} - \psi_i) - (\psi_i - \psi_{i-1}) \right) \qquad \text{for } i = 1, \dots N \quad ,$$

$$\frac{\partial^2 \psi}{\partial t^2}[x,t] \simeq a^2 \omega_0^2 \frac{\partial^2 \psi}{\partial x^2}[x,t] \simeq \frac{L^2 K}{M} \frac{\partial^2 \psi}{\partial x^2}[x,t] \quad .$$

The equation is the **D'Alembert non-dispersive wave-equation** and it is normally written as:

$$\boxed{\frac{\partial^2 \psi}{\partial t^2}[x,t] = v^2 \frac{\partial^2 \psi}{\partial x^2}[x,t]} \quad ,$$

in term of a velocity, which takes the meaning of speed of propagation of the wave. Read § 44. The speed of the continuum limit, v, is given by equation (45.02.04), (45.13.01), (45.13.02).

The meaning of the interpolating function $\psi[x,t]$ is: the longitudinal displacement with respect to the equilibrium position of the element of the chain whose longitudinal position at equilibrium is at x.

Cut-Off Frequency

Note that equation (25.07.01) shows that, when N increases the maximum frequency goes as:

$$\omega_N \simeq 2\omega_0 = 2N \sqrt{\frac{K}{M}} \quad .$$

The fact that the solutions for large N are, up to a large cut-off frequency, similar to the continuum-wave one is good to tell us that we can use the continuum approximation even if we know we are describing a large but finite number of atoms.

DRAFT-IN-PROGRESS

Some oscillatory systems which are not closed, are such that the external action amounts only to a time variation of some of the parameters. One simple case is a simple pendulum whose length is changed by some external agent.

Several systems can be described by a second-order differential similar to the damped linear oscillator equation but with time-dependent coefficients:

$$\ddot{\xi} + \Gamma\dot{\xi} + \omega_0^2[t]\xi = 0 \quad .$$

25.08.01
Simple Model for a See-Saw

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|10.6||
©|D.Garanin - Analytical Dynamics - Graduate Center CUNY - Parametric resonance|WEB - URL |*Full detailed solution*|

A very simple model of the oscillation amplitude increase in a **see-saw** goes as follow.

This example emphasizes:

- non conservation of mechanical energy;
- internal work.

Consider a pendulum, of mass m and length l whose length can be changed by pushing or pulling the string. The string tension, $\mathbf{T}$, does no work if the length of the pendulum is kept constant.

Suppose the length is slightly decreased every time the pendulum passes by the vertical position, $\theta = 0$, by an amount $\Delta l_+ \ll l$. During this process the tension does a positive work, L_+, on the mass. Suppose the length is slightly increased every time the pendulum passes at the maximum elongation, $\theta = \pm\theta_{\text{M}}$, by an equal and opposite amount $\Delta l_- = -\Delta l_+ \ll l$. During this process the tension does a negative work, L_-, on the mass. Let us calculate the overall balance as total work per full cycle.

Assume:

$$0 \le \Delta l \equiv |\Delta l_+| = |\Delta l_-| \ll l \quad .$$

Solution by the Cardinal Equations

$$mgl\,(1 - \cos[\pm\theta_{\text{M}}]) = \frac{mv^2}{2} \qquad \text{energy conservation} \quad ,$$

$$L_+ = +2|T[\theta = 0]|\Delta l = +2\left(mg + m\frac{v^2[\theta = 0]}{l}\right)\Delta l \ge 0 \quad ,$$

$$L_- = -2|T[\theta = \pm\theta_{\text{M}}]|\Delta l = -2\left(mg\cos[\pm\theta_{\text{M}}] + m\frac{v^2[\theta = \pm\theta_{\text{M}}]}{l}\right)\Delta l = -2\,(mg\cos[\pm\theta_{\text{M}}])\,\Delta l \le 0 \quad ,$$

$$L_+ + L_- = 2\left(mg + m\frac{v^2[\theta = 0]}{l} - mg\cos[\pm\theta_{\text{M}}]\right)\Delta l = 6mg\,(1 - \cos[\pm\theta_{\text{M}}])\,\Delta l > 0 \quad .$$

Note the factor 2, taking into account that the elongate/shorten operation is carried on twice per cycle.

The result shows that a positive energy is given to the system per cycle.

la perdita di energia meccania per unità di tempo vale

$$\frac{\mathrm{d}e}{\mathrm{d}t} = -m\Gamma v^2 \quad .$$

2. Dimostare che, nel caso debolmente smorzato, ($Q > 1/2$), si può scrivere l'espressione per l'energia meccanica media in un periodo, $\langle e \rangle$, come

$$\frac{\mathrm{d}\langle e \rangle}{\mathrm{d}t} \simeq -\Gamma \langle e \rangle \quad .$$

3. Dimostrare che in un periodo si ha:

$$\frac{\Delta e}{e} = -\frac{2\pi}{Q} \quad .$$

25-003 Moto Armonico Semplice E Condizioni Iniziali

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.31||

Dimostrare che il legame generale tra la soluzione del moto armonico semplice

$$x[t] = A \cos[(\omega t - \phi)] \quad ,$$

e le condizioni iniziali $x_0 = x[t = 0]$ e $v_0 = v[t = 0]$ sono

$$A = \sqrt{x_0^2 + \left(\frac{v_0}{\omega}\right)^2}$$

$$\begin{cases} \tan[\phi] = \dfrac{v_0}{\omega x_0} & \text{se } x_0 > 0 \quad , \\ \tan[\phi] = \dfrac{v_0}{\omega x_0} + \pi \quad , & \\ \quad \text{se } x_0 < 0 \ \tan[\phi] = +\pi/2 \quad , & \\ \quad \text{se } x_0 = 0 \text{ e } v_0 > 0 \ \tan[\phi] = -\pi/2 \quad , & \\ \quad \text{se } x_0 = 0 \text{ e } v_0 < 0 & \end{cases} \quad .$$

DRAFT-IN-PROGRESS

25-004 Moto Armonico Semplice E Risposta in Velocità

©|D.Halliday & R.Resnick, *Fisica*, 1978, C.E.A., 3rdEd., ...|P-15.55||

Si consideri il moto armonico smorzato forzato

$$\ddot{\phi} + \Gamma\dot{\phi} + \omega_0^2\phi \equiv G_0 \cos[\omega t + \alpha] \qquad G_0 > 0 \quad .$$

1. Si calcoli la risposta in velocità, cioè la velocità in funzione del tempo, $\dot{\phi}[t]$, e si studino l'ampiezza e la fase delle oscillazioni della velocità in fuzione della frequenza esterna ω.
2. Confrontare la frequenza della risonanza in velocità con la frequenza della risonanza in posizione.

25-005 Critical Damped Motion

Show that both equations (25.04.07), (25.04.09) give the same expression in the limit towards critical damping and determine expression (25.04.08).

25-006 Molle in Serie E in Parallelo

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.21 15.22||

Due molle di costante elastica k_1 e k_2 sono collegate in serie, cioè con un estremo di una molla collegato ad un estremo dell'altra. I due estremi liberi sono così gli estremi di una nuova molla. Quanto vale la costante elastica equivalente della molla complessiva?

Le due molle sono poi collegate in parallelo, cioè con entrambi gli estremi collegati tra loro. Le due coppie di estremi collegate tra loro sono così gli estremi di una nuova molla. Quanto vale la costante elastica equivalente della molla complessiva?

WORKED SOLUTION

$k_{\text{SER}} = k_1 k_2 / (k_1 + k_2)$; $k_{\text{PAR}} = k_1 + k_2$.

25-007 A Mass Particle Kept by Two Springs

Consider (see figure 25.16) two identical springs having one extreme attached to a mass particle of mass m and their second extreme fixed in such a way that at equilibrium the springs and mass are on straight line (the x axis, with origin at the middle, that is the equilibrium position of the mass). All the parts are on a horizontal plane with negligible friction.

Consider the oscillations on the median line (y axis).

Show under which conditions the oscillations are linear.

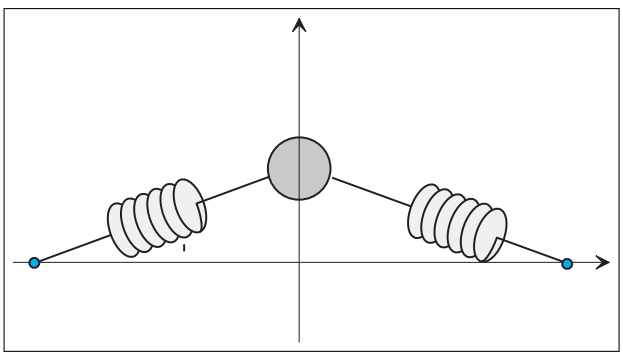

Figure 25.16: Amass particle kept by two springs - linear oscillations

25-008 Oscillazioni Verticali Di Un'automobile

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.7||

Per quello che riguarda le oscillazioni verticali un'automobile può essere considerata montata su quattro molle (gli ammortizzatori). Gli ammortizzatori di un'automobile di massa $M = 1460\ \mathrm{kg}$ sono regolate in modo che le vibrazioni verticali dell'automobile abbiano frequenza $\nu = 2.95\ \mathrm{Hz}$.

1. Determinare la costante elastica di ciascuna delle quattro molle (supposte identiche) che formano gli ammortizzatori.
2. Quale sarà la frequenza di vibrazione se sull'auto viaggiano cinque persone aventi in media la massa $m = 73.2\ \mathrm{kg}$?

WORKED SOLUTION

$k = 1250\ \mathrm{N}cm.\ \nu = 2.63\ \mathrm{Hz}.$

25-009 Misura Della Massa Degli Astronauti

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.11||

Per misurare la massa M di un astronauta su un veicolo spaziale si usa un dispositivo costituito da un seggiolino, di massa m, montato su molle. L'astronauta misura il proprio periodo di oscillazione sulla sedia e deduce la massa dalla relazione tra massa e periodo di un sistema oscillante.

1. Dimostrare che
$$M = \frac{kT^2}{4\pi^2} - m$$
dove T è il periodo di oscillazione e k la costante elastica.
2. La costante elastica per il dispositivo usato sullo Skylab era $k = 605\ \mathrm{N/m}$ e il periodo di oscillazione della sedia vuota era $T_0 = 0.90149\,\mathrm{sec}$. Calcolare la massa della sedia.
3. Il periodo di oscillazione con un astronauta sulla sedia diventava $T = 2.08832\,\mathrm{sec}$. Determinare la massa dell'astronauta.

WORKED SOLUTION

$m = 12.47\ \mathrm{kg}.\ M = 72.85\ \mathrm{kg}.$

25-010 Potenziale Di Interazione Di Due Atomi in Una Molecola Biatomica

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.17||

La forza di interazione tra due atomi in una molecola biatomica può essere rappresentata dalla relazione
$$F[r] = -\frac{a}{r^2} + \frac{b}{r^3}$$
dove a e b sono costanti positive ed r è la distanza tra i due atomi. Rappresentare graficamente $F[r]$ in funzione di r.

1. Dimostrare che la distanza di equilibrio è data da $r_0 = b/a$.
2. Dimostrare che per piccole oscillazioni attorno a questa distanza di equilibrio la costante della forza vale a^4/b^3.
3. Trovare il periodo T delle piccole oscillazioni attorno alla distanza di equilibrio.

DRAFT - Internet Print

WORKED SOLUTION

$T = 2\pi\sqrt{mb^3/a^4}$.

25-011 Proiettile Fermato Da Un Sistema Blocco-Molla

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.34||

Un blocco di massa M è in quiete su un piano orizzontale privo di attrito ed è connesso ad un supporto rigido mediante una molla di costante elastica k. Un proiettile di massa m e velocità v_0 viaggia orizzontalmente colpisce il blocco e vi rimane conficcato. Determinare l'ampiezza del moto armonico semplice risultante in funzione di m, M, v_0 e k.

25-012 Sistema Blocco-Molla Ed Effetto Della Forza Di Gravità

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.35||

Si consideri una molla di massa trascurabile e di costante elastica k in un campo gravitazionale uniforme. si supponga di fissare alla molla un oggetto di massa m.

1. Se $x = 0$ è la posizione di riposo della molla dimostrare che la posizione di equilibrio statico è $x_e = mg/k$.
2. Dimostrare che l'equazione del moto del sistema è
$$m\ddot{x} + kx = mg \quad , \tag{25.10.01}$$
→ 1432
e che la soluzione di tale equazione è
$$x[t] = A\cos\left[(\omega t + \phi)\right] + \frac{mg}{k} \quad ,$$
con $\omega = k/m$, come nel caso di assenza di gravità.
3. Dimostrare che nel campo di gravità costante ω, v, a e T sono gli stessi che si ottengono in assenza di gravità con la sola differenza che la posizione di equilibrio è spostata di mg/k.
4. Si consideri l'energia totale del sistema, costante, e si dimostri che differenziando rispetto al tempo si ottiene l'equazione del moto (25.10.01).

25-013 Cilindro E Molla

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.37||

Un cilindro di massa M rotola senza strisciare su un piano orizzontale ed è collegato al suo centro con una molla, di costante elastica $k = 2.94$ Ncm,
il cui secondo estremo è fissato ad un muro. Se il sistema viene lasciato libero da fermo quando la molla è allungata di 23.9 cm determinare

1. l'energia cinetica di traslazione;
2. l'energia cinetica di rotazione del cilindro quando passa per la posizione di equilibrio.
3. Dimostrare che il centro di massa del cilindro si muove di moto armonico semplice con periodo $T = 2\pi\sqrt{3M/2k}$.

DRAFT-IN-PROGRESS

25-014 Il Pendolo Di Kater

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|15.53||

Il pendolo di Kater può essere utilizzato per misurare l'accelerazione di gravità. Si immagini di avere un pendolo fisico che può essere imperniato in due punti. La posizione del primo punto è fissa mentre quella del secondo punto può essere spostata lungo il pendolo. Quando il pendolo è sospeso dalla posizione fissa il suo periodo è T. Successivamente il pendolo viene capovolto e sospeso al perno mobile. Per successivi tentativi la posizione del perno mobile viene variata fino a che il periodo è uguale a quello determinato quando il pendolo è sospeso dal perno fisso, T. Dimostrare che l'accelerazione di gravità vale $g = 4\pi^2 L/T^2$ essendo L la distanza tra i due punti di oscillazione. Si osservi che con questo metodo si può determinare g senza conoscere nulla delle proprietà del pendolo eccetto la distanza, misurata, L.

25-015 Oscillazioni a Due Corpi

©|D.Halliday & R.Resnick, *Fisica*, 1978, C.E.A., 3rdEd., ...|§ 15.8 P-15.53||

Si consideri un sistema formato da due masse, m_1 e m_2, legate da una molla di costante elastica k.

1. Determinare le frequenze proprie di oscillazione del sistema e le ampiezze relative della due coordinate posizione delle due masse nei due modi normali.
2. Determinare il moto del centro di massa delle due masse.
3. Scrivere l'espressione dell'energia cinetica del sistema.
4. Scrivere le equazioni del moto in termini della massa ridotta del sistema.
5. Dimostrare che nel caso in cui $m_1 \gg m_2$ la massa ridotta tende ad assumere il valore della massa m_2 e il moto del sistema diventa essenzialmente quello del moto ad un solo grado di libertà della massa m_2.

25-016 Coupled RLC Circuits

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|27.3.3||

- Consider two independent RLC series circuits, made of a resistor R, a capacitance C and an inductance L. The two circuits are coupled in the following way: the two circuits are opened and, afterwards, they are both closed on another capacitor, C_0, to form a circuit with two loops, symmetrical with respect to the coupling capacitor. This circuit has capacitive coupling.
  1. Write down the equations of the circuit.
  2. Write down the proper frequencies and the amplitudes of the normal modes.
- Consider two independent RLC series circuits, made of a resistor R, a capacitance C and an inductance L. The two circuits are coupled in the following way: the inductances of the two circuits put one near the other is such a way that they couple by their mutual inductance M. This circuit has inductive coupling.
  1. Write down the equations of the circuit.
  2. Write down the proper frequencies and the amplitudes of the normal modes.

DRAFT - PRE-PRESS

25-017 Molecule of Carbon Dioxide

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|P-27.6||

Consider the longitudinal vibrations of a molecule of CO_2, that is assume that the three atoms move on a straight line. The two oxygen atoms have mass m (oxygen molar mass $16\ \mathrm{g/mol}$) and the Carbon atom has mass M (carbon molar mass $12\ \mathrm{g/mol}$). Each oxygen atom is supposed to be linked to the central carbon atom by a force which can be described by a linear restoring force with elastic constant k, for small displacement. The system has three degrees of freedom.

1. Write the equations of motion in the Center-Of-Mass Reference Frame. Note that in this Reference Frame the system has only two degrees of freedom.
2. Determine the proper frequencies and the amplitudes of the normal modes.

SHEET-IN-PROGRESS

26.01 Introduction

By definition, a rigid-body is a model a physical system such that the distance between any two particles, k and j, never changes:

$$|\mathbf{x}_k - \mathbf{x}_j| = \text{costant} \quad . \tag{26.01.01}$$

→ 1439

Let us model a rigid-body as a continuous system made of particles of known properties, whose relative positions are immutable, by integrating overs macroscopically small and microscopically large integration volumes.

When considering the internal structure of the particles making the rigid-body, a few different cases may arise:

- The classical rigid-body, made of mass points with no internal structure, that is spinless.
- A rigid-body made of rigidly fixed particles: let us call it a rigid-rigid-body.
  The particles making the rigid-body, must be endowed with some intrinsic vector properties (such as spin, **Dipole** moment, ...) and may have to be subject to a torque, $\boldsymbol{\gamma}[\mathbf{x}]$. A rigid-body made of rigidly fixed particles is an extension of the rigid-body concept to include the requirement that each particle has its intrinsic constant vector property, fixed relative to all the others.
  In this case the angular velocity $\boldsymbol{\omega}$ of the rigid-body is the same for every particle making the rigid body as well as for the intrinsic vector property, that is it does not depend on $\mathbf{x}$. This model, for instance, can apply to a ferroelectric/ferromagnetic material with fixed Polarization/Magnetization in external Electric|Magnetic field.
- A rigid-body made of particles with fixed positions but possibly rotating orientation of the intrinsic vector property: let us call it a rigid-nonrigid-body.
  In this case the angular velocity $\boldsymbol{\omega}$ of the rigid-body is the same for every particle making the rigid body, that is it does not depend on $\mathbf{x}$; However, the intrinsic vector property, at any point, $\mathbf{x}$, can rotate independently of the overall angular velocity $\boldsymbol{\omega}$ of the rigid-body.

Legenda:

- Q_P: Q is a property of the point P, e.g.: $\mathbf{R}_{\mathtt{CM}}$, $\mathbf{v}_{\mathtt{P}}$. ...;
- Q' a property relative to the Center-Of-Mass, measured in the Reference Frame of the Center-Of-Mass, e.g.: $\mathbf{L}'$, ... A **prime** is used, in agreement with the general convention to use $\mathcal{I}$ for the **observer/laboratory** Reference Frame and $\mathcal{I}'$ for the **observed/moving** Reference Frame.

DRAFT IN PROGRESS

26.02 Coordinate Systems

When studying the mechanics of rigid-bodies, it is useful to use different Reference Frame and Coordinate System, depending on which one is more suitable.

Assume to describe the motion from an Inertial Reference Frame , $\mathcal{I}$, and introduce a orthonormal Cartesian Coordinates Coordinate System: $\mathcal{I} \equiv \{\mathcal{O}; \mathbf{e}_k\}$.

A second useful Reference Frame, as for the general case, is the non-Inertial Reference Frame moving with the Center-Of-Mass of the body, with origin at the Center-Of-Mass of the body and with axes parallel to the axes of the inertial frame $\mathcal{I}$: $\mathcal{I}' \equiv \mathcal{I}_{\mathtt{CM}}$. Note that this Reference Frame is non-rotating with respect to $\mathcal{I}_0$.

A third useful Reference Frame is any non-Inertial Reference Frame rigidly fixed to the body. This Reference Frame is usually, but not necessarily, centered at the Center-Of-Mass of the body, with, a priori, arbitrary orientation: $\mathcal{I}'' \equiv \mathcal{I}_{\mathtt{RB}}$. It will be shown later that setting the origin at the Center-Of-Mass and setting some specific orientation of the axes can provide a much simpler analysis of motion. Note that this Reference Frame is, in general, rotating with respect to both $\mathcal{I}_0$ and $\mathcal{I}_{\mathtt{CM}}$ and in general not inertial. This Reference Frame is useful because, with respect to it, the mass distribution and all static properties derived from it are described in the most simple way. For instance, the mass density is a given time-independent function, fixed once and for ever, irrespective of the motion of the body.

DRAFT-IN-PROGRESS

26.03 Rigid-Body Kinematics

This § is referenced at pages:
[1149, 1192, 1241]

©|Uniqueness of the angular velocity of a rigid body: Correction of two faulty proofs|Am.J.Phys, , ..., ..., ...Ed., ... 68, 668 ...

Read also sections § 17.03, § 20.05, § 23.06. This section presents the implementation to the kinematics of rigid-bodies.

Note that a Reference Frame is by definition based on some rigid-body, to the define the rigid axes.

The definition of rigid-body, equation (26.01.01), implies that:

$$\text{constant} = |\mathbf{x}_k - \mathbf{x}_j|^2 = (\mathbf{x}_k - \mathbf{x}_j)\cdot(\mathbf{x}_k - \mathbf{x}_j) \implies (\mathbf{x}_k - \mathbf{x}_j)\cdot(\mathbf{v}_k - \mathbf{v}_j) = 0 \quad .$$

The interpretation of the above relation (26.03.02) is that, any infinitesimal displacement of the rigid-body is given by a translation of any body-fixed point O plus a rotation around it. In fact equation (26.01.01),

$$(\mathbf{x}_P - \mathbf{x}_0)\cdot(\mathbf{v}_P - \mathbf{v}_0) = 0 \quad ,$$

when it is seen as a vector equation in the unknown $(\mathbf{v}_P - \mathbf{v}_0)$ implies

$$\mathbf{v}_P = \mathbf{v}_0 + \mathbf{A}\wedge(\mathbf{x}_P - \mathbf{x}_0) \quad , \tag{26.03.01}$$

→ 1439 1449

for any body-fixed point O and any other arbitrary body-fixed point P, and where $\mathbf{A}$ is an arbitrary vector, which can depend on time, a priori. It is clear that the vector $\mathbf{A}$ is actually the angular velocity of any Reference Frame rigidly fixed to the rigid-body relative to the fixed Reference Frame. This is obvious by applying equations (23.07.02).

Conversely, it is immediate to show that whenever equation (26.03.01) is valid then equation (26.01.01) is satisfied:

$$(\mathbf{x}_A - \mathbf{x}_B)\cdot(\mathbf{v}_A - \mathbf{v}_B) = (\mathbf{x}_A - \mathbf{x}_B)\cdot(\mathbf{A}\wedge(\mathbf{x}_A - \mathbf{x}_B)) = 0$$

Therefore, the velocity, $\mathbf{v}_P$, of any body-fixed point P, can be expressed as

$$\boxed{\mathbf{v}_P = \mathbf{v}_0 + \boldsymbol{\omega}\wedge(\mathbf{x}_P - \mathbf{x}_0)} \quad , \tag{26.03.02}$$

→ 1128 1439 1440 1441 1442 1443

as a function of the angular velocity of the rigid-body, $\boldsymbol{\omega}$, of the position, $\mathbf{x}_0$, and velocity, $\mathbf{v}_0$, of any other body-fixed point O. The point O is usually named **center of reduction of the velocities of the rigid-body**, abbreviated CRV.

It follows, therefore, that all and only motions described by equation (26.03.01) with any arbitrary time-dependent vector $\mathbf{A}$ is compatible with the rigidity constraint (26.01.01) and therefore describe rigid motions.

Similarly, by deriving equation (26.03.02) with respect to time, one finds the law of accelerations:

$$\boxed{\mathbf{a}_P = \mathbf{a}_0 + \dot{\boldsymbol{\omega}}\wedge(\mathbf{x}_P - \mathbf{x}_0) + \boldsymbol{\omega}\wedge(\mathbf{v}_P - \mathbf{v}_0) = \mathbf{a}_0 + \dot{\boldsymbol{\omega}}\wedge(\mathbf{x}_P - \mathbf{x}_0) + \boldsymbol{\omega}\wedge(\boldsymbol{\omega}\wedge(\mathbf{x}_P - \mathbf{x}_0))} \quad , \tag{26.03.03}$$

as a function of the angular velocity and angular acceleration of the rigid-body, $\boldsymbol{\omega}$ and $\dot{\boldsymbol{\omega}}$, of the position, $\mathbf{x}_0$, velocity, $\mathbf{v}_0$, and acceleration, $\mathbf{a}_0$, of any other body-fixed point O.

DRAFT - IN PROGRESS

26.03.01
Most General Motion of a Rigid-Body

The most general motion of a rigid-body is the same as the general motion of a Reference Frame: a combination of a translation, described by the motion of the origin of any Reference Frame rigidly fixed to the body, plus a rotation, described by the angular velocity, $\boldsymbol{\omega}$, that is a roto-translation.

26.03.02
Instantaneous Axis of Rotation

At any instant time, the rigid motion in 3D is such that the moving Reference Frame is instantaneously rotating about an axis, the instantaneous axis of rotation; this axis need not be the same at different times.

It can be determined from equation (26.03.02),

$$\boxed{\mathbf{v}_P = \mathbf{v}_0 + \boldsymbol{\omega}\wedge(\mathbf{x}_P - \mathbf{x}_0)} \quad ,$$

by imposing $\mathbf{v}_P = 0$, and using the results of § 17.02, to obtain:

$$\boxed{\mathbf{x}_P = \mathbf{x}_0 + \frac{\boldsymbol{\omega}\wedge\mathbf{v}_0}{\omega^2} + \lambda\boldsymbol{\omega} \qquad \lambda \text{ arbitrary real number}} \quad .$$

This equation defines all the points that have zero velocity at any instant, which is then a straight line parallel to the angular velocity, called axis of instantaneous rotation. This axis, in general, varies with time.

26.03.03
Euler Theorem

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|4.6||

Euler theorem states that any sequence of arbitrary displacements of a rigid-body such that one point on the rigid-body, say S, remains fixed, is equivalent to a suitable rotation about a suitable fixed axis through the point S. In algebraic terms, it expresses the fact that rotations form a group; that is, any sequence of rotations is equivalent to one suitable single rotation.

Read § 20.05.06

DRAFT-IN-PROGRESS

26.03.04
Mozzi/Chasles Theorem

©|W.B. Heard|rigid-body Mechanics|*2.1.5*|

Mozzi/Chasles theorem states that the most general rigid-body displacement can be composed by a translation along an axis plus a rotation about that same axis. This is the transformation executed by a turning screw and is referred to as screw transformation; the axis is named screw axis.

26.03.05
Rolling and Slipping

Consider two rigid surfaces in contact at a single point. Pure rolling happens when the relative velocity of the two contact points on the two rigid surfaces is zero.

If one of the two surfaces is fixed, the condition of pure rolling can be obtained imposing that the velocity of the contact point of the moving surface is zero, using equation (26.03.02).

In case the two surfaces are in contact at multiple points, the zero relative velocity condition must apply to all contact points.

DRAFT – IN-PROGRESS

26.04 Dynamics of Rigid-Bodies

Legenda: $Q_{\mathtt{CM}}$ is a property of the Center-Of-Mass, such as $\mathbf{R}_{\mathtt{CM}}$; Q' a property relative to the Center-Of-Mass, such as $\mathbf{x}'$.

26.04.01 Linear Momentum of Rigid-Bodies

$$\boxed{\mathbf{P} = M\mathbf{V}_{\mathtt{CM}}} \quad .$$

26.04.02 Angular Momentum of Rigid-Bodies

It is useful to distinguish three cases: use, as a pole, either a fixed and body-fixed pole (if it does exist!), or a generic body-fixed pole, or any arbitrary pole, via **Koënig theorem** .

Moreover, the CRV of the rigid-body is another, a priori different, point which must be considered: it may be either a fixed and body-fixed pole (if it does exist!), or a generic body-fixed pole, as the CRV of a rigid-body must be a body-fixed point. The pole and the CRV may be different but when using a body-fixed pole it is normally easier to use the same as the CRV.

26.04.02.01 Angular Momentum With Respect to a Fixed and Body-Fixed CRV

If the rigid-body has a fixed point, S, such that $\mathbf{v}_{\mathtt{S}} = \mathbf{0}$, then:

$$\boxed{\mathbf{L}_{\mathtt{S}} = \underset{\mathtt{S}}{\mathbb{I}}\cdot\boldsymbol{\omega}} \quad . \tag{26.04.01}$$

26.04.02.02 Angular Momentum With Respect to a Generic Body-Fixed CRV

If S is a body-point, such that in general $\mathbf{v}_{\mathtt{S}} \neq \mathbf{0}$, then, using equation (26.03.02) one finds:

$$\boxed{\mathbf{L}_{\mathtt{S}} = M\,(\mathbf{X}_{\mathtt{CM}} - \mathbf{x}_{\mathtt{S}})\wedge\mathbf{v}_{\mathtt{S}} + \underset{\mathtt{S}}{\mathbb{I}}\cdot\boldsymbol{\omega}} \tag{26.04.02}$$

The equation can be also applied, as a particular case, to $S = CM$ and it reduces to equation (26.04.03).

26.04.02.03 Angular Momentum via Koënig theorem

Il momento angolare di un corpo rigido rispetto ad un polo O qualunque può essere espresso tramite la (24.11.02)

$$\boxed{\mathbf{L}_{\mathtt{O}} = (\mathbf{X}_{\mathtt{CM}} - \mathbf{x}_{\mathtt{O}})\wedge\mathbf{P} + \mathbf{L}' = (\mathbf{X}_{\mathtt{CM}} - \mathbf{x}_{\mathtt{O}})\wedge\mathbf{P} + \underset{\mathtt{CM}}{\mathbb{I}}\cdot\boldsymbol{\omega}} \quad . \tag{26.04.03}$$

→ 1442

26.04.02.04 Angular Momentum via the Law of Transformation of Momentum

For the system of applied vectors $\mathbf{v}[\mathbf{x}, t]$, defining the field of velocities of the rigid-body, the law of of transformation of angular momentum when varying the pole is, from equation (15.04.07):

$$\boxed{\mathbf{L}_{\mathtt{B}} = \mathbf{L}_{\mathtt{A}} + (\mathbf{x}_{\mathtt{A}} - \mathbf{x}_{\mathtt{B}})\wedge\mathbf{P}} \quad , \tag{26.04.04}$$

of which equations (26.04.03) is a particular case when $B \equiv O$ and $A \equiv CM$.

DRAFT-IN-PROGRESS

26.04.03
Kinetic Energy of Rigid-Bodies

It is useful to distinguish three cases: use, as a CRV, either a fixed and body-fixed point (if it does exist!), or a generic body-fixed point, or the Center-Of-Mass, via **Koënig theorem** .

In this case there is no pole, so that the different cases refer to the CRV.

26.04.03.01 Kinetic Energy With Respect to a Fixed and Body-Fixed CRV

If the rigid-body has a fixed point, S, such that $\mathbf{v}_{\mathrm{S}} = \mathbf{0}$, then:

$$\mathcal{K} = \frac{1}{2}\left(\boldsymbol{\omega}\cdot\underset{\mathrm{S}}{\mathbb{I}}\cdot\boldsymbol{\omega}\right) \quad . \tag{26.04.05}$$

26.04.03.02 Kinetic Energy With Respect to a Generic Body-Fixed CRV

If S is a body-point, such that in general $\mathbf{v}_{\mathrm{S}} \neq \mathbf{0}$, then, using equation (26.03.02) one finds:

$$\mathcal{K} = \frac{1}{2}M\mathbf{v}_{\mathrm{S}}^2 + M\,\mathbf{v}_{\mathrm{S}}\cdot(\boldsymbol{\omega}\wedge(\mathbf{X}_{\mathrm{CM}} - \mathbf{x}_{\mathrm{S}})) + \frac{1}{2}\left(\boldsymbol{\omega}\cdot\underset{\mathrm{S}}{\mathbb{I}}\cdot\boldsymbol{\omega}\right) \quad . \tag{26.04.06}$$

→ 1448

It can be also applied, as a particular case, to $S = CM$, and it reduces to equation (26.04.07).

26.04.03.03 Kinetic Energy via Koënig Theorem

The kinetic energy of rigid-bodies can be expressed by means of equation (24.11.05)

$$\mathcal{K} = \frac{1}{2}MV_{\mathrm{CM}}^2 + \frac{1}{2}\left(\boldsymbol{\omega}\cdot\underset{\mathrm{CM}}{\mathbb{I}}\cdot\boldsymbol{\omega}\right) \quad . \tag{26.04.07}$$

→ 1443

26.04.04
Inertia Matrix|Tensor

The inertia Matrix|Tensor can be considered as the representation of the linear transformation from the angular velocity to the angular momentum for a rigid body. It is actually a second-order tensor.

For a fixed rigid-body the inertia Matrix|Tensor depends on:

- the origin of the body-fixed Coordinate System;
- the orientation of the body-fixed Coordinate System.

Therefore, the notation $\underset{\mathrm{S}}{\mathbb{I}}$ implies that both the position of the origin of the body-fixed Coordinate System, $\mathbf{x}_{\mathrm{S}}$, and the orientation of the body-fixed Coordinate System, $\mathbf{e}_k^{(\mathrm{S})}$, are given:

$$\mathrm{S} \equiv \left\{\mathbf{x}_{\mathrm{S}}, \mathbf{e}_k^{(\mathrm{S})}\right\} \quad .$$

It is important to emphasize that use of any base fixed in the Inertial Reference Frame would give time-dependent elements of the inertia Matrix|Tensor which make the successive time-derivations complex. On the contrary, if a base rigidly fixed to the rigid-body is used, the elements of the inertia Matrix|Tensor are time-independent and only depending on the mass geometry of the rigid-body.

Introduce a Reference Frame fixed to the rigid-body, with origin $\mathcal{O}'$ and Coordinate System $\mathbf{x}'$. For ease of writing and reading $\mathbf{y} \equiv \mathbf{x}'$ will be used. La matrice di inerzia di un corpo rigido continuo avente densità $\rho[\mathbf{y}]$, rispetto ad un punto $\mathbf{y}_{\mathrm{S}}$ solidale con il corpo rigido, è definito dalla

$$\underset{\mathrm{S}}{\mathbb{I}}_{rs} \equiv \iiint \rho[\mathbf{y}]\left[y^2\delta_{rs} - y_r y_s\right]\,\mathrm{d}V_{\mathbf{y}} \tag{26.04.08}$$

→ 1571

dove le $\mathbf{y}$ sono le coordinate di un Coordinate System cartesiane, solidale con il corpo rigido, centrato in $\mathbf{y}_{\mathrm{S}}$ e definito dalla terna intrinseca $\mathbf{e}_k^{(\mathrm{S})}$.

As a consequence of its definition, with respect ot a body-fixed Coordinate System, the inertia Matrix|Tensor elements are time-independent and only dependent of the geometry of the masses.

The integral can be considered to be extended either to the rigid-body or the full space, as the mass density is zero outside the body.

DRAFT - IN PROGRESS

CC BY NC ND

La matrice è reale e simmetrica per costruzione. I termini diagonali sono detti momenti di inerzia, quelli non diagonali prodotti di inerzia.

The following property can be demonstrated by direct calculation:

$$\mathrm{Tr}\, \mathbb{I}_{\mathrm{S}} \equiv \mathbb{I}_{\mathrm{S}}^{ij}\delta_{ij} = \mathbb{I}_{\mathrm{S}}^{ij}\delta_{ij} = \mathbb{I}_{\mathrm{S}}^{ii} = 2\iiint \rho[\mathbf{y}]y^2 \,\mathrm{d}V_{\mathbf{y}} \qquad \text{invariant under rotation of the Coordinate System } \mathbf{y} \quad .$$

26.04.04.01 Tensor Character

This § is referenced at pages:
[1570]

The second-order tensor character can be immediately demonstrated by the fact that it links angular velocity and angular momentum, which are vectors, thanks to the **Quotient Law** § 20.03.07.

The second-order tensor character can be also directly demonstrated from the definition. Consider a second rotated orthonormal Cartesian Coordinates Coordinate System with the same origin as the first one, both in the Reference Frame fixed to the rigid-body. The rotation does not change the volume element in the integral and it changes the components of the position vector with the rotation matrix. Using the fact that the rotation matrix is orthogonal, the **Kronecker tensor** can be re-written factoring the same two rotation matrix elements as for the product of two coordinates. The common factor given by the product of two rotation matrix elements is exactly the one needed for the inertia Matrix|Tensor to behave as a second-order tensor.

26.04.04.02 Additivity of the Geometry of Masses

From its definition, the inertia Matrix|Tensor of a any system is the sum of the inertia Matrix|Tensor of the subsystems composing it.

In fact, the inertia Matrix|Tensor, for a given Coordinate System rigidly fixed to a rigid body, is additive in the mass density; in other words it is an extensive quantity.

26.04.04.03 Principal Axes of Inertia of a Rigid-Body

La matrice di inerzia è reale e simmetrica e può quindi essere sempre diagonalizzata; its eigenvalues are always non-negative and there exists a basis of orthogonal eigenvectors, possibly not a unique one.

Gli assi, che necessariamente esistono ma non sono necessariamente unici, del Coordinate System in cui la matrice è diagonale sono detti assi principali di inerzia.

Equivalently, a principal axis of inertia is any axis of the rigid-body such that whenever the angular velocity is along the direction of the axis then the angular momentum is along the direction of the axis as well.

If z' is a principal axis of inertia (that is one eigenvector of the inertia Matrix|Tensor): $L'_z = I_{z'z'}\omega'_z$ but, in general: $\mathbf{L}_{\mathrm{S}} \nparallel \boldsymbol{\omega}$. In order to have: $\mathbf{L}_{\mathrm{S}} \parallel \boldsymbol{\omega}$ it is necessary and sufficient that either $I_{x'x'} = I_{y'y'} = I_{z'z'}$ or $\boldsymbol{\omega}$ parallel to any principal axis of inertia. In summary, $\mathbf{L}_{\mathrm{S}} \parallel \boldsymbol{\omega}$ if and only if $\boldsymbol{\omega}$ is an eigenvector of the inertia Matrix|Tensor.

For the kinetic energy, after choosing a Coordinate System made of principal axes of inertia, one has:

$$\mathcal{K}' = \frac{1}{2}\left(I_1\omega_1^2 + I_2\omega_2^2 + I_3\omega_3^2\right) = \frac{1}{2}\left(\frac{L_1^2}{I_1} + \frac{L_2^2}{I_2} + \frac{L_3^2}{I_3}\right) \quad .$$

Whenever $I_{x'x'} = I_{y'y'} = I_{z'z'}$ one uses to name the rigid-body spherical top. However, this does not imply spherical symmetry (but the reverse is clearly true); consider for example the inertia Matrix|Tensor of any homogeneous cube with respect to its center.

Whenever there exists a set of axes such that $I_{x'x'} = I_{y'y'} \neq I_{z'z'}$ one uses to name the rigid-body symmetrical top. In this case, clearly, all other axes perpendicular to z' are principal axes with the same inertia moment as $I_{x'x'} = I_{y'y'}$.

Whenever $I_{x'x'} \neq I_{y'y'} \neq I_{z'z'}$ one uses to name the rigid-body asymmetrical top.

After choosing a Coordinate System made of principal axes of inertia, the inertia Matrix|Tensor becomes diagonal. From the definition of the elements of the inertia Matrix|Tensor it immediately follows that:

PREPRINT

- $I_{x'x'} \geq 0$,
- $I_{y'y'} \geq 0$,
- $I_{z'z'} \geq 0$;
- $I_{x'x'} + I_{y'y'} \geq I_{z'z'}$,
- $I_{y'y'} + I_{z'z'} \geq I_{x'x'}$,
- $I_{z'z'} + I_{x'x'} \geq I_{y'y'}$.

26.04.04.04 Variazione Della Matrice Di Inerzia Al Variare Dell'origine

Dati due Coordinate System cartesiani ortogonali solidali con un corpo rigido, con assi tra loro paralleli e con origine uno nel centro di massa e l'altro nel punto S solidale al copro rigido, la relazione tra i due tensori di inerzia relativi ai due punti è

$$\boxed{\mathbb{I}^{\cdot\cdot}_{S\,ij} = \mathbb{I}^{\cdot\cdot}_{CM\,ij} + M\left[a^2\delta^{\cdot\cdot}_{ij} - a_i a_j\right]} \tag{26.04.09}$$

dove $\pm\mathbf{a}$ è il vettore posizione del centro di massa rispetto ad S, e l'espressione non dipende dal segno di $\pm\mathbf{a}$.

It is important to stress that the theorem is only valid whenever one of the origins is the Center-Of-Mass.

$$\mathbf{y} \equiv P - O' = (P - CM) + \left(CM - O'\right) \equiv \mathbf{y}' + \mathbf{a} \quad ,$$

$$\mathbb{I}^{\cdot\cdot}_{S\,rs} \equiv \iiint \rho[\mathbf{y}]\left[\delta^{\cdot\cdot}_{rs}|\mathbf{y}|^2 - y_r y_s\right] \mathrm{d}V_{\mathbf{y}} = \iiint \rho[\mathbf{y}]\left[\delta^{\cdot\cdot}_{rs} y_k y_k - y_r y_s\right] \mathrm{d}V_{\mathbf{y}} = \quad ,$$

$$\int \rho'[\mathbf{y}']\left[\delta^{\cdot\cdot}_{rs}\left(y'_k + a_k\right)\left(y'_k + a_k\right) - \left(y'_r + a_r\right)\left(y'_s + a_s\right)\right] \mathrm{d}\mathbf{y}' = \quad ,$$

$$\int \rho'[\mathbf{y}']\left[\delta^{\cdot\cdot}_{rs}|\mathbf{y}'|^2 - y'_r y'_s\right] \mathrm{d}\mathbf{y}' + M\left(\delta^{\cdot\cdot}_{rs}|\mathbf{a}|^2 - a_r a_s\right) \quad ,$$

$$\rho'[\mathbf{y}'] = \rho[\mathbf{y}] \qquad \mathrm{d}\mathbf{y}' = \mathrm{d}\mathbf{y} \quad ,$$

$$\iiint \rho'[\mathbf{y}'] y'_p a_q \, \mathrm{d}V'_{\mathbf{y}} = 0 \qquad \text{as } \mathbf{y}' \text{ is the position relative to the Center-Of-Mass} \quad .$$

Teorema Degli Assi Paralleli (Di Huygens-Steiner)

Come caso particolare si ha il teorema di Huygens-Steiner. Il momento di inerzia di un corpo rigido di massa M rispetto ad un asse qualunque, I, è legato al momento di inerzia rispetto all'asse parallelo al precedente e passante per il centro di massa del corpo rigido, I_{CM}, dalla relazione

$$\boxed{I = I_{CM} + Md^2} \quad ,$$

dove d è la distanza tra i due assi.

26.04.04.05 Teorema Degli Assi Ortogonali

Dato un sistema rigido piano (una lamina bidimensionale omogenea) il momento di inerzia rispetto ad un asse perpendicolare alla lamina, z', e passante per il punto S della lamina è uguale alla somma dei momenti di inerzia rispetto a due assi perpendicolari tra loro, x' e y', giacenti sul piano e passanti per S, può essere espresso come

$$\boxed{I_{z'} = I_{x'} + I_{y'}} \quad .$$

26.04.04.06 Inertia Moment With Respect to an Arbitrary Axis

Il momento di inerzia rispetto ad un asse qualunque passante per S e definito dal unit vector $\hat{\mathbf{n}}$, vale:

$$\boxed{\mathbb{I}_{S}[\hat{\mathbf{n}}] = n_i n_j \mathbb{I}^{\cdot\cdot}_{S\,ij}} \quad , \tag{26.04.10}$$

as can be shown by direct calculation from the definition, as the expression gives the distance from the axis of any point.

→ 1571

DRAFT-IN-PROGRESS

26.04.04.07 Raggio Di Girazione

Per un sistema di massa M che ruota attorno ad un asse fisso con momento di inerzia I, si definisce il raggio di girazione

$$r_g \equiv \sqrt{\frac{I}{M}} \quad .$$

Rappresenta la distanza dall'asse a cui occorrerebbe concentrare la massa del sistema per avere momento di inerzia I.

26.04.04.08 Properties of the Inertia Matrix|Tensor Deriving From Symmetries of the Mass Geometry

1. If the $x'y'$ plane is a symmetry plane, then the mass distribution is invariant for: $z' \to -z'$ and therefore $I_{z'x'} = I_{y'z'} = 0$. Therefore, by definition, z' is a principal axis.
2. If the z' axis is a symmetry axis, then the mass distribution is invariant for: $x' \to -x'$ and $y' \to -y'$ (at the same time). and therefore $I_{z'x'} = I_{y'z'} = 0$ but, in general, $I_{x'y'} \neq 0$. Therefore, by definition, z' is a principal axis.
3. If the z' axis is a revolution axis, then the mass distribution is invariant for any rotation around the z' axis, $\theta \to \theta + \delta$. Therefore $I_{x'x'} = I_{y'y'}$, in addition to $I_{z'x'} = I_{y'z'} = 0$, as the z' axis is also a symmetry axis. Moreover, as $z'x'$ and $y'z'$ planes are also symmetry planes, it follows that: $I_{z'x'} = I_{y'z'} = I_{x'y'} = 0$. Therefore, by definition, z' is a principal axis and also x' and y' are principal axes of inertia (and the inertia Matrix|Tensor is diagonal). Any axis in the $x'y'$ plane is a principal axis.
4. If the shape and mass distribution of a rigid-body is symmetric with respect to a plane, its Center-Of-Mass and two of its principal axes lie in that plane. The third principal axis is perpendicular to it.
5. When the body possesses axial symmetry, that is if it is symmetric under rotations about a certain axis, then the Center-Of-Mass lies on the symmetry axis and that axis is a principal axis. The remaining two are perpendicular to it. The corresponding moments of inertia being degenerate, they must be chosen by hand in the plane through the Center-Of-Mass that is perpendicular to the symmetry axis.

26.04.05 Third Cardinal Equation for a Rigid-Body

26.04.05.01 Work and Power on a Rigid-Rigid-Body

Let us evaluate the power of an arbitrary system of Force|Torque, $\mathbf{f}[\mathbf{x}]$ and $\boldsymbol{\gamma}[\mathbf{x}]$, modeling the system as a continuous rigid-body.

Let S be any arbitrary point rigidly fixed to the body. The total power can be expressed in terms the total force, $\mathbf{F}$, the total torque with respect to the pole S, $\boldsymbol{\Gamma}_S$, angular velocity $\boldsymbol{\omega}$, and velocity $\mathbf{v}_S$ as:

$$\begin{aligned}\Pi \equiv \frac{\mathrm{d}W}{\mathrm{d}t} &= \int \mathbf{v}\cdot \mathrm{d}\mathbf{f}[\mathbf{x}] + \int \boldsymbol{\omega}\cdot \mathrm{d}\boldsymbol{\gamma}[\mathbf{x}] \quad , \\ &= \int (\mathbf{v}_S + \boldsymbol{\omega}\wedge(\mathbf{x}-\mathbf{x}_S))\cdot \mathrm{d}\mathbf{f} + \int \boldsymbol{\omega}\cdot \mathrm{d}\boldsymbol{\gamma} = \int \mathbf{v}_S\cdot \mathrm{d}\mathbf{f} + \int \boldsymbol{\omega}\cdot(\,(\mathbf{x}-\mathbf{x}_S)\wedge \mathrm{d}\mathbf{f}\,) + \int \boldsymbol{\omega}\cdot \mathrm{d}\boldsymbol{\gamma} \quad , \\ &= \mathbf{v}_S\cdot\mathbf{F} + \boldsymbol{\omega}\cdot\boldsymbol{\Gamma}_S \quad .\end{aligned}$$

Therefore:

$$\Pi \equiv \frac{\mathrm{d}W}{\mathrm{d}t} = \mathbf{v}_S\cdot\mathbf{F} + \boldsymbol{\omega}\cdot\boldsymbol{\Gamma}_S \quad . \tag{26.04.11}$$

It immediately follows that the total power of internal forces is always zero, because the total force, $\mathbf{F}$, and the total torque with respect to any pole S, $\boldsymbol{\Gamma}_S$, of a system of internal Force|Torque is zero:

$$\mathbf{F}^{(\mathrm{I})} = \boldsymbol{\Gamma}_S^{(\mathrm{I})} = 0 \implies \Pi^{(\mathrm{I})} = 0 \quad .$$

DRAFT-IN-PROGRESS

CC BY NC ND

Therefore, for any body-fixed point S:

$$\Pi \equiv \frac{\mathrm{d}W}{\mathrm{d}t} = \mathbf{v}_S \cdot \mathbf{F}^{(\mathrm{E})} + \boldsymbol{\omega} \cdot \boldsymbol{\Gamma}_S^{(\mathrm{E})} \quad . \tag{26.04.12}$$

→ 1447 1448

Equation (26.04.12) shows the important results that, for a rigid-body, the work/power only depend on the external Force|Torque and, actually, only on total Force|Torque from external agents.

The classical rigid-body is a special case of the above with $\boldsymbol{\gamma}[\mathrm{x}] = 0$.

26.04.05.02 Work and Power on a Rigid-Nonrigid-Body

The Einsten-deHaas effect involves the magnetic moment vector of the molecules changing direction.

26.04.05.03 Third Cardinal Equation

Equation (26.04.12), when used with the Center-Of-Mass, $S = CM$, gives:

$$\Pi = \mathbf{V}_{\mathrm{CM}} \cdot \mathbf{F}^{(\mathrm{E})} + \boldsymbol{\omega} \cdot \boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} \quad . \tag{26.04.13}$$

The first and second **Cardinal Equations** , and the result discussed in section § 26.07.01, imply:

$$\mathbf{V}_{\mathrm{CM}} \cdot \mathbf{F}^{(\mathrm{E})} + \boldsymbol{\omega} \cdot \boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} = M\, \mathbf{V}_{\mathrm{CM}} \cdot \frac{\mathrm{d}\mathbf{V}_{\mathrm{CM}}}{\mathrm{d}t} + \boldsymbol{\omega} \cdot \frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t} = \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{M\mathbf{V}_{\mathrm{CM}}^2}{2}\right) + \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\left(\boldsymbol{\omega} \cdot \mathbb{I}_{\mathrm{CM}} \cdot \boldsymbol{\omega}\right)}{2}\right) = \frac{\mathrm{d}\mathcal{K}_{\mathrm{CM}}}{\mathrm{d}t} + \frac{\mathrm{d}\mathcal{K}'}{\mathrm{d}t} = \frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} \equiv \Pi \quad , \tag{26.04.14}$$

→ 1447

where the last equality is actually the third **Cardinal Equation** for a rigid body, deduced by only using the first and second equations, as well as the peculiar properties of the rigid-body.

Note the importance of the results discussed in section § 26.07.01 for the above derivation, because the inertia Matrix|Tensor is time-independent in the body-fixed Reference Frame while the time-derivative in the **Cardinal Equations** are in the absolute Reference Frame.

Clearly, in the case of a rigid-body, the third **Cardinal Equation** is a consequence of the first and second **Cardinal Equations** . In fact, equation (26.04.14), the third **Cardinal Equation** , has been derived only from the first and second **Cardinal Equations** . Therefore, for a rigid-body, the third **Cardinal Equation** is a consequence of the first and second **Cardinal Equations** , not an independent one.

The derivation of the latter equation also shows that the total force changes the kinetic energy of the Center-Of-Mass, and only that one, while the total torque with respect to the Center-Of-Mass changes the kinetic energy relative to the Center-Of-Mass, and only that one. In fact, the above derivation shows that the two addenda in the third **Cardinal Equation** give separately the change of the kinetic energy of the Center-Of-Mass and relative to the center of mass:

$$\frac{\mathrm{d}\mathcal{K}_{\mathrm{CM}}}{\mathrm{d}t} = \mathbf{V}_{\mathrm{CM}} \cdot \mathbf{F}^{(\mathrm{E})} \qquad \frac{\mathrm{d}\mathcal{K}'}{\mathrm{d}t} = \boldsymbol{\omega} \cdot \boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} \quad . \tag{26.04.15}$$

→ 1448

DRAFT - IN PROGRESS

CC BY NC ND

26.04.05.04 Free Rigid-Body

In case the rigid-body is free, $\mathbf{0} = \mathbf{F}^{(\mathrm{E})} = \boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})}$:

- the Center-Of-Mass moves with constant velocity, and therefore there is a Reference Frame such that the Center-Of-Mass is fixed;
- in any Reference Frame such that the Center-Of-Mass is fixed, the rigid-body rotates around the Center-Of-Mass.

26.04.05.05 Pole at the Center-Of-Mass of the Rigid-Body

In case the resultant external torque with respect to the Center-Of-Mass is zero, $\boldsymbol{\Gamma}_{\mathrm{CM}} = \mathbf{0}$, equation (26.04.15) implies:

$$\boldsymbol{\Gamma}_{\mathrm{CM}} = \mathbf{0} \implies \frac{\mathrm{d}\mathcal{K}'}{\mathrm{d}t} = 0 \implies \mathcal{K}' = \text{constant} \quad , \tag{26.04.16}$$

→ 1452

that is, the kinetic energy about the Center-Of-Mass is constant.

26.04.05.06 Pole at a Fixed and Body-Fixed Point of the Rigid-Body

In case the rigid-body has a fixed and body-fixed point, S, and the resultant external torque with respect to S is zero, $\boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})} = \mathbf{0}$, equations (26.04.06), (26.04.12), (26.04.15) imply, as $\mathbf{v}_{\mathrm{S}} = \mathbf{v}_{\mathrm{S}}{}' = 0$:

$$\mathbf{0} = \boldsymbol{\omega} \cdot \boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})} = \boldsymbol{\omega} \cdot \frac{\mathrm{d}\mathbf{L}_{\mathrm{S}}}{\mathrm{d}t} = \Pi = \frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\left(\boldsymbol{\omega} \cdot \mathbb{I}_{\mathrm{S}} \cdot \boldsymbol{\omega}\right) = \frac{\mathrm{d}\mathcal{K}}{\mathrm{d}t} \implies \mathcal{K} = \text{constant} \quad , \tag{26.04.17}$$

→ 1452

that is, the total kinetic energy is constant.

DRAFT-IN-PROGRESS

26.05 Statics of Rigid-Bodies

© - QUOTE

©|J.L. Synge and B.A. Griffiths|Principles of Mechanics|*slightly adapted*|

It is important to note that the equilibrium equations are three in number, for plane problems. This means that, in any problem concerning the plane statics of a rigid-body, we can find three unknowns and no more; actually three maximum, and less than three in case the forces are unidimensional. If there are more than three unknowns, the problem is a statically indeterminate problem, which means that it cannot be solved by means of the conditions of equilibrium alone. Similarly, equilibrium equations are six in number, for space problems and one can get at most six unknowns.
Apparently our mathematical methods have failed us; they have not provided us with the answer to a question of physical interest. The fault actually lies in the selection of a mathematical model. rigid-bodies do not exist in nature, and this problem is one where the use of a rigid-body as a mathematical model is not justified. We should take an elastic bar as a model instead

The basic principle of static equilibrium states that a system is in equilibrium if and only if all its parts are in equilibrium as well; it obviously applies to rigid-bodies as well.

For general systems,

$$\mathbf{F}^{(\mathrm{E})} = 0 \qquad \boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})} = 0 \quad ,$$

is a necessary but non sufficient condition for equilibrium. For rigid-bodies, it is a sufficient condition for equilibrium.

A rigid-body has at most six degrees of freedom, for instance, the Center-Of-Mass position and the three Euler angles; if it is constrained it may have less than six.

A rigid-body is in static equilibrium if and only if, in some Inertial Reference Frame , the velocity of all the points of the rigid-body are zero.

Whenever at least three not-aligned points of a rigid-body have zero velocity, the rigid-body is in equilibrium. In fact, if three not-aligned points of a rigid-body have zero velocity, then all the points have zero velocity. Moreover, the angular velocity, thanks to equation (26.03.01), must be aligned with the three sides of the triangle defined by the three not-aligned points at rest; therefore the angular velocity is zero.

A rigid-body is in static equilibrium if and only if, at some time: the velocity of any one of its points, $\mathbf{v}_{\mathrm{S}}$, is zero, in some Inertial Reference Frame ; the angular velocity, $\boldsymbol{\omega}$, is zero; the resultant of external forces, $\mathbf{F}^{(\mathrm{E})}$, is zero; the resultant external torque with respect to the pole S, $\boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})}$, is zero. In fact, in this case,

$$\begin{aligned}
&\mathbf{v}_{\mathrm{S}} = 0 \quad \boldsymbol{\omega} = 0 \quad \longrightarrow \quad \mathbf{v}_{\mathrm{P}} = 0 && \text{all points of the rigid-body have zero velocity;} \quad ,\\
&\qquad\qquad \longrightarrow \quad \mathbf{V}_{\mathrm{CM}} = 0 && \text{stays zero, due to lack of unbalanced external forces;} \quad ,\\
&\mathbf{F}^{(\mathrm{E})} = 0 \quad \boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})} = 0 \quad \longrightarrow \quad \boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} = 0 && \text{law of transformation of momentum;} \quad ,\\
&\boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} = 0 \quad \boldsymbol{\omega} = 0 \quad \longrightarrow \quad \mathbf{L}' = 0 && \text{stays zero, due lack of unbalanced external Force|Torque} \quad .
\end{aligned}$$

For 3D problems, the first and second **Cardinal Equations** provide, in general, six scalar equations, and therefore equating to zero the sum of external forces and torques the necessary equilibrium condition becomes, for rigid-bodies, also a sufficient one. Therefore no more than six unknowns can be determined by requiring static equilibrium for a space rigid-body.

For 2D problems, the first and second **Cardinal Equations** provide, in general, three scalar equations, therefore no more than three unknowns can be determined by requiring static equilibrium for a planar rigid-body problem.

Law Problems

For 1D problems, the first and second **Cardinal Equations** provide, in general, one scalar equation, therefore no more than one unknown can be determined by requiring static equilibrium for a linear rigid-body problem.

Obviously, for rigid-bodies, the third **Cardinal Equation** does not change the conclusions above as it is dependent on the first two.

DRAFT-IN-PROGRESS

26.06 Euler Equations

Consider the second **Cardinal Equation** with pole at the Center-Of-Mass of a rigid-body:

$$\boxed{\boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = \frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t}} \quad . \tag{26.06.01}$$

→ 1451 1469

It is convenient to project equation (26.06.01) onto an orthonormal Coordinate System rigidly fixed with the rigid-body, in order to have time-independent elements of the inertia Matrix|Tensor. The inertia Matrix|Tensor elements thus represent just mass-geometrical properties of the rigid-body, calculated once for all. Moreover, among all the possible Coordinate System, it is useful to use a Coordinate System made of principal axes of inertia rigidly fixed to the rigid-body, unless stated otherwise. In other words, the **Cardinal Equations** are projected onto the moving principal axes.

One can then project the vector equation (26.06.01),

$$\boxed{\boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = \frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t} \equiv \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{\mathrm{A}}\mathbf{L}' = \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{\mathrm{R}}\mathbf{L}' + \boldsymbol{\omega}\wedge\mathbf{L}'} \quad , \tag{26.06.02}$$

→ 1451

onto the principal axes of inertia of the rigid-body.

Note that vector equation (26.06.01) is written in an Inertial Reference Frame , and no inertial forces appear. The second **Cardinal Equation** written in an Inertial Reference Frame is then projected onto the principal axes of inertia of the body, which is a orthonormal Coordinate System moving in the inertial Laboratory Reference Frame, which causes the equation to be transformed into equation (26.06.02). The orthonormal Coordinate System rigidly fixed to the rigid-body defines a non-Inertial Reference Frame , but the second cardinal equation is not written in this non-Inertial Reference Frame .

Therefore: Euler equations use a moving orthonormal Coordinate System, fixed to the rigid-body, to describe the physics in the inertial Laboratory frame.

The following notations will be used in this section:

$$I \equiv \mathbb{I}_{\mathrm{CM}} \qquad I_k \equiv \mathbb{I}_{\mathrm{CM}}\dot{k}\dot{k} \quad .$$

The relation between angular velocity and angular momentum is:

$$\dot{\mathbf{e}'}_i \cdot \mathbf{L}' = \mathbb{I}_{\mathrm{CM}}\dot{i}\dot{j}\dot{\omega'}_j \quad .$$

The Euler equations follow, in terms of the components with respect to a Coordinate System fixed on the rigid-body:

$$\mathbb{I}_{\mathrm{CM}}{}_{11}\dot{\omega}'_1 + \omega'_2\omega'_3\left(\mathbb{I}_{\mathrm{CM}}{}_{33} - \mathbb{I}_{\mathrm{CM}}{}_{22}\right) = \mathbf{e}'_1 \cdot \boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} \tag{26.06.03}$$

→ 1453

$$\mathbb{I}_{\mathrm{CM}}{}_{22}\dot{\omega}'_2 + \omega'_3\omega'_1\left(\mathbb{I}_{\mathrm{CM}}{}_{11} - \mathbb{I}_{\mathrm{CM}}{}_{33}\right) = \mathbf{e}'_2 \cdot \boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} \tag{26.06.04}$$

$$\mathbb{I}_{\mathrm{CM}}{}_{33}\dot{\omega}'_3 + \omega'_1\omega'_2\left(\mathbb{I}_{\mathrm{CM}}{}_{22} - \mathbb{I}_{\mathrm{CM}}{}_{11}\right) = \mathbf{e}'_3 \cdot \boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} \quad .$$

Euler equations are a set of three non-linear equations, whose solution, in general, is rather difficult.

Clearly, the same procedure of using a basis fixed to the rigid-body can be applied to the first **Cardinal Equation** .

DRAFT IN PROGRESS

26.06.01
Free Tops

A rigid, rotating body is usually called a top. A top is called symmetric top if two of its principal moments of inertia are equal. If the three principal moments of inertia are all equal the top is called spherical top. If the three principal moments of inertia are all different the top is called asymmetrical top.

Two different cases arise which can be treated, formally, in the same way, because in both cases the second **Cardinal Equation** reduces to the short-form:

$$\boldsymbol{\Gamma}_{\mathrm{P}}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{L}_{\mathrm{P}}}{\mathrm{d}t} \quad ,$$

with $P \equiv CM$, the Center-Of-Mass, or $P \equiv S$, any fixed and body-fixed point.

One can distinguish between the free top and the heavy top:

- the free top assumes that no external Force|Torque act on the body, so that the torque with respect to some fixed point vanishes;
- the heavy top is acted on by external Force|Torque, for example gravity, centrifugal forces, friction forces, ...

The use of any other pole must take into account the second **Cardinal Equation** for a generic pole.

26.06.01.01 Zero Resultant External Force|Torque With Respect to the Center-Of-Mass

In this case:

$$\boxed{\mathbf{L}' = \underset{\mathrm{CM}}{\mathbb{I}} \cdot \boldsymbol{\omega} \qquad \mathcal{K}' = \frac{1}{2}\left(\boldsymbol{\omega} \cdot \underset{\mathrm{CM}}{\mathbb{I}} \cdot \boldsymbol{\omega}\right)} \quad .$$

Moreover, from the second **Cardinal Equations** and from the third **Cardinal Equation** in the form of equation (26.04.16), one has, whenever $\boldsymbol{\Gamma}_{\mathrm{CM}}^{(\mathrm{E})} = 0$; there are two constants of motion of Euler equations:

$$\boxed{\mathbf{L}' = \underset{\mathrm{CM}}{\mathbb{I}} \cdot \boldsymbol{\omega} = \text{constant} \qquad \mathcal{K}' = \frac{1}{2}\left(\boldsymbol{\omega} \cdot \underset{\mathrm{CM}}{\mathbb{I}} \cdot \boldsymbol{\omega}\right) = \text{constant}} \quad .$$

Note that $\mathbf{L}'$ is constant in the Laboratory Frame, not necessarily in the rigid-body frame. On the other hand, the scalar $\mathcal{K}'$ is the same in both Reference Frames, as well as $\mathbf{L}' \cdot \mathbf{L}'$. In the body-fixed Reference Frame the angular momentum vector, in general, precesses.

The integrals of motions are not four in number, because for a rigid body the third **Cardinal Equation** is not independent from the second one.

Note that the total kinetic energy might be non constant, as $\mathbf{F}^{(\mathrm{E})}$, in general, might be different from zero.

Example: a rigid-body falling in free rotation in a uniform gravitational field.

The Center-Of-Mass system might be a non-inertial one but this is not relevant.

26.06.01.02 Zero Resultant External Force|Torque With Respect to a Fixed and Body-Fixed Point

In this case, let S be a fixed and body-fixed point, $\mathbf{v}_{\mathrm{S}} = \mathbf{v}_{\mathrm{S}}{}' = 0$, and:

$$\boxed{\mathbf{L}_{\mathrm{S}} = \underset{\mathrm{S}}{\mathbb{I}} \cdot \boldsymbol{\omega} \qquad \mathcal{K} = \frac{1}{2}\left(\boldsymbol{\omega} \cdot \underset{\mathrm{S}}{\mathbb{I}} \cdot \boldsymbol{\omega}\right)} \quad .$$

Moreover, from the second **Cardinal Equations** and from the third **Cardinal Equation** in the form of equation (26.04.17), one has, whenever $\boldsymbol{\Gamma}_{\mathrm{S}}^{(\mathrm{E})} = 0$:

$$\boxed{\mathbf{L}_{\mathrm{S}} = \underset{\mathrm{S}}{\mathbb{I}} \cdot \boldsymbol{\omega} = \text{constant} \qquad \mathcal{K} = \frac{1}{2}\left(\boldsymbol{\omega} \cdot \underset{\mathrm{S}}{\mathbb{I}} \cdot \boldsymbol{\omega}\right) = \text{constant}} \quad ,$$

that is there are two constants of motion of Euler equations.

Note that $\mathbf{L}_{\mathrm{S}}$ is constant in the Laboratory Frame, not necessarily in the rigid-body frame. On the other hand, the scalar $\mathcal{K}$ is the same in both Reference Frames, as well as $\mathbf{L}_{\mathrm{S}} \cdot \mathbf{L}_{\mathrm{S}}$. In the body-fixed Reference Frame the angular momentum vector, in general, precesses.

DRAFT - IN PROGRESS

The integrals of motions are not four in number, because for a rigid body the third **Cardinal Equation** is not independent from the second one.

Note that it might be $\mathbf{F}^{(\mathrm{E})} \neq 0$, in general, because the point might be constrained at S and $\mathcal{K}_S$ is the total kinetic energy, a constant.

26.06.02
Euler Equations: Permanent Rotations

In case of a free body, $\boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = 0$, Euler equations (equations (26.06.03), (26.06.03), (26.06.03)) show that, a motion with constant angular velocity, a permanent rotation, is possible if and only if, $\boldsymbol{\omega}$ it is parallel to one of the principal axes of inertia.

In fact, under the previous hypothesis, $\dot{\boldsymbol{\omega}} = 0$, implies:

- for $I_1 \neq I_2 \neq I_3$, that at least two of the components of $\boldsymbol{\omega}$ must be zero;
- for $I_1 = I_2 \neq I_3$, that either $\omega_3 = 0$, that is ω lies in the $1-2$ plane, where all axes are principal axes, or $\omega_1 = \omega_2 = 0$, that is ω is parallel to the 3 axis;
- for $I_1 = I_2 = I_3$, any constant $\boldsymbol{\omega}$ can be a solution, but also any axis is a principal axis.

An alternative way to demonstrate the same result is to observe that the constancy of $\boldsymbol{\omega}$, in the Laboratory Frame, implies (from Poisson relations for the angular velocity)

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \boldsymbol{\omega} = \mathbf{0} \Longrightarrow \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \boldsymbol{\omega} = \mathbf{0} \Longrightarrow \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \mathbf{L}' = \mathbf{0} \quad ,$$

because the time derivative of the angular velocity vector is the same in both the laboratory and rigid-body Reference Frame, and therefore

$$\mathbf{0} = \boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{A}} \mathbf{L}' = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{\mathrm{R}} \mathbf{L}' + \boldsymbol{\omega} \wedge \mathbf{L}' = \boldsymbol{\omega} \wedge \mathbf{L}' \Longrightarrow \boldsymbol{\omega} \parallel \mathbf{L}' \quad .$$

26.06.03
Euler Equations: The Free Spherical Top

One first case when Euler equations are easily solved is the case of a free spherical top

$$\boxed{I_1 = I_2 = I_3 \equiv I} \quad .$$

In this case Euler equations are trivially solved:

$$\boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = \frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t} = I \frac{\mathrm{d}\boldsymbol{\omega}}{\mathrm{d}t} \quad ,$$

$$\boldsymbol{\Gamma}^{(\mathrm{E})}_{\mathrm{CM}} = 0 \Longrightarrow \boldsymbol{\omega} = \text{constant} \quad .$$

26.06.04
Euler Equations: The Free Symmetrical Top

One second case when Euler equations are easily solved is the case of the free symmetrical top. A symmetrical top is a rigid-body with two principal moment of inertia equal and different from the third one:

$$\boxed{I_1 = I_2 \equiv I \neq I_3} \quad .$$

Note that a sufficient condition for a body to be a symmetrical top is that the body has an axis of revolution, but this condition is by no means necessary (e.g. one homogeneous cube).

Read § 26.07.16 for the detailed solution.

PLEASE-EN-PROGRESS

CC BY NC ND

26.06.05
Euler Equations: The Free Asymmetrical Top

Whenever

$$\boxed{I_1 \neq I_2 \neq I_3} \quad ,$$

the system is called an asymmetrical, or triaxial top.

A general solution, in the body-fixed Reference Frame, in this case is complex but can be found by quadrature by making use of the conservation of kinetic energy and module of the angular momentum. In fact, by using the two constants of motion, the three Euler equations can be reduced to one equation, which can be integrated via elliptic integrals.

From the solution in the body-fixed Reference Frame, the solution in the Laboratory Frame can be also determined.

26.06.06
Euler Equations: Deficiencies

The solutions of Euler equations yield the time variation of the angular velocity as seen from the frame fixed with the rigid-body. The position of the body is unknown: Euler equations do not tell us where the body is at time t.

A second but related deficiency appears when the applied moment of external forces is not zero: in fact its components will not generally be known, since the orientation of the body is unknown. In such a case, one cannot even start the solution.

These difficulties disappear when the motion of the body is given, and we wish to find the moments that are being applied to the body to permit that motion: in such a case, Euler equations give the answer immediately.

26.06.07
Stability of the Motion of a Free Rigid-Body Around a Principal Axis

This § is referenced at pages:
[1405]

Any rigid-body with three different principal moments of inertia is stable to small perturbations when rotating about the principal axes with the largest and smallest moments; it is unstable when rotating about the axis with the intermediate moment. If two of the principal moments are equal the body is only stable to small perturbations when rotating about the principal axis whose moment is different from the other two.

WORKED SOLUTION

Assume $I_z > I_y > I_x$ and let $\{\widehat{\mathbf{e}}_1, \widehat{\mathbf{e}}_2, \widehat{\mathbf{e}}_3\}$ be the Reference Frame rigidly fixed to the rigid-body.
Start with the body rotating around the z axis: $\omega = \omega_0 \widehat{\mathbf{e}}_3$. The system is given a small perturbation such that $\omega = \omega_{x0}\widehat{\mathbf{e}}_1 + \omega_{y0}\widehat{\mathbf{e}}_2 + \omega_0\widehat{\mathbf{e}}_3$ with $\omega_{y0} \ll \omega_0$ and $\omega_{x0} \ll \omega_0$.
Replace the perturbed ω into the free Euler equations and retain only first-order terms. It follows that ω_0 stays constant while ω_{x0} and ω_{y0} satisfy harmonic motions equations. Therefore the motion is stable.
The same conclusion is obtained starting from a rotation around the x axis.
On the other hand, when starting from a rotation around the y axis, one find an exponentially growing solution. Therefore the motion is unstable.
A similar reasoning leads to the conclusion when two of the principal moments are equal: the body is only stable to small perturbations when rotating about the principal axis whose moment is different from the other two.
Clearly, when all three principal moments are equal, the motion is stable as every axis is a possible rotational axis with constant angular velocity.

DRAFT - IN - PROGRESS

26.07 Examples and Physical Applications

26.07.01 Absolute and Relative Derivative

This § is referenced at pages:
[1447, 1447]

Let us show that:

$$\boldsymbol{\omega}\cdot\frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t}=\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\left(\boldsymbol{\omega}\cdot\mathbb{I}_{\mathrm{CM}}\cdot\boldsymbol{\omega}\right)}{2}\right)\quad .$$

The left-hand side has the same value whether one uses the absolute of relative time-derivative, because the scalar product with $\boldsymbol{\omega}$ sets to zero the $\boldsymbol{\omega}\wedge\mathbf{L}'$ term in the Poisson relation. Also, for both terms either the absolute or the relative time-derivative can be used, because they are scalars.

Therefore the relative time-derivative and the symmetry of $\mathbb{I}_{\mathrm{CM}}$ imply:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\left(\boldsymbol{\omega}\cdot\mathbb{I}_{\mathrm{CM}}\cdot\boldsymbol{\omega}\right)}{2}\right)=\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\omega'_k\,\mathbb{I}_{\mathrm{CM}kj}\,\omega'_j}{2}\right)=\frac{1}{2}\left(\dot{\omega}'_k\,\mathbb{I}_{\mathrm{CM}kj}\,\omega'_j+\omega'_k\,\mathbb{I}_{\mathrm{CM}kj}\,\dot{\omega}'_j\right)=\omega'_k\,\mathbb{I}_{\mathrm{CM}kj}\,\dot{\omega}'_j=\omega'_k\,\frac{\mathrm{d}L'_k}{\mathrm{d}t}\quad .$$

26.07.02 Rigid-Bodies With Mass

Even if a rigid-body is ideally rigid, Force|Torque must be present internally to keep the body rigid. Ideally, these Force|Torque can have arbitrary strength, but in real life, when modeling any body as a rigid-body one should take into account that internal Force|Torque, above certain limits, cannot keep the body rigid anymore, eventually leading to breaking.

Determine the distribution of internal Force|Torque for a rigid thin cylindrical bar of mass M and length L, under its own weight, in the following cases:

- bar resting horizontally on two vertical supports, sustaining the bar at its two extremes;
- as above with an additional support at the middle of the bar;
- as above but with the support at a generic position between the two extremes;
- the bar as an horizontal cantilevered beam (read § 27.07.11);
- as above, with a mass m hanging at the free end (read § 27.07.11);
- as above but with the mass hanging at an arbitrary point;
- bar statically hanging vertically, sustained at one end (read § 27.07.09);
- bar hanging vertically, sustained at one end, and oscillating as a physical pendulum;
- the falling chimney (read § 26.07.09).

At any geometrical section of the bar, perpendicular to the axis of the bar, normal and tangential forces, as well as torsion and flexing torques are acting (read § 24.18.02).

DRAFT-IN-PROGRESS

26.07.03
Momento D'inerzia Di Un'asta Sottile

Determinare, usando solo le proprietà generali dei momenti di inerzia, il momento d'inerzia di un'asta sottile di massa M e lunghezza L rispetto ad un asse perpendicolare all'asta passante per il suo centro.

WORKED SOLUTION

Sia I_c il momento di inerzia rispetto ad un asse perpendicolare all'asta e passante per il centro. Sia I_e il momento di inerzia rispetto ad un asse perpendicolare all'asta e passante per un estremo. Si ha

$$I_c(M,L) = 2I_e(\frac{M}{2},\frac{L}{2}) = \frac{1}{4}I_e(M,L)$$

per l'additività dei momenti di inerzia rispetto ad un asse e per la proporzionalità del momento di inerzia alla massa e al quadrato delle dimensioni. Inoltre dal teorema di Steiner

$$I_e(M,L) = I_c(M,L) + \frac{ML^2}{4}$$

Mettendo a sistema le due equazioni si trova

$$I_c(M,L) = \frac{ML^2}{12} \qquad I_e(M,L) = \frac{ML^2}{3}$$

26.07.06
Momento Angolare Di Un Manubrio Ruotante

This § is referenced at pages:
[1459]

Read also § 26.07.07.03.

Un manubrio è formato da un'asta rigida di massa trascurabile e lunghezza $2r$ che connette due masse puntiformi di massa m. L'asta ruota con velocità angolare costante ω attorno ad un asse verticale passante per il centro dell'asta formando un angolo costante θ con l'asse di rotazione.

1. Determinare l'espressione del momento angolare dell'asta rispetto al suo centro.
2. Determinare il momento richiesto per mantenere l'asta in rotazione a velocità angolare costante.

WORKED SOLUTION

Let $\widehat{\mathbf{n}}$ be the oriented unit vector along the rotation axis.
Sia ℓ il momento angolare di una delle due masse rispetto al centro dell'asta ed $\mathbf{r}$ il vettore posizione della massa rispetto al centro dell'asta.

$$\widehat{\mathbf{n}} \equiv \widehat{\mathbf{e}}_3 \qquad |\widehat{\mathbf{n}}| = 1 \qquad \widehat{\mathbf{e}}_r \equiv \frac{\mathbf{r}}{r} \qquad \widehat{\mathbf{u}}_r \equiv \mathbf{n}\wedge(\mathbf{r}\wedge\mathbf{n}) \qquad |\widehat{\mathbf{u}}_r| = 1 \quad .$$

T.I.N.-PROCESS

CC BY NC ND

Si ha

$$\boldsymbol{\ell} = \mathbf{r}\wedge\mathbf{p} = m\,\mathbf{r}\wedge\mathbf{v} = m\,\mathbf{r}\wedge(\boldsymbol{\omega}\wedge\mathbf{r}) = m\left[\boldsymbol{\omega}r^2 - (\boldsymbol{\omega}\cdot\mathbf{r})\,\mathbf{r}\right] = m\left[\boldsymbol{\omega}r^2 - \omega r\cos[\theta]\,\mathbf{r}\right]$$

Il momento angolare del sistema è allora un vettore che ha una componente parallela alla velocità angolare ω ed una componente proporzionale al vettore posizione $\mathbf{r}$ che ruota attorno all'asse di rotazione di moto circolare uniforme. La componente ortogonale all'asse di rotazione si annulla se e solo se $\theta = \pi/2$. Dalla relazione ricavata si deduce il modulo al quadrato del momento angolare ℓ

$$\ell^2 = \mathbf{l}\cdot\mathbf{l} = \left(m\omega r^2\sin[\theta]\right)^2$$

Il modulo di $\boldsymbol{\ell}$ è quindi costante mentre la direzione, se $\theta \neq \pi/2$, varia. Si possono anche ricavare le componenti del momento angolare parallela e perpendicolare all'asse di rotazione (componente radiale)

$$\boldsymbol{\ell}_{\parallel} = \boldsymbol{\ell}\cdot\widehat{\mathbf{e}}_z = m\omega r^2\sin^2\theta$$

$$\boldsymbol{\ell}_{\perp} = \boldsymbol{\ell}\cdot\widehat{\mathbf{u}}_r = -m\omega r^2\sin[\theta]\cos[\theta]$$

Si osservi che il vettore momento angolare va considerato un vettore applicato nella posizione del punto materiale $\mathbf{r}$. Il segno di $\boldsymbol{\ell}_{\perp}$ dipende dal valore di θ. Il momento angolare della seconda massa è uguale a quello della prima massa in quanto per passare da una all'altra occorre effettuare le sostituzioni $\mathbf{r} \to -\mathbf{r}$ e $\mathbf{v} \to -\mathbf{v}$. Quindi per il momento totale si ha $\mathbf{L} = 2\boldsymbol{\ell}$. Si verifica anche che $\mathbf{L}$ è ortogonale ad $\mathbf{r}$ cioè all'asta, essendo $\mathbf{l}\cdot\mathbf{r} = 0$. Solo nel caso $\theta = \pi/2$ si ha $\mathbf{L} \parallel \boldsymbol{\omega}$.
La seconda **Cardinal Equation** (24.06.06), essendo il polo fisso, fornisce

$$\boldsymbol{\Gamma}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{L}}{\mathrm{d}t} = -2m\omega r\cos[\theta]\,\mathbf{v} = -2m\omega r\cos[\theta]\,(\boldsymbol{\omega}\wedge\mathbf{r})$$

Da questa relazione risulta che non è necessario alcun momento per la rotazione con $\boldsymbol{\omega}$ e θ costante se e solo se $\theta = \pi/2$. Per ogni altro angolo $\mathbf{L}$ non è costante ma lo è il suo modulo. Per $\theta \neq \pi/2$ è necessario applicare un momento parallelo alla velocità $\mathbf{v}$, cioè perpendicolare all'asse di rotazione, che può essere fornito, ad esempio, da una coppia di forze che giacciano nel piano definito dall'asse di rotazione e dall'asta.
Se il giunto si rompe improvvisamente non esiste più alcun momento esterno esercitato e il momento angolare si conserva. L'asta si mette a ruotare con velocità angolare parallela al momento angolare e di modulo $\omega' = \omega\cos[\theta]$.
Nel caso θ è costante ma $\boldsymbol{\omega}$ cambia modulo mantenendo però direzione costante.
Come caso particolare delle relazioni generali dedotte sopra si ha che, per $\theta = \pi/2$ per variare il modulo di $\boldsymbol{\ell}$ occorre variare ω e serve un momento parallelo all'asse. Per variare la direzione di $\boldsymbol{\ell}$ senza variare il modulo occorre un momento perpendicolare all'asse di rotazione.

26.07.07
Motion Around a Fixed Axis

Consider a rigid-body constrained to rotate around a fixed axis.

26.07.07.01 Kinematics

Take an infinitesimal mass element, P, with mass, $\mathrm{d}m \equiv \rho\,\mathrm{d}V$, whose position is described by the position vector $\mathbf{r}$ with respect to any arbitrary point, O, on the rotations axis and having a velocity $\mathbf{v}$. Let the z axis be along the angular velocity $\boldsymbol{\omega} \equiv \omega\widehat{\mathbf{n}}$. The velocity of the point P is:

$$\mathbf{v} = \mathbf{v}_0 + \boldsymbol{\omega}\wedge\mathbf{r} = \boldsymbol{\omega}\wedge\mathbf{r} \quad .$$

We assume that the angle θ between the position vector $\mathbf{r}$ and the angular velocity $\boldsymbol{\omega}$ is fixed for any infinitesimal mass element, as it is appropriate for a rigid-body.

Its angular momentum is:

$$\mathrm{d}\mathbf{L} \equiv \mathbf{r}\wedge\mathrm{d}\mathbf{p} = \mathrm{d}m\,\mathbf{r}\wedge\mathbf{v} = \mathrm{d}m\,\mathbf{r}\wedge(\boldsymbol{\omega}\wedge\mathbf{r}) = \mathrm{d}m\left(\boldsymbol{\omega}r^2 - (\boldsymbol{\omega}\cdot\mathbf{r})\,\mathbf{r}\right) \quad .$$

PRESS

CC BY NC ND

The projection of the angular momentum along the z axis, is:

$$\mathrm{d}\mathbf{L}\cdot\hat{\mathbf{n}} \equiv \frac{\boldsymbol{\omega}\cdot\,\mathrm{d}\mathbf{L}}{\omega} \equiv \frac{\mathrm{d}m}{\omega}\left(\omega^2 r^2 - (\,\boldsymbol{\omega}\cdot\mathbf{r})^2\right) = \mathrm{d}m\omega r^2\sin^2[\theta] = \mathrm{d}m\omega r_\perp^2 \quad .$$

We also have:

$$\begin{aligned}
|\boldsymbol{\ell}| &= \mathrm{d}mrv = \mathrm{d}mr^2\omega\sin[\theta] \quad , \\
|\boldsymbol{\ell}| = 0 \qquad &\Leftrightarrow \qquad \sin[\theta] = 0 \quad , \\
\ell_z = |\boldsymbol{\ell}|\sin[\theta] &= \mathrm{d}mr^2\omega\sin^2[\theta] \quad , \\
\ell_\perp &= \mathrm{d}mr^2\omega\sin[\theta]\cos[\theta] \quad , \\
\ell_\perp = 0 \qquad &\Leftrightarrow \qquad \theta = \{0, \pi/2, \pi\} \quad .
\end{aligned}$$

The integration over all the rigid-body gives:

$$\mathbf{n}\cdot\mathbf{L} = \iiint \omega r_\perp^2\,\mathrm{d}m = \iiint \rho\omega r_\perp^2\,\mathrm{d}V = \omega\iiint \rho r_\perp^2\,\mathrm{d}V \equiv I_{zz}\omega \quad .$$

Therefore the component of the angular momentum along the angular velocity is proportional to the angular velocity and to a factor depending only on the geometry and mass distribution of the rigid-body and on the location of the fixed rotation axis with respect to the rigid-body. The quantity

$$I_{zz} \equiv \iiint \rho r_\perp^2\,\mathrm{d}V \quad ,$$

is called the (axial) moment of inertia of the rigid-body with respect to the z axis.

Note that, in general the angular momentum is not parallel to the angular velocity:

$$\mathbf{L} \nparallel \boldsymbol{\omega} \quad .$$

However, if the rotation axis is a symmetry axis of the rigid-body then the angular momentum is parallel to the angular velocity, because for any mass element there is an identical symmetrical mass element such that the pair gives an angular momentum parallel to the angular velocity.

Actually it is not necessary that the axis is fixed in space: it is sufficient that the axis moves parallel to itself in such a way that the angular velocity does not change its direction.

The kinetic energy is:

$$k \equiv \frac{1}{2}\mathrm{d}mv^2 = \frac{1}{2}\mathrm{d}m\,(\,\boldsymbol{\omega}\wedge\mathbf{r})^2 = \frac{1}{2}\mathrm{d}m\left(\omega^2 r^2 - (\,\boldsymbol{\omega}\cdot\mathbf{r})^2\right) = \frac{1}{2}\mathrm{d}m\omega^2 r_\perp^2 \quad .$$

The integration over all the rigid-body gives:

$$\mathcal{K} = \frac{1}{2}\iiint \omega^2 r_\perp^2\,\mathrm{d}m = \frac{1}{2}I_{zz}\omega^2 \quad .$$

The kinetic energy is thus expressed in terms of the angular velocity and the (axial) moment of inertia.

26.07.07.02 Dynamics

Applying the second **Cardinal Equation** of dynamics with any pole on the rotation axis, as we can choose any arbitrary pole on the axis, the pole will not be explicitly written in the following equations. As the rotation axis is supposed to be fixed, we can write:

$$\boldsymbol{\Gamma}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{L}}{\mathrm{d}t} \Longrightarrow \Gamma_z^{(\mathrm{E})} = \frac{\mathrm{d}L_z}{\mathrm{d}t} = I_{zz}\dot{\omega} \quad .$$

Even when the angular velocity is constant, if $\ell_\perp \neq 0$, the angular momentum vector will change, because the component of the angular momentum perpendicular to rotation axis will rotate in the xy plane. However, its module, $\ell_\perp = mr^2\omega\sin[\theta]\cos[\theta]$, will remain constant.

Note that, the two angular momenta of the two masses are vectors applied at the position of the masses; the total angular momentum is a free vector.

DRAFT IN PROGRESS

26.07.07.03 Toy Model: A Rotating Dumbbell

This § is referenced at pages:
[1456]

Read also § 26.07.06.

Consider a dumbbell made of two identical masses of mass m, joined by an ideal rigid bar of length $d = 2r$ and negligible mass, whose center is fixed to the vertical fixed rotation axis, z, at a fixed angle θ. Let $\Delta\phi$ be the angle of rotation of the dumbbell-axis plane around the axis and $\omega = \dot{\phi}$ be constant. Use, as a pole, the point where the dumbbell is constrained to the rotation axis; while always using this pole, it will not be explicitly mentioned in the symbols.

Let the positions be $\mathbf{r}_\pm$, with $\pm\mathbf{r}_+ = \mp\mathbf{r}_-$. The angle $\phi = 0$ shall correspond to the position of the mass at $\mathbf{r}_+$. Let $\mathbf{L} \equiv \boldsymbol{\ell}_+ + \boldsymbol{\ell}_- = 2\boldsymbol{\ell}_+ = 2\boldsymbol{\ell}_-$, as the two angular momenta are identical:

$$\boldsymbol{\ell}_\pm = m\,\mathbf{r}_\pm \wedge \mathbf{v}_\pm = m\,\mathbf{r}_\pm \wedge (\boldsymbol{\omega} \wedge \mathbf{r}_\pm) = m\left(\boldsymbol{\omega} r^2 - \mathbf{r}_\pm\,(\boldsymbol{\omega}\cdot\mathbf{r}_\pm)\right) \quad ,$$

$$\widehat{\mathbf{n}} \equiv \boldsymbol{\omega}/\omega \quad ,$$

$$\widehat{\mathbf{n}}\cdot\boldsymbol{\ell}_\pm = m\omega r^2\left(1 - \cos^2[\theta]\right) = m\omega r^2 \sin^2[\theta] \quad ,$$

$$[\boldsymbol{\ell}_\pm]_\perp = [-m\mathbf{r}_\pm\,(\boldsymbol{\omega}\cdot\mathbf{r}_\pm)]_\perp = -m\,(\boldsymbol{\omega}\cdot\mathbf{r}_\pm)\,[\mathbf{r}_\pm]_\perp = -m\,(\boldsymbol{\omega}\cdot\mathbf{r}_\pm)\left(\widehat{\mathbf{n}} \wedge (\mathbf{r}_\pm \wedge \widehat{\mathbf{n}})\right) = -m\,(\boldsymbol{\omega}\cdot\mathbf{r}_\pm)\,(\mathbf{r}_\pm - \widehat{\mathbf{n}}\,(\widehat{\mathbf{n}}\cdot\mathbf{r}_\pm)) \quad .$$

There is one very tricky issue here, related to vector operations while using bases which depend on the point, as for cylindrical coordinates. When the total angular momentum is calculated, $\mathbf{L} \equiv \boldsymbol{\ell}_+ + \boldsymbol{\ell}_-$, two vectors applied at different points, the two masses, are added. Geometrically, this implies translating either one or both vectors to let them have the same origin. At this point, and only at this point, operations in components can be done.

Only the component perpendicular to the axis changes:

$$\frac{\mathrm{d}\boldsymbol{\ell}}{\mathrm{d}t} = \frac{\mathrm{d}\boldsymbol{\ell}_\perp}{\mathrm{d}t} + \frac{\mathrm{d}\boldsymbol{\ell}_\parallel}{\mathrm{d}t} = \frac{\mathrm{d}\boldsymbol{\ell}_\perp}{\mathrm{d}t} \quad .$$

The total angular momentum vector, $\mathbf{L}$ of the dumbbell is perpendicular to the dumbbell bar. As it is a resultant momentum, it can be considered as an applied vector on the pole, but this is not at all relevant here. The component perpendicular to the rotation axis has constant module:

$$L_\perp \equiv |\mathbf{L}_\perp| = 2mr^2\omega \sin[\theta]\cos[\theta] \quad ,$$

and it is rotating with angular velocity $\boldsymbol{\omega}$ around the axis. Therefore:

$$\left|\frac{\mathrm{d}\mathbf{L}_\perp}{\mathrm{d}t}\right| \equiv \left|\lim_{\Delta t\to 0}\frac{\mathbf{L}[t+\Delta t] - \mathbf{L}[t]}{\Delta t}\right| = \left|\lim_{\Delta t\to 0}\frac{2L_\perp \sin[\Delta\phi/2]}{\Delta t}\right| = L_\perp\omega \quad ,$$

$$\left|\frac{\mathrm{d}\mathbf{L}_\perp}{\mathrm{d}t}\right| = \omega|\mathbf{L}_\perp| \quad .$$

The direction is clearly the direction of $\widehat{\mathbf{e}}_\psi$, but it is not trivial to determine the orientation, geometrically.

In a algebraic way, translating all the vectors to the position of the particle at $\mathbf{r}_+$, in order to use, at that point, the same base in cylindrical coordinates, $\{\widehat{\mathbf{e}}_r, \widehat{\mathbf{e}}_\psi, \widehat{\mathbf{e}}_3\}$, for all vectors, one has:

$$\mathbf{L}_\perp = -L_\perp\widehat{\mathbf{e}}_r \implies \boldsymbol{\Gamma}^{(\mathrm{E})} = \frac{\mathrm{d}\mathbf{L}_\perp}{\mathrm{d}t} = -L_\perp\omega\widehat{\mathbf{e}}_\psi \qquad \left|\Gamma^{(\mathrm{E})}\right| = L_\perp|\omega| \quad .$$

Therefore in the case $\mathbf{L}_\perp \neq 0$ a torque is required to make the angular momentum precess around the rotation axis, and the direction of the torque is perpendicular to the plane defined by the angular velocity and $\mathbf{r}$.

The torque is provided by the centripetal forces which keeps the two masses rotating, finally provided by the joint on the axis, and transmitted to the two masses by the rigid bar.

CC BY NC ND

26.07.07.04 Static and Dynamical Balancing of Car Wheels

When the motion of the rigid-body is given, one can find the moments that are being applied to the rigid-body to permit that motion by using Euler equations.

Consider an axially symmetric tire, considered as a rigid-body, constrained to rotate about the wheel rotation axis, which is inaccurately mounted so that the rotation axis is not exactly coincident with the symmetry axis and|or the Center-Of-Mass does not lie exactly on the wheel rotation axis.

Static balancing refers to adding small masses at suitable places in order to get the Center-Of-Mass to lie on the wheel rotation axis.

Dynamic balancing refers to adding small masses at suitable places in order to get the wheel rotation axis to be a principal axis.

Replacing the above expressions into Euler equations one finds zero, for the two components of the external moment in the plane containing the dumbbell and the rotation axis and, letting I_3 be the moment of inertia along the axis of the dumbbell and $I > I_3$ be the moment of inertia along any axis perpendicular to the axis of the dumbbell, one finds the absolute value of the component of the external moment perpendicular to the plane plane containing the dumbbell and the rotation axis:

$$\Gamma_{\perp} = (I - I_3)\,\omega^2 \cos[\theta] \sin[\theta] \quad .$$

La Sfera/Cilindro Che Rotola Sul Piano Inclinato

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|12.53 13.18||

Una sfera/cilindro omogenei di massa M e raggio R inizia a rotolare da ferma giú da un piano inclinato di angolo α, $0 \leq \alpha \leq 90°$.

1. Supponendo che rotoli senza strisciare, determinare l'accelerazione del centro di massa, l'accelerazione angolare e la condizione sotto la quale rotola senza strisciare.
2. Risolvere il problema usando come polo il Centro di Massa, prima, e il punto mobile di contatto con il piano, dopo.
3. Si risolva inoltre il problema usando sia le **Cardinal Equation** che il principio di conservazione dell'energia meccanica.

WORKED SOLUTION

Si scelga un Reference Frame con asse x parallelo al piano e diretto verso il basso e asse y perpendicolare al piano e diretto verso l'alto. Sia θ l'angolo di rotazione di un punto fisso rispetto ad una direzione fissata, considerato positivo/negativo in base all'orientamento di $\hat{\mathbf{e}}_3$. Le equazioni per il moto del centro di massa e l'equazione dei momenti con polo il centro di massa sono, indicando con I il momento di inerzia rispetto al suo centro

$$M g \sin\alpha + f_x = M A_x \qquad (26.07.01)$$ → 1462

$N - Mg\cos\alpha = MA_y = 0$ vincolo cinematico: la sfera/cilindro resta appoggiata al piano inclinato (26.07.02) → 1462

$$f_x R = I\ddot{\theta} \equiv I\dot{\omega} \qquad (26.07.03)$$ → 1462

con le quattro incognite A_x, f_x, N e $\dot{\omega}$. Il vincolo di puro rotolamento, che significa che il punto di contatto non striscia e cioè che la sua velocità relativa al piano è nulla, si scrive

$\Delta x = -R\Delta\theta$ notare il segno $-$ dovuto alla convenzione sugli assi cartesiani . (26.07.04) → 1461

DRAFT - LIVE PRO

La soluzione del sistema di equazioni porta a

$$\boxed{A_x = \frac{gMR^2 \sin\alpha}{I + MR^2}} = \begin{cases} A_x = \frac{5}{7} g \sin\alpha \leq g \sin\alpha & \text{per una sfera, minore che per il punto materiale} \\ A_x = \frac{2}{3} g \sin\alpha g \sin\alpha & \text{per un cilindro, minore che per il punto materiale} \end{cases} ,$$

$$\boxed{f_x = -\frac{MgI \sin\alpha}{I + MR^2}} \quad ,$$

$$\boxed{N = Mg\cos\alpha}$$

In ogni caso si ha $|A_x| \leq g \sin\alpha$, l'accelerazione del centro di massa della sfera è minore di quella del punto materiale avente la stessa massa e si riduce a questa nel caso $I = 0$. Si osservi che nel caso $\alpha = 0$ (puro rotolamento nel piano) si ha $f_x = 0$ cioè il puro rotolamento su un piano non richiede alcuna forza di attrito. Ciò è altresì evidente se si considera che un puro rotolamento ha momento della quantità di moto costante e momento angolare costante. Dalle espressioni per N ed f_x si ricava la condizione che deve essere soddisfatta per aver il puro rotolamento:

$$\boxed{\tan[\alpha] \leq \mu_s \left(\frac{I + MR^2}{I} \right)} = \begin{cases} \frac{7\mu_s}{2} & \text{per una sfera} \\ 3\mu_s & \text{per un cilindro} \end{cases} ,$$

Notare il valore maggiore dell'angolo limite per la sfera rispetto al cilindro. Infatti, a parità di altre condizioni, il cilindro, con momento di inerzia maggiore, richiede una maggiore forza di attrito rispetto alla sfera.

Una soluzione alternativa si può ottenere scegliendo come polo per l'equazione dei momenti il punto di contatto istantaneo, inteso come il punto mobile che si muove rispetto al suolo parallelamente al Centro di Massa per cui, quindi, il termine $\mathbf{v} \wedge \mathbf{P}$ della seconda **Cardinal Equation** si annulla. Notare che non si tratta del **centro di rotazione istantanea**.

L'espressione della componente z del momento angolare rispetto al polo mobile può essere ricavata dalla decomposizione del momento angolare di un sistema in una parte di spin e una parte orbitale

$$\mathbf{L} = \mathbf{R} \wedge \mathbf{P} + \mathbf{L}' \tag{26.07.05}$$

da cui si deduce

$$L_z = -MRV_x + I\omega \quad ,$$

che, per il vincolo di puro rotolamento (26.07.04) diventa $L_z = \omega \left(I + MR^2 \right) \equiv I'\omega$.

Nel caso di rotolamento con strisciamento, invece, l'espressione $L_z = -MRV_x + I\omega$ non può essere ridotta ad una espressione che dipende solo da V_x oppure ω, che restano due variabili indipendenti.

Il problema può pure essere risolto utilizzando la conservazione dell'energia meccanica, nel caso in cui ci sia puro rotolamento. Infatti, in tal caso, la forza di attrito statico non compie lavoro e l'energia meccanica è conservata in quanto la reazione normale non compie lavoro e la forza peso è conservativa. La conservazione dell'energia meccanica si scrive allora, denotando con D lo spazio percorso lungo il piano inclinato

$$\frac{1}{2} M V_x^2 + \frac{1}{2} I \omega^2 = MgD \sin\alpha$$

ed essendo, per il vincolo di puro rotolamento,

$$V_x = -R\omega$$

si ricava

$$\boxed{V_x^2 = \frac{2gDMR^2 \sin\alpha}{I + MR^2}}$$

coerentemente con quello che si otterrebbe dalla relazione (23.03.09.02) usando l'accelerazione del centro di massa A_x calcolata in precedenza.

CC BY NC ND

In questo approccio si determina solo il moto della sfera, mentre per determinare le reazioni vincolari occorre usare le equazioni del moto (26.07.01), (26.07.02), (26.07.03).
Si noti che la forza di attrito statico non fa lavoro cioè non dissipa energia. La sua presenza è però indispensabile per la rotazione. La sua presenza converte parte dell'energia potenziale gravitazionale in energia cinetica rotazionale, anziché trasformare tutta dell'energia potenziale gravitazionale in energia cinetica di traslazione del centro di massa.

La Ciminiera Che Cade E Si Rompe

This § is referenced at pages:
[1455]

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|§ 11.5 12.33 12.38||

Una ciminiera di forma cilindrica, massa M e altezza L molto maggiore del suo diametro, viene abbattuta alla base da una carica esplosiva e inizia a cadere rigidamente. Il centro di massa della ciminiera si trova ad un'altezza H rispetto alla base B.

1. Determinare l'accelerazione radiale e tangenziale della cima della ciminiera C in funzione dell'angolo θ che la ciminiera forma con la verticale.
2. Scrivere le equazioni del moto della cima della ciminiera.
3. Determinare l'accelerazione radiale e tangenziale di un punto generico della ciminiera in funzione dell'angolo θ che la ciminiera forma con la verticale.
4. Scrivere le equazioni del moto di un punto generico della ciminiera.
5. Determinare lo sforzo in direzione perpendicolare alla ciminiera in funzione della posizione lungo la ciminiera.
6. Determinare la reazione vincolare del suolo sulla base della ciminiera, necessaria a tenere la base ferma.

WORKED SOLUTION

Si misuri l'angolo θ tra la ciminiera e la verticale partendo dalla verticale; quindi θ cresce mentre la ciminiera cade. La seconda **Cardinal Equation** della dinamica con polo la base B della ciminiera si scrive:

$$MgH\sin[\theta] = I_{\mathrm{B}}\ddot{\theta} \quad . \tag{26.07.06}$$

→ 1463

Tale equazione è analoga a quella del pendolo fisico tranne che il segno relativo dei due membri è opposto nei due casi. La scelta della base B come polo permette di eliminare la reazione vincolare incognita che agisce alla base della ciminiera e dovuta al suolo. Ovviamente tale scelta non permette di determinare la reazione vincolare alla base.
Per determinare la reazione vincolare al suolo occorre utilizzare la prima **Cardinal Equation** , dopo aver risolto il moto della ciminiera.
Alternativamente, si applichi il principio di conservazione dell'energia meccanica alla ciminiera considerata come un corpo rigido. Si trova

$$MgH = \frac{1}{2}MV_{\mathrm{CM}}^2 + \frac{1}{2}I_{\mathrm{CM}}\omega^2 + MgH\cos[\theta] = \frac{1}{2}I_{\mathrm{B}}\omega^2 + MgH\cos[\theta] \qquad I_{\mathrm{B}} = I_{\mathrm{CM}} + MH^2$$

in cui l'energia cinetica della ciminiera è stata espressa in due possibili modi, attraverso le coordinate del centro di massa e attraverso le coordinate della base fissa B. La reazione del suolo non interviene

cc BY NC ND

perch,` fino a che la base è fissa, non fa lavoro siccome non sposta il punto di applicazione.
Vale la relazione

$$V_{\mathtt{CM}} = H\omega \quad ,$$

tra la componente tangenziale di $\mathbf{V}_{\mathtt{CM}}$ (modulo e segno) e la componente z della velocità angolare, ω (modulo e segno). Risolvendo rispetto ad ω^2:

$$\omega = \dot{\theta} = \sqrt{\frac{2MgH\,(1-\cos[\theta])}{I_{\mathtt{CM}} + MH^2}} = \sqrt{\frac{2MgH\,(1-\cos[\theta])}{I_{\mathtt{B}}}}$$

L'accelerazione angolare si può ricavare sia derivando l'espressione per ω, che direttamente dalla relazione (26.07.06).
Nel caso di asta sottile omogenea si hanno per i momenti di inerzia i valori

$$I_{\mathtt{CM}} = \frac{ML^2}{12} \qquad I_{\mathtt{B}} = \frac{ML^2}{3}$$

Ne segue l'espressione per l'accelerazione radiale della cima C della ciminiera

$$a_{\mathtt{R}} = -\omega^2 L = -\frac{2MgHL\,(1-\cos[\theta])}{I_{\mathtt{B}}} < 0$$

che è negativa essendo un'accelerazione centripeta. Per un'asta omogenea ($H = L/2$) si ottiene

$$a_{\mathtt{R}} = -3g\,(1-\cos[\theta])$$

L'espressione per l'accelerazione tangenziale della cima C della ciminiera vale invece

$$a_{\mathtt{T}} = \frac{\mathrm{d}v_{\mathtt{C}}}{\mathrm{d}t} = L\frac{\mathrm{d}\omega}{\mathrm{d}t} = \frac{MgHL\sin[\theta]}{I_{\mathtt{B}}} > 0$$

Per un'asta omogenea si ottiene

$$a_{\mathtt{T}} = \frac{3}{2}g\sin[\theta]$$

Si osservi che in tal caso si ha

$$a_{\mathtt{T}}[\theta = \frac{\pi}{2}] = \frac{3}{2}g > g$$

Su ogni mattone agiscono, oltre alla forza peso, le forze dovute agli altri mattoni vicini la cui risultante può essere scomposta in uno sforzo di taglio e uno sforzo parallelo alla ciminiera.
L'esistenza di un'accelerazione tangenziale significa che i vari punti della ciminiera devono essere soggetti ad una forza tangenziale per essere accelerati tangenzialmente. Tale forza può essere fornita dalla componente tangenziale della forza peso oppure dallo sforzo di taglio. Nel caso la componente verticale dell'accelerazione tangenziale risulti maggiore dell'accelerazione di gravità tale accelerazione addizionale deve essere fornita dallo sforzo di taglio. In particolare il fatto che l'accelerazione tangenziale possa diventare maggiore di g a $\theta = \pi/2$ significa che lo sforzo di taglio in quella posizione deve fornire l'accelerazione addizionale di $g/2$ oltre a quella fornita al mattone dalla forza peso.
Finché la ciminiera cade rigidamente le accelerazioni sono determinate dalle relazioni ricavate sopra per il corpo rigido. Tali accelerazioni devono essere fornite ad ogni mattone dalla forza peso e dalle forze interne dovute ai mattoni adiacenti. Se i mattoni adiacenti non sono in grado di fornire le forze interne necessarie per l'accelerazione richiesta il moto non può essere quello di un corpo rigido e la ciminiera si rompe cadendo non appena in qualche punto viene richiesta una forza superiore alla forza massima che può essere fornita. Nel caso di caduta rigida essendo note le accelerazioni le forze richieste possono essere calcolate tramite le **Cardinal Equation** .
Sia $T[r] \equiv SF_T[r]$ lo sforzo in funzione della distanza r dalla base della ciminiera, considerato positivo nella direzione di θ crescente. L'equazione del moto per l'elemento di ciminiera posto a distanza r rispetto alla base, di spessore Δr e sezione di area A, è

$$A\,(T[r] - T[r+\Delta r]) + (\rho[r]A\Delta r)\,g\sin[\theta] = (\rho[r]A\Delta r)\,a_{\mathtt{T}}[r] = (\rho[r]A\Delta r)\,\frac{MgHr\sin[\theta]}{I_{\mathtt{B}}} > 0$$

CC BY NC ND

Passando al limite per $\Delta r \to 0$ si trova

$$\frac{\mathrm{d}T}{\mathrm{d}r}[r,\theta] = \rho[r] g \sin[\theta] \left[1 - \frac{MHr}{I_{\mathrm{B}}}\right] \qquad \text{con} \qquad T[r=L] = 0 \quad .$$

Se la ciminiera non è omogenea, $\rho = \rho[r]$, che interviene nell'equazione differenziale. Nel seguito si considererà quindi ciminiera omogenea in r.
La derivata della funzione $T[r]$ si annulla per $I_{\mathrm{B}} = MHr$ che corrisponde ad un punto di massimo relativo della funzione come si verifica dal fatto che la derivata seconda della $T[r]$ è negativa. Tuttavia il punto di massimo assoluto del valore assoluto di $T[r]$ è in $r = 0$, ai bordi dell'insieme di definizione della funzione.
Risolvendo,

$$T[r] = \rho g \sin[\theta] (L-r) \left(\frac{MH(L+r)}{2I_{\mathrm{B}}} - 1\right) \longrightarrow T[r] = \rho g \sin[\theta] (L-r) \left(\frac{3r-L}{4L} - 1\right) \qquad \text{per ciminiera omogenea} \quad .$$

Ne segue che i punti in alto devono essere accelerati tangenzialmente, mentre quelli vicini alla base devono essere decelerati tangenzialmente. Naturalmente, per ogni angolo θ esiste una distribuzione di sforzo di taglio dalla dalla precedente relazione.
Analogamente, ogni mattone della ciminiera deve soddisfare la seconda **Cardinal Equation** , in quanto ha anche una accelerazione angolare, la stessa della ciminiera nel complesso. Ne segue:

.....

La base della ciminiera può anche muoversi, se la reazione del suolo non è sufficiente.

WORKED SOLUTION

1) $a_{\mathrm{R}} = -\dfrac{2MgHL(1-\cos[\theta])}{I_{\mathrm{B}}}$; $a_{\mathrm{T}} = \dfrac{MgHL\sin[\theta]}{I_{\mathrm{B}}}$.

26.07.10
Il Tiro Della Palla Al Biliardo

This § is referenced at pages:
[1330]

©|Barger & Olsson, , ..., ..., ...Ed., ...|§ 6.10||

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|12.60 13.19 13.23 13.24 13.25||

Una palla da biliardo di massa M e raggio R è appoggiata a riposo sul tavolo da biliardo. Un giocatore la colpisce con la stecca disposta orizzontalmente, a distanza h dal piano del biliardo e nel piano mediano verticale della sfera.

- Determinare la relazione tra la velocità iniziale v_0 e la velocità angolare iniziale ω_0.
- Determinare sotto quali condizioni la palla inizia a rotolare senza strisciare.
- Nel caso la palla parta strisciando determinare dopo quanto tempo smette di strisciare e per iniziare un moto di puro rotolamento.

WORKED SOLUTION

La palla è soggetta alla forza impulsiva che deriva dal colpo che riceve dalla stecca, alla forza peso, alla reazione normale del piano e alla forza di attrito del piano del tavolo.
Si scelga un Coordinate System con asse x parallelo al piano del tavolo e diretto nel verso della forza impressa dalla stecca, e asse y verticale. Si scelga come verso positivo per le rotazioni quello antiorario.

CC BY NC ND

La prima **Cardinal Equation** della dinamica, proiettata sugli assi x e y, e la proiezione sull'asse z della seconda **Cardinal Equation** con polo nel centro di massa della palla forniscono, detta **F** la forza esercitata dalla stecca e **f** la forza di attrito

$$F + f_x = Ma \tag{26.07.07}$$
→ 1466

$$N - Mg = 0 \tag{26.07.08}$$

$$Rf_x - F\,(h - R) = I_{\text{CM}}\ddot{\theta} \tag{26.07.09}$$
→ 1466

Si è denotato con I_{CM} il momento di inerzia della sfera, che può anche non essere omogenea in generale.
Durante l'azione della forza impulsiva **F** si può trascurare l'effetto della forza di attrito a condizione che il modulo della forza impulsiva sia molto maggiore della forza di attrito ($F \gg \mu_s N$) e che la durata dell'azione della forza impulsiva sia così breve da poter considerare la palla ferma in quell'intervallo di tempo.
In tal caso, considerando la forma impulsiva delle equazioni del moto, si ricava il valore della velocità del centro di massa, v, e della velocità angolare della palla, ω, a seguito dell'impulso

$$M\,(v - v_0) = \int F\,\mathrm{d}t \qquad \text{con } v_0 = 0 \tag{26.07.10}$$
→ 1466

$$I_{\text{CM}}\,(\omega - \omega_0) = (R - h)\int F\,\mathrm{d}t \qquad \text{con } \omega_0 = 0 \tag{26.07.11}$$
→ 1466

da cui, eliminando l'impulso $\int F\,\mathrm{d}t$, si ricava la relazione tra la velocità del centro di massa e la velocità angolare

$$\boxed{\omega = \frac{M\,(R-h)}{I_{\text{CM}}}v} = \frac{5}{2}\left(\frac{R-h}{R^2}\right)v$$

avendo usato il valore $I_{\text{CM}} = 2MR^2/5$ del momento di inerzia di una sfera omogenea. La relazione vale in generale per una sfera non omogenea purché a simmetria sferica. Nel caso $h = R$ si ha $\omega = 0$.
Nell'ipotesi di poter trascurare l'effetto della forza di attrito durante l'azione della forza impulsiva e nell'ipotesi che l'impulso sia di durata sufficientemente breve, dunque, la velocità iniziale del centro di massa e la velocità angolare iniziale si determinano in funzione del valore dell'impulso ricevuto. La relazione tra le due è invece indipendente dal valore dell'impulso ricevuto. Al termine dell'azione della forza impulsiva, la palla si muove con la velocità del centro di massa e la velocità angolare legate dalla relazione trovata. L'evoluzione successiva dipende da queste condizioni iniziali.
Per determinare sotto quali condizioni il moto è di puro rotolamento occorre calcolare la velocità del punto di contatto, v_p, che vale

$$\boxed{v_p = v + \omega R = v\left[\frac{I_{\text{CM}} + MR\,(R-h)}{I_{\text{CM}}}\right]} = \left[\frac{7R-5h}{2R}\right]v = \frac{\omega R}{5}\left[\frac{7R-5h}{R-h}\right] \qquad \omega = 0 \text{ se } h = R \tag{26.07.12}$$
→ 1466

Si trova

$$v_p = 0 \qquad \Leftrightarrow \qquad v = -\omega R \qquad \Leftrightarrow \qquad h = \frac{I_{\text{CM}} + MR^2}{MR} = \frac{7}{5}R$$

In tali condizioni il punto di contatto istantaneo è in quiete relativamente al piano, quindi non striscia e la forza di attrito è quella di attrito statico. Tale forza deve essere nulla in quanto una forza, ad esempio, diretta nel verso negativo dell'asse x, diminuirebbe la velocità del centro di massa e aumenterebbe il valore assoluto della velocità angolare che è negativa, producendo un valore di v_p negativo. Ma questo implicherebbe a sua volta una forza di attrito cinetico diretta nel verso positivo dell'asse x, in contraddizione con quanto supposto. Nel caso di puro rotolamento,

CC BY NC ND

infatti, le **Cardinal Equation** della dinamica si scrivono (dalle (26.07.07) ed (26.07.09) con $\mathbf{F} = 0$)

$$f_x = Ma \tag{26.07.13}$$

$$Rf_x = I_{\text{CM}}\ddot{\theta} \tag{26.07.14}$$

che, con il vincolo di puro rotolamento, $a = -R\ddot{\theta}$, implicano $f_x = 0$. Si possono riassumere i segni di v_p e di ω (v è sempre positivo in questo problema)

$$\begin{aligned} 0 \le h < R &\Longrightarrow \omega > 0, \qquad v_p > 0 \quad , \\ h = R &\Longrightarrow \omega = 0, \qquad v_p > 0 \quad , \\ R < h < 7R/5 &\Longrightarrow \omega < 0, \qquad v_p > 0 \quad , \\ h = 7R/5 &\Longrightarrow \omega < 0, \qquad v_p = 0 \quad , \\ 7R/5 < h < 2R &\Longrightarrow \omega < 0, \qquad v_p < 0 \quad . \end{aligned}$$

Il verso di v_p determina il verso della forza di attrito cinetico f_x. Si può anche vedere come, nel caso $h \neq 7R/5$, la forza di attrito fa sempre in modo che il moto della palla evolva verso un moto di puro rotolamento. Infatti supponiamo, per esempio, che sia inizialmente $v > 0$, $\omega < 0$ e $v_p < 0$. Il verso di v_p implica $f_x > 0$ (attrito cinetico radente). Quindi la forza di attrito accelera il centro di massa e produce un'accelerazione angolare positiva. Ne segue che nella (26.07.12) entrambi i termini aumentano con il tempo e questo aumento procede fino quando non si arriva a $v_p = 0$ in quanto il verso della forza di attrito dipende solo dal segno di v_p. Una volta raggiunto il puro rotolamento questo si mantiene come descritto sopra e la palla non ricomincia a strisciare. Si osservi, per inciso, che non è possibile in presenza di strisciamento applicare la seconda **Cardinal Equation** della dinamica usando come polo il punto di contatto nella forma $\Gamma = I'\ddot{\theta}$ in quanto, in presenza di strisciamento il punto di contatto non è istantaneamente fermo, quindi il polo non è un punto di quiete istantanea del corpo rigido e quindi il momento angolare non può essere posto nella forma $I'\ddot{\theta}$.

Determiniamo il moto nel caso $7R/5 < h < 2R$. In tal caso si ha $f_x > 0$ essendo $v_p < 0$. Dalle equazioni (26.07.13), (26.07.14) il moto del centro di massa è uniformemente accelerato con $a = f_x/M$ e il moto rotatorio attorno al centro di massa è uniformemente accelerato con accelerazione angolare $\ddot{\theta} = Rf_x/I$. Denotando con v_0 e ω_0 le velocità del centro di massa e angolare iniziali, cioè quelle acquisite a seguito del colpo della stecca, e che sono determinate dalle (26.07.10), (26.07.11) si ha

$$v(t) = v_0 + \frac{f_x t}{M} \tag{26.07.15}$$

$$\omega(t) = \omega_0 + \frac{Rf_x t}{I}$$

Come già discusso il moto evolve verso un moto di puro rotolamento che viene raggiunto al tempo $\bar{t}$ determinato dalla condizione di puro rotolamento $v(t) = -R\omega(t)$

$$\boxed{\bar{t} = -\frac{MIv_{p0}}{f_x\,(I + MR^2)} = -\frac{Mv_0\,[I + MR\,(R-h)]}{f_x\,(I + MR^2)} > 0} \tag{26.07.16}$$

da cui si deduce

$$v(\bar{t}) = -\omega(\bar{t})R = \left[\frac{MRh}{I + MR^2}\right] v_0$$

Il valore massimo di tale velocità finale si ottiene per $h = 2R$ e vale $v = 10/7v_0 > v_0$

La velocità del punto di contatto in funzione del tempo si determina come nella (26.07.12) usando le (26.07.15), (26.07.16), e vale

$$v_p(t) = v(t) + \omega(t)R = v(t)\left[\frac{I_{\text{CM}} + MR\,(R-h)}{I_{\text{CM}}}\right] = v_0 + \omega_0 R + tf_x\left[\frac{I + MR^2}{MI}\right] = v_p(t=0)\left[1 - \frac{t}{\bar{t}}\right]$$

Da questa relazione si deduce che $v(\bar{t}) \lessgtr v_0$ a seconda che $h \lessgtr 7R/5$

26.07.11
Centro Di Percussione Di Una Mazza Da Baseball

This § is referenced at pages:
[1330]

©|Alonso & Finn, , ..., ..., ...Ed., ...|10.23||

DRAFT

Una mazza da baseball di massa M è appoggiata su un piano orizzontale, diretta lungo l'asse y crescente, con l'estremo dalla parte del manico coincidente con l'origine. Il centro di massa giace all'ordinata y_{CM}. Una forza impulsiva, diretta lungo l'asse x nel verso positivo, agisce sulla mazza ad un'ordinata $y_{\text{CM}} + h$.

Determinare se esiste un punto della mazza che resta inizialmente fisso a seguito dell'impulso in funzione del valore di h.

WORKED SOLUTION

Scegliendo come positivo il verso antiorario per le rotazioni la prima **Cardinal Equation** della dinamica e la seconda applicata con polo il centro di massa dell'asta si scrivono

$$\begin{aligned} F &= Ma_x \\ N - Mg &= Ma_y = 0 \quad , \\ -Fh &= I_{\text{CM}}\ddot{\theta} \end{aligned} \tag{26.07.17}$$

→ 1467

Dalle equazioni (26.07.17) si deduce, integrando rispetto al tempo,

$$I_{\text{CM}}\omega + Mvh = 0 \tag{26.07.18}$$

→ 1467 1468

Si osservi che la forza **F** dipende dal tempo ma la relazione tra v ed ω è indipendente dal tempo. La velocità v_p del punto generico del corpo rigido che dista b dal centro di massa, con b crescente nel verso negativo dell'asse y, è data da

$$v_p = v + \omega b = v\left[\frac{I - Mab}{I}\right] \tag{26.07.19}$$

→ 1467

da cui

$$v_p = 0 \qquad \Leftrightarrow \qquad I = Mhb$$

Conseguenza immediata della (26.07.19) è che h e b hanno lo stesso segno, e cioè, date le convenzioni scelte, si trovano da parti opposte rispetto al centro di massa. Il punto così determinato (centro di percussione) è dunque istantaneamente in quiete all'istante dell'urto. Ad istanti successivi la velocità del punto non sarà però nulla come evidente dalla forma vettoriale dall'atto di moto del corpo rigido in quanto dopo l'urto $\mathbf{v}$ non è più parallelo a $\boldsymbol{\omega}\wedge\mathbf{b}$. Inizialmente la velocità del entro di percussione è nulla mentre la velocità di qualunque altro punto (ad esempio il centro di massa) varia senza continuità da zero ad una valore diverso da zero. Altra conseguenza della (26.07.19) è che se $h = 0$ allora non esiste soluzione per b per cui la mazza trasla senza ruotare. Si osservi che la seconda **Cardinal Equation** assume la stessa forma (26.07.17) se come polo si sceglie il punto fisso solidale con il piano che coincide con il punto in cui l'asta è colpita. Infatti il momento della forza impulsiva rispetto a questo polo vale zero, e vale zero pure il momento totale delle forze esterne rispetto a tale polo, e il polo è fisso. Ne segue che il momento angolare dell'asta rispetto a questo polo è costante e vale zero perché è nullo prima del colpo. D'altra parte scomponendo il momento angolare in una parte orbitale ed una parte di spin si ha che il momento angolare orbitale dell'asta vale $+Mvh$ mentre il momento angolare di spin vale $I_{\text{CM}}\omega$. Se ne deduce ancora l'equazione (26.07.18). Alternativamente si può usare come polo il punto fisso solidale con il piano che coincide con il centro di massa dell'asta. In tale caso il momento risultante delle forze esterne rispetto al polo vale $-Fh$ e scomponendo il momento angolare il parte orbitale e di spin si ha che il momento angolare orbitale è nullo perché l'impulso totale dell'asta è un vettore che passa per

il polo scelto. Resta solo il momento angolare di spin che si esprime come $I_{CM}\omega$. Si deduce allora anche in questo modo la relazione (26.07.18).

[1453]

26.07.16.01 Euler Equations for a Free Symmetrical Top: Body System

Consider a free symmetrical top and describe the motion in the body Reference Frame, according to Euler equations.

The kinetic energy is constant, as it follows from the third **Cardinal Equation** .

The third component of the angular velocity is constant:

$$\omega_3[t] = \omega_3 = \text{constant} \quad .$$

The use of the latter result allows to write:

$$\dot{\omega}_1 + \Omega\omega_2 = 0 \quad ,$$
$$\dot{\omega}_2 - \Omega\omega_1 = 0 \quad ,$$

in terms of the quantity:

$$\Omega \equiv \omega_3 \left(\frac{I_3 - I}{I} \right) \quad .$$

The solution for the other two components of the angular velocity is then:

$$\omega_1[t] = C \cos\left[\Omega t - \phi\right] \quad ,$$
$$\omega_2[t] = C \sin\left[\Omega t - \phi\right] \quad ,$$

DRAFT-IN-PROGRESS

where C and ϕ are two arbitrary integration constants.

Note that, as it is consistent with a set a two first-order differential, the solution depends on two arbitrary integration constants, C and ϕ, to be determined by the initial conditions.

The solution shows that, in the body system, the angular velocity vector, $\boldsymbol{\omega}$, precesses around the third axis, $\widehat{\mathbf{k}}_3$, (rigidly fixed to the rigid-body) with an angular velocity of precession Ω. As $\mathbf{L}'_1 = I\omega_1$ and $\mathbf{L}'_2 = I\omega_2$ the angular momentum also precess around the $\widehat{\mathbf{k}}_3$ axis.

Free Precession of the Earth as a Symmetrical Top

This problem describes, for instance, how an observer on the Earth sees the direction of the angular velocity of the Earth changing. The latter can be detected by observing the north/south poles on the sky. In the case of the Earth predictions are not accurate has the Earth is not free and non axially symmetric.

If the angular momentum axis and the figure axis do not coincide, the figure axis performs precession about the angular momentum axis.

The Earth is expected to undergo a free precession with a period of about 450 days and an amplitude of precession of about $0.2''$. On the contrary, the free precession is known to have a period of about 300 days. This is due to the meant differences of the Earth with a rigid-body (non rigidity, ...)

26.07.16.02 Euler Equations for a Free Symmetrical Top: Laboratory System

Consider a free symmetrical top and describe the motion from the laboratory system, according to Euler equation (26.06.01).

Both angular momentum and kinetic energy are conserved:

$$0 = \frac{\mathrm{d}\mathbf{L}'}{\mathrm{d}t} \quad ,$$

$$0 = \frac{\mathrm{d}\mathcal{K}'}{\mathrm{d}t} = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\left(\boldsymbol{\omega}\cdot\mathbf{L}'\right) \implies \boldsymbol{\omega}\cdot\mathbf{L}' = \text{constant} \quad .$$

The vector ω describe a fixed plane in space, as a consequence of equation $\boldsymbol{\omega}\cdot\mathbf{L}' = \text{constant}$ and of the fact that $\mathbf{L}'$ is a fixed vector in the laboratory system.

In the rigid-body frame all the axes in the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_2\right\}$ plane are equivalent. Choose the $\widehat{\mathbf{k}}_1$ axis in the plane determined by $\mathbf{L}'$ and $\widehat{\mathbf{k}}_3$. Note that this construction is only possible because the top is symmetrical, otherwise the axes in the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_2\right\}$ plane are not equivalent.

By construction $\mathbf{L}'_2 = 0$, which implies, as $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_2, \widehat{\mathbf{k}}_3\right\}$ is a set of principal axes of inertia, that $\omega_2 = 0$. That is ω lies in the plane $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$. Therefore, as both the $\widehat{\mathbf{k}}_3$ axis and the angular velocity lye in the plane $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$, the velocity of any point on the $\widehat{\mathbf{k}}_3$ axis is:

$$\mathbf{v} = \boldsymbol{\omega}\wedge\mathbf{x} \implies \delta\mathbf{x} \perp \left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\} \quad .$$

The above construction can be repeated at any instant of time without nay change. At any instant, therefore, the points on the $\widehat{\mathbf{k}}_3$ axis have a velocity perpendicular to the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$ plane, which also contains the angular velocity vector. Therefore the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$ plane and, in particular, the $\widehat{\mathbf{k}}_3$ axis rotates around the fixed angular momentum vector, $\mathbf{L}'$, as the points on the $\widehat{\mathbf{k}}_3$ axis always have a velocity perpendicular to the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$ plane.

The precession angular velocity is given by the projection of the angular velocity on the rotation axis, that is the angular momentum vector, $\mathbf{L}'$. It can be calculated as follows. Let θ be the angle between the angular momentum vector, $\mathbf{L}'$, and the axis $\widehat{\mathbf{k}}_3$. This angle is constant because it has been shown that the velocity of the points of the axis $\widehat{\mathbf{k}}_3$ are orthogonal to the $\left\{\widehat{\mathbf{k}}_1, \widehat{\mathbf{k}}_3\right\}$ plane and zero component on the plane itself. The same conclusion can be found observing that:

$$\omega_3 = \text{constant} = \frac{\mathbf{L}'_3}{I_3} = \frac{|\mathbf{L}'|\cos[\theta]}{I_3} \implies \theta = \text{constant} \qquad \left(\text{because} \qquad |\mathbf{L}'| = \text{constant}\right) \quad .$$

DRAFT-IN-PROGRESS

One finds:

$$\frac{|\mathbf{L}'|\sin[\theta]}{I_1} = \frac{\mathbf{L}'_1}{I_1} = \omega_1 = \Omega_P \sin[\theta] \quad ,$$
$$\Omega_P = \frac{|\mathbf{L}'|}{I_1} \quad ,$$
$$\omega_3 = \frac{\mathbf{L}'_3}{I_3} = \frac{|\mathbf{L}'|\cos[\theta]}{I_3} \quad .$$

In the laboratory system, therefore, both the angular velocity and the $\widehat{\mathbf{k}}_3$ axis precess around the fixed angular momentum vector, $\mathbf{L}'$.

Free Symmetrical Top: Constancy of the Module of the Angular Velocity

The constancy of the module of the angular velocity can be alternatively deduced as follows, by only using first integral of motion and not using Euler equations.

$$|\mathbf{L}'|^2 = I_1^2\left(\omega_1^2+\omega_2^2\right) + I_3^2\omega_3^2 = \text{constant} \quad ,$$
$$2|\mathcal{K}'|^2 = I_1\left(\omega_1^2+\omega_2^2\right) + I_3\omega_3^2 = \text{constant} \quad .$$

Solving the system for $\left(\omega_1^2+\omega_2^2\right)$ and ω_3^2:

$$\left(\omega_1^2+\omega_2^2\right) = \text{constant} \quad ,$$
$$\omega_3^2 = \text{constant} \quad ,$$

implying

$$|\boldsymbol{\omega}|^2 = \text{constant} \quad .$$

Free Symmetrical Top: Spin Plus Precession

One can write:

$$\begin{aligned}\mathbf{L}' &= I\omega_1\widehat{\mathbf{k}}_1 + I\omega_2\widehat{\mathbf{k}}_2 + I_3\omega_3\widehat{\mathbf{k}}_3 \quad ,\\ &= I\omega_1\widehat{\mathbf{k}}_1 + I\omega_2\widehat{\mathbf{k}}_2 + I\omega_3\widehat{\mathbf{k}}_3 + (I_3\omega_3 - I\omega_3)\,\widehat{\mathbf{k}}_3 \quad ,\\ &= I\boldsymbol{\omega} + (I_3 - I)\,\omega_3\widehat{\mathbf{k}}_3 \quad .\end{aligned}$$

Therefore:

$$\boldsymbol{\omega} = \frac{\mathbf{L}'}{I} + \frac{(I-I_3)}{I}\omega_3\widehat{\mathbf{k}}_3 \quad . \tag{26.07.20}$$

→ 1470

Both $\mathbf{L}'$ and ω_3 are constant. Equation (26.07.20) shows that the motion of the top is a precession and the angular velocity is the sum of two (non-orthogonal) angular velocities:

$$\boldsymbol{\omega} = \Omega_L + \Omega_S \quad , \tag{26.07.21}$$

one rotation around the constant angular momentum $\mathbf{L}'$ (precession axis) with constant angular velocity $\Omega_L = \mathbf{L}'/I$, and one rotation around the axis $\widehat{\mathbf{k}}_3$, with angular velocity of constant module and directed around the solidal axis $\widehat{\mathbf{k}}_3$. As the angular velocity ω is constant in module (not in direction) the motion is a regular precession.

26.07.16.03 Gyroscope and Gyrocompass

©|WEB - URL |||

A gyroscope is a device made of a rigid-body with a point which is kept fixed by a suitable set of constraints. The gyroscope undergoes a very fast rotation around an axis passing by the fixed point, but this axis, in general, changes with time. In absence of external Force|Torque it keeps the same rotation axis in an Inertial Reference Frame .

A gyrocompass ia an instrument always pointing to the north. One important component of a gyrocompass is a gyroscope, but a gyrocompass is built to use the effect of gyroscopic precession. Gyrocompasses are widely used for navigation on ships, because they have two significant advantages over magnetic

DRAFT-IN-PROGRESS

compasses: they find true north as determined by Earth rotation, which is different from, and navigationally more useful than, magnetic north, and they are unaffected by ferromagnetic materials, such as a ship steel hull, which change the magnetic field.

Free Gyroscope

If the fixed point is the Center-Of-Mass, if the resultant external torque with respect to the Center-Of-Mass is zero, and the body rotates around a principal axis of inertia it turns out that the angular velocity is constant. In fact $\mathbf{L}'$ is constant and $\mathbf{L} \parallel \boldsymbol{\omega}$ because the body rotates around a principal axis of inertia. Therefore the rotation axis keeps the same direction in space. This is used in dynamic stabilizers: as the axis of the gyroscope keeps the same direction in space its direction relative to the host device measures the deviation of the host device from a fixed direction in space.

Typical applications are in artificial satellites and airplanes as well ship stabilisers.

Another typical application is in projectiles which are imparted a rotation around their axis.

Non-Free Gyroscope (Heavy Gyroscope)

Assume the fixed point is the Center-Of-Mass, the body rotates around a principal axis of inertia but the resultant external torque with respect to the Center-Of-Mass is not zero.

Assume that a force acts perpendicular to the rotation axis, applied, for instance, on the rotation axis (but any other application point would be good as well). The change of the angular momentum with respect to the Center-Of-Mass is perpendicular to the rotation axis that is perpendicular to the force. The module of the angular momentum with respect to the Center-Of-Mass is constant, because the angular momentum with respect to the Center-Of-Mass and its variation are perpendicular. Therefore the angular momentum with respect to the Center-Of-Mass undergoes a precession.

26.07.17
Free Asymmetrical Top

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|||

The motion of the asymmetrical top is more complex.

In the case of a free asymmetrical top the motion of precession is superimposed to a motion of nutation.

26.07.18
Why Do Satellites Spin?

Why do satellites spin?

WORKED SOLUTION

Satellites are given a spinning motion around an axis of rotation passing through their own center of mass, in order to stabilize them in orbit. When they rotate, they acquire an angular momentum. If no external disturbances are present then the vector angular momentum is constant in time. Therefore it is constant both in magnitude and direction. A constant direction of angular momentum means a constant orientation of the axis of rotation, therefore a stable attitude of the satellite in orbit.

©|M.R.Spiegel, *Theory And Problems Of Theoretical Mechanics*, 1967, McGraw-Hill, ...Ed., ...|problem 10.25|*solved* ...

Assume that initial conditions have been set up so that the heavy symmetrical top spins around its symmetry axis, the Center-Of-Mass trajectory is a circle around the vertical axis and the symmetry axis makes a constant angle with the vertical. Note that these are special initial conditions to make solution simpler, but more general solutions are possible.

1. Assuming that the angular momentum due to the angular velocity around the symmetry axis is much larger than any other angular momentum in the problem, and that the angular velocity around the symmetry axis is much larger than any other angular velocity, find the expression for the frequency of precession.
2. Solve the problem without the previous assumption.
3. Determine the motion of the Center-Of-Mass.
4. Determine the reaction of the table on the tip, both the vertical component and the horizontal one (static friction).

$$\boldsymbol{\gamma}_S = Mgh \sin[\theta]\, \widehat{\mathbf{K}} \quad ,$$

Trave Incernierata Al Muro E Sorretta Da Una Corda

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...|E14.5||

Una trave rigida uniforme di lunghezza $L = 3.3\ \mathrm{m}$ e massa $M = 8.5\ \mathrm{kg}$ è incernierata ad un muro ad un estremo. All'altro estremo è collegata una fune ideale attaccata al muro che la sorregge. L'angolo tra la trave e l'orizzontale è $0 \leq \beta \leq 90°$ e l'angolo tra la fune e l'orizzontale è α. La distanza tra la cerniera e il punto in cui la fune è attaccata al muro vale $d = 2.1\ \mathrm{m}$. Un peso di massa $m = 56\ \mathrm{kg}$ è attaccato all'estremo della trave.

1. Determinare la reazione della cerniera, $\mathbf{R}$, e la tensione della fune, T, nel caso in cui $\beta = 30°$.

DRAFT - IN - PROGRESS

WORKED SOLUTION

Si scelga un Coordinate System con asse x orizzontale e verso uscente dal muro e asse y verticale. Siano R_x ed R_y le componenti della reazione della cerniera e T il modulo della tensione della fune. Si noti che la tensione della fune è necessariamente diretta lungo la fune mentre la reazione vincolare sulla cerniera non ha necessariamente la direzione della trave. Infatti questa è un corpo rigido e quindi è in grado di esercitare idealmente sulla cerniera una forza avente direzione arbitraria e non necessariamente parallela a sé stessa. La reazione che la cerniera esercita sulla trave non ha di conseguenza necessariamente la direzione della trave. Occorre anzitutto determinare l'angolo α che è dato da

$$\tan[\alpha] = \frac{d - L\sin\beta}{L\cos\beta} = 0.157 \implies \alpha = 8.94^\circ$$

La prima **Cardinal Equation** e la seconda equazione cardinale usando come polo la cerniera si scrivono

$$\begin{aligned} &R_x - T\cos\alpha = 0 \quad , \\ &R_y + T\sin\alpha - mg - Mg = 0 \quad , \\ &TL\sin(\alpha+\beta) - mgL\cos\beta - MgL/2\cos\beta = 0 \quad . \end{aligned}$$

La scelta di un polo rispetto al quale entrambe le componenti di $\mathbf{R}$ sono nulle permette di ottenere un'equazione con la sola incognita T.

$$T = g\cos\beta\left[\frac{m + M/2}{\sin(\alpha+\beta)}\right] = 814\ \text{N} \quad ,$$

$$R_x = g\cos\beta\cos\alpha\left[\frac{m + M/2}{\sin(\alpha+\beta)}\right] = 804\ \text{N} \quad ,$$

$$R_y = -g\cos\beta\sin\alpha\left[\frac{m + M/2}{\sin(\alpha+\beta)}\right] + (m+M)\,g = 506\ \text{N} \quad .$$

La reazione esercitata dalla cerniera sulla trave vale

$$R = \sqrt{R_x^2 + R_y^2} = 950\ \text{N}$$

Si noti che sia R che T sono considerabilmente più grandi dei pesi combinati della trave e del peso. L'angolo che la reazione della cerniera forma con l'orizzontale vale

$$\tan[\phi] = \frac{R_y}{R_x} = 0.629 \implies \phi = 32.2^\circ$$

Per un valore di β fissato, cioè per una inclinazione della trave fissata, la tensione minima, al variare di α occorre quando $\alpha + \beta = 90^\circ$.

WORKED SOLUTION

1) $T = 814$ N; $R_x = 804$ N; $R_y = 506$ N.

26-029 A Cylinder Rolling Outside A Cylinder

This § is referenced at pages:
[1067, 1480]

Read § 26-030.

Consider a fixed rigid circular cylinder of radius R and a second rigid circular cylinder of radius $r < R$. The two cylinders have parallel axes. The small cylinder rolls without slipping on the large cylinder. Introduce the two angles: θ, defining the position of the center of the small cylinder with respect to the center of large cylinder; ϕ, defining the absolute rotation of small cylinder.

Determine the relation between θ and ϕ such that the rolling is without slipping.

26-030 A Sphere Rolling Inside a Sphere

This § is referenced at pages:
[1067, 1396, 1468, 1480]

Read § 26-029.

A sphere of radius r is rolling without slipping inside a larger semi-sphere of radius $R > 2r$, with vertex facing down. The motion is a plane motion, in a plane containing the center of both spheres. In this plane, measure all angles from the downward vertical direction and let θ be the angle of the center of the small sphere and ϕ the angle of rotation of the small sphere, both measured as positive in the counter-clockwise direction. One specific point of the small sphere, fixed with the small sphere, makes an angle ϕ_0 with the downward vertical direction when the small sphere is in the lowest position, $\theta = 0$.

1. Determine the rolling without slipping condition.
2. In case of rolling without slipping, determine the axis of instantaneous rotation.
3. In case of rolling without slipping, determine the acceleration of all the points of the edge.
   Let C be the center of the small sphere; P be the generic point on the edge of the small sphere; H be the generic point of contact of the two spheres; O be the center of the large semi-sphere and global origin.

WORKED SOLUTION

$$\mathbf{R}_C - \mathbf{R}_0 = (R-r)\left(+\widehat{\mathbf{e}}_1 \sin[\theta] - \widehat{\mathbf{e}}_2 \cos[\theta]\right) \quad ,$$

$$\mathbf{R}_P - \mathbf{R}_C = r\left(+\widehat{\mathbf{e}}_1 \sin[\phi+\phi_0] - \widehat{\mathbf{e}}_2 \cos[\phi+\phi_0]\right) \quad ,$$

$$\mathbf{v}_P = \dot{\theta}(R-r)\left(+\widehat{\mathbf{e}}_1 \cos[\theta] - \widehat{\mathbf{e}}_2 \sin[\theta]\right) + \dot{\phi} r\left(+\widehat{\mathbf{e}}_1 \cos[\phi+\phi_0] - \widehat{\mathbf{e}}_2 \sin[\phi+\phi_0]\right) \quad ,$$

$$\text{P is in contact with the semi-sphere} \quad \Leftrightarrow \quad P \to H \quad \Leftrightarrow \quad \phi + \phi_0 = \theta \quad ,$$

$$\Longrightarrow \mathbf{v}_H = +\widehat{\mathbf{e}}_1 \cos[\theta]\left(\dot{\theta}(R-r) + \dot{\phi} r\right) - \widehat{\mathbf{e}}_2 \sin[\theta]\left(\dot{\theta}(R-r) + \dot{\phi} r\right) \quad ,$$

$$\mathbf{v}_H = 0 \quad \Leftrightarrow \quad \dot{\theta}(R-r) + \dot{\phi} r = 0 \quad .$$

Note that the contact condition, $\phi + \phi_0 = \theta$, cannot be used to imply $\dot{\theta} = \dot{\phi}$, because angle and

CC BY NC ND

angular velocity must be treated as independent variables.

26-031 Rotation Around a Fixed Axis

Consider the rotation around a fixed axis, z. Determine, by explicit calculation from its definition, the angular velocity.

26-032 A Spinning Top

A spinning top rotates around its axis with angular velocity $\boldsymbol{\omega}$, while the axis stays always at a constant angle θ with respect to the vertical and rotates around the vertical with angular velocity $\boldsymbol{\Omega}$. Determine the angular velocity vector of the top.

26-033 Inertia Matrix|Tensor for a Homogeneous Cube

Determine the inertia Matrix|Tensor for a homogeneous cube with origin at one vertex and axes along the sides, by:

1. direct integration;
2. from the generalized Huygens-Steiner theorem and a minimal number of integrations.

WORKED SOLUTION

$$\mathbb{I} = ML^2 \begin{pmatrix} +2/3 & -1/4 & -1/4 \\ -1/4 & +2/3 & -1/4 \\ -1/4 & -1/4 & +2/3 \end{pmatrix},$$

26-034 Matrix of Inertia of a Thin Bar Without Integrations

Only use general theorems for the inertia Matrix|Tensor to calculate the moment of inertia with respect to the center of a thin cylindrical bar of mass M and length L.

26-035 A Special Cylinder

What must the ratio of height to radius of a cylinder be so that every axis is a principal axis (with the Center-Of-Mass as the origin)?

26-036 Matrix of Inertia of a Truncated Cone With Respect to Its Axis

Calculate the matrix of inertia of a truncated homogeneous cone, of height H and base radii a and b, with respect to its axis.

WORKED SOLUTION

$$\frac{\pi\rho H}{10}\frac{b^5 - a^5}{b - a} \quad .$$

DRAFT-IN-PROGRESS

27.01 Introduction

In this section the study of **solid elastic materials which are both homogeneous and isotropic** is introduced. While both solids and fluids can deform, the study of elasticity theory is typically targeted to solids, while the elastic properties of fluids are typically studied in the realm of fluid mechanics and ThermoDynamics.

This introductory discussion is a purely mechanical one, while a full treatment should be a thermo-mechanical one, in order to deal with transfers of mechanical energy from/to internal energy. As long as one studies purely mechanical processes, it must be assumed that mechanical energy is conserved, and there is no heat transfer. Read also § 32.

Under the effect of Force|Torque a material medium may deform in many ways. Whenever **the Force|Torque and deformations are small enough**, the deformation is proportional to the Force|Torque, as it follows while considering the first-order approximation of the functions relating Force|Torque and deformation. In these cases the process is said to be a **linear or elastic process**. Linearity is a combined property of the Force|Torque values, of the material, as well as of any other condition affecting the response of the material. **The superposition principle can be applied in elasticity theory, as it deals with linear systems.** Linearity and small deformations will always be assumed. In fact the discussion of large deformations, with possibly non-linear effects, is much more complex. However, most materials show, under small deformations, an elastic behavior, that is a deformation proportional to the applied Force|Torque. This behavior is observed in many common processes.

Non-elastic (non-linear) behavior includes: **non-linear response**; **hysteresis**, that is dependence of the response not only on the actual values but also on the history; **permanent deformations**; **breaking**.

We consider only continuous media made of non-dipolar particles.

© - QUOTE

©|L.E.Malvern|Introduction to the Mechanics of a Continuous Medium|*1969 - § 5.3 - WEB - URL* |

...
Up to this point we have assumed the non-dipolar case with no distributed assigned torques per unit area on the boundary surfaces and no distributed assigned body-torques (per unit volume or per unit mass), but only external surface traction forces and body forces; and with no torque-stress es, i.e., no distributed torques per unit area across internal surfaces.
Assigned external torque distributions could result from the action of an external magnetic field on Magnetized particles of the material or the action of an electric field on Polarized matter. Even without assigned external torques, torque-stress can arise from interactions between adjacent parts of the material other than central-force interactions. Torque|Stress were included in continuum mechanics by Voigt (1887, 1894) and the Cosserats (1909), but these formulations were not much applied. More recently Truesdell and Toupin (1960) have discussed them; Aero and Kuvshinskii (1960), Toupin (1962), and Mindlin and Tiersten (1962) have considered elastic materials with torque-stress; and several authors have considered possible effects on stress concentration.
We assume that the interaction across any internal surface consists of equal, opposite, and collinear forces plus equal and opposite torques.
...

PRELIMINARY

27.01.01
Small Force|Torque and Small Deformations

This § is referenced at pages:
[1032]

In general, a generic infinitesimal deformation $\mathfrak{d}\xi$ of a generic systems will depend on the applied Force|Torque, $\mathbf{f}/\gamma$, and the linear/elastic regime is given by approximating the displacement to first-order.

Specific examples, for special simple case, are defined in equations (27.02.01), (27.02.02), (27.02.03), (27.02.04).

DRAFT-IN-PROGRESS

27.02 Uniform and Isotropic Deformations of Homogeneous Isotropic Elastic Solids

This § is referenced at pages:
[1645]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.38||

A configuration is a set defining the positions of all particles of the body.

Deformation, in continuum mechanics, is the transformation of a body from a reference configuration to a current configuration.

Uniform and Isotropic deformations are such that, for every direction, every element of the solid shows the same relative change in length at all points, for any direction:

$$\frac{\Delta \ell_w}{\ell_w} = \text{the same at any point for any direction } w \quad .$$

As the small elastic deformations are linear, the **superposition principle** can be applied to determine the overall deformation by **summing the deformations induced by all the Forces|Torques**.

Two independent constants, out of the total of four basic constants which are usually defined (the Young modulus, the Poisson module, the shear modulus and the bulk modulus), completely describe the elastic properties of any LHI solid.

27.02.01 Change of Size of a Cylindrical Bar under longitudinal force

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|3.1||

Consider a cylindrical bar made of LHI solid material, with rest length given by l_0, and cross-section, at rest, with surface S_l.

27.02.01.01 Elongation and Compression

Suppose that the deformation is small enough to treat it as a linear process.

If the bar undergoes either a traction or a compression, via the uniform application at its bases of a force F_l parallel to its axis, one can define the normal stress:

$$f_l \equiv \frac{F_l}{S_l} \quad .$$

By convention the external force F_l is positive for a force pulling the bar (a traction) while it is negative for a force pushing the bar (a compression):

$$F_l > 0 \quad \Leftrightarrow \quad \text{traction} \quad ,$$

$$F_l < 0 \quad \Leftrightarrow \quad \text{compression} \quad .$$

Note that this convention is the opposite of the one normally used in elementary treatments of the pressure, when the convention is that a positive pressure compresses the system.

The fractional stretch (stretch per unit length) is called the longitudinal strain:

$$\epsilon_l \equiv \frac{\Delta l}{l_0} \quad .$$

UNDER-PROGRESS

The Young modulus is defined as the ratio between the normal stress and the longitudinal strain:

$$f_l \equiv Y \epsilon_l \qquad \Leftrightarrow \qquad \frac{F_l}{S_l} \equiv Y \frac{\Delta l}{l_0} \quad . \tag{27.02.01}$$

→ 1488 1490 1497

The definition of the Young modulus allows one to introduce a coefficient of proportionality, the Young modulus, which does not depend on the dimensions of the block of material and it is thus a property of the material itself.

Equation (27.02.01), in case the Young modulus is a constant, is called Hooke law.

Heuristically it is clear that the elastic constant of the elementary Hooke law must be proportional to the cross-sectional area of the bar and inversely proportional to the length of the bar. Read § 27.07.01.

Hooke law is actually a constitutive equation for the material.

Young modulus must be non negative, read § 27.07.02.

$$Y \geq 0 \quad .$$

A perfectly rigid material is such that: $Y \to +\infty$, while $Y = 0$ means a structure-less material: any force can give any deformation.

27.02.01.02 Lateral Shrinking and Expansion

Suppose that the deformation is small enough to treat it as a linear process.

A change of length of a material, as just described, is accompanied, in general, by a change in the transverse dimensions. Let d be any transverse dimension of the bar.

The Poisson module, Σ, is defined as the negative ratio between the transverse strain, ϵ_d, and the longitudinal strain, ϵ_l:

$$\epsilon_d \equiv \frac{\Delta d}{d_0} \equiv -\Sigma \frac{\Delta l}{l_0} \equiv -\Sigma \epsilon_l = -\frac{\Sigma}{Y} \frac{F_l}{A_l} \quad . \tag{27.02.02}$$

→ 1488 1490

Equation (27.02.02), in case the Poisson modulus is a constant, is called Poisson law.

It can be shown that Poisson module is constrained to be

$$-1 \leq \Sigma \leq \frac{1}{2} \quad ,$$

read § 27-004.

No common material is known with a negative Poisson ratio (called auxetics) even if this is not forbidden by any law of Nature. However, complex materials with negative Poisson ratio do exist. One common example is Gore-TeX (see **WEB - URL**).

Note that Poisson law is actually a constitutive equation for the material.

A material such that $\Sigma = 0$ does not show any change in its lateral dimensions for a longitudinal traction/compression.

It can be shown that materials such that $\Sigma = 1/2$ may change shape but not volume, see equation (27.02.07) and § 27.07.06.

27.02.02
Plane Shear Distortions

This § is referenced at pages:
[1649]

DRAFT IN PROGRESS

Read also section § 16.12.18, § 16.12.17.

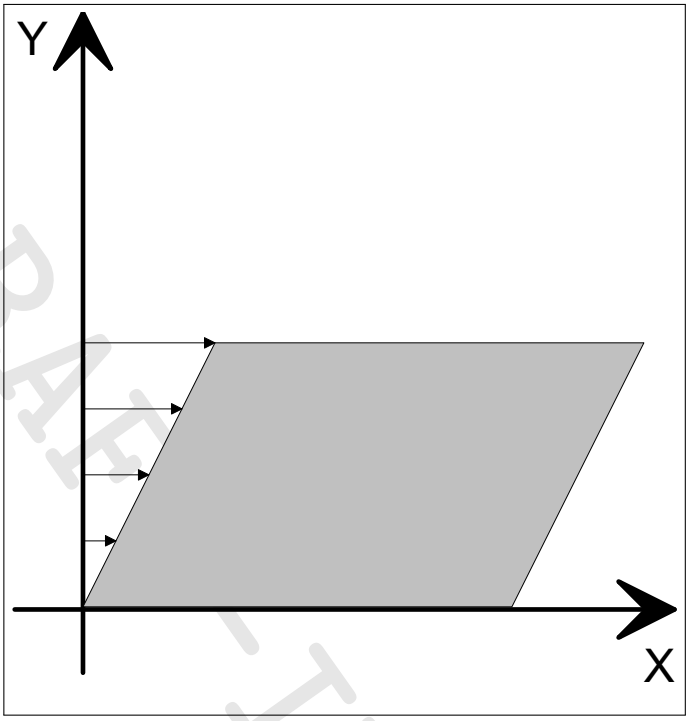

Figure 27.11: ShearStrain

Suppose that the deformation is small enough to treat it as a linear process.

Suppose to apply to a parallelepiped of LHI material a shearing stress, with forces along the $\pm x$ axis, causing a change of shape without change of volume, such that the two opposite faces where the forces are applied move parallel to themselves. All displacements of all the points are parallel each other. Any section, which at fixed z was a rectangle, deforms into a parallelogram.

The shear modulus is defined as the ratio between the shear stress and the shear strain, that is the displacement along x divided by the height of the parallelepiped, y_0:

$$\boxed{\frac{F_{xy}}{S_{xz}} \equiv \frac{F_{xy}}{x_0 z_0} \equiv g = G\theta = G\frac{\Delta x}{y_0}} \quad . \tag{27.02.03}$$

→ 1488

- F_{xy}: force along the x axis applied to a surface perpendicular to the y axis.
- S_{xz}: area of the element of surface perpendicular to the y axis.

As the deformation is small the angle can be approximated with the tangent.

The shear modulus must be positive or otherwise one could get work out of a self-shearing medium:

$$\boxed{G \geq 0} \quad .$$

27.02.03
Volume Changes

Suppose that the deformation is small enough to treat it as a linear process.

A fourth constant is usually introduced. It is the bulk modulus, B, defined in terms of the **volume change under a uniform pressure** all around the material:

$$\boxed{\frac{1}{B} \equiv -\frac{1}{V}\frac{\partial V}{\partial p}} \quad . \tag{27.02.04}$$

→ 1488

Note that this concept is only useful for uniform pressure, that is normal stress, which is typically the case for a fluid, but not necessarily for a solid.

It can be shown that the bulk modulus is necessarily non-negative:

$$\boxed{B \geq 0} \quad .$$

DRAFT - IN PROGRESS

A material such that $B \to \infty$ is incompressible.

27.04 General Non-Uniform Deformation in One Dimension

This § is referenced at pages:
[1502]

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|3||

A more general approach is required to treat general non-uniform deformation in one dimension.

See figure 27.12. We designate the bar axis as the z axis and introduce the function $\xi[z]$ to measure the displacement with respect to the equilibrium position (or to any other predefined reference position) of the point which is at z in the equilibrium (or any other reference) position. Consider a small section of length Δz of the bar. It follows that:

$$\epsilon_z \equiv \frac{((z+\Delta z+\xi[z+\Delta z])-(z+\xi[z]))-\Delta z}{\Delta z} = \frac{\Delta\xi}{\Delta z} \longrightarrow \frac{\partial\xi}{\partial z} \quad .$$

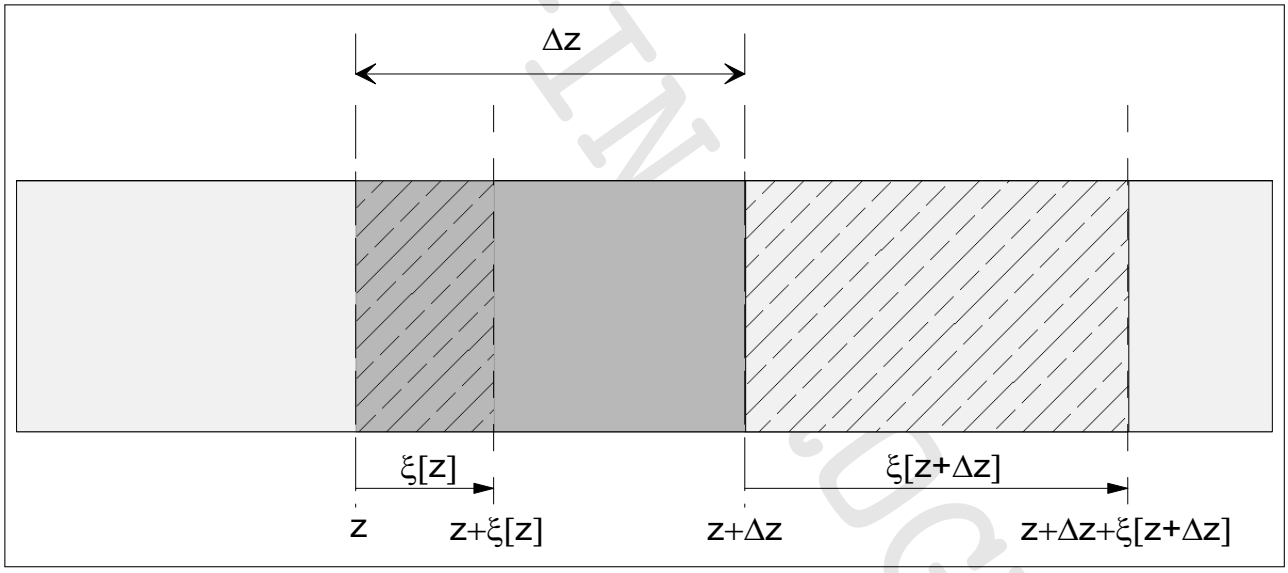

Figure 27.12: Kinematics of longitudinal waves

PRELIMINARY PROGRESS

27.05 Statics of Continuous Media

Any continuous medium as a whole is in equilibrium if and only if every part of it is in equilibrium.

DRAFT-IN-PROGRESS

27.06 Some Related Concepts From Thermodynamics

Strictly speaking, all the definitions of the four parameters should apply under some thermodynamical condition, such as: fixed temperature (isothermal); fixed entropy (iso-entropic), that is non exchange of heat..... All the parameters, a priori, depend on thermodynamical parameters, such as temperature.

27.06.01 Coefficienti Di Dilatazione Lineare Ed Espansione Volumetrica

Il coefficiente di dilatazione termica lineare è definito come

$$\boxed{\alpha \equiv \frac{1}{L}\left(\frac{\partial L}{\partial T}\right)_{\mathcal{X}} = \alpha[T,\mathcal{X}]} \quad .$$

Il coefficiente di espansione termica volumetrica è definito come

$$\boxed{\beta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{\mathcal{X}} = \beta[T,\mathcal{X}]} \quad .$$

Nelle definizioni si assume che le eventuali altre variabili, $\mathcal{X}$, da cui dipende lo stato del sistema, oltre alla temperatura, siano tenute fisse. In generale i coefficienti così definiti dipendono quindi anche da tali variabili.

Per una sostanza isotropa il coefficiente di dilatazione termica lineare non dipende dalla direzione. In tal caso si ha

$$\beta = 3\alpha \quad .$$

In generale per una sostanza non isotropa, detti α_1, α_2 ed α_3 i coefficienti di dilatazione lineare lungo tre assi ortogonali si ha:

$$\boxed{\beta = \alpha_1 + \alpha_2 + \alpha_3} \quad .$$

DRAFT-IN-PROGRESS

27.07 Examples and Physical Applications

27.07.01 Definition of the Young Modulus

This § is referenced at pages:
[1490]

Show how the Young module definition, for a homogeneous and isotropic material, makes the definition independent of the geometry of the block.

WORKED SOLUTION

The definition of the Young modulus for a homogeneous and isotropic material, equation (27.02.01), is motivated by two facts. Start from Hooke law:

$$F = k\Delta l \quad .$$

First of all one expects the elongation Δl to be proportional to the length of the bar. This can be understood by imagining a single bar divided in two parts along its length. If the bar is in equilibrium the stress is the same at any section but the elongation of any of the two parts will be proportional to its length at rest. In fact:

$$\Delta l = \Delta l_1 + \Delta l_2 = F\left(\frac{1}{k_1} + \frac{1}{k_2}\right) \equiv \frac{F}{k} \quad .$$

One has that doubling the (rest) length of the bar the elastic constant is halved:

$$\left\{ \Delta l_1^{(0)} = \Delta l_2^{(0)} = \frac{\Delta l^{(0)}}{2} \equiv \Delta l_{1/2}^{(0)} \qquad k = \frac{k_{1/2}}{2} \right\} \qquad \Longrightarrow \qquad \boxed{k \propto \frac{1}{\Delta l^{(0)}}} \quad .$$

Secondly one expects that the elongation Δl will be inversely proportional to the section of the bar. This can be understood by imagining a single bar divided longitudinally in two identical parts. In order to obtain a certain Δl the applied force has to be the sum of the two forces to be applied to each of the two longitudinal sections. Therefore, proceeding as in the previous case,

$$F = F_1 + F_2 = (k_1 + k_2)\,\Delta l \equiv k\Delta l \qquad S = S_1 + S_2 \quad .$$

One has that doubling the cross-sectional area of the bar the elastic constant is doubled:

$$\left\{ S_1 = S_2 = \frac{S}{2} \equiv S_{1/2} \qquad k = 2k_{1/2} \right\} \qquad \Longrightarrow \qquad \boxed{k \propto S} \quad .$$

The Young module is thus related to the elastic constant by the equation:

$$\boxed{k \equiv Y\frac{S}{l^{(0)}}} \quad .$$

27.07.02
Positivity of the Young Modulus

This § is referenced at pages:
[1490, 1498]

Show that the Young modulus must be positive.

WORKED SOLUTION

Suppose that the Young modulus is negative, by absurd.
Consider a bar of material immersed in a gas at constant pressure enclosed in a container with rigid walls. Due to random fluctuations there will be instants when the pressure on the two opposite sides of the base increases and the normal force, due to the gas pressure, acting on the two bases would then become more negative than at equilibrium, tending to compress the bar. The length of the bar would increase, as $Y < 0$, compressing the surrounding gas and thus increasing its pressure once more. The increase of pressure of the gas would increase the force on the bases of the bar which would expand and so on: the situation would be unstable.

27.07.03
Positivity of the Bulk Modulus

This § is referenced at pages:
[Never referenced.]

As in section § 27.07.02.

27.07.04
Positivity of the Shear Modulus

Show that the shear modulus must be positive.

WORKED SOLUTION

Consider, for instance, a block, kept, from one extreme, in the horizontal direction in a gravity field (a cantilevered beam, for instance) with a mass hanging at the free end. Suppose that the shear modulus is negative. In this case the beam would deform rising its free end in the gravity field. This behavior would make any solid object unstable under random fluctuation in its shear deformations.

Examples of shears

1. Shearing along the x axis:

$$\begin{pmatrix} 1 & \tan(\theta) \\ 0 & 1 \end{pmatrix} \tag{27.07.01}$$

2. Shearing along the y axis:

$$\begin{pmatrix} 1 & 0 \\ \tan(\theta) & 1 \end{pmatrix} \tag{27.07.02}$$

3. Shearing in the $x-y$ plane along the x axis:

$$\begin{pmatrix} 1 & 0 & \tan(\theta) \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{27.07.03}$$

4. Shearing the $x-z$ plane along the x axis:

$$\begin{pmatrix} 1 & \tan(\theta) & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{27.07.04}$$

5. A shearing by angle θ in the $1,1$ direction in the line $1,-1\cdot p == 0$:

$$\begin{pmatrix} \frac{1}{2}(\tan(\theta)+2) & -\frac{\tan(\theta)}{2} \\ \frac{\tan(\theta)}{2} & \frac{1}{2}(2-\tan(\theta)) \end{pmatrix} \tag{27.07.05}$$

27.07.06
A Block under uniform Pressure

This § is referenced at pages:
[1490, 1659, 2057]

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...- 2.38.2

The two constants Y and Σ completely define the elastic properties of any homogeneous and isotropic solid. The relation between Y, Σ and B is derived.

Materials are subject to uniform stresses when the stresses are uniform across the medium. For arbitrary stresses the **superposition principle** can be applied as elasticity theory deals with linear systems.

Apply a uniform change of pressure, Δp, to a parallelepiped block, starting from some equilibrium condition. The stress is then uniform. By applying the **superposition principle** we have that any pair of opposite faces is subject to the elongation|compression, as described by the Young modulus, and by shrinking, due to the elongation|compression on the two other pairs of opposite faces. Consider in fact each of the three axes: the elongation|compression along any of them is caused by the elongation|compression on the two opposite faces perpendicular to the axis plus the effect of the Poisson shrinking on the other two pairs of opposite faces. The problem is obviously symmetrical in all the three faces.

Fix one of the three directions, for instance z. Let the l_z variable denote the lengths and change of lengths along the chosen fixed direction caused by stresses on the two faces perpendicular to the chosen

DRAFT-IN-PROGRESS

direction. Let the d_x and d_y variables denote the lengths and change of lengths, along the same fixed direction z, caused by the stresses on the two faces perpendicular to the other two directions, x and y. Then one has, for the longitudinal strain along the z direction:

$$\epsilon_z \equiv \frac{\Delta l_z}{l_z} + \frac{\Delta d_x}{d_x} + \frac{\Delta d_y}{d_y} = -\frac{\Delta p}{Y}(1-2\Sigma) \quad . \tag{27.07.06}$$

→ 1500

Note that the result does not depend on the chosen fixed direction z.

The volume change follows:

$$\boxed{\frac{\Delta V}{V_0} = \epsilon_x + \epsilon_y + \epsilon_z = -3\frac{\Delta p}{Y}(1-2\Sigma)} \quad . \tag{27.07.07}$$

→ 1500

From equation (27.07.07) the upper limit of the Poisson module follows:

$$\Sigma \leq \frac{1}{2} \quad . \tag{27.07.08}$$

→ 1510

An incompressible solid is therefore characterized by a value of the Poisson module equal to $1/2$.

27.07.07
A Constrained Bar

This § is referenced at pages:
[2034]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.38.2||

This problem involves non isotropic deformations.

Consider a cylindrical bar with rectangular cross-section which is compressed/elongated along one of the directions of its sides (call it the longitudinal direction) while its sides are prevented from expanding/contracting. Note that on the practical side it is technically easier to setup the problem in such a way that the bar is compressed while its sides are prevented from expanding.

Calculate the relation between the longitudinal stress and the longitudinal strain under these conditions.

WORKED SOLUTION

To avoid the expansion/contraction of the sides we need some kind of forces to prevent the sides from contracting. The magnitude of these forces needs to be calculated.

Let z be the longitudinal axis and let the sides of the rectangular cross-section be parallel to the x and y axes. Let F_x, F_y and F_z be the external forces applied to the system along the x, y and z axes. Thanks to the assumed linearity for small deformations we can sum the changes in length due to all the forces. Following equation (27.07.06), we then have:

$$\epsilon_z \equiv \frac{\Delta l_z}{l_z} = \frac{1}{Y}\frac{F_z}{A_z} - \frac{\Sigma}{Y}\left(\frac{F_x}{A_x} + \frac{F_y}{A_y}\right) = \frac{1}{Y}\left(\frac{F_z}{A_z} - \Sigma\left(\frac{F_x}{A_x} + \frac{F_y}{A_y}\right)\right) \equiv \frac{1}{Y}(\sigma_z - \Sigma(\sigma_x + \sigma_y)) \quad , \tag{27.07.09}$$

→ 1501

$$\epsilon_x \equiv \frac{\Delta l_x}{l_x} = \frac{1}{Y}\frac{F_x}{A_x} - \frac{\Sigma}{Y}\left(\frac{F_y}{A_y} + \frac{F_z}{A_z}\right) = \frac{1}{Y}\left(\frac{F_x}{A_x} - \Sigma\left(\frac{F_y}{A_y} + \frac{F_z}{A_z}\right)\right) \equiv \frac{1}{Y}(\sigma_x - \Sigma(\sigma_y + \sigma_z)) \quad , \tag{27.07.10}$$

$$\epsilon_y \equiv \frac{\Delta l_y}{l_y} = \frac{1}{Y}\frac{F_y}{A_y} - \frac{\Sigma}{Y}\left(\frac{F_z}{A_z} + \frac{F_x}{A_x}\right) = \frac{1}{Y}\left(\frac{F_y}{A_y} - \Sigma\left(\frac{F_z}{A_z} + \frac{F_x}{A_x}\right)\right) \equiv \frac{1}{Y}(\sigma_y - \Sigma(\sigma_z + \sigma_x)) \quad . \tag{27.07.11}$$

It is assumed that the sides are kept from changing their direction by suitable forces. Therefore we

DRAFT - NOT FOR

CC BY NC ND

must have:

$$\epsilon_x = \epsilon_y = 0 \quad .$$

We are left with three equations with four unknowns: σ_x, σ_y, σ_z, ϵ_z. This implies a well-defined relation among F_z, F_x and F_y:

$$\sigma_x = \sigma_y = \frac{\Sigma}{1-\Sigma}\sigma_z \qquad \left\{ \frac{\Sigma}{1-\Sigma} > 0 \qquad \Leftrightarrow \qquad \Sigma > 0 \right\} \quad .$$

The previous relation correctly implies that if the force F_z is a traction force then also the forces F_x and F_y must be positive, that is a traction must be exerted on the lateral sides to keep it from contracting as well if and only if $\Sigma > 0$.
By substituting back into the above expression (27.07.09) for $\Delta l_z / l_z$:

$$\epsilon_z = \frac{1}{Y}\left(\frac{1-\Sigma-2\Sigma^2}{1-\Sigma}\right)\sigma_z \quad ,$$

$$\sigma_z = \left(\frac{1-\Sigma}{(1+\Sigma)(1-2\Sigma)}\right) Y \frac{\Delta l_z}{l_z} \quad .$$

That is when the sides are constrained the Young modulus gets multiplied by a complex factor of the Poisson module. The factor is always larger than one, and therefore the block becomes stronger in case the sides are constrained. This factor acts in fact as a effective Young modulus for a constrained bar.
Refer to § 45.04.01 for the general longitudinal motion, where the same factor $\left(\frac{1-\Sigma}{(1+\Sigma)(1-2\Sigma)}\right)$ as above shows up.

27.07.08
The Ideal String|Bar

This § is referenced at pages:
[1502, 1991, 1994]

An ideal String|Bar is, by definition, inextensible (that is its length never changes) with no mass (that is mass negligible with respect to other masses in the problem) and perfectly flexible.

- **Inextensible**: the kinematic constraint that the distance between any two points along the string never changes is effective.
- **Massless**: the tension along the string does not change, as the mass is assumed to be zero.
- **Perfectly flexible**: changing the curvature and|or the torsion of the string at any point requires no work.

In practice, the above characteristics of the ideal string are often just approximated.

IPL Preprint

27.07.09
An Inextensible Massive String|Bar Hanging in the Gravity Field

This § is referenced at pages:
[1455, 1502]

Consider an ideal string (read § 27.07.08) of length L fixed to the ceiling and with a small mass M at the free extreme. Find the tension along the string as a function of the position. Note that, in fact, the problem would have the same solution if the string were replaced by a rigid cylindrical bar.

Determine the equation of equilibrium assuming no strain and no lateral change of dimensions.

WORKED SOLUTION

Introduce a vertical z axis, oriented downwards, with origin at the point where the string is hanging. Let $T[z]$ be the force that the piece of String|Bar before z exerts on the piece after z. The first **Cardinal Equation** for the piece of String|Bar which, in the unstretched String|Bar, is between z and $z+\Delta z$ reads:

$$(T[z]-T[z+\Delta z])+\rho S\Delta z g=0 \quad ,$$

$$\frac{\mathrm{d}T}{\mathrm{d}z}=\rho S g>0 \quad ,$$

$$T[L]=-Mg \quad ,$$

$$T[z]=mg\left(\frac{z}{L}-1\right)-Mg \quad .$$

We expect the tension to be negative and increasing in value, while deceasing in module when z increases. However, the tension is the unknown to be determined for this problem.

In fact, it turns out that the tension has maximum absolute value at $z=0$, where the derivative is maximum as it has to sustain the mass and the proper mass o the String|Bar.

Note that the tension is not zero at $z=L$, as the mass M must be sustained,

Compare with problem § 27.07.10: in this probllem the partial derivative of ξ with respect to z is zero.

The condition of constant tension, typically used in elementary problem, is related to the mass of the String|Bar, via the tension one would calculate neglecting the mass of the String|Bar, $|T[L]|$:

$$\frac{|T[0]-T[L]|}{|T[L]|}=\frac{m}{M}\ll 1 \quad .$$

27.07.10
A LHI String|Bar Statically Hanging in the Gravity Field

This § is referenced at pages:
[1502, 2049]

Read § 45.12.06 for the dynamics.

Consider an elastic String|Bar, made of an homogeneous and isotropic material, hanging in the gravity field from one extreme. The rest length is L, its cross-sectional area is S, the sound speed is c and its total mass m; a mass M is hanging on the String|Bar.

Determine the configuration of equilibrium assuming small strain and no lateral change of dimensions.

CC BY NC ND

WORKED SOLUTION

Note: the **reference configuration is not, here, equilibrium; it is equilibrium when there are no external forces on the String|Bar, that is the un-stretched String|Bar.**
Introduce a vertical z axis, oriented downwards, with origin at the point where the String|Bar is hanging.
Read § 27.04 for the general setup of the problem and let $\xi[z]$ be the displacement with respect to the equilibrium condition of the parts of the string at z. Let $T[z^\star]$ the force, positive when directed along the z axis, that any part at $z < z^\star$ exerts on the part at $z > z^\star$.

Elementary solution

From the first **Cardinal Equation** applied to a small disk of thickness Δz one has:

$$(T[z] - T[z + \Delta z]) + \rho A g \Delta z = 0 \quad ,$$

$$\frac{\mathrm{d}T}{\mathrm{d}z}[z] = \rho A g \quad ,$$

$$T[z] = \rho A g z - g\,(m + M) = \rho A g\,(z - L) - M g = -Y A \frac{\mathrm{d}\xi}{\mathrm{d}z} < 0 \quad .$$

The solution is formally the same as in section § 27.07.09 but the meaning is quite different. In fact for the inextensible string z correspond in any case to the position along the string, while for the extensible string z denotes the position in the equilibrium condition while the real position changes after deformation.

General solution from d'Alembert (classical) wave equation

The equation is equation (45.02.03). Therefore, the equation is:

$$\frac{\partial^2 \xi}{\partial t^2}[z,t] - c^2 \frac{\partial^2 \xi}{\partial z^2}[z,t] = \frac{f_{\mathrm{v}}}{\rho_0} = g \qquad c^2 = \frac{Y}{\rho} \quad .$$

At equilibrium the acceleration is zero. Therefore:

$$\frac{\partial^2 \xi}{\partial t^2}[z,t] = 0 \implies -c^2 \frac{\partial^2 \xi}{\partial z^2}[z,t] = g \quad .$$

The general solution, in terms of two integration constants, β_0 and β_1, is:

$$\xi[z,t] \longrightarrow \xi[z] = -\frac{g}{2c^2} z^2 + \beta_1 z + \beta_0 \quad .$$

Assume $M = 0$. The boundary conditions for the specific problem are:

- the String|Bar has its fixed extreme attached to a fixed point, therefore it cannot undergo any displacement: $\xi[z = 0] = 0$;
- the free extreme of the String|Bar, being free, does not exert any force, its stress is null, because it has nothing to sustain: $\dfrac{\partial \xi}{\partial z}[z = L] = 0$

It follows:

$$\xi[z] = -\frac{g}{2c^2} z^2 + \frac{gL}{c^2} z \quad .$$

The plot of $\xi[z]$ is a parabola whose vertex is a maximum located at $z = L$ and passing by the origin at $z = 0$. The displacement is maximum at $z = L$: $\xi[z = L] = \dfrac{gL^2}{2c^2}$.
The stress along the String|Bar is:

$$S_{zz}[z] = \frac{F_\ominus}{S} = -Y \frac{\partial \xi}{\partial z} = \frac{gY}{c^2}\,(z - L) < 0 \quad .$$

Its maximum value is:

$$S_{zz}[z = 0] = -gL \frac{Y}{c^2} = -gL\rho = -\frac{mg}{S} \quad ,$$

CC BY NC ND

The stress, that is the first derivative, $\frac{\partial \xi}{\partial z}$, is maximum at $z = 0$, because there the String|Bar must support the weight of whole String|Bar. That is also the most likely point where the String|Bar might break.
Read § 45.12.06 for $M \neq 0$.

27.07.11
A Fixed Horizontal Cylindrical Rigid Cantilevered Beam

This § is referenced at pages:
[1455, 1455, 1508]

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|3.5||

Consider a fixed horizontal cylindrical rigid cantilevered beam. Determine the distribution along the beam of forces and torques assuming that the beam is exactly rigid, that is its geometrical shape is not altered.

Consider the same problem with an additional vertical downward force, $\mathbf{F}_0$, applied at $x = h$.

WORKED SOLUTION

When the entire beam is in equilibrium, any portion of it must be in equilibrium as well.
Let the x axis be along the beam, exiting the wall with origin at the point where the beam enters the wall.
Assume the beam is perfectly rigid, so that any deformation is negligible. Let the uniform cross-sectional area of the beam be A and let ρ be the mass density. Let M be the total mass and L be the length of the beam.
Consider any section perpendicular to the beam axis, at x_0: $\mathcal{S}[x_0]$. The system of forces that the part of the beam at $x < x_0$ applies on the part at $x > x_0$ can be reduced to a total force applied at any point on $\mathcal{S}[x_0]$, $\mathbf{F}[x_0]$, plus the total torque, with pole at the point where the resultant force is applied, $\mathbf{\Gamma}[x_0]$. Once the point of application of the total force is chosen and the resultant external torque with respect to the pole is calculated, the pole used is not relevant, as the torque is independent of the pole. Therefore we will omit to mention that the torques are evaluated with respect to a pole, O, and just write: $\mathbf{\Gamma} \equiv \mathbf{\Gamma}_0$.
All the forces and torques we will use are those applied by the part of the beam at $x < x_0$ on the part at $x > x_0$. These are often named $\mathbf{F}^-[x_0]$ and $\mathbf{\Gamma}^-[x_0]$. The forces applied by the part of the beam at $x > x_0$ on the part at $x < x_0$ are often named: These are often named $\mathbf{F}^+[x_0]$ and $\mathbf{\Gamma}^+[x_0]$.
Both $\mathbf{F}[x_0]$ and $\mathbf{\Gamma}[x_0]$ can be decomposed into their components perpendicular to $\mathcal{S}[x_0]$ and parallel to $\mathcal{S}[x_0]$:

- the component of $\mathbf{F}[x_0]$ perpendicular to $\mathcal{S}[x_0]$, F_x, is the normal stress (also known as pressure);
- the component of $\mathbf{F}[x_0]$ parallel to $\mathcal{S}[x_0]$, $\mathbf{F}_\perp$, is the shear stress;
- the component of $\mathbf{\Gamma}[x_0]$ perpendicular to $\mathcal{S}[x_0]$, Γ_x, is the twisting moment (torsional moment due to torsional stress);
- the component of $\mathbf{\Gamma}[x_0]$ parallel to $\mathcal{S}[x_0]$, $\mathbf{\Gamma}_\perp$, is the bending moment.

We can write the **Cardinal Equations** along the x direction. let the y axis oriented vertically up.
One should note that $F_\perp[x]$ is required to balance the weight and $\Gamma_\perp$ is required to balance the bending action of the weight. Therefore $F_\perp[x]$ will be along the vertical direction (y axis) while $\Gamma_\perp$ will be along the horizontal direction perpendicular to x, that is along the z axis.
The first and second **Cardinal Equations** applied to a small cylinder of the beam of length Δx,

taking into account that the generalized third Newton law implies:

$$\mathbf{F}[x_0] \equiv \mathbf{F}^-[x_0] = -\mathbf{F}^+[x_0] \qquad \mathbf{\Gamma}[x_0] \equiv \mathbf{\Gamma}^-[x_0] = -\mathbf{\Gamma}^+[x_0]$$

read:

$$A\,(F[x] - F[x+\Delta x]) - \rho A \Delta x g = 0 \qquad (27.07.12)$$

→ 1505

$$A\,(\Gamma[x] - \Gamma[x+\Delta x]) - \rho A \Delta x g \frac{\Delta x}{2} - AF[x+\Delta x]\Delta x = 0 \qquad \text{pole at } x \quad .$$

→ 1505

Note that the first two terms of the second **Cardinal Equation** above do not depend on the choice of the pole, while the last two terms do depend on it. It is easy to check that the result would not change by choosing the pole, for instance, at $x + \Delta x$. The limit for $\Delta x \longrightarrow 0$ gives:

$$\frac{\mathrm{d}F}{\mathrm{d}x} = -\rho[x]g \quad ,$$

$$\frac{\mathrm{d}\Gamma}{\mathrm{d}x} = -F[x] \quad .$$

At the free end, both F and Γ must vanish.
At the clamped end, $x = 0$, both F and Γ must have the value required to support the full beam:

$$F[x=0] = Mg \qquad \Gamma[x=0] = MgL/2$$

The solution of the system gives:

$$F[x] = -\rho g A x + F[x=0] \implies F[x] = \frac{Mg}{L}(L-x) \geq 0 \quad ,$$

$$\Gamma[x] = \frac{Mg}{2L}(x-L)^2 + \Gamma[x=L] \implies \Gamma[x] = \frac{Mg}{2L}(x-L)^2 \geq 0 \quad .$$

Note that, in case the beam is sustained at the second extreme too, at $z = L$, the problem of a rigid beam would be, a priori, under-determined, even if a reasonable assumption, in some cases, might be the equality of the forces of the two supports.
Consider the case when the additional force is applied. The **Cardinal Equations** of motion (27.07.12), (27.07.11) become, in terms of the generic external vertical force per unit volume $w[x]$:

$$\boxed{\frac{\mathrm{d}F}{\mathrm{d}x} = -w[x] \qquad \frac{\mathrm{d}\Gamma}{\mathrm{d}x} = -F[x]} \quad ,$$

which implies

$$\boxed{\frac{d^2\Gamma[x]}{\mathrm{d}x^2} = w[x]} \quad .$$

In case of a discrete force, applied at $x = h$, the shear stress has a discontinuity at $x = h$ of amplitude F_0 which translates into a non derivable bending moment at $x = h$ (first specie discontinuity of its first derivative).

27.07.12
Torsion of a Cylindrical Bar

This § is referenced at pages:
[1666, 1666]

Consider a cylindrical bar, made of an homogeneous and isotropic material, having length L and a uniform circular section of radius R. The bar is in static equilibrium under a uniform torsion by an angle ϕ, kept by a suitable set of external forces. Calculate the required torsional torque along the bar as a function of the torsion angle ϕ.

WORKED SOLUTION

Let the z axis be coincident with the axis of the cylinder, let its origin be located at one of the ends and let its orientation be such that the bar is defined by $0 \leq z \leq L$.
Just consider the equilibrium of the bar under torsion along and around its axis, the z axis. That is assume that a suitable set of forces exist to guarantee both the translational equilibrium and the rotational equilibrium around the x and y axes which are outside the interests of the present problem. The equilibrium condition is thus driven by the components of the torques along the z axis only. Only the components of the forces perpendicular to the z axis contribute to the components of the torques along the z axis.
Consider any section $\mathcal{S}[z_0]$ of the bar defined by a plane perpendicular to the z axis at the position z_0. Let $\Gamma_O^-[z_0]$ be the component along z of the total torque with respect to the point $O = \{0, 0, z_0\}$ (the point of $\mathcal{S}[z_0]$ lying on the z axis) of all the forces that the part of the bar at $z < z_0$ applies to the part of the bar at $z > z_0$. Moreover, let $\Gamma_O^+[z_0]$ be the component along z of the total torque with respect to the point $O = \{0, 0, z_0\}$ (the point of $\mathcal{S}[z_0]$ lying on the z axis) of all the forces that the part of the bar at $z > z_0$ applies to the part of the bar at $z < z_0$. The forces involved are applied at the section $z = z_0$ separating the two parts (they are contact forces) and, as it was already said, only the components of those forces perpendicular to the z axis contribute to $\Gamma_O[z_0]$.
At equilibrium, for any section $\mathcal{S}[z_0]$, we must have:

$$\Gamma_O^-[z_0] + \Gamma_O^+[z_0] = 0 \quad ,$$

because the two parts apply equal and opposite torques on each other.
Consider any slice of the bar defined by the two sections $\mathcal{S}[z_0]$ and $\mathcal{S}[z_0 + \Delta z]$, perpendicular to the axis of the bar and separated by a distance Δz. At equilibrium, for any pair of sections $\mathcal{S}[z_0]$ and $\mathcal{S}[z_0 + \Delta z]$, we must have:

$$\Gamma_O^-[z_0] + \Gamma_O^+[z_0 + \Delta z] = 0 \quad ,$$

because any slice of the bar is in equilibrium.
It follows that:

$$\boxed{\Gamma_O^+[z_0] = \Gamma_O^+[z_0 + \Delta z] \qquad \Gamma_O^-[z_0] = \Gamma_O^-[z_0 + \Delta z]} \quad ,$$

that is both $\Gamma_O^-[z]$ and $\Gamma_O^+[z]$ do not depend on z:

$$\boxed{\frac{\mathrm{d}\Gamma_O^-[z]}{\mathrm{d}z} = \frac{\mathrm{d}\Gamma_O^+[z]}{\mathrm{d}z} = 0} \quad .$$

One can therefore calculate either $\Gamma_O^-[z]$ or $\Gamma_O^+[z]$ at any section $\mathcal{S}[z]$.
In order to calculate $\Gamma_O^-[z]$ consider the torsion of a small slice of length Δz, located between z and $z + \Delta z$. Assume, for more generality, that the cylindrical bar is a hollow bar with internal radius r_1 and external radius r_2.
Introduce polar coordinates, $\{r, \theta\}$, on the circular basis of the bar. Consider an infinitesimal element of the small slice of the bar spanning an angle $\mathrm{d}\theta$, with a radial span $\mathrm{d}r$ and height Δz. This element, when considered as an infinitesimal element, is actually an infinitesimal parallelepiped.
Let $\mathrm{d}\mathbf{F}_\theta$ the infinitesimal shear force acting on an infinitesimal element of the basis of the small slice, spanning an angle $\mathrm{d}\theta$ and with a radial span $\mathrm{d}r$. Only the tangential component of the shear force on the basis contributes to $\Gamma_O^-[z]$. Radial components, if any, would contribute to the compression or expansion of the bar in the transverse direction.
The infinitesimal parallelepiped is deformed, as a consequence of the shear forces on its infinitesimal

CC BY NC ND

bases. Its deformation angle, γ, is linked to the total angle of rotation of the bar, ϕ by the relation:

$$\gamma = \frac{r\phi}{L} \quad .$$

In fact, for a given angle ϕ, the deformation angle of the infinitesimal parallelepiped depends linearly on its distance from the axis. The tangential component of the shear stress, f_θ, is thus:

$$\mathrm{d}F_\theta = f_\theta \, (r \, \mathrm{d}r \, \mathrm{d}\theta) = G\gamma \, (r \, \mathrm{d}r \, \mathrm{d}\theta) \quad .$$

Note that the radial component of the shear stress will just try to cause either a lateral expansion of contraction of the bar.
The value of $\Gamma_O^-[z]$, the component along z of the total torque with respect to the point O of the external shear forces on the section $\mathcal{S}[z]$ acting on the slice and caused by the part of the bar at the left of z, is finally given by the integral:

$$\Gamma_O^-[z] = \int\limits_{\text{BASE}} \mathrm{d}\Gamma_O^- = \int\limits_{\text{BASE}} r \, \mathrm{d}F_\theta = \int\limits_{r=r_1}^{r_2} \int\limits_{\theta=0}^{2\pi} (r f_\theta) \, r \, \mathrm{d}r \, \mathrm{d}\theta = \int\limits_{r=r_1}^{r_2} \int\limits_{\theta=0}^{2\pi} G \left(r \frac{r\phi}{L} \right) r \, \mathrm{d}r \, \mathrm{d}\theta = \quad , \qquad \rightarrow 1507$$

$$\int\limits_{r=r_1}^{r_2} \int\limits_{\theta=0}^{2\pi} G \left(\frac{\phi}{L} \right) r^3 \, \mathrm{d}r \, \mathrm{d}\theta = \frac{\pi G}{2L} \left(r_2^4 - r_1^4 \right) \phi \quad ,$$

where the z dependence has been dropped because there is no dependence on z.
Note that in fact equation (27.07.12) just applies to the absolute values. In fact the full relation must express the fact that, as long as $\phi[z=0] = 0$ and $\phi[z=L] \equiv \Delta\phi$,

$$\boxed{\Gamma_O^-[z] = -\Gamma_O^+[z] - \frac{\pi G}{2L} \left(r_2^4 - r_1^4 \right) \Delta\phi} \quad . \qquad \rightarrow 1507\ 1510\ 1666\ 1667$$

In fact the positive orientation for both the angle $\Delta\phi$ and $\Gamma_O^-[z]$ are chosen to be the same.
It should be emphasised that all the internal stresses between shells cancel out, as far as the equilibrium of the bar is concerned, in agreement with the **Cardinal Equations** .
Note also that the rotational equilibrium is guaranteed by the fact that a pair of equal and opposite torques act on the two basis of any slice of the bar, due to the neighboring material. Therefore the torque on one basis of the shell gives the uniform torque along any section of the bar, equal, in the end, to the required external torque. Any external torque applied to any of the extremes of the bar has an absolute value equal, at equilibrium, to the internal torques $\Gamma_O^-[z]$ and $\Gamma_O^+[z]$.
The coefficient of ϕ is the torsional constant of the bar:

$$\Gamma_O^-[z] = \chi\phi \quad .$$

27.07.14
Bending of a Simple Beam

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...- 38.4

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|3.6||

DRAFT

Consider a cylindrical beam whose length is large with respect to its section. Assume that the bending radius of the beam is much larger than the transverse dimensions of the beam (its thickness). Assume the beam is bent in such a way that its deformed shape still is a planar shape. Furthermore assume that the beam is subject to simple bending, that is no stretching nor compression is applied at the two extremes (obviously at the internal points there will be stretching/compression). It is known that there exists a neutral surface all along the beam, whose points are not stretched nor compressed. Determine the deflection of the beam if it is cantilevered and a weight W is hanging at its free extreme. Assume the weight W is much higher than the weight of the beam itself.

WORKED SOLUTION

It is quite obvious that a neutral surface exists because the upper part of the beam will be stretched, while the lower part will be compressed. What is not self-evident is where the neutral surface lies. Small local curvature will be considered because in any case the linear theory of elasticity would not be applicable for large deformations. Note, however, that small local curvatures on a long beam might result in large deflections anyway. This does not contradict the necessity to stay in the linear regime, because locally the deformations will be small.
For a pure bending a slice of the beam is deformed in such a way that the material above/below the neutral surface has a stretching/compression which is proportional to the distance from the neutral surface the constant of proportionality being the radius of curvature:

$$\frac{\Delta l}{l_0} = \frac{y}{R[x]} \quad .$$

As a consequence the normal stress in a small strip at a distance y from the neutral surface is given by:

$$f = \frac{F}{A} = Y\frac{y}{R[x]} \qquad \Longrightarrow \qquad \mathrm{d}F = \frac{Y}{R[x]} y \, \mathrm{d}\mathbf{S} \quad .$$

This amount to assume that the bending is due only to the normal internal stresses.
The torque of the bending force with respect to any point P on the neutral surface is:

$$\Gamma_P[x] = \int\limits_{\text{SECTION}} y \, \mathrm{d}F = \frac{Y}{R[x]} \int\limits_{\text{SECTION}} y^2 \, \mathrm{d}\mathbf{S} \frac{YI}{R[x]} \quad .$$

Therefore the torque acting at any section of the beam is proportional to the moment of inertia, I, of the geometric section about an horizontal axis through its neutral surface.
In other words the stiffness of the beam is proportional to Y and to I. That is why for a given mass one tries to increase I as much as possible by designing **I** shaped beams. Of course one cannot go too much to the extreme along this way because the beam would twist and buckle. The formula shows that the product YI gives the strength of the beam, because when the factor YI increases/decreases for the same $R[x]$ the torque Γ_P increases/decreases. Moreover, for any given mass the value of Γ_P is determined by the value required at the fixed extreme, which has to sustain all the beam. However, Γ_P is not uniform, if the mass of the beam is not negligible.
Let x denote the coordinate along the beam, when it is not bent. Let $z[x]$ be the shape of the bent

beam. We have:

$$\frac{1}{R[x]} = \frac{\frac{d^2 z}{\mathrm{d}x^2}}{\left(1+\left(\frac{\mathrm{d}z}{\mathrm{d}x}\right)^2\right)^{3/2}} \simeq \frac{d^2 z}{\mathrm{d}x^2} \quad .$$

One needs to know the bending moment as a function of x. Neglecting the weight of the beam the torque at x is:

$$\Gamma_P[x] = W\,(L-x) \quad ,$$

because the part of beam in between x and L is in static equilibrium and thus it just transfers to the element at x the torque at its boundary, because the mass of the beam is negligible with respect to the hanging weight. Consider in fact the part of beam located between x and L. That system is in equilibrium under the effect of the torque $\Gamma_P[x] = W\,(L-x)$, applied at the free end, and the internal moment due to the internal normal forces at the section at x (always use the point P on the neutral surface at x as a pole).
Note that the equation $\Gamma_P[x] = W\,(L-x)$ actually fixes the condition at the free extreme by saying that $\Gamma_P[x=L] = 0$.
It follows:

$$\frac{d^2 z}{\mathrm{d}x^2} = \frac{W}{YI}(L-x) \quad ,$$

$$z[x=0] = 0 \qquad \frac{\mathrm{d}z}{\mathrm{d}x}[x=0] = 0 \quad ,$$

$$z[x] = \frac{W}{YI}\left(\frac{Lx^2}{2} - \frac{x^3}{6}\right) \qquad z[x=L] = \frac{W}{YI}\frac{L^3}{3} \quad .$$

Note that the function $z[x]$ describes the geometrical position of the neutral surface. As the mass of the beam is negligible with respect to the hanging weight, only W enters the equation. If the Young modulus increases one finds, in the limit of very large Y, the rigid cantilevered beam is found (read § 27.07.11).
The derivation was based on the assumption that the section of the beam did not change under bending. When the thickness of the beam is small with respect to the radius of curvature this is a good assumption. In general this is not true, for instance with a soft-rubber eraser, which expands on the compressed side die to the Poisson module effect. Rubber is almost incompressible, this is expressed by the fact that the Poisson module is close to $1/2$.

28.01.01 Classical Fluids

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||

A fluid substance is a substance that continually deforms and flows, under an applied shear force-stress and|or twisting torque-stress; depending on the container it can also deform and flow under an applied normal force/stress (e.g. put a finger into a glass of water) Fluids include liquids (hardly compressible) and gases (easily compressible).

Si dimostra in generale che il tensore force-stress è simmetrico se e solo se sono assenti body-torques and surface-torques.

I fluidi che obbediscono a tale caratterizzazione sono definiti **fluidi classici**, in breve semplicmente fluidi.

Read § 32.03.01 for the more general discussion.

Classical fluids only will be discussed here.

28.01.02 Ideal Versus Real Fluids

Ideal fluids, by definition, cannot resist any shear force-stress and|or twisting torque-stress applied to them without flowing, when they are in static equilibrium in any Reference Frame, possibly a non-Inertial Reference Frame ; they have zero shear modulus.

While the shear modulus of an ideal fluid is zero, the shear-modulus of a real fluid might be non zero, implying that the fluid will deform and flow but with non zero shear force-stress and|or twisting torque-stress; this is the concept of viscosity, read § 28.05.

28.01.03 Pressure - Surface Forces

For any continuous system, given an infinitesimal oriented flat surface $\mathbb{d}\mathbf{S}$, the normal force due to pressure exerted along $\mathbb{d}\mathbf{S}$, that is with the same orientation, by the subsystem "below" $\mathbb{d}\mathbf{S}$ on the subsystem "above" $\mathbb{d}\mathbf{S}$ is:

$$\mathbb{d}\mathbf{F} \equiv p[\mathbf{x}]\,\mathbb{d}\mathbf{S} \equiv p[\mathbf{x}]\widehat{\mathbf{n}}\,\mathbb{d}\mathbf{S} \qquad \text{most often, but not necessarily, } p[\mathbf{x}] \geq 0 \quad .$$

Pressure is omni-present in fluid mechanics. Both the total force and the total torque of the pressure forces, which are surface forces, on an arbitrary volume of fluid, the system, can be expressed as a volume integral over the volume force, by a mathematical theorem (see section § 16.12.15):

$$\mathbf{f}^{\mathrm{V}}_{\mathrm{p}}[\mathbf{x}] = -\mathbf{grad}p[\mathbf{x}] \quad . \tag{28.01.01}$$

→ 1514

Note that the above expression (28.01.01) is just a mathematical equivalence, not a physical equivalence at all. It means that one can calculate the total force and the total torque of the pressure forces, as a volume integral, instead of a surface integral, the former being, most often, easier to calculate than the latter.

28.02 Elements of Fluid Statics

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...||*Excellent*|

A fluid is in static mechanical equilibrium if and only if all its parts are, with respect to some, in general non inertial, Reference Frame. This is just the same definition as for a general continuous medium.

DRAFT - NOT FOR PUBLICATION

28.02.01
Static Equilibrium - Hydrostatics

Un fluido a riposo in un certo Reference Frame, anche non inerziale, è in equilibrio sotto l'azione delle forze di volume e di quelle di superficie, che si riducono solitamente alla sola pressione essendo il fluido a riposo.

Se si denota con $\mathbf{f}^{\mathtt{M}}$ la risultante, per unità di massa, di tutte le forze di volume agenti sul fluido, e con ρ la densità, la condizione di equilibrio è data dalla relazione:

$$\mathbb{d}\mathbf{F}[\mathbf{x}] \equiv \mathbf{f}^{\mathtt{M}}[\mathbf{x}]\ \mathbb{d}M \equiv \rho[\mathbf{x}]\mathbf{f}^{\mathtt{M}}[\mathbf{x}]\ \mathbb{d}V \equiv \mathbf{f}^{\mathtt{V}}[\mathbf{x}]\ \mathbb{d}V \qquad 0 = \mathbf{f}^{\mathtt{V}} + \mathbf{f}^{\mathtt{V}}_{\mathtt{p}} = \rho\mathbf{f}^{\mathtt{M}} - \mathbf{grad}p \quad . \tag{28.02.01}$$

→ 1534

Nel caso le forze di volume siano conservative, introduciamo l'energia potenziale:

- energia potenziale, $\Phi[\mathbf{x}]$;
- energia potenziale per unità di massa, $\phi[\mathbf{x}]$.

Allora si ha la condizione di equilibrio:

$$\mathbb{d}\Phi[\mathbf{x}] \equiv \phi[\mathbf{x}]\ \mathbb{d}M \qquad \mathbf{f} = -\mathbf{grad}\phi[\mathbf{x}] \qquad \mathbf{grad}p[\mathbf{x}] + \rho[\mathbf{x}]\mathbf{grad}\phi[\mathbf{x}] = 0 \quad ,$$

da cui l'equazione fondamentele dell'idrostatica in presenza di sole forze conservative:

$$\mathbf{grad}p[\mathbf{x}] + \rho[\mathbf{x}]\mathbf{grad}\phi[\mathbf{x}] = 0 \quad .$$

Note that, conservative forces may include inertial conservative forces, in any non-Inertial Reference Frame .

© - QUOTE

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...
The equation of hydrostatics, in general, has no solution. If the density varies in space in an arbitrary way, there is no way for the forces to be in balance, and the fluid cannot be in static equilibrium. Convection currents will start up. We can see this from the equation since the pressure term is a pure gradient, whereas for variable ρ the other term is not. Only when ρ is a constant is the potential term a pure gradient. Then the equation has a solution $p + \rho\phi =$ constant. Another possibility which allows hydrostatic equilibrium is for ρ to be a function only of p.

28.02.02
Pascal Principle

Se il fluido è incompressibile, cioè se la densità $\rho[\mathbf{x}, t] = \rho$ è uniforme e costante, si può scrivere il principio di Pascal:

$$\boxed{p[\mathbf{x}] + \rho\phi[\mathbf{x}] = \text{constant}} \quad . \tag{28.02.02}$$

→ 1516

e quindi per un fluido incompressibile in un campo di forze conservativo le superfici isobare coincidono con le superfici equipotenziali.

From the previous property (28.02.02), since potential energy changes are functions only of the place and the pressure variations are equal to potential energy variations, the Pascal principle follows: **every pressure variation applied to an enclosed incompressible fluid at equilibrium is transmitted unaltered to any other point in the fluid and to any walls of the container**. In fact, at fixed geometry, given two any fixed points:

$$\boxed{\Delta p[\mathbf{x}_2] = \Delta p[\mathbf{x}_1]} \quad .$$

28.02.03
Archimedes Principle

Un corpo immerso in un fluido nel campo gravitazionale riceve una spinta verso l'alto pari al peso della massa di fluido spostata. La forza è applicata al baricentro della massa di fluido spostata. In presenza di altre forze di volume oltre alla forza peso (per esempio forze fittizie) il principio di Archimede è ancora valido pur di considerare la forza totale di volume agente sul fluido spostato.

La dimostrazione del principio di Archimede si fonda sulla condizione di equilibrio del fluido per cui, data una qualunque porzione di fluido, la risultante delle forze di volume sullo stesso è uguale ed opposta alla risultante delle forze di superficie. Quando un oggetto è immerso nel fluido la risultante delle forze e il momento risultante di volume sarà quella che compete all'oggetto in questione, mentre la risultante delle forze di superficie sarà la stessa che si avrebbe se la posto dell'oggetto ci fosse il fluido.

Read § 16.12.15 for the demonstration.

DRAFT – WORK IN PROGRESS

28.03 Elements of Fluid Kinematics

La cinematica del moto di un fluido può essere descritta con due approcci:

- la descrizione lagrangiana,
- la descrizione euleriana,

read § 32.01.

Nel primo caso ogni porzione infinitesima di fluido viene seguita nel suo moto, come un qualunque sistema materiale chiuso, mentre nel secondo caso si descrive il moto del fluido fornendo, per ogni punto dello spazio e ad ogni istante, come varia nel tempo la velocità delle diverse porzioni di fluido che all'istante dato transitano per il punto dato. La descrizione euleriana è ottenuta dunque attraverso un campo vettoriale, il campo di velocità, $\mathbf{v}[\mathbf{x},t]$ funzione dello spazio e del tempo, in generale. Ad un dato istante il valore del campo vettoriale in un punto è la velocità della porzione di fluido che all'istante dato transita per quel punto.

La velocità di un elemento di fluido che si muove con legge $\mathbf{x}[t]$ sarà data da $\mathbf{v}[\mathbf{x}(t),t]$.

L'accelerazione si ottiene prendendo la derivata totale rispetto al tempo della velocità.

Le quantità cinematiche di un elemento di fluido che si muove con legge $\mathbf{x}[t]$ nell'approccio euleriano sono dunque

$$\mathbf{r}_{\mathrm{P}}[t] \implies \mathbf{v}_{\mathrm{P}}[t] \equiv \frac{\mathrm{d}\mathbf{r}_{\mathrm{P}}}{\mathrm{d}t} = \mathbf{v}[\mathbf{x}[t],t] \implies \mathbf{a}_{\mathrm{P}}[t] \equiv \frac{\mathrm{d}\mathbf{v}_{\mathrm{P}}}{\mathrm{d}t} = \left(\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t}\cdot\mathbf{grad}\right)\mathbf{v} + \partial_t\mathbf{v} \quad .$$

Important kinematics definitions are as follows.

- Velocity field: $\mathbf{v}[\mathbf{x},t]$.
- steady flow: $\mathbf{v}[\mathbf{x},t] = \mathbf{v}[\mathbf{x}]$.
- Divergence-less fluid flow: $\mathbf{div}\mathbf{v} = 0$.
- Irrotational fluid flow: $\mathbf{rot}\mathbf{v} = 0$.
- The field lines of the velocity field define the stream-line (or stream filament).
- All stream-lines passing through any open surface form a stream-tube. Since, by definition, the fluid has zero velocity perpendicularly to the stream-line there is no leak of liquid in/out the walls of a stream-tube.
- A stream-line is an infinitesimally thin stream-tube.
- For a steady flow, the trajectory of any infinitesimal volumes follows the flow field lines.

28.03.01 Types of Motions of Fluids

Types of fluid motions are as follows.

- Fluid flows such that stream-lines stay side by side, in a orderly fashion, without mixing are called laminar flows, which are always realized whenever the frictional forces are large enough.
- Turbulent flows are characterized by large random fluctuations of the velocity field, with vortices which can intermix the stream-lines completely.

DRAFT - IN PROGRESS

28.03.02
Equazione Di Continuità Della Massa

L'equazione di continuità della massa, che descrive la conservazione della massa, nel caso generale si scrive:

$$\boxed{\mathbf{div}\mathbf{j} + \partial_t \rho = 0} \quad . \tag{28.03.01}$$

→ 2738

Nel caso di un moto puramente convettivo (in contrasto ad un moto diffusivo, in cui non c'è moto di insieme dei singoli elementi infinitesimi di massa):

$$\boxed{\mathbf{j}[\mathbf{x}, t] = \rho[\mathbf{x}, t]\mathbf{v}[\mathbf{x}, t]} \quad .$$

Nel caso di densità omogenea e costante l'equazione di continuità della massa per un fluido si riduce a:

$$\boxed{\mathbf{div}\mathbf{v} = 0 \qquad \Leftrightarrow \qquad \rho[\mathbf{x}, t] = \rho = \text{fixed}} \quad .$$

In general, density will also depend on temperature and pressure.

Nel caso di moto stazionario, l'equazione di continuità lungo un tubo di flusso di sezione A si riduce alla costanza del flusso di massa:

$$\boxed{\text{steady motion} \implies \frac{\mathrm{d}M}{\mathrm{d}t} = \rho A v = \text{constant}} \quad .$$

DRAFT-IN-PROGRESS

Let us consider infinitesimal fluid volumes of fluid such that its overall linear momentum is null: $\mathbf{P} = 0$. The momenta of the individual molecules, in general, are not zero but show a velocity distribution with directions uniformly spread over all directions (typically, the Maxwell distribution).

The macroscopic treatment of fluids motion neglects the thermal motion of the individual molecules considering instead the average motion of the infinitesimal fluid volume elements.

Let us now consider infinitesimal fluid volumes of fluid such that its overall linear momentum is not null: $\mathbf{P} \neq 0$. In this case the macroscopic velocity of the infinitesimal fluid volume must be interpreted as the Center-Of-Mass velocity of the microscopic particles constituting it (**Koënig theorem**).

Definitions:

- Hydrodynamics: fluids with zero or negligible compressibility;
- Aerodynamics: fluids with non negligible compressibility.

Interactions determining the dynamics include:

- pressure differences between different local positions, which are equivalent to a volume force: $\mathbf{f}[\mathbf{x}] = -\mathbf{grad}p[\mathbf{x}]$.
- pressure forces induce surface forces normal to every surface, either real surfaces (solid surfaces such as walls) or purely geometrical surfaces;
- the gravity force provides a volume force density: $\mathbb{d}\mathbf{F} = g[\mathbf{x}]\ \mathbb{d}m = g[\mathbf{x}]\rho[\mathbf{x}]\ \mathbb{d}V$.
- whenever the flow velocity depends on the position, friction forces, between layers of the fluid with different values of velocities, are generated (internal friction);
- friction forces between the fluid and the solid surfaces with which it is in contact exist (external frictions);
- in presence of external ElectroMagnetic fields, as well as any other external potential field, additional Force|Torque may exist;
- in non-Inertial Reference Frame , inertial forces exist;
- other external sources of interaction may exist, such as those due to a moving solid surface in a pump or in a fan.

Whenever the friction forces are negligible compared to the other forces, the approximation of ideal liquid helps.

Consider a fluid of density ρ and any open surface of area A and define (across the surface):

- the mass flow rate, $\dot{M}$;
- the volumetric flow rate: $Q \equiv \dot{M}/\rho$;
- the average velocity: $\langle v \rangle \equiv v \equiv Q/A$; it averages out the random velocities at the molecular level and it corresponds to the Center-Of-Mass velocity of any infinitesimal fluid volume.

There are pressure and density changes along the flow path, velocity changes, and possibly elevation changes and|or effects from other external potential fields.

Friction due to fluid contact with the wall and|or internal fluid friction causes mechanical energy to be converted into internal energy, with possible changes of temperatures.

Possibly, external mechanical devices put energy into or extract energy from the system, in the form of the so-called **shaft work**.

The macroscopic energy balance that may be applied to a single-input, single-output system with no chemical reactions, no phase changes, and little heat loss or heat generation is the mechanical energy balance,

28.04.01
Cardinal Equations

In flowing systems, the laws of conservation of mass, linear momentum and energy allow to calculate the dynamics, studying the conservation laws that apply to microscopic systems (in control volumes). **The conservation of angular momentum is implemented, for classical fluids, by the symmetry of the force-stress tensor**. In fact, as the stress tensor is symmetrical for a classical fluid/solid, it can be shown that the first and second **Cardinal Equations** are equivalent. For fluids with non zero body-torques and|or surface torques, the conservation of angular momentum is a necessary and independent equation.

Energy Balance - Bernoulli Equation

© - QUOTE

Introduction to Fluid Mechanics Edward J. Shaughnessy, Jr. Ira M. Katz James P. Schaffer
The state of stress in an inviscid fluid is characterized solely by the pressure distribution. Since there is no fluid whose viscosity is zero, one might ask **why we study the flow of an inviscid fluid, i.e., frictionless flow**.
One answer, which is particularly relevant in engineering design, is that **the highest performance that can be achieved from a fluid-handling device is that which would occur in the absence of friction**. Thus the study of frictionless flow through a device may allow us to optimize a preliminary design.
A second answer, which is of great importance in aerodynamics, is that the principal phenomenon that arises from the existence of viscosity, i.e. **shear stress, is not significant in all flows**. To better understand this comment, consider the flow of the two fluids of greatest engineering interest, air and water. The viscosity of these fluids is not zero, but it is small in comparison to many other fluids. Now from the relationship between shear stress, viscosity, and velocity gradient is given it is easy to see that if the viscosity is zero, then the shear stress must also be zero. The equation also shows, however, that if the velocity gradient at a point in a flow of air or water is small, then the local shear stress may be negligible (from an engineering point of view) even though the viscosity is non-zero. A number of important flows in engineering contain regions in which shear stresses are in fact negligible. In these regions the flow is approximately frictionless and indistinguishable from the flow of an inviscid fluid.
...
The Bernoulli equation is an approximate relation between pressure, velocity, and elevation, and is valid in regions of steady, incompressible flow where net frictional forces are negligible. The Bernoulli equation is an approximate equation that is valid only in inviscid regions of flow where net viscous forces are negligibly small compared to inertial, gravitational, or pressure forces. Such regions occur outside of boundary layers and wakes.

Il **moto laminare e stazionario di un fluido incomprimibile e non viscoso nel campo di gravità** è descritto dal Bernoulli equation

$$p + \rho g h + \frac{1}{2}\rho v^2 = \text{costante lungo ogni linea di flusso} \quad ,$$

in assenza di scambi di calore, lavoro di altro tipo rispetto al lavoro della forze di pressione, o modifiche del fluido come reazioni chimiche o cambiamenti di fase.

Nel caso di moto irrotazionale il valore della costante è indipendente dalla linea di flusso considerata.

Un secondo caso in cui la costante non dipende dalla linea di flusso è il caso in cui tutte le linee di flusso originano da una regione in cui la costante è la stessa per tutte le linee di flusso.

Anche quando il fluido è viscoso l'equazione di Bernoulli può servire come buona approssimazione del moto reale.

CC BY NC ND

Notare che in opportune condizioni l'equazione di Bernoulli può prevedere pressioni arbitrariamente basse (e anche negative). In realtà un gas non può avere pressione negativa e un liquido bolle quando la pressione si abbassa al di sotto del valore della tensione di vapore (cavitazione). L'equazione di Bernoulli non può quindi essere applicata quando predice pressioni prossime alla tensione di vapore, o peggio pressioni negative.

The Bernoulli equation is one of the most frequently used and mis-used equations in fluid mechanics. In order to apply Bernoulli equation:

- the flow must be steady;
- viscous effects should be negligible, as well as any other friction effect between the liquid and any other object;
- surface tension effects are negligible;
- incompressible flow (but there exists a simple more general formulation for compressible flow, see equation (28.04.01);
- no shaft work (that is, only work done by pressure forces);
- no heat exchanges;
- any other irreversible effects are negligible;
- unless the flow is irrotational, flow along a stream-line and the value of the constant is different for different stream-lines.

28.04.03
Generalized Bernoulli Equation

The general form of the Bernoulli equation in the gravity field applies to the frictionless flow of a compressible or incompressible fluid reads:

$$\frac{1}{2}\left(v_2^2 - v_1^2\right) + g\left(h_2 - h_1\right) + \int_1^2 \frac{\mathrm{d}p}{\rho} + \int_1^2 \partial_t v \, \mathrm{d}L = 0 \quad . \tag{28.04.01}$$

→ 1521

The only restriction is that the path connecting the two points must be an instantaneous stream-line.

28.05 Shear Force|Torque - Viscosity

This § is referenced at pages:
[1202, 1514]

28.05.01 Elementary Definition

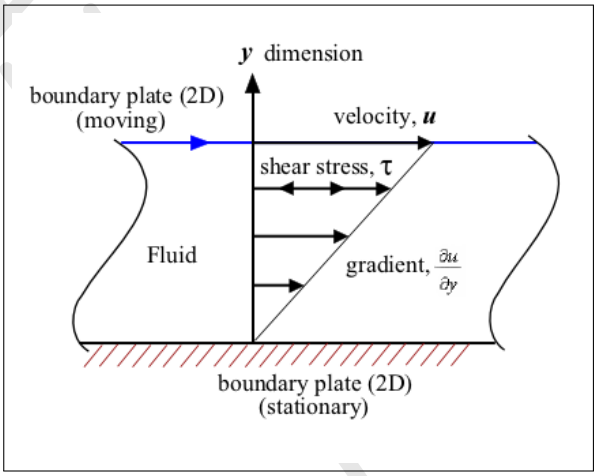

Figure 28.11: Elementary definition of viscosity (from WEB - URL)

Viscous fluid obey the co-called no-slip condition: the velocity of any viscous fluid in contact with a solid buondary is zero.

Examples: dust on the blades of a fan does not fly away when the blades rotate.

Si osserva sperimentalmente che un fluido viscoso a contatto con una superficie solida ha sempre velocità relativa alla superficie nulla a contatto con la superficie. This is an experimental fact.

Si supponga un moto rettilineo (e quindi laminare) di un fluido: le velocità di tutti gli elementi del fluido sono nella stessa direzione. Per un gran numero di fluidi la relazione tra lo sforzo di taglio e il gradiente di velocità è lineare. Il coefficiente di proporzionalità definisce la viscosità η.

Nel caso partcolare di un moto di un fluido con velocità lungo una direzione fissa, z, di modulo variabile lungo la direzione s, perpendiclare a z, lo sforzo di taglio che occorre esercitare sul fluido per mantenerlo in moto a velocità costante è dato da

$$\tau_{zs} \equiv \pm\eta\frac{\partial v_z}{\partial s} \qquad \eta \geq 0 \qquad \text{1D motion along the } z \text{ axis with velocity changing along } s \text{ perpendicular to } z \quad , \tag{28.05.01}$$

→ 1202 1523

che definisce la viscosità e dove la scelta del segno deve essere accuratamente definita definendo origine e recettore della forza.

A fluid flow between two parallel surfaces with relative motion is called **Couette flow**.

DRAFT - Preliminary Release

28.05.02
General Definition of Viscosity

This § is referenced at pages:
[1203]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||

Nel caso di moto generale di un fluido classico in 3D il tensore degli sforzi di viscosity deve essere generalizzato alla forma forma simmetrica, in quanto il tensore delgi sforzi è simmetrico. Lo sforzo di taglio che occorre esercitare sul fluido per mantenerlo in moto a velocità costante è dato quindi da:

$$\tau_{ij}^{\cdot\cdot} \equiv \pm\eta\left(\frac{\partial v_i}{\partial x_j}+\frac{\partial v_j}{\partial x_i}\right) \qquad \eta \geq 0 \quad . \tag{28.05.02}$$

In fact, the anti-symmetrical part of the second-order tensor, $\frac{\partial v_i}{\partial x_j}$, must be taken out, as rotations are rigid motions and do non involve any shear stress. Therefore, using the general method in section § 20.03.06 the particular definition in equation (28.05.01) is written in covariant form via a second-order tensor, but with its symmetrical part only. In fact, also the trace could be retained, and in fact, a second viscosity coefficient is in general necessary, for compressible fluids.

$$\tau_{ij}^{\cdot\cdot} = \eta'\delta_{ij}^{\cdot\cdot}\mathbf{div}\,\mathbf{v} + \eta\left(\frac{\partial v_i}{\partial x_j}+\frac{\partial v_j}{\partial x_i}\right) \quad . \tag{28.05.03}$$

→ 1202 1523 1530 2742

28.05.03
Units of Measure and Common Values

The SI (read § B) physical unit of dynamic viscosity, η, is the pascal-second $\mathrm{Pa\,s}$

The CGS physical unit for dynamic viscosity is the poise P named after Jean Louis Marie Poiseuille. It is more commonly expressed, particularly, as centipoise cP. The centipoise is commonly used because water has a viscosity of $1.0020\ \mathrm{cP}$ at $20\,^{\circ}\mathrm{C}$; the closeness to one is a convenient coincidence.

Kinematic viscosity, η/ρ, has SI units $\mathrm{m^2 s^{-1}}$ (read § B). The CGS physical unit for kinematic viscosity is the stokes, named after George Gabriel Stokes. It is sometimes expressed in terms of centistokes.

28.05.04
Newtonian Fluids

I fluidi caratterizzati dalla relazione (28.05.03), che definisce la viscosità, sono detti fluidi newtoniani, di cui la stessa relazione (28.05.03) è la **relazione costitutiva**.

I fluidi per i quali la relazione tra lo sforzo di taglio e il gradiente di velocità non soddisfa la relazione lineare sono detti fluidi non-Newtoniani.

Note that viscous forces are dissipative forces, which transfer mechanical energy into internal energy. The study of viscous fluids, therefore, must be carried on in the realm of thermo-mechanics. Viscosity is in fact internal friction caused by relative velocities of different parts inside the fluid. Viscous forces, dissipating mechanical energy, cause, among other things damping of sound waves.

28.05.05
Non-Newtonian Fluids

© - QUOTE

FAMorrison § 5.3
As discussed previously in this section, experiments on the parallel-plate apparatus confirm the validity of Newton law of viscosity and the Newtonian constitutive equation for many materials, including water, oil, honey, milk, and solvents. Many materials, however, do not follow the Newtonian constitutive equation. Fluids that are compressible, for example, have an additional contribution to stress other than what we described; Chapter 10 presents modifications to the Newtonian constitutive equation that account for compressibility. Many incompressible fluids, including foods such as mayonnaise, peanut butter, and ketchup, do not follow the Newtonian constitutive equation. Many industrial materials, including molten plastics, asphalt, and concrete, are non- Newtonian. Biological fluids, including blood and mucus, are almost universally non-Newtonian. In addition, the stresses in geological flows, such as those involving soil and lava, fail to follow the Newtonian constitutive equation.
The field of study that addresses the many effects seen in non-Newtonian fluids is called rheology, and there is considerable literature on the subject. In this section, we introduce the basic nature of non-Newtonian flows and constitutive models for non-Newtonian fluids; in-depth information on non-Newtonian fluids is in the cited literature. Although there is a single Newtonian constitutive equation, for non-Newtonian fluids, we have many different constitutive equations.
We need a variety of constitutive equations for non-Newtonian fluids because of what the constitutive equation is. Recall that the stress tensor accounts for the molecular-force contributions to the momentum balance. Molecular contact forces are different in every fluid because they arise from chemical interactions, and the atoms and molecules are different in every substance (see Figure 4.3). We take the continuum approach in our modeling of fluid motion but, ultimately, we must match our models to the actual chemical behavior of the fluid systems under study. The constitutive equation is the link between the continuum model and the chemical properties of the molecules that comprise the fluid. There could be as many constitutive models as there are chemicals, but it turns out to be less complicated. For thousands of fluids, including water, oil, and even gases under most circumstances, the Newtonian constitutive equation is the stress-velocity relationship. For many materials that do not follow the Newtonian constitutive equation, simple modifications often are adequate. Other materials, such as polymer melts and solutions, require complex visco-elastic constitutive equations; a detailed study of such equations is beyond the scope of this book.

28.06 Shear Force|Torque - Surface Tension

This § is referenced at pages:
[2572]

28.06.00.01 Definition

Consideriamo il caso di **una fase liquida a contatto con una fase gassosa** a livello esemplificativo; **anche nel contatto liquido-liquido si ha lo stesso fenomeno**.

Le forze inter-molecolari entro un liquido danno origine a forze debolmente attrattive tra le molecole. Una molecola all'interno di un liquido risente di una forza risultante mediamente nulla mentre le molecole prossime alla superficie (**a distanza dalla superficie inferiore al raggio d'azione delle forze inter-molecolari**) risentono di una forza risultante media perpendicolare alla superficie del liquido e diretta verso l'interno. Di conseguenza **per portare una molecola dall'interno di un liquido verso la sua superficie occorre fare lavoro**. Occorre quindi fare lavoro per aumentare la superficie di un liquido. E viceversa un liquido tende ad assumere la configurazione corrispondente alla superficie minima compatibile con i vincoli, perchè le forze sulle molecole alla superficie tendono ad attirarle verso la massa del liquido, riducendo la superficie.

Analogamente al caso della tensione e della pressione si può definire il lavoro per aumentare una superficie A come

$$\boxed{\mathrm{d}W \equiv \gamma \, \mathrm{d}S} \quad , \tag{28.06.01}$$

→ 1525

dove γ è la tensione superficiale, definita dalla stessa relazione (28.06.01).

Equivalentemente, dalla relazione (28.06.01), si ha che il lavoro adiabatico necessario in considizoni quasi-statiche corrisponde all'aumento di energia del liquido, conformente alla definiozne di energia intenra e primi principo della termodinamica, per cui:

$$\boxed{\mathrm{d}\mathcal{U} \equiv \gamma \, \mathrm{d}S} \quad . \tag{28.06.02}$$

Si consideri una linea, anche ideale, alla superficie del liquido. La tensione superficiale origina una forza tangente alla superficie del liquido, perpendicolare alla linea e tendente ad allontanare le particelle da parti opposte della linea. Il modulo di tale forza per unità di lunghezza vale

$$\boxed{\mathrm{d}F = \gamma \, \mathrm{d}L} \quad .$$

L'analogia con la tensione superficiale di una membrana elastica è limitata dal fatto che la forza dovuta alla tensione superficiale di un liquido non dipende dalla superficie.

La forza dovuta alla tensione superficiale di un liquido dipende a rigore, oltre che dalla temperatura, anche dalle caratteristiche della fase gassosa con cui il liquido è a contatto in quanto dipende dal bilancio tra le forze di coesione delle molecole del liquido e le forze di adesione tra le molecole del liquido e quelle del gas a contatto.

Surface tension is thus surface energy as well.

DRAFT IN PROGRESS

28.06.00.02 Units of Measure and Common Values

For many liquids and solid, surface energy / surface tension is of the order of $\approx 1\ \mathrm{J/m^2} = 1\ \mathrm{N/m}$.
For water at NTP: $\gamma \simeq 0.07\ \mathrm{J/m^2} = 0.07\ \mathrm{N/m}$.
For mercury at NTP: $\gamma \simeq 0.4\ \mathrm{J/m^2} = 0.4\ \mathrm{N/m}$.
For ethanol at NTP: $\gamma \simeq 0.02\ \mathrm{J/m^2} = 0.02\ \mathrm{N/m}$.

D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 1994, C.E.A., 4thEd., ...
Leaves and insects can be observed to float on the surface of a body of water. They are not partially submerged and thus not buoyed up because of Archimedes' principle. In this case the object is completely on the surface and none of it is submerged. The object is kept afloat by the surface tension of the liquid. You can demonstrate the surface tension of water by carefully floating a steel needle or a razor blade. There is of course no way for steel to float by Archimedes' principle, since its density is greater than that of water. If you submerge the needle or the razor blade, it will sink as Archimedes' principle predicts. Only when it is entirely on the surface can it float. You can add to the water a chemical, called a surface-active agent or surfactant, which reduces the surface tension (by reducing the cohesive force between molecules) and makes it more difficult to float the object. Detergents are common surfactants. If you carefully introduce detergent into the water on which a razor blade is floating, the surface tension suddenly decreases and the razor blade sinks to the bottom. A floating object depresses the surface layer of the fluid slightly which stretches the surface layer and thus tends to increase its potential energy. Somewhat like a trampoline, the stretched surface layer exerts a restoring force, the vertical component of which can maintain equilibrium with the weight of the object. However, this analogy of the behavior of the surface layer is not strictly correct.
...
A razor blade floating on the surface of water, supported only by surface tension. The surface is distorted by the floating object, which is kept afloat by the vertical components of the surface force.

28.07.06 Hydrostatic Equilibrium in Uniform Gravity for Rotating Fluid at Uniform Temperature

©|I.E.Irodov, *Problems In General Physics*, 1988, MIR publishers Moscow, ...Ed., ...|2.20||

This a a centrifuge for either a liquid or a gas.

Un recipiente rigido cilindrico, di raggio r_0 e altezza h, contiene una certa quantità di moli di un fluido di massa molecolare $\mathcal{M}_0$, a temperatua uniforme, e ruota con velocità angolare costante ω attorno al proprio asse. Si suppne che la rotazione sia stata accesa da un tempo sufficiente tale che il moto del fluido sia diventato rigido e il fluido abbia raggiunto una configurazione idrostatica, a seguito degli attriti viscosi interni. Read § 71.04.

1. Assume a container with an incompressible liquid. The cylindrical container has its axis along the vertical direction. Its upper base is open in atmosphere.
   a) Consider the equilibrium situation under the effects of the gravity and centrifugal forces and determine the shaper of the equipotential surfaces and the complete equation of the surface of separation between liquid and atmosphere. The number of moles of liquid is fixed, n.
2. Assume a container with and ideal gas. Consider first as negligible the effect of gravity on the gas. Determinare l'andamento della pressione del gas all'interno del recipiente in funzione di r supponendo il gas ideale e in condizioni di equilibrio termodinamico a temperatura uniforme. Si considerino i due casi seguenti.

DRAFT NEW PROGRESS

a) Si supponga che il recipiente, chiuso, contenga un piccolo foro al centro delle due basi in contatto con l'atmosfera esterna in modo che la pressione del fluido sull'asse del contenitore sia uguale a quella dello stesso fluido all'esterno, p_0, pressione atmosferica. Il numero di moli dentro al contenitore non è dunque fissato.
b) Si supponga che il contenitore sia sigillato. Il numero di moli dentro al contenitore è dunque fissato, n.

3. Assume again a container with and ideal gas but do not ignore the effect of the gravity field on the gas. The cylindrical container has its axis along the vertical direction.

Ocean Water Density Change With Depth

This § is referenced at pages:
[1511]

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|17.20||

Determinare la legge di variazione della densità dell'acqua in funzione della profondità nell'oceano, conoscendo il coefficiente di compressibilità k dell'acqua: $1/k \equiv B = 2.2{\cdot}10^4$ atm. Si supponga che la densità dipenda solo dalla pressione ma non dalla temperatura e che B sia costante nell'intervallo di interesse.

WORKED SOLUTION

Per definizione il coefficiente di compressibilità k è legato al bulk modulus

$$\frac{1}{k} \equiv B \equiv -V\frac{\partial p}{\partial V} = \rho\frac{\partial p}{\partial \rho} \tag{28.07.03}$$

dove le derivate parziali vanno calcolate con il vincolo opportuno al processo considerato: isotermo, adiabatico o altro. Dato che per ipotesi $\rho = \rho(p)$ le derivate parziali possono essere sostituite dalla derivata semplice. L'equivalenza delle due espressioni si deduce considerando una massa fisssata, Δm, in un volume, ΔV, fissato, e quindi costanti, da cui si deduce

$$\Delta m \equiv \rho\Delta V \implies 0 = \mathrm{d}\Delta m = \rho\,\mathrm{d}\Delta V + \Delta V\,\mathrm{d}\rho$$

Dall'equazione dell'equilibrio idrostatico si ha

$$\boxed{\frac{\mathrm{d}p[z]}{\mathrm{d}z} = -\rho[z]g} \tag{28.07.04}$$

che può essere riscritta come

$$\frac{\mathrm{d}p}{\mathrm{d}\rho}\frac{\mathrm{d}\rho}{\mathrm{d}z} = -\rho[z]g = \frac{B}{\rho}\frac{\mathrm{d}\rho}{\mathrm{d}z}$$

da cui separando le variabili

$$\frac{\mathrm{d}\rho}{\rho^2} = -\frac{g}{B}\,\mathrm{d}z$$

che integrata, con B costante da

$$\rho[z] = \rho_0\left[1 + \frac{\rho_0 g}{B}(z - z_0)\right]^{-1} \simeq \rho_0\left[1 - \frac{\rho_0 g}{B}(z - z_0)\right] \simeq \rho_0\left[1 + \frac{\rho_0 g}{B}h\right]$$

avendo denotato con $h \equiv z_0 - z$ la profondità. Per $h = 10$ km si ha $\rho/\rho_0 = 1.05$.
The pressure as a function of depth is:

$$\frac{\mathrm{d}p[z]}{\mathrm{d}z} = -\rho[z]g = -g\rho_0\left[1 - \frac{\rho_0 g}{B}(z - z_0)\right] \quad ,$$

$$p[z] = -g\rho_0 \ldots\ldots \quad .$$

28.07.08
Equazione Di Poiseuille

Descrive il moto stazionario di un fluido incomprimibile viscoso in un condotto rettilineo a sezione circolare costante di raggio R lungo un tratto Δz. Il profilo di velocità, in funzione della distanza dall'asse del tubo, r, è:

$$v[r] = \frac{1}{4\eta}\frac{|\Delta p|}{\Delta z}\left(R^2 - r^2\right) \quad ,$$

dove Δp è la differenza di pressione ai capi di Δz.

La portata volumetrica (volume di fluido per unità di tempo) risultante vale:

$$\frac{\mathrm{d}V}{\mathrm{d}t} = \frac{\pi R^4}{8\eta}\frac{|\Delta p|}{\Delta z} \quad .$$

La velocità media vale

$$\langle v \rangle = \frac{R^2}{8\eta}\frac{|\Delta p|}{\Delta z} \quad .$$

The larger the viscosity the larger the pressure difference required to get the same volumetric rate.

Note that the flow is a rotational one.

28.07.09
Viscous Fluid Between Two Circular Coaxial Rotating Cylinders

This § is referenced at pages:
[1530]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||

Read also § 28.07.10.

Consider two long circular cylindrical coaxial rotating cylinders with a viscous fluid in between (viscosity η). Let the radii and angular velocities of the two cylinders be R_1 (with angular velocity ω_1) and R_2 (with angular velocity ω_2), with $R_2 > R_1$. Let the length be $L \gg R_2$ The fluid in between the cylinders is rotating in a steady flow. Let $\omega[r]$ be the angular velocity as a function of the distance from the axis.

The problem is best analysed in cylindrical coordinates. This would imply to convert the expression of the gradient velocity tensor into cylindrical coordinates.

In this simple case, where only a radial dependence exists, a simplified heuristic approach goes as follows. Let us assume ($v[r] = r\omega[r]$)

$$\frac{\Delta F}{\Delta \mathbf{S}} = \eta\frac{\mathrm{d}v[r]}{\mathrm{d}r} = \eta\left(r\frac{\mathrm{d}\omega[r]}{\mathrm{d}r} + \omega[r]\right) \quad .$$

This expression cannot be accepted without changes. In fact the second term, $\eta\omega[r]$, is non zero for a rigid rotation also. We know that in a rigid rotation viscosity cannot have any effect and therefore the second term must be subtracted out. In fact it looks reasonable that the shear stress depends on the derivative of the angular velocity with respect to the radial distance. Finally, we then have the heuristic result:

$$\frac{\mathrm{d}F}{\mathrm{d}A} = \eta r\frac{\mathrm{d}\omega[r]}{\mathrm{d}r} \quad .$$

The total torque on an infinitesimal cylindrical shell at radius r is calculated from the shear torque. let us calculate, for instance, $\Gamma^-[r]$, the total torque that the part of fluid at distance less that r applies on the fluid at distance greater than r:

$$\Gamma^- = -2\pi\eta r^3 L\frac{\mathrm{d}\omega[r]}{\mathrm{d}r} \quad .$$

DRAFT - In Progress

Note the minus sign coming from the fact that if, for instance, $\frac{\mathrm{d}\omega[r]}{\mathrm{d}r} > 0$ the interior part of the fluid tend to slow down a shell of fluid rotating with $\omega[r] > 0$.

As the situation is a steady one, the angular momentum of any shell of fluid is constant and therefore the torques on its internal and external layers must be equal and opposite. Therefore one finds the equilibrium condition:

$$-2\pi\eta r^3 L\frac{\mathrm{d}\omega[r]}{\mathrm{d}r} = \text{constant} = \Gamma_0 \quad .$$

The solution gives of the differential equation with the appropriate boundary conditions give:

$$\omega[r] = -\frac{K_0}{2r^2} + K_1 \qquad K_0 = \frac{2R_1^2R_2^2}{R_2^2 - R_1^2}(\omega_2 - \omega_1) \qquad K_1 = \frac{R_2^2\omega_2 - R_1^2\omega_1}{R_2^2 - R_1^2} \quad .$$

The torque can be calculated from:

$$\Gamma^- = 2\pi\eta L K_0 \quad .$$

If the two angular velocities are given, the required torque can be calculated. If the torque and one angular velocity are given, the second angular velocity can be calculated.

Viscosity is often measured by using such a kind of apparatus.

Viscous Fluid Between Two Circular Coaxial Rotating Cylinders (2)

This § is referenced at pages:
[1529]

Read also § 28.07.09.

Un fluido di viscosità η si trova tra due cilindri coassiali di raggio, rispettivamente, r_1 ed r_2 con $r_1 < r_2$. Il cilindro interno è vincolato a ruotare con velocità angolare costante ω_1 mentre quello esterno viene fatto ruotare con velocità angolare costante ω_2. Mostrare come dalla misura delle velocità angolari e dei momenti da applicare ai due gusci si possa determinare la viscosità del fluido.

WORKED SOLUTION

Lo sforzo di taglio, per fluidi newtoniani, è legato alla viscosità dalla relazione (28.05.03), (sforzo applicato ad una superficie del fluido dall'esterno).
Fissiamo un Coordinate System con asse z coincidente con l'asse dei due cilindri. In situazione stazionaria si avrà il campo di velocità tale che:

$$x[r,t] = r\cos[\omega[r]t] \implies v_x = -\omega y \quad ,$$
$$y[r,t] = r\sin[\omega[r]t] \implies v_y = +\omega x \quad ,$$

con:

$$\omega[r,t] = \omega[r] \quad .$$

Quindi si ha, per τ_{xy},

$$\tau_{xy} = \tau_{yx} = \eta\left[\frac{\partial v_x}{\partial y} + \frac{\partial v_y}{\partial x}\right] = \eta\left[x\frac{\partial\omega}{\partial x} - y\frac{\partial\omega}{\partial y}\right] = \eta\frac{\partial\omega}{\partial r}\left[x\frac{\partial r}{\partial x} - y\frac{\partial r}{\partial y}\right] = \eta\frac{\partial\omega}{\partial r}\left[x\frac{x}{r} - y\frac{y}{r}\right] = \quad ,$$
$$\implies \{f_x, f_y\} = \tau_{ij}\{\cos\theta, \sin\theta\} \quad ,$$
$$\tau_{xx} = \tau_{yy} = 2\eta\frac{\partial v_x}{\partial x} = 2\eta\frac{\partial v_y}{\partial y} = -2\eta\frac{xy}{r}\frac{\partial\omega}{\partial r} \quad ,$$
$$f_x = -\eta y\frac{\partial\omega}{\partial r}????? \quad .$$

CC BY NC ND

Lo sforzo di taglio calcolato per $y = 0$, quando $x = r$, diventa allora

$$\tau_{r\theta} = \eta r \frac{\partial \omega}{\partial r} = \eta r \frac{\mathrm{d}\omega}{\mathrm{d}r} \tag{28.07.05}$$

→ 1531

essendo ω funzione di r ma non di θ.
è ragionevole che lo sforzo di taglio sia non nullo solo nel caso in cui la velocità angolare varia con r. Nel caso opposto, in cui la rotazione è rigida, non c'è scorrimento tra gli strati adiacenti ad r diverso per cui non c'è sforzo di taglio.
La relazione (28.07.05) può anche essere ricavata osservando che, in coordinate cilindriche, la velocità tangenziale vale $\omega(r)r$. Ne segue

$$\tau'_{r\theta} \approx \eta \frac{\Delta(\omega(r)r)}{\Delta r} \Longrightarrow \tau'_{r\theta} = \eta \frac{\mathrm{d}(\omega(r)r)}{\mathrm{d}r}$$

L'espressione ricavata non è tuttavia accettabile perché prevede uno sforzo di taglio anche nel caso di rotazione rigida del fluido con velocità angolare costante. Occorre sottrarre tale termine dall'espressione e si deduce allora, svolgendo la derivata, l'espressione (28.07.05).
Se la velocità angolare di ogni guscio di fluido è costante il momento complessivo delle forze che agiscono sul guscio è nullo e quindi il momento complessivo sulla faccia interna del guscio deve essere uguale ed opposto a quello che agisce sulla faccia esterna. Cioè il modulo del momento è indipendente da r. In particolare il momento da applicare ai due gusci ha lo stesso modulo. Si ha

$$\Gamma = 2\eta\pi L r^3 \frac{\mathrm{d}\omega}{\mathrm{d}r} = \Gamma_0$$

Allora l'equazione differenziale per ω

$$\frac{\mathrm{d}\omega}{\mathrm{d}r} = \frac{\Gamma_0}{2\pi\eta L r^3} \tag{28.07.06}$$

→ 1531

può essere integrata

$$\omega(r) = \frac{\Gamma_0}{4\pi\eta L r^2} + K$$

è un fatto sperimentale che un fluido a contatto con una parete ha velocità relativa nulla rispetto alla parete. Quindi la velocità del fluido nel punto di contatto con i due cilindri sarà la stessa velocità dei cilindri. Imponendo le condizioni $\omega[r_1] = \omega_1$ e $\omega[r_2] = \omega_2$ si determinano le costanti Γ_0 e K

$$\Gamma_0 = \frac{4\pi\eta L\,(\omega_2 - \omega_1)\, r_1^2 r_2^2}{r_2^2 - r_1^2} \quad ,$$
$$K = \frac{\omega_2 r_2^2 - \omega_1 r_1^2}{r_2^2 - r_1^2}$$

da cui segue l'espressione per la velocità angolare

$$\omega(r) = \frac{(\omega_2 - \omega_1)\, r_1^2 r_2^2}{\left(r_2^2 - r_1^2\right) r^2} + \frac{\omega_2 r_2^2 - \omega_1 r_1^2}{r_2^2 - r_1^2}$$

Non essendo interessati all'andamento di $\omega(r)$ ma volendo determinare solo l'espressione del momento si poteva integrare direttamente la (28.07.06) tra i due estremi, $r_1,\ \omega_1$ e $r_2,\ \omega_2$, ottenendo direttamente

$$\omega_2 - \omega_1 = \frac{\Gamma_0}{4\eta\pi L} \frac{r_2^2 - r_1^2}{r_1^2 r_2^2}$$

Pressione All'interno Di Una Goccia Sferica D'acqua

©|M.W.Zemansky & M.M.Abbot & H.C.VanNess, *Fondamenti Di Termodinamica per Ingegneri*, ..., ..., ...Ed., ...|E???||

This § is referenced at pages:
[1532, 1532, 1532, 1532]

Si consideri una goccia d'acqua sferica di raggio R in sospensione nell'atmosfera.

1. Determinare la differenza tra la pressione atmosferica esterna, p_e, e quella interna alla goccia, p_i, in termini della tensione superficiale del liquido γ.

Si trascuri l'effetto della forza di gravità. Si veda pure il problema § 28.07.12.

WORKED SOLUTION

Si consideri metà della goccia. Su tale sistema agiscono la risultante delle forze di pressione esterne (pressione atmosferica), la risultante delle forze di pressione interne (pressione esercitata dall'altra semisfera) e la risultante delle forze di tensione superficiale sul contorno circolare della semisfera. Si trascura il peso. La risultante di tutte queste tre forze è diretta parallelamente all'asse della semisfera (per simmetria). In condizioni di equilibrio si ha

$$(p_i - p_e)\,\pi R^2 - 2\pi R\gamma = 0$$

da cui si deduce

$$\boxed{p_i - p_e = \frac{2\gamma}{R}} \qquad (28.07.07)$$

e la pressione interna è maggiore di quella esterna per effetto della tensione superficiale.
Le relazioni ricavate nei problemi § 28.07.12 , § 28.07.11 possono essere ricavate direttamente dalla legge di Laplace (28.06.03), che da la differenza di pressione Δp dalle due parti della superficie di tensione superficiale γ e i cui raggi di curvatura principali sono R_1 e R_2.

WORKED SOLUTION

1. $p_i - p_e = 2\gamma/R$

28.07.12
Pressione All'interno Di Una Bolla Sferica Di Acqua Saponata

This § is referenced at pages:
[1532, 1532]

Si consideri una bolla di sapone sferica in sospensione nell'atmosfera di raggio R. Si supponga la bolla sottile rispetto al raggio R trascurando quindi la differenza tra i raggi interno ed esterno della bolla.

1. Determinare la differenza tra la pressione atmosferica esterna p_e e quella interna alla goccia p_i in termini della tensione superficiale del liquido γ.
2. Determinare il raggio della bolla se il gas all'interno può essere considerato un gas ideale a temperatura uguale alla temperatura esterna T_0. Si veda pure il paragrafo § 28.07.11.

WORKED SOLUTION

Rispetto al paragrafo § 28.07.11 ora le superfici sono due: quella interna e quella esterna. Ragionando come nel paragrafo § 28.07.11 e trascurando il peso si ha allora

$$(p_i - p_e)\,\pi R^2 - 4\pi R\gamma = 0$$

da cui si deduce

$$p_i - p_e = \frac{4\gamma}{R} \tag{28.07.08}$$

e la pressione interna è maggiore di quella esterna per effetto della tensione superficiale.
L'equazione di stato dei gas perfetti applicata al gas all'interno della bolla diventa

$$\left[p_e + \frac{4\gamma}{R}\right]\frac{4\pi}{3}R^3 = Nk_{\text{B}}T$$

da cui si può ricavare il raggio della bolla R.
Read also **Laplace equation** (28.06.03).

WORKED SOLUTION

1. $p_i - p_e = 4\gamma/R$.

Equilibrium of a Gravitating Non-Rotating Spherical Fluid Mass

This § is referenced at pages:
[1543, 1543, 1543, 1667]

Equilibrium is give by the balance between gravity and thermal pressure.
Spherical cap of radius r, height h and polar angle θ, and limits for small θ.

$$A_c[\theta] = 2\pi r^2\left(1-\cos\theta\right) \to \pi r^2\theta^2 \qquad \text{surface of the cap} \quad ,$$
$$A_b[\theta] = \pi r^2 \sin^2\theta \to \pi r^2\theta^2 \qquad \text{surface of the plane base of the cap} \quad ,$$
$$L[\theta] = 2\pi r\sin\theta \to 2\pi r\theta \qquad \text{length of the circumference} \quad .$$

The mass of fluid contained at a radius smaller than r is:

$$\boxed{\frac{\mathrm{d}M[r]}{\mathrm{d}r} = 4\pi r^2\rho[r] \qquad \text{first stellar structure equation}} \quad .$$

Spherical and spherically symmetric fluid mass. Consider a right circular cone of radius, centered at the center of the spherical mass, of fixed angle θ.

$$p[r]A_b[r] - p[r+\Delta r]A_b[r+\Delta r] + L[r]\Delta r p[r+\Delta r/2]\sin\theta = \mathcal{G}\rho[r]A_c\Delta r\frac{M[r]}{r^2} \quad , \quad ,$$

$$p[r]\pi r^2\sin^2\theta - p[r+\Delta r]\pi\left(r+\Delta r\right)^2\sin^2\theta + 2\pi r\sin\theta\Delta r p[r+\Delta r/2]\sin\theta = \mathcal{G}\rho[r]\Delta r\frac{M[r]}{r^2}2\pi r^2\left(1-\cos\theta\right) \quad , \quad ,$$

$$p[r]r^2 - p[r+\Delta r]\left(r+\Delta r\right)^2 + 2r\Delta r p[r+\Delta r/2] = \mathcal{G}\rho[r]\Delta r\frac{M[r]}{r^2}r^2 \qquad \text{limit for } \theta\to 0 \quad , \quad ,$$

$$-\frac{\mathrm{d}p[r]r^2}{\mathrm{d}r} + 2rp[r] = -r^2\frac{\mathrm{d}p[r]}{\mathrm{d}r} = \mathcal{G}\rho[r]M[r] \qquad \text{limit for } \Delta r\to 0 \quad , \quad ,$$

$$\boxed{-\frac{\mathrm{d}p[r]}{\mathrm{d}r} = \frac{\mathcal{G}\rho[r]M[r]}{r^2}} \qquad \text{second stellar structure equation} \quad .$$

Note that $\theta = \Delta\theta$ in this problem, as the polar angle is counted from zero.

cc BY NC ND

Application of formula (28.02.01) would give directly:

$$\boxed{\frac{\mathrm{d}p[r]}{\mathrm{d}r}\widehat{\mathbf{e}}_r = -\frac{\mathcal{G}\rho[r]M[r]}{r^2}\widehat{\mathbf{e}}_r \equiv -\rho[r]\mathbf{g}} \quad .$$

The pressure is the sum of the gas pressure (molecules, ions and electrons) and the photon radiation pressure:

$$\boxed{p = \eta_{\mathrm{N}} k_{\mathrm{B}} T + \frac{4\sigma_{\mathrm{SB}}}{3c}T^4} \qquad \text{treating the molecular gas as a ideal gas} \quad .$$

Gas pressure is most important in low mass stars; radiation pressure is most important in high mass stars.

This system of two equations may be solved by specifying an equation of state relating these quantities. The simplest model is obtained by assuming that the pressure is only a function of the density so that one can solve these two equations independently from the equations involving temperature.

28-001 Icebergs

1. Un iceberg di volume $1000\ \mathrm{km}^3$ si scioglie. Di quanto sale il livello del mare?
2. Di quanto emerge dall'acqua un iceberg di forma sferica?

28-002 Spinta Di Archimede Su Una Sfera Sommersa

Una oggetto sferico omogeneo di raggio R è immerso in un liquido di densità ρ.

1. Se il centro della sfera si trova ad un profondità H sotto il livello del liquido, $H > R$. Mostrare, con il calcolo esplicito, che la spinta di Archimede risultante è diretta verso l'alto e ha modulo $F_A = m_a g$ dove m_a è la massa di liquido spostata.
2. Se la sfera non è completamente immersa e $0 \leq H \leq R$ calcolare la forza di Archimede.

WORKED SOLUTION

Si scelga un Coordinate System con origine nel centro della sfera sommersa e asse z rivolto verso l'alto. Si introduca l'angolo polare θ, che misura gli angoli a partire dall'asse z, ($0 \leq \theta \leq \pi$) e l'angolo azimuthale ϕ ($0 \leq \phi \leq 2\pi$). Sia $\widehat{\mathbf{e}}_r$ il versore radiale. Si ponga l'origine degli assi al centro della sfera.

L'andamento della pressione del liquido, all'equilibrio, è dato dalla legge di Stevino (28.07.01). La pressione di riferimento, $p_{\mathrm{A}} + \rho g H$, è la pressione alla quota a cui si trova il centro della sfera.

La forza infinitesima che agisce sull'elemento infinitesimo della superficie della sfera di area $\mathrm{d}\mathbf{S}$ e dovuta alla pressione vale

$$\mathrm{d}\mathbf{F} = -p[z]\ \mathrm{d}\mathbf{S}\widehat{\mathbf{e}}_r \quad .$$

La componente orizzontale di tale forza è tale che il suo integrale sull'angolo azimuthale ϕ fa zero, per ragioni di simmetria. La componente verticale vale

$$\mathrm{d}F_z = -p[z]\cos[\theta]\ \ \mathrm{d}\mathbf{S} \quad ,$$

DRAFT - IN - PROGRESS

con

$$\mathbb{d}\mathbf{S} = r^2\, \mathbb{d}\Omega = r^2 \sin[\theta]\ \mathbb{d}\theta\, \mathbb{d}\phi \quad ,$$

e ha integrale non nullo sull'angolo azimuthale ϕ. Inoltre

$$p[z] = p_{\text{A}} + \rho g H - \rho g r \cos[\theta] \quad .$$

Ne segue

$$\mathbb{d}F_z = -\left(p_{\text{A}} + \rho g H - \rho g r \cos[\theta]\right) r^2 \cos[\theta] \sin[\theta]\ \mathbb{d}\theta\, \mathbb{d}\phi \quad .$$

1. La forza risultante vale:
$$F_z = \int_{\theta=0}^{\pi} \int_{\phi=0}^{2\pi} \mathbb{d}F_z = \frac{4\pi}{3}\rho g r^3 = m_a g \quad .$$
il cui valore e modulo coincidono con quanto previsto dalla spinta di Archimede.
La forza risultante non dipende dalla profondità H a cui è immerso l'oggetto, purché esso sia completamente immerso.
2. La forza risultante vale:
$$F_z = \int_{\cos\theta=H/R}^{\pi} \int_{\phi=0}^{2\pi} \mathbb{d}F_z = \frac{4\pi}{3}\rho g r^3 = m_a g \quad .$$
La forza risultante dipende dalla profondità H a cui è parzialmente immerso l'oggetto.

28-003 Forze E Momenti Agenti Sulla Parete Di Una Diga

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|17.14||

Una diga ha un muraglione di forma rettangolare, verticale, di larghezza L ed il livello dell'acqua è H.
1. Calcolare la forza risultante che agisce sul muro dovuta alla pressione della massa d'acqua.
2. Si consideri il momento risultante delle forze di pressione che agiscono sul muro rispetto ad un polo, F, posto alla base della parete della diga, al livello del fondo. Calcolare la componente di tale momento rispetto alla direzione orizzontaLE della linea di intersezione tra la superficie libera dell'acqua e la parete verticale della diga.

WORKED SOLUTION

Si scelga un Coordinate System con asse z verticale coincidente con la facciata del muro della diga rivolta verso l'acqua, asse x orizzontale, perpendicilarmente alla parte della diga e diretto dall'acqua verso il muro e coincidente con il livello dell'acqua. Con tale scelta il livello del fondo è $z = -H < 0$. La pressione idrostatica si esprime con la relazione

$$p = p_0 - \rho_a g z$$

dove p_0 è la pressione atmosferica.

1. La forza infinitesima che agisce sul muro della diga dovuta all'acqua posta alla quota z e diretta lungo la direzione positiva dell'asse x vale
$$\mathbb{d}F = p\ \mathbb{d}\mathbf{S} = (p_0 - \rho_a g z)\, L\, \mathbb{d}z$$
Ne segue l'espressione per la forza risultante
$$F = \int_{-H}^{0} \mathbb{d}F = LH\left(p_0 + \rho_a g \frac{H}{2}\right) = LHp(z = -\frac{H}{2})$$
che risulta essere uguale all'area della superficie immersa moltiplicata per il valore della pressione alla quota del centroide della superficie immersa stessa. Il valore della forza risultante sul muro dovuta alla sola pressione differenziale dell'acqua si ottiene dalla relazione

CC BY NC ND

precedente ponendo $p_0 = 0$:

$$F^{\Delta} = \rho_a g \frac{LH^2}{2}$$

2. Per la scelta fatta del Coordinate System occorre calcolare la componente del momento delle forze di pressione rispetto all'asse y. Consideriamo nel seguito implicitamente le componenti dei momenti rispetto a tale asse. Essendo il sistema delle forze di pressione applicato dall'acqua al muro un sistema di forze parallele possiamo calcolare la quota del centro di tale sistema di forze, z_c:

$$z_c \equiv \frac{1}{F}\int_{-H}^{0} z \, \mathrm{d}F = -\frac{LH^2}{F}\left[\frac{p_0}{2} + \frac{\rho_a g H}{3}\right] = -H\left[\frac{\frac{p_0}{2} + \frac{\rho_a g H}{3}}{p_0 + \frac{\rho_a g H}{2}}\right] = -\frac{\Gamma_S}{F} \qquad (28.08.01)$$

→ 1536

dove $\mathbf{\Gamma}_S$ è il momento risultante sul muro dovuto alle forze di pressione rispetto ad un polo posto sul muro al livello della superficie. La quota del centro del sistema di forze sul muro dovute alla sola pressione differenziale dell'acqua si ottiene dalla relazione precedente ponendo $p_0 = 0$

$$z_c = -\frac{2}{3}H$$

Il sistema di forze sul muro dovute alla sola pressione differenziale dell'acqua è dunque equivalente (ha cioè la stessa risultante e lo stesso momento rispetto ad un polo qualunque) al sistema costituito dalla forza risultante applicata al centroide della superficie immersa che ha coordinate $x_c = 0$ e z_c dato dalla relazione (28.08.01). Il momento totale delle forze di pressione rispetto ad un polo a livello del fondo si calcola allora tenendo conto che il braccio della forza rispetto al fondo vale

$$b = z_c + H = \frac{H}{2}\left[\frac{p_0 + \frac{\rho_a g H}{3}}{p_0 + \frac{\rho_a g H}{2}}\right]$$

per cui il momento risulta

$$\Gamma_F = -\frac{LH^2}{2}\left[p_0 + \rho_a g \frac{H}{3}\right]$$

e quello differenziale

$$\Gamma_\Delta = \rho_a g \frac{LH^3}{6}$$

la relazione tra $\mathbf{\Gamma}_F$ e $\mathbf{\Gamma}_S$ può essere anche ricavata dalla legge di trasformazione di un momento al variare del polo (15.04.03).

WORKED SOLUTION

1. $F = LH\,(p_0 + \rho_a g H/2)$;
2. $\Gamma_F = -LH^2\,[p_0/2 + \rho_a g H/6]$.

28-004 Parete Inclinata Di Una Diga

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|17.Q.7||

Una vasca ha una delle pareti laterali di lunghezza L inclinata di un angolo α rispetto all'orizzontale. Se il livello di acqua nella vasca è H determinare la forza totale agente sulla parete della vasca dovuta alla pressione differenziale dell'acqua. Utilizzare tale risultato per spiegare il peso di un recipiente con acqua le cui pareti non sono verticali.

WORKED SOLUTION

Si scelga un Coordinate System con asse z verticale rivolto verso l'alto passante per e avente origine sullo spigolo inferiore della vasca. Si introduca poi un altro Coordinate System avente la stessa origine e asse z' coincidente con la parete inclinata. Con tale scelta il livello dell'acqua vale $z = H > 0$ oppure $z' = H/\sin[\alpha] > 0$. Essendo $z = z'\sin[\alpha]$ la pressione idrostatica si esprime con la relazione

$$p[z] = p_0 - \rho_a g\,(z - H) = p_0 - \rho_a g\,(z' - H')\sin[\alpha]$$

dove p_0 è la pressione atmosferica. La forza infinitesima che agisce sul muro della diga dovuta all'acqua posta alla quota z è diretta perpendicolarmente alla parete, verso l'esterno ed ha modulo

$$\mathrm{d}F = pL\,\mathrm{d}z' = \left(p_0 - \rho_a g\,(z' - H')\sin[\alpha]\right) L\,\mathrm{d}z'$$

da cui

$$F = \int_0^{H'} \mathrm{d}F = LH'\left(p_0 + \rho_a g\frac{H'}{2}\sin[\alpha]\right) = \frac{LH}{\sin[\alpha]}\left(p_0 + \rho_a g\frac{H}{2}\right) = LH' p(\frac{H}{2})$$

che coincide con la superficie della parete LH' moltiplicato per la pressione calcolata alla metà profondità $z = H/2$. Il valore della forza risultante sul muro dovuta alla sola pressione differenziale dell'acqua si ottiene dalla relazione precedente ponendo $p_0 = 0$

$$F^{\Delta} = \rho_a g\frac{LH^2}{2\sin[\alpha]}$$

Il momento risultante rispetto al punto in cui la parete giunge al livello dell'acqua si calcola usando il sistema risultante delle forze applicate e vale

$$\Gamma_0 = |\,\mathbf{F}\wedge\mathbf{r}_c| = \frac{LH^2}{\sin^2\alpha}\left(\frac{p_0}{2} + \rho_a g\frac{H}{3}\right)$$

che coincide con il momento della forza risultante F, calcolato sopra, moltiplicato per il braccio della retta di applicazione della forza risultante del sistema di forze applicate, $H'/3$.
La componente verticale della forza risultante sul muro dovuta alla sola pressione differenziale dell'acqua ha modulo

$$F_v = F\cos[\alpha] = \frac{\rho_a g H^2 L}{2\tan[\alpha]}$$

Tale forza coincide con il peso della massa di acqua che sta sopra/sotto la parete inclinata. Tale forza spiega il valore del peso di un recipiente a pareti inclinate. Si noti che se $-\pi/2 < \alpha < 0$ tale forza è diretta verso l'alto, mentre se $0 < \alpha < +\pi/2 <$ tale forza è diretta verso il basso.
Si noti che il contributo dovuto alla pressione atmosferica p_0 è compensato, nel caso il lato esterno della parete sia esposto alla pressione atmosferica, da un contributo uguale ed opposto alla forza risultante dovuto alla pressione esterna.

CC BY NC ND

28-005 A Floating Sphere

A homogeneous sphere of radius R and density ρ is floating on a fluid of density $\rho_0 > \rho$. A vertical force acting on the sphere and applied on a straight line passing by the center, presses downward the sphere. Determine the depth of immersion of the sphere as a function of the force.

28-006 Liquido in Un Recipiente in Rotazione Uniforme

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|17.29||

Un fluido incomprimibile ruota con velocità angolare costante ω attorno all'asse verticale di un recipiente cilindrico. Dopo una fase transitoria, il liquiodo si trova a ruotare come un corpo rigido.

Determinare la forma della superficie del liquido; determinare la variazione di pressione entro il fluido nella direzione radiale; determinare la variazione di pressione entro il fluido nella direzione verticale.

WORKED SOLUTION

Si scelga un Reference Frame non inerziale solidale con la massa di fluido ruotante e in esso un Coordinate System cilindrico con asse z coincidente con l'asse del cilindro e orientato verso l'alto. La forza di volume infinitesima che agisce sull'elemento di massa $\mathrm{d}m$ è la somma della forza peso e della forza centrifuga

$$\mathrm{d}\mathbf{F} = \left(\omega^2 r \widehat{\mathbf{e}}_r - g\widehat{\mathbf{e}}_3\right)\,\mathrm{d}m \quad ,$$

ovvero una forza per unità di volume

$$\mathbf{f}_{\mathrm{V}} = \rho\left(\omega^2 r \widehat{\mathbf{e}}_r - g\widehat{\mathbf{e}}_3\right) \quad .$$

Tale forza, all'equilibrio, deve essere compensata da una forza di pressione uguale ed opposta. Alla forza di volume corrisponde un'energia potenziale

$$\mathrm{d}\Phi(r,z) = \left(-\frac{1}{2}\omega^2 r^2 + gz\right)\,\mathrm{d}m \quad ,$$

cioè un energia potenziale per unità di volume

$$\phi(r,z) = \rho\left(-\frac{1}{2}\omega^2 r^2 + gz\right) \quad .$$

Le superfici equipotenziali sono date da

$$u(r,z) = \text{costante} \implies -\frac{1}{2}\rho\omega^2 r^2 + \rho g z = \text{costante} \quad .$$

Da cui segue l'equazione delle superfici equipotenziali

$$z = \frac{\omega^2 r^2}{2g} + z_0$$

La forza di volume per unità di volume vale:

$$\mathbf{f}_{\mathrm{V}} = -\mathbf{grad}\phi \quad ,$$

e la forza di superficie dovuta alle forze di pressione vale, per unità di volume:

$$\mathbf{f}_{\mathrm{p}} = -\mathbf{grad}p \quad ,$$

e la condizione di equilibrio statico fornisce:

$$p = -u + \text{constant} \quad ,$$

e quindi

$$p = -u(r,z) = \frac{1}{2}\rho\omega^2 r^2 - \rho g z + p_0$$

Alternativamente si possono risolvere le equazioni di equilibrio:

$$\frac{\partial p}{\partial r} = \mathbf{f}_V \cdot \hat{\mathbf{e}}_r = \rho\omega^2 r \quad ,$$
$$\frac{\partial p}{\partial z} = \mathbf{f}_V \cdot \hat{\mathbf{e}}_3 = -\rho g \quad ,$$

e, integrando per $p = p(r, z)$ si deduce:

$$p(r, z) = -\rho g z + \frac{1}{2}\rho\omega^2 r^2 + \text{costante} \quad .$$

28-007 Total Force From a Uniform Pressure

Consider an open surface whose boundary lies on a plane, while all the surface is on the same side of the plane. The open surface is subjected to a uniform external pressure. Show that the total force perpendicular to the plane, due to pressure, equals the product of the pressure times the projected area of the surface on the plane.

28-008 Piccole Oscillazioni Di Un Oggetto Galleggiante

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|17.30||

©|H.C.Ohanian, , ..., ..., ...Ed., ...|18.37||

Si supponga di avere un'asta di sezione uniforme A, lunghezza L e massa M con una piccola massa puntiforme m appesa ad un estremo. Immersa in acqua l'asta galleggia con la massa m rivolta verso il basso.

1. Determinare la frequenza delle piccole oscillazioni dell'asta trascurando le perturbazioni al fluido circostante causate dal movimento dell'asta.
2. Stimare la frequenza delle piccole oscillazioni verticali per una petroliera.

WORKED SOLUTION

Detta x la lunghezza della parte di asta sommersa $0 \le x \le L$ l'equazione del moto delle piccole oscillazioni, detta ρ_a la densità dell'acqua e detta ρ la densità dell'asta e trascurando le perturbazioni al fluido circostante causate dal movimento dell'asta, è

$$(m + M)\,\ddot{x} = -\rho_a A g x + mg + \rho A g L$$

La posizione di equilibrio è dunque

$$x_{EQ} = \frac{m + M}{\rho A}$$

Se $m = 0$

$$x_{EQ} = \frac{\rho}{\rho_a} L$$

da cui è evidente che l'asta galleggia se e solo se $\rho < \rho_a$. La frequenza delle piccole oscillazioni vale

$$\omega^2 = \frac{\rho A g}{m + M} = \frac{g}{x_{EQ}}$$

Con i dati del testo $T = 3.17$ s.
Per una petroliera $T \approx 1$ s.

WORKED SOLUTION

1. $\omega^2 = \rho A g / (m + M)$;
2. $T \approx 1$ s.

28-009 Lead an Cork

There is a well known riddle: "What is heavier, a ton of lead or a ton of cork?" Determine how much the actual weight of the cork which is 1 ton in air, exceeds the actual weight of the lead, which is also 1 ton in air. The temperature of the air is 17 °C and the pressure 760 mm Hg.

28-010 Pallone Aerostatico

What should the weight of the rubber skin of a balloon 25 cm in diameter filled with hydrogen be for the resulting lifting force of the balloon to equal zero, i.e., for the balloon to be suspended? The air and hydrogen are in standard conditions. The pressure inside the balloon is equal to the external pressure.

28-011 Vasi Comunicanti Con Mercurio

Find the difference in the levels of mercury in two identical communicating glass tubes if the left-hand tube is maintained at a temperature of 0°Cand the right-hand one is heated to 100°C. The height of the left-hand tube is 90 cm. The coefficient of volume expansion of mercury is $1.82 \cdot 10^{-4}$ deg^{-1} Disregard the expansion of the glass.

28-012 Pressione Atmosferica - Relazione Politropica Di Gas Ideale

This § is referenced at pages:
[2708]

©|Mic, , ..., ..., ...Ed., ...|§ 1.5||
©|Lim Yung-Kuo, *Problems And Solutions On Thermodynamics And Statistical Physics*, 1990, World Scientific, ...Ed., ...

Determinare l'andamento della pressione atmosferica supponendo che l'equazione di stato del gas atmosferico sia $p = K\rho^{\delta}$. Si supponga di poter trattare l'atmosfera come un gas ideale di massa molecolare media $\mathcal{M}_0 = 28.8$ g/mol e descritto dall'equazione di stato del gas ideale, $pV = nRT$, in cui $R = 8.31$ J mol^{-1} K^{-1} è la costante universale del gas ideale, T la temperatura assoluta ed $\mathcal{M}_0$ la massa molare del gas.

1. Si determini l'andamento della pressione atmosferica nel caso T sia uniforme (atmosfera isoterma): $\delta = 1$ e $K = RT/\mathcal{M}_0$.
2. Si determini l'andamento della pressione atmosferica nel caso la temperatura assoluta in funzione della quota z sia assegnata e pari a $T[z] = T_0 - \alpha z$: $\delta \neq 1$ e K costante. Verificare il caso $\delta = 1$. Show that: $\alpha = \dfrac{g\mathcal{M}_0}{R}\dfrac{\delta - 1}{\delta}$.
3. Show that for this case no atmosphere exists above a $z_{\mathtt{MAX}}$ and find $z_{\mathtt{MAX}}$.

Si assuma l'accelerazione di gravità g indipendente dalla quota.

Read also § 67.14.21.

DRAFT - IN PROGRESS

WORKED SOLUTION

- In condizioni statiche si ha

$$\frac{\mathrm{d}p[z]}{\mathrm{d}z} = -g[z]\rho[z] \tag{28.08.02}$$

Utilizzando l'equazione di stato $p = K\rho$ e integrando si ha

$$p[z] = p_0 \exp\left[-\frac{g\,(z-z_0)}{K}\right] \equiv p[z] = p_0 \exp\left[-\frac{(z-z_0)}{\ell}\right] \qquad \ell \equiv K/g \tag{28.08.03}$$

→ 1541

La quantità ℓ assume allora il significato di lunghezza caratteristica di variazione della pressione atmosferica. L'equazione di stato dei gas perfetti fornisce l'espressione

$$K = \frac{RT}{\mathcal{M}_0}$$

Nel caso dell'atmosfera, assumendo una massa molecolare media $\mathcal{M}_0 = 28.8\ \mathrm{g/mol}$, e temperatura assoluta $T = 300\ \mathrm{K}$ si trova $L = 8.4\ \mathrm{km}$.

- Nel caso la temperatura decresca linearmente con la quota si ha

$$\frac{\mathrm{d}p}{\mathrm{d}z} = -g[z]\rho[z] = -\frac{g\mathcal{M}_0}{R}\left(\frac{p}{T_0 - \alpha z}\right)$$

L'integrazione fornisce

$$p[z] = p_0\left(\frac{T_0 - \alpha z}{T_0 - \alpha z_0}\right)^{\frac{g\mathcal{M}_0}{\alpha R}} \tag{28.08.04}$$

Nel limite $\alpha \to 0$ tale equazione si riduce correttamente alla (28.08.03).
Nel caso $\delta \neq 1$ e K costante l'integrazione fornisce

$$p[z] = p_0^{1/(1-\delta)}\left(p_0 + \frac{g\rho_0\,(z-z_0)\,\delta}{(1-\delta)}\right)^{\delta/(\delta-1)} \tag{28.08.05}$$

Questa equazione è stata ricavata integrando sotto la condizione che $\delta \neq 1$. Per ottenere il risultato calcolato in precedenza occorre calcolare il limite per $\delta \to 1$ dell'espressione ottenuta.

- $$z_{\mathtt{MAX}} = \frac{\delta}{\delta - 1}\frac{RT}{\mathcal{M}_0 g} \quad .$$

28-013 Serbatoio Bucato E Coefficiente Di Efflusso

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|18.15 18.16||

Un serbatoio di forma cilindrica con altezza H ha un piccolo buco, di area A da cui fuoriesce un piccolo getto di liquido. Si supponga il buco così piccolo da poter considerare il moto laminare, stazionario, e si supponga di poter trascurare la viscosità.

1. Se il serbatoio è aperto all'atmosfera e ha il buco al centro della base, si calcoli la velocità del getto all'uscita dal buco.
2. Se il buco è ad un'altezza h dal fondo e fuoriesce un piccolo getto di liquido in direzione orizzontale e il serbatoio è aperto all'atmosfera, si calcoli per quale posizione del buco il getto che fuoriesce arriva a terra alla massima distanza.
3. Se il serbatoio è chiuso e contiene gas a pressione p_1, quanto vale la velocità di efflusso?

Si supponga che la pressione del gas all'interno sia così elevata da poter trascurare il contributo di energia potenziale gravitazionale del gas.

WORKED SOLUTION

Si applichi il Bernoulli equation ad una linea di flusso tra un punto alla superficie del liquido del serbatoio ed un punto all'orifizio. Si ha:

$$p_0 + \rho g z_0 + \frac{\rho v_0^2}{2} = p_1 + \rho g z_1 + \frac{\rho v_1^2}{2} \quad . \tag{28.08.06}$$

→ 1542

L'equazione di continuità fornisce:

$$v_0 A_0 = v_1 A_1 \quad .$$

Però all'uscita del foro il tubo di flusso è in fase di restringimento e solo dopo essere uscita un poco le velocità tendono a diventare parallele e la sezione costante (vena contracta) ed è tale valore che dovrebbe essere usato per la sezione nell'equazione $v_0 A_0 = v_1 A_1$, non la sezione dell'orifizio. è a questo punto che l'equazione di continuità può essere applicata. Se però $A_0 \gg A_1$ si può trascurare v_0 rispetto a v_1. Il flusso uscente non può essere calcolato moltiplicando la velocità v_1 per l'area del foro A_1. Infatti, in generale, le velocità del liquido che esce dal buco avranno anche una componente di velocità radiale, all'uscita. Il flusso reale sarà allora inferiore a $A_1 v_1$ e dipende dalla forma dell'ugello. Il flusso sarà dato dalla velocità moltiplicata per la sezione del tubo di flusso nel punto in cui le velocità sono diventate parallele.

1. ...
2. Essendo il serbatoio aperto $p_0 = p_1$, la pressione atmosferica. Allora la velocità di efflusso vale
$$v_1 = \sqrt{2g\,(H-h)} \quad .$$
Il punto in cui il getto arriva a terra, rispetto al cilindro, è dato dalla relazione
$$\Delta x = \sqrt{\frac{2v_1^2 h}{g}} = 2\sqrt{h\,(H-h)}$$
la distanza massima si ha allora quando è massimo il prodotto $h\,(H-h)$ cioè per $h = H/2$. Si noti che la velocità dipende dall'altezza della colonna di liquido nel serbatoio.
3. Dall'equazione (28.08.06) ora, supponendo ancora di poter trascurare v_0 rispetto a v_1, e trascurando il termine di energia potenziale gravitazionale, si ha
$$v_1 = \sqrt{\frac{2\,(p_1 - p_0)}{\rho}}$$
dove la densità è quella del fluido uscente dal foro. La velocità di efflusso di un gas può essere grande, anche per basse pressioni, perché la densità è piccola. Occorre tuttavia tener presente che se la pressione è troppo grande può non essere lecito trattare il fluido come incomprimibile. Inoltre se la velocità è troppo grande il moto del fluido può diventare turbolento. In entrambi i casi l'equazione di Bernoulli non può essere applicata. Nel caso di applicabilità del Bernoulli equation si può calcolare la spinta F prodotta dall'uscita del gas ad alta velocità:
$$F = 2A\,(p_1 - p_0) \quad .$$

Consider, in a plane, a point P, a fixed point, F, the focus, and a straight line, D, the directrix, such that F does not belong to D. Let Q be one of the two points such that FP is parallel to the directrix. Let K be the intersection between the directrix and the perpendicular to it passing by P.

Let:

- h be the distance between the focus and the directrix;
- $f \equiv \overline{PF}$ be the distance between the point P and the focus;
- $d \equiv \overline{PK}$ be the distance between the point P and the directrix;
- $p \equiv \overline{FQ}$.

A conic is the locus of the points, P, in the plane such that the ratio

$$e \equiv \frac{f \equiv \overline{PF}}{d \equiv \overline{PK}} \geq 0 \quad ,$$

is a fixed non negative constant e (the eccentricity); see figure 29.11.

Introduce polar coordinates (r and φ) in the plane, centered in F and with $\varphi = 0$ being the line passing by the focus and perpendicular to the directrix; positive angles counter-clockwise.

Note that as long as $0 \leq e \leq 1$ the point P can only be in the half-plane on the same side as F with respect to the directrix. On the other hand, if $e > 1$, the point P can be on both sides of the directrix.

DRAFT - IN PROGRESS

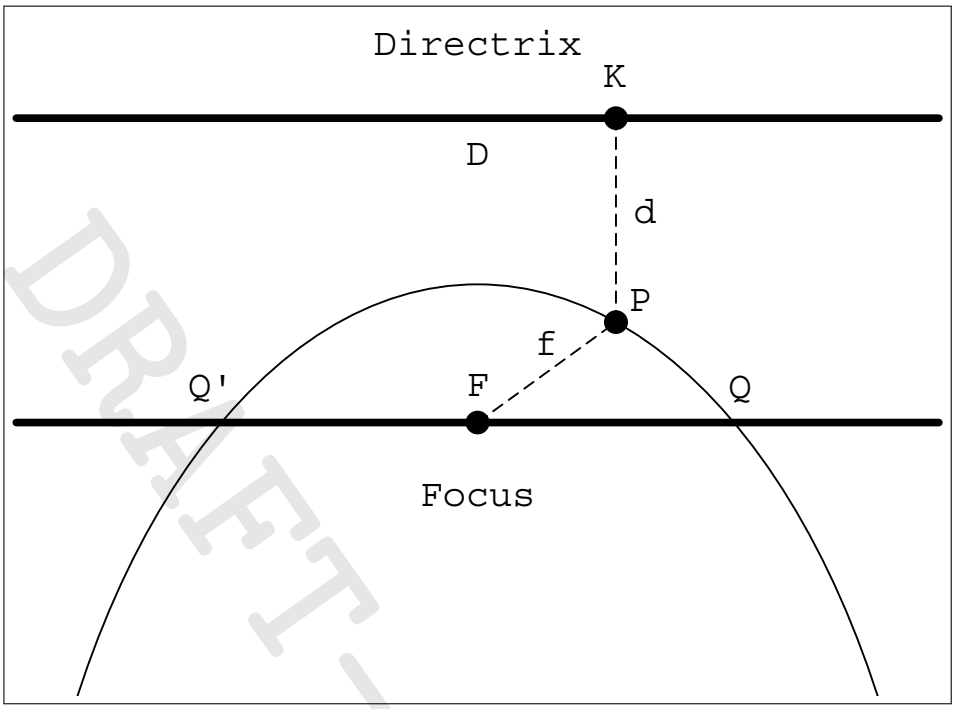

Figure 29.11: FIGURE

The following relations apply:

$$\boxed{0 \leq e = \frac{f}{d} \equiv \frac{\rho}{d}} \quad , \qquad \rightarrow 1547$$

$$e = \text{constant} = \frac{f}{d} \equiv \frac{\overline{FQ}}{\overline{KQ}} \equiv \frac{p}{h} \quad ,$$

$$\boxed{d = |h - \rho \cos[\varphi]|} \quad , \qquad \rightarrow 1547$$

$$\begin{cases} h = d + \rho \cos[\varphi] & \text{for } 0 \leq e \leq 1 \\ h = \pm d + \rho \cos[\varphi] & \text{for } e > 1 \end{cases} \quad ,$$

$$h = \alpha d + \rho \cos[\varphi] \qquad \begin{cases} \alpha \equiv +1 & \text{for } 0 \leq e \leq 1 \\ \alpha \equiv \pm 1 & \text{for } e > 1 \end{cases} \quad ,$$

$$h = \frac{\rho}{e}(\alpha + e \cos[\varphi]) \quad ,$$

$$\boxed{\rho[\varphi] = \frac{p}{\alpha + e \cos[\varphi]} \qquad \begin{cases} \alpha \equiv +1 & \text{for } 0 \leq e \leq 1 \\ \alpha \equiv \pm 1 & \text{for } e > 1 \end{cases}} \quad . \qquad \rightarrow 1548$$

One defines:

- the ellipse for $0 \leq e < 1$, defined for $0 \leq \varphi \leq 2\pi$;
- the parabola for $e = 1$, defined for $0 \leq \varphi < 2\pi$;
- the hyperbola for $e > 1$:
  - the branch $\alpha \equiv +1$ is defined for $-\arccos[-1/e] < \varphi < +\arccos[-1/e]$;
  - the branch $\alpha \equiv -1$ is defined for $-\arccos[+1/e] < \varphi < +\arccos[+1/e]$.

Note that the $\pm$ sign applies to, and only to, the case of $e > 1$, when the conic has two branches on the two different sides of the directrix with respect to the focus (the two branches of the hyperbola). In this case, and only in this case, the absolute value in equation (29.01.02) is mandatory. In the other cases: $\rho \leq d$, as from equation (29.01.02).

In physics problems both branches of the hyperbola must be considered, a priori, because depending

DRAFT - IN PROGRESS

of the specific physic problem one or the other might intervene, read § 29.04.04.02.

In the case $e = 1$ (parabola) one can write:

$$\rho[\varphi] = \frac{p}{2\cos^2[\varphi/2]} \quad .$$

Note that the case $e = 0$ gives the circle. This is obtained when the directrix is located at infinity.

The curve is limited if and only if $0 \leq e < 1$ (ellipse).

In the other cases, $e \geq 1$, (parabola and hyperbola) the asymptotes, where the distance goes to infinity, are given by: $\alpha + e\cos[\varphi] = 0$, showing that for the parabola one should consider two degenerate asymptotes at $\varphi = \pi$.

There are (at least) six geometric parameters defining the conics: h, e, p, a, c and b, (to be defined below). The starting geometric parameters are h and e. The first one, h, is immediately replaced by p via

$$\boxed{e \equiv \frac{p}{h}} \quad .$$

The semi-major axis is defined as half of the distance between the two vertexes, relative extrema of the distance as a function of φ:

$$2a \equiv \frac{p}{+1-e} + \frac{p}{+1+e} = \boxed{\frac{2p}{1-e^2} = 2a > 0 \implies p = a\left(1-e^2\right)} \qquad \text{for } 0 \leq e < 1 \quad ,$$

$$2a \equiv \frac{p}{-1+e} - \frac{p}{+1+e} = \boxed{\frac{2p}{e^2-1} = 2a > 0 \implies p = a\left(e^2-1\right)} \qquad \text{for } e > 1 \quad ,$$

$$a = +\infty \qquad \boxed{p \text{ is the meaningful parameter for the parabola}} \qquad \text{for } e = 1; \quad .$$

The last one, the parabola, is found as the limiting case of the other two cases.

The distance from the center of the conic to the foci is:

$$\boxed{c = ea} \quad ,$$

which is $+\infty$ for $e = 1$.

The semi-minor axis (except for $e = 1$) is:

$$\boxed{b = \sqrt{|a^2 - c^2|} = a\sqrt{|1-e^2|}} \quad ,$$

which is $+\infty$ for $e = 1$.

Moreover:

$$\boxed{p = a|1-e^2| = |a - ce| \implies ap = b^2} \quad , \quad ,$$

$$\boxed{(2a-p)^2 = 4c^2 + p^2 \implies p = a\left(1-e^2\right) \implies ap = b^2} \quad .$$

29.01.02.01 Cartesian Equations for Conics With One Focus at the Origin

Starting from the conic equation (29.01.02) one can deduce the Cartesian equation. In fact

$$\alpha\rho = p - \rho e\cos[\varphi] \quad ,$$

and therefore, taking the square of both members, one finds:

$$\boxed{x^2\left(1-e^2\right) + y^2 + 2pex = p^2} \quad . \qquad (29.01.01) \quad \rightarrow 1548$$

The equation (29.01.01) shows that the conic is symmetrical with respect to the y axis.

Except for the case $e = 1$ one can do the change of variables:

$$x = X + \frac{pe}{e^2-1} \qquad y = Y \quad ,$$

to find the equation:

$$X^2\left(1-e^2\right) + Y^2 = \frac{p^2}{1-e^2} \quad . \qquad (29.01.02) \quad \rightarrow 1549$$

DRAFT - IN PROGRESS

The equation (29.01.02) shows that the conic (except for the case $e = 1$) is symmetrical not only with respect to the y axis but also with respect to the X axis: $X = x - \dfrac{pe}{e^2 - 1}$. Therefore the center of symmetry of the conic (except for the case $e = 1$) is given by:

$$x = x_0 = \frac{pe}{e^2 - 1} \qquad \begin{cases} x_0 \equiv -c < 0 & \text{for } 0 \leq e < 1 \\ x_0 \equiv +c > 0 & \text{for } e > 1 \end{cases} , \qquad c \equiv \frac{pe}{|e^2 - 1|} .$$

Equation (29.01.02) can be written in the standard Cartesian form:

$$\boxed{X^2 \frac{\left(1 - e^2\right)^2}{p^2} + Y^2 \frac{\left(1 - e^2\right)}{p^2} = 1} . \tag{29.01.03}$$

The comparison with the standard Cartesian equation provides the identification with the major and minor axes:

$$a \equiv \frac{p}{|1 - e^2|} ,$$

$$b \equiv \frac{p}{\sqrt{|1 - e^2|}} ,$$

$$p = \frac{b^2}{a} .$$

The relations among the quantities a, b and c follow:

$$a^2 = c^2 + b^2 \qquad \text{for } 0 \leq e < 1 ,$$
$$a^2 = c^2 - b^2 \qquad \text{for } e > 1 .$$

DRAFT-IN-PROGRESS

29.02 General Properties of Central Force Fields

This § is referenced at pages:
[1552]

©|H.Pollard, *Mathematical Introduction To Celestial Mechanics*, 1966, Prentice-Hall, ...Ed., ...|1||

DRAFT IN PROGRESS

The interest of the study of the general Central Force Fields comes from the fact that different central force fields appear in many applications. Moreover, most often, real problems can be solved by approximate methods based on central force fields. Central force fields are therefore the basis for the study of a great many of problems.

Some examples are: the motion in a pure gravitational or ElectroStatic field, the motion of a point mass in the equatorial plane of a gravitational field with cylindrical symmetry (having a **Quadrupole** , and possibly higher-order **Multipoles** , potential), the motion of a star in a galaxy or the motion of a galaxy in a cluster of galaxies, the general motion of an artificial satellite around the Earth, the classical motion of an electron in the field of the nucleus plus the mean field of other electrons. Moreover, any mass distribution at large enough distances, appears approximately, as a mass point.

Consider a point particle with mass m subject to the interaction with an external field and assume that the interaction of the particle with the field is fully described by a force field only (no torques, for instance, nor any other effect of the interaction due, for instance, to higher order **Multipole** fields).

By definition, a force field is named a radial force field (around the pole $\mathbf{r}_0$) if and only if

$$(\mathbf{r}-\mathbf{r}_0)\wedge\mathbf{f}[\mathbf{r}]=0 \quad , \tag{29.02.01}$$

for every point $\mathbf{r}$ in one Inertial Reference Frame . A radial force field has zero momentum with respect to the pole $\mathbf{r}_0$.

Usually one chooses: $\mathbf{r}_0=0$; this is always possible as long as the pole has constant velocity in some Inertial Reference Frame thanks to the homogeneity of space.

When dealing with radial force fields it is therefore assumed that the only interaction is the force and there is no torque nor anything else.

A radial and conservative force field is named a central force field. A Central Field is necessarily a field with spherical symmetry, that is has the most general expression

$$\boxed{\mathbf{f}=f_r[r]\widehat{\mathbf{e}}_r} \quad ,$$

as discussed in sections § 16-013 and § 16-017. Conversely: a non spherically symmetric field is either non radial or non conservative (quite unlikely for physical fields).

Let us consider the central force acting on a point mass. As the torque of the central force is null, the angular momentum of the point mass with respect to the pole is constant:

$$\boldsymbol{\ell}\equiv\mathbf{r}\wedge\mathbf{p}=m\,\mathbf{r}\wedge\dot{\mathbf{r}}\equiv m\mathbf{c} \quad , \qquad \text{with} \qquad \boxed{\dot{\boldsymbol{\ell}}=0} \quad . \tag{29.02.02}$$

→ 1550

Therefore the mass point lies in a fixed plane passing by the pole. In fact equation (29.02.02) implies, by taking the dot product with $\mathbf{r}$,

$$\mathbf{r}\cdot\mathbf{c}=0 \quad ,$$

that is the position vector is always perpendicular to the constant vector $m\mathbf{c}\equiv\boldsymbol{\ell}$. If $\mathbf{c}=\mathbf{0}$ then the trajectory becomes a straight line. The vectors $\mathbf{c}$ and $\boldsymbol{\ell}$ are determined by the initial conditions.

The motion lies in the plane orthogonal to the angular momentum $\boldsymbol{\ell}$, for $\boldsymbol{\ell}\neq 0$, and passing by the center of the force. Therefore one can consider the corresponding plane motion and use a polar Coordinate System in this plane, centered on the force center. Let the z axis be perpendicular to the plane of the orbit. Due to the previous considerations the simplified notation $\ell\equiv\ell_z$ will be always used.

From the discussion in section § 23.04.04.02 the constancy of the angular momentum can be stated in terms of areolar velocity:

$$\boxed{\frac{\mathrm{d}A}{\mathrm{d}t} \equiv \frac{1}{2}|\,\mathbf{x}\wedge\mathbf{v}\,| = \frac{1}{2}r^2\dot{\varphi} \equiv \frac{c}{2}} \quad . \tag{29.02.03}$$

→ 1135 1591

Quindi la conservazione del momento angolare equivale alla costanza della velocità areolare (equation (23.04.03)), fatto che si suole esprimere dicendo che il raggio vettore spazza aree uguali in tempi uguali. This is in fact **the second Kepler law**, which is thus valid for any central force field.

It also follows that:

$$\boxed{\mathbf{r}\wedge\ddot{\mathbf{r}} = 0} \quad . \tag{29.02.04}$$

DRAFT-IN-PROGRESS

29.03 Motion in a Central Force Field

All the previous discussions only depend on the central character of the force and not on the specific form of its radial dependence. The latter only enters in the shape of the trajectory. While the determination of the time dependence $r[t]$ and $\varphi[t]$ is normally complex the determination of the trajectory or orbit, $r[\varphi]$, is often easier.

A motion in a central force field,

$$\mathbf{f}[\mathbf{r}] = f_r[r]\widehat{\mathbf{e}}_r \equiv f[r]\widehat{\mathbf{e}}_r \qquad \begin{cases} f_r[r] > 0 & \text{repulsive force} \\ f_r[r] < 0 & \text{attractive force} \end{cases} ,$$

is a plane motion (section § 29.02). Let z be the axis perpendicular to the plane of motion, that is parallel to $\boldsymbol{\ell}$, oriented as $\boldsymbol{\ell}$ and passing by the center of force. With this choice the motion is in the counter-clockwise direction in the xy plane.

The equation of motion in the plane of the orbit can be written in polar coordinates with origin at the pole of the force field:

$$ma_r = m\left(\ddot{r} - r\dot{\varphi}^2\right) = f[r] \tag{29.03.01}$$

→ 1552 1577

$$ma_\varphi = m\left(2\dot{r}\dot{\varphi} + r\ddot{\varphi}\right) = \frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}t}\left(mr^2\dot{\varphi}\right) = 0 \Longrightarrow \boxed{\ell_z = \text{constant}} \quad .$$

29.03.01 Conservation of the Angular Momentum

Note that the use of the conservation of angular momentum, equation (29.03.01), allows to reduce the system of two differential equations in two variables, $r[t]$ and $\varphi[t]$, to one single differential equation in the variable $r[t]$.

Note that:

$$\boldsymbol{\ell} \equiv \mathbf{r}\wedge\mathbf{p} = m\,\mathbf{r}\wedge\mathbf{v} = m\,(r\widehat{\mathbf{e}}_r)\wedge(\dot{r}\widehat{\mathbf{e}}_r + r\dot{\varphi}\widehat{\mathbf{e}}_\theta) = mr^2\dot{\varphi}\widehat{\mathbf{e}}_3 \quad .$$

→ 1552 1556 1577

From equations (29.03.01), (29.03.01) one can derive:

$$m\ddot{r} = mr\dot{\varphi}^2 + f[r] = \frac{\ell^2}{mr^3} + f[r] \equiv f_{\mathrm{E}}[r] \quad ,$$

in terms of the effective radial force, $f_{\mathrm{E}}[r]$, taking into account the real force and the centrifugal force seen by the observer rotating with the point particle. Note that the additional force appearing in the radial equation, the centrifugal force $\dfrac{\ell^2}{mr^3} \geq 0$ is always repulsive.

29.03.02 Conservation of Mechanical Energy

Le equazioni del moto piano, espresse in coordinate polari, (29.03.01), (29.03.01), si possono combinare come

$$\boxed{m\ddot{r} - \frac{\ell^2}{mr^3} = f[r]} \quad . \tag{29.03.02}$$

→ 1556

The central force, $f[r]$, gives rise to a radial potential energy, $\Phi[r]$:

$$\Phi[r] - \Phi[r_0] \equiv -\int_{r_0}^{r} f[s]\,\mathrm{d}s \qquad \Leftrightarrow \qquad f[r] = -\frac{\mathrm{d}\Phi[r]}{\mathrm{d}r} \quad . \tag{29.03.03}$$

→ 1553 1582

Similarly, the effective central force, $f_{\mathrm{E}}[r]$, gives rise to an effective radial potential energy, $\Phi_{\mathrm{E}}[r]$:

$$\Phi_{\mathrm{E}}[r] - \Phi_{\mathrm{E}}[r_0] \equiv -\int_{r_0}^{r} f_{\mathrm{E}}[s]\,\mathrm{d}s = \Phi[r] - \Phi[r_0] + \frac{\ell^2}{2mr^2} - \frac{\ell^2}{2mr_0^2} \qquad \Leftrightarrow \qquad f_{\mathrm{E}}[r] = -\frac{\mathrm{d}\Phi_{\mathrm{E}}[r]}{\mathrm{d}r} \quad . \tag{29.03.04}$$

ISRAEL-LN-PROGRESS

Note that it is customary to choose:

- $r_0 \longrightarrow \infty$ when the improper integral in equation (29.03.03) exists, typically for forces like $f[r] \propto r^{-\alpha}$, with $\alpha > 1$;
- $r_0 = 0$ when the force is such that $|f[r=0]| < \infty$, typically for forces like $f[r] \propto r^{+\alpha}$, with $\alpha > 0$.

The derivative is not a partial derivative because in a central field the dependence on r only is allowed.
Si ottiene allora

$$E = \frac{1}{2}m\dot{r}^2 + \frac{\ell^2}{2mr^2} + \Phi[r] = \frac{1}{2}m\dot{r}^2 + \Phi_{\text{E}}[r] \quad , \tag{29.03.05}$$

→ 1554 1556 1560 1586

che esprime la conservazione dell'energia e permette di vedere il moto come un moto one-dimensionale con l'energia potenziale effettiva

$$\Phi_{\text{E}}[r] \equiv \frac{\ell^2}{2mr^2} + \Phi[r] \quad . \tag{29.03.06}$$

Clearly, the angular momentum provides a fictitious force, in the co-rotating Reference Frame, pushing the particle out, which is the centrifugal force, in the co-rotating Reference Frame, read § 29.06.01. This repulsive force is an inverse cube force law. It is sometimes called **the centrifugal-barrier force term**.

29.03.03
Equation of the Orbit: Binet Equation

This § is referenced at pages:
[1556, 1556]

While the integration of the equations of motion as a function of time is often difficult if not impossible in closed form, it is often easier to calculate the equation of the orbit, thanks to the Binet equation.
In order to derive it one can write for the equation of the orbit, taking into account that $r^2\dot{\varphi} = c$:

$$r[\varphi[t]] \Longrightarrow \dot{r} = \left(\frac{\mathrm{d}}{\mathrm{d}\varphi} r[\varphi]\right)\dot{\varphi} = \dot{\varphi}\frac{\mathrm{d}r}{\mathrm{d}\varphi} = \frac{c}{r^2}\frac{\mathrm{d}r}{\mathrm{d}\varphi} = -c\frac{\mathrm{d}}{\mathrm{d}\varphi}\frac{1}{r} \tag{29.03.07}$$

→ 1560

$$r[\varphi[t]] \Longrightarrow \ddot{r} = \frac{\mathrm{d}}{\mathrm{d}t}\dot{r} = -c\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{d}}{\mathrm{d}\varphi}\frac{1}{r}\right) = -c\dot{\varphi}\frac{d^2}{\mathrm{d}\varphi^2}\frac{1}{r} = -\frac{c^2}{r^2}\frac{d^2}{\mathrm{d}\varphi^2}\frac{1}{r} = -\frac{\ell^2}{m^2r^2}\frac{d^2}{\mathrm{d}\varphi^2}\frac{1}{r} \quad .$$

It follows:

$$a_r = \left(\ddot{r} - r\dot{\varphi}^2\right) = -\frac{\ell^2}{m^2r^2}\left(\frac{d^2}{\mathrm{d}\varphi^2}\frac{1}{r} + \frac{1}{r}\right) \quad ,$$

from which the Binet formula follows:

$$-\frac{\ell^2}{mr^2}\left(\frac{d^2}{\mathrm{d}\varphi^2}\frac{1}{r} + \frac{1}{r}\right) = f[r] \quad , \tag{29.03.08}$$

→ 1554

usually written in terms of the variable $u \equiv r^{-1}$ as

$$\frac{d^2u}{\mathrm{d}\varphi^2} + u = -\frac{m}{u^2\ell^2}f\left[\frac{1}{u}\right] \quad . \tag{29.03.09}$$

→ 1559 1581 1586

DRAFT - IN PROGRESS

29.03.04
Energy Conservation From Binet Equation

This § is referenced at pages:
[1585]

One should notice that equation (29.03.08) is equivalent to energy conservation as it can be shown by multiplying both sides by $\frac{\mathrm{d}r}{\mathrm{d}\varphi}$ and integrating with respect to φ to obtain:

$$\frac{\ell^2}{2m}\left(\frac{1}{r^2}+\left(\frac{\mathrm{d}}{\mathrm{d}\varphi}\frac{1}{r}\right)^2\right)+\Phi[r]=E \quad .$$

Note the expression of the kinetic energy:

$$K=\frac{m}{2}v^2=\frac{m}{2}(\dot{r}^2+r^2\dot{\varphi}^2)=\frac{\ell^2}{2m}\left(\frac{1}{r^2}+\left(\frac{\mathrm{d}}{\mathrm{d}\varphi}\frac{1}{r}\right)^2\right) \quad .$$

The Binet equation (29.03.08) can be reduced to quadrature. In fact multiply both members of equation (29.03.08) by $\frac{\mathrm{d}r}{\mathrm{d}\varphi}$ and then integrate with respect to φ to obtain:

$$\frac{\mathrm{d}}{\mathrm{d}\varphi}\left(\frac{mc^2}{2}\left(\frac{\mathrm{d}u}{\mathrm{d}\varphi}\right)^2+\frac{mc^2u^2}{2}+\Phi[\frac{1}{u}]\right)=0\Longrightarrow\boxed{\frac{mc^2}{2}\left(\frac{\mathrm{d}u}{\mathrm{d}\varphi}\right)^2+\frac{mc^2u^2}{2}+\Phi[\frac{1}{u}]=E} \quad . \qquad (29.03.10)$$

→ 1554

The interpretation in terms of energy is clear.

29.03.05
Determination of the Orbit in Terms of Physical Parameters

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|3.7||

Note that by integration of the Binet equation (29.03.08) one would determine the orbit in terms of initial parameters whose physical meaning might be non immediate.

It is better to start from the energy conservation equation (29.03.05) and use $\dot{r}=\left(\frac{\mathrm{d}}{\mathrm{d}\varphi}r[\varphi]\right)\dot{\varphi}$ to obtain:

$$\left(\frac{\mathrm{d}r}{\mathrm{d}\varphi}\right)^2=\frac{m^2r^4}{\ell^2}\left(\frac{2\left(E-\Phi[r]\right)}{m}-\frac{\ell^2}{m^2r^2}\right) \quad .$$

Note that, according to problem § 29.06.08 it is sufficient to calculate the orbit in the portion $\frac{\mathrm{d}r}{\mathrm{d}\varphi}\geq 0$, for instance, and then extending it by symmetry. The equation can be solved by separation of the variables.

It is even better to start from equation (29.03.10), in terms of u instead of r:

$$\frac{mc^2}{2}\left(\frac{\mathrm{d}u}{\mathrm{d}\varphi}\right)^2+\frac{mc^2u^2}{2}+\Phi[\frac{1}{u}]=E\Longrightarrow\boxed{\frac{\mathrm{d}u}{\mathrm{d}\varphi}=\pm\sqrt{\frac{2m\left(E-\Phi[1/u]\right)}{\ell^2}-u^2}} \quad . \qquad (29.03.11)$$

The $\pm$ in front of the integral means that the choice of the sign depends on the specific part of the orbit, between apsidal vectors, that one is considering.

29.03.06.01 Determination of the Position as a Function of Time

This § is referenced at pages:
[1556]

Thanks to the conservation of angular momentum the two-dimensional problem has been reduced to a one-dimensional problem. Energy conservation allows, in general, to solve any one-dimensional problem. In fact equation (29.03.05) can be reduced to quadrature, thus determining, in principle, the function $\mathbf{r}[t]$:

$$\dot{r}^2 = \frac{2}{m}(E - \Phi_{\mathrm{E}}[r]) \implies \pm \int_{r_0}^{r} \frac{\mathrm{d}r}{\sqrt{\frac{2}{m}(E - \Phi_{\mathrm{E}}[r])}} = t - t_0 \quad . \tag{29.03.12}$$

→ 1556

The $\pm$ sign must be chosen according to whether one is considering a part of orbit with increasing or decreasing radius. However, as a consequence of the Binet equation (Read § 29.03.03, § 29.06.08), when a part of the orbit is known between the minimum distance and the maximum distance from the center of force, the full orbit can be reconstructed. It is then enough to integrate equation (29.03.12) between the minimum distance and the maximum distance from the center of force, with any one choice of the sign in front of the integral.

Once equation (29.03.12) is solved equation (29.03.01) allows to calculate $\varphi[t]$.

29.03.06.02 Determination of the Orbit

This § is referenced at pages:
[Never referenced.]

The orbit can be determined from Binet equation, read § 29.03.03.

Another way to accomplish the same result consists in starting again from equation (29.03.05) and replace:

$$\dot{r} = \frac{\mathrm{d}r}{\mathrm{d}\varphi}\dot{\varphi} = \frac{\mathrm{d}r}{\mathrm{d}\varphi}\frac{\ell}{mr^2} \quad ,$$

to obtain:

$$\mathrm{d}\varphi = \pm \frac{\ell}{\sqrt{2m}} \frac{\mathrm{d}r}{r^2\sqrt{E - \frac{\ell^2}{2mr^2} - \Phi[r]}} \quad .$$

The $\pm$ sign must be chosen according to whether one is considering a part of orbit with increasing or decreasing radius, as discussed in section § 29.03.06.01.

29.03.07 Circular and Near-Circular Orbits in a Central Force Field (Orbit Precession)

This § is referenced at pages:
[Never referenced.]

From equation (29.03.02) and the condition for a circular orbit, $\dot{r} = 0$, one has that the condition for a circular orbit at a distance $r = r_0$, for one given value of the angular momentum, ℓ_0, is:

$$r = r_0 \implies -\frac{\ell_0^2}{mr_0^3} = f[r_0] = -\frac{\mathrm{d}\Phi}{\mathrm{d}r}[r_0] \quad \Leftrightarrow \quad \frac{\mathrm{d}\Phi_{\mathrm{E}}}{\mathrm{d}r}[r_0] = 0 \implies f[r_0] = -\frac{\mathrm{d}\Phi}{\mathrm{d}r}[r_0] < 0 \quad . \tag{29.03.13}$$

→ 1557 1582

All and only attractive forces admit circular orbits, because the centrifugal force need to be exactly balanced at all times.

CC BY NC ND

For each value of the angular momentum a well defined distance exists at which the circular orbit is possible, the value of which is determined by solving equation (29.03.13). Note that equation (29.03.13) corresponds to the condition for extrema of the effective potential energy, $\Phi_{\text{E}}[r]$: $\frac{\mathrm{d}\Phi_{\text{E}}}{\mathrm{d}r}[r_0] = 0$. The resulting radius of the circular orbit can be calculated in terms of the angular momentum:

$$r_0 = r_0[\ell_0] \quad .$$

Circular orbits with different radii are characterized by a different value of the angular momentum. The radius of the circular orbit corresponds to the minimum of the effective potential energy, for stable circular orbits, while it corresponds to the maximum of the effective potential energy, for unstable circular orbits).

The corresponding energy is:

$$\boxed{r = r_0 \implies E = \Phi_{\text{E}}[r_0] = \Phi[r_0] + \frac{\ell_0^2}{2mr_0^2}} \quad . \tag{29.03.14}$$

→ 1557

The elimination of r_0 between equations (29.03.13), (29.03.14) yields the unique relation between energy and angular momentum for a circular orbit. Read § 29.04 for the implementation of this in the case of an inverse square law.

29.03.07.01 Period of Circular Orbits in a Central Force Field

Consider an attractive force field: $\frac{\mathrm{d}\Phi}{\mathrm{d}r}[r_0] > 0$.

As the orbit is circular one can write:

$$\boxed{\ell_0 = m\omega_0 r_0^2} \quad ,$$

and equation (29.03.13) implies:

$$f[r_0] = -\frac{\mathrm{d}\Phi}{\mathrm{d}r}[r_0] = -\frac{\ell_0^2}{mr_0^3} = -m\omega_0^2 r_0 \implies \boxed{\omega_0^2 = \frac{1}{mr_0}\frac{\mathrm{d}\Phi}{\mathrm{d}r}[r_0]} \quad . \tag{29.03.15}$$

→ 1557 1582 1583

The above condition (29.03.15) is actually just the radial equilibrium equation.

29.03.08
Conditions for Closed Orbits (Bertrand Theorem)

This § is referenced at pages:
[1583]

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|3.6||

Bertrand Theorem states: The only central forces that lead to closed orbits for all bound particles states are the inverse square and harmonic forces.

Note that it is indeed possible to find closed particular orbits for any attractive force.

DRAFT-IN-PROGRESS

29.04 Moto in Un Campo Gravitazionale O Coulombiano

This § is referenced at pages:
[1557]

Si consideri un campo con forza dipendente dall'inverso del quadrato della distanza

$$f[r] = -\frac{\gamma}{r^2} \propto \frac{1}{r^2} \quad , \tag{29.04.01}$$

quali il campo gravitazionale e Coulombiano.

The effective potential energy is:

$$\boxed{\Phi_{\text{E}}[r] = -\frac{\gamma}{r} + \frac{\ell^2}{2mr^2}} \quad .$$

In the repulsive case, $\gamma < 0$, the effective potential energy is always positive.

The qualitative behavior of the effective potential energy for the two cases of attractive and repulsive forces are shown in figure 29.14.

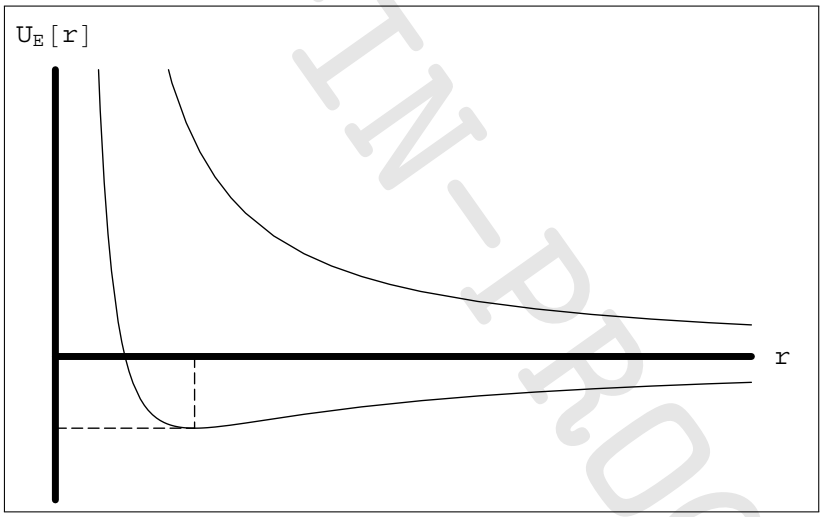

Figure 29.14: FIGURE

29.04.01 Orbite in Un Campo Proporzionale All'inverso Del Quadrato Della Distanza

This § is referenced at pages:
[1561]

We want to show that in an inverse square (either attractive or repulsive) central force field,

$$f_r[r] = -\gamma r^{-2} \quad , \tag{29.04.02}$$

→ 1558

the particle trajectory is always a conic.

The physically important cases of applicability of equation (29.04.02) are:

- gravitational force between two mass point particles: $\gamma = \mathcal{G} m_1 m_2$;
- electric force between two charged point particles: $\gamma = -\frac{1}{4\pi\varepsilon_0} q_1 q_2$.

FREE-IN-PROGRESS

We can use the Binet formula (29.03.09):

$$\frac{d^2u[\varphi]}{\mathrm{d}\varphi^2} + u[\varphi] = \frac{m\gamma}{\ell^2} \quad ,$$

whose general solution is:

$$\boxed{u[\varphi] = B\cos\left[\varphi - \varphi_0\right] + \frac{m\gamma}{\ell^2}} \quad . \tag{29.04.03}$$

→ 1559 1560 1594

Two constants of integration appears, B and φ_0, to be determined from the initial conditions. The constant φ_0 can be chosen such that $\varphi_0 = 0$. In fact φ_0 is the angle where $r[\varphi]$ has an extremum, either a minimum or a maximum according to the sign of B:

- $B > 0$ implies that $r[\varphi] = 1/u$ has a minimum for $\varphi = 0$;
- $B < 0$ implies that $r[\varphi] = 1/u$ has a maximum for $\varphi = 0$ and a minimum for $\varphi = \pi$.

From the expression of effective potential energy one knows that for any orbit a minimum distance exists. One can therefore choose to count the angles form this minimum distance: $\varphi_0 =$ angle of perihelion.

The choice $\varphi_0 =$ angle of perihelion $= 0$ corresponds to fixing the initial condition:

$$\frac{\mathrm{d}u}{\mathrm{d}\varphi} = 0 \qquad \text{for} \qquad \varphi_0 = \text{angle of perihelion} = 0 \quad .$$

This choice implies $B > 0$. Moreover, note that taking $B < 0$ is completely equivalent to choosing the location of the perihelion at $\varphi = \varphi_0 = \pi = \varphi_{\mathrm{P}}$. Therefore $B > 0$ will be chosen and the perihelion ia always:

$$\boxed{\varphi = \varphi_0 = 0 = \varphi_{\mathrm{P}}} \quad .$$

The stress on the location of the perihelion is motivated by the fact that the orbit is symmetrical with respect to the position of the perihelion (as well as of the aphelion) and the perihelion always exists for any orbit, while the aphelion is missing for parabolas and hyperbolas (or, alternatively, it is located at infinity in these cases).

29.04.01.01 First Method

Two kind of orbits may exist: bounded and unbounded orbits, according to the total energy, E. This can be deduced from the study of the effective potential energy:

$$\boxed{\Phi_{\mathrm{E}}[r] = -\frac{\gamma}{r} + \frac{\ell^2}{2mr^2}} \quad .$$

Solve for the extremes of the radial distance, where $\dot{r} = 0$:

$$\dot{r} = 0 \implies \Phi_{\mathrm{E}}[r] = -\frac{\gamma}{r} + \frac{\ell^2}{2mr^2} = E \implies \boxed{u[\dot{r}=0] = \frac{m\gamma}{\ell^2} \pm \sqrt{\left(\frac{m\gamma}{\ell^2}\right)^2 + \frac{2mE}{\ell^2}}} \quad . \tag{29.04.04}$$

→ 1559

The analysis of the result shows the following, taking into account that, by definition $u > 0$.

- If $\gamma > 0$ the $+$ solution is always acceptable (minimum distance), while the $-$ solution is acceptable if and only if $E < 0$ (maximum distance). This is the attractive case: there is always a minimum distance extreme, for any value of the energy and, in the case of negative energy, there is also a second extreme, at the maximum distance, such that the orbit is bounded.
- If $\gamma < 0$ only the $+$ solution is acceptable (minimum distance), provided $E > 0$. This is the repulsive case: there is only one extreme, at a minimum of the distance, and this only happens for positive energy.

Compare equation (29.04.04) with equation (29.04.03) for $\varphi = \varphi_0 = 0$ at the minimum distance. In fact we know from the study of the effective potential energy that a minimum distance exists in any case. One finds:

$$B = \pm\sqrt{\left(\frac{m\gamma}{\ell^2}\right)^2 + \frac{2mE}{\ell^2}} \quad .$$

In order to ensure that equation (29.04.03) represents the perihelion at $\varphi = \varphi_0 = 0$, as stipulated, we are forced to choose $B > 0$.

DRAFT - PROOF

CC BY NC ND

29.04.01.02 Second Method

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|||

We know from the study of the effective potential energy that a minimum distance exist in any case. The total energy at perihelion is:

$$E = \text{constant} = E_P = \frac{\ell^2}{2m} u_P^2 - \gamma u_P \quad ,$$

valid for any value of γ.

In equation (29.04.03) the perihelion at $\varphi_0 = 0$ is obtained for $B > 0$:

$$u_P \equiv u[\varphi = 0] = B + \frac{m\gamma}{\ell^2} \quad .$$

By eliminating u_P from the two equations one finds

$$E = E_P = \frac{B^2\ell^2}{2m} - \frac{m\gamma^2}{2\ell^2} \Longrightarrow \boxed{B = \frac{m|\gamma|}{\ell^2}\sqrt{1 + \frac{2E\ell^2}{m\gamma^2}}} \quad .$$

29.04.01.03 Third Method

One can write:

$$r[\varphi] = \left(\frac{\left(\frac{\ell^2}{m}\right)}{\gamma + \left(\frac{B\ell^2}{m}\right)\cos[\varphi]} \right) = \left(\frac{\left(\frac{\ell^2}{m|\gamma|}\right)}{\frac{\gamma}{|\gamma|} + \left(\frac{B\ell^2}{m|\gamma|}\right)\cos[\varphi]} \right) \equiv \frac{p}{\pm 1 \pm e\cos[\varphi]} \quad ,$$

with

$$\boxed{p \equiv \frac{\ell^2}{m|\gamma|} \geq 0} \qquad \boxed{e \equiv \frac{|B|\ell^2}{m|\gamma|} \geq 0} \quad .$$

The equation of the orbit is still expressed in terms of one more arbitrary constant, which can be expressed in terms of the energy (the angular momentum is already accounted for by the Binet formula). From equation (29.03.05) and from equation (29.03.07) one can write:

$$\dot{r} = -c\frac{\mathrm{d}u}{\mathrm{d}\varphi} = cB\sin[\varphi] \quad ,$$

$$E = \frac{B^2\ell^2}{2m} - \frac{m\gamma^2}{2\ell^2} \Longrightarrow B^2 = \frac{2m}{\ell^2}\left(E + \frac{m\gamma^2}{2\ell^2}\right) \Longrightarrow \boxed{e \equiv \frac{|B|\ell^2}{m|\gamma|} \equiv |B|p = \sqrt{1 + \frac{2E\ell^2}{m\gamma^2}}} \qquad (29.04.05)$$

→ 1560

$$\boxed{B = \pm\sqrt{\frac{m^2\gamma^2}{\ell^4} + \frac{2mE}{\ell^2}} = \pm\frac{m|\gamma|}{\ell^2}\sqrt{1 + \frac{2E\ell^2}{m\gamma^2}}} \quad .$$

→ 1560 1594

The choice of $B > 0$ amounts to choose the position of the perihelion at $\varphi = \varphi_0 = 0$. The choice of $B < 0$ amounts to choose the position of the perihelion at $\varphi = \varphi_0 = \pi$.

The following considerations can be carried on from equations (29.04.05), (29.04.01.03).

From the comparison with the equations of the conics in polar coordinates one can see that for $\gamma < 0$, a repulsive potential, the orbit is an hyperbola. In fact in this case one has $E > 0$ implying $e > 1$ and $\gamma/|\gamma| = -1$. The two possible choices for the sign of B give the two possible orbits, symmetric with respect to the y axis, with perihelion at $\varphi = 0$, for $B > 0$, and with perihelion at $\varphi = \pi$, for $B < 0$. In this case of repulsive force the center of force is in the one of the focii outside the branch of the hyperbola.

For $\gamma > 0$, an attractive potential, the orbit can be an ellipse, a parabola or an hyperbola, according to the sign of E and, consequently, the value of e. Moreover, $\gamma/|\gamma| = +1$. The two possible choices for the sign of B give the two possible orbits, symmetric with respect to the y axis, with perihelion at $\varphi = 0$,

DRAFT - IN PROGRESS

for $B > 0$, and with perihelion at $\varphi = \pi$, for $B < 0$. In this case of attractive force the center of force is in the one of the focii inside the branch of the hyperbola or parabola.

Note that the physical parameters, E and ℓ, must be related to the geometrical parameters, p, e, a, b, c in order to relate physics and geoetry, by means of the relationa derived in the present section.

29.04.02
Properties of Orbits in Inverse Square Fields

29.04.02.01 Equation of the Orbit

The different expressions of the orbits can be summarized as follows.

$$r[\varphi] = \frac{a\left(1-e^2\right)}{1 \pm e\cos[\varphi]} \qquad \text{orbita ellittica, } 0 \leq e < 1 \quad , \tag{29.04.06}$$

$$r[\varphi] = \frac{p}{1 \pm \cos[\varphi]} \qquad \text{orbita parabolica, } e = 1 \quad , \tag{29.04.07}$$

$$r[\varphi] = \frac{a\left(e^2-1\right)}{+e\cos[\varphi]+1} \qquad \text{orbita iperbolica, } e > 1\text{, attrattivo, } \varphi = 0 \text{ perielio} \quad , \tag{29.04.08}$$

→ 1561 1563

$$r[\varphi] = \frac{a\left(e^2-1\right)}{+e\cos[\varphi]-1} \qquad \text{orbita iperbolica, } e > 1\text{, repulsivo, } \varphi = 0 \text{ perielio} \quad , \tag{29.04.09}$$

→ 1561

$$r[\varphi] = \frac{a\left(e^2-1\right)}{-e\cos[\varphi]-1} \qquad \text{orbita iperbolica, } e > 1\text{, repulsivo, } \varphi = \pi \text{ perielio} \quad , \tag{29.04.10}$$

→ 1561

$$r[\varphi] = \frac{a\left(e^2-1\right)}{-e\cos[\varphi]+1} \qquad \text{orbita iperbolica, } e > 1\text{, attrattivo, } \varphi = \pi \text{ perielio} \quad . \tag{29.04.11}$$

→ 1562

The location of the perihelion, either $\varphi = 0$ or $\varphi = \pi$, is consistent with the sign of B as discussed in problem § 29.04.01.

Note that, in general, the plus sign in front of the term $e\cos[\varphi]$ implies that the perihelion is at $\varphi = 0$, while the minus sign implies that the perihelion is at $\varphi = \pi$. From this point of view it is really irrelevant to keep both versions of the equations, as they only differ by a mirror reflections around the y axis, that is $\varphi \longrightarrow \pi - \varphi$. One can only keep all and only the forms with the positive sign, assuming the convention that the perihelion is always at $\varphi = 0$.

Note also that the sign in front of the factor 1 in the denominator is always $+1$ for an attractive potential energy and it is always -1 for a repulsive potential energy (always leading to an hyperbolic orbit).

Note that reflecting the conics around the y axis is equivalent to changing φ into $\pi - \varphi$, changing the sign of $\cos[\varphi]$ without changing the sign of $\sin[\varphi]$.

Equation (29.04.08) describes an hyperbola constrained such that:

$$+e\cos[\varphi]+1 > 0 \implies \cos[\varphi] > -\frac{1}{e} \implies |\varphi| < +\arccos\left(-\frac{1}{e}\right) \quad . \tag{29.04.12}$$

Equation (29.04.09) describes an hyperbola constrained such that:

$$+e\cos[\varphi]-1 > 0 \implies \cos[\varphi] > +\frac{1}{e} \implies |\varphi| < +\arccos\left(+\frac{1}{e}\right) \quad . \tag{29.04.13}$$

Equation (29.04.10) describes an hyperbola constrained such that:

$$-e\cos[\varphi]-1 > 0 \implies \cos[\varphi] < -\frac{1}{e} \implies |\varphi-\pi| < +\arccos\left(-\frac{1}{e}\right) \quad . \tag{29.04.14}$$

DRAFT - IN PROGRESS

Equation (29.04.11) describes an hyperbola constrained such that:

$$-e\cos[\varphi]+1>0 \implies \cos[\varphi]<+\frac{1}{e} \implies |\varphi-\pi|<+\arccos\left(+\frac{1}{e}\right) \quad . \tag{29.04.15}$$

29.04.02.02 Relations

The relations linking the geometrical and physical parameters of the orbit are summarized.
The constant B from the integration of Binet equation is:

$$B=\pm\frac{m|\gamma|}{\ell^2}\sqrt{1+\frac{2E\ell^2}{m\gamma^2}} \qquad \text{but we can always choose } B>0 \text{ and } \varphi=\varphi_0=0 \text{ at perihelion} \quad .$$

L'eccentricità in funzione dell'energia e del momento angolare vale sempre:

$$e=\sqrt{1+\frac{2E\ell^2}{m\gamma^2}} \quad . \tag{29.04.16}$$

→ 1562 1624 1627

Si ha, per un moto ellittico,

$$p=\frac{\ell^2}{m|\gamma|}=\frac{\ell^2}{m\gamma}=a\left(1-e^2\right) \qquad \text{nel caso } 0\le e<1\text{; in this case, } \gamma>0 \quad . \tag{29.04.17}$$

→ 1562 1624

Si ha, per un moto parabolico,

$$p=\frac{\ell^2}{m|\gamma|} \qquad \text{nel caso } e=1 \quad . \tag{29.04.18}$$

→ 1562

Si ha, per un moto iperbolico,

$$p=\frac{\ell^2}{m|\gamma|}=a\left(e^2-1\right) \qquad \text{nel caso } e>1 \quad . \tag{29.04.19}$$

→ 1562

The total energy can be expressed as follows.
Equation (29.04.16) implies:

$$E=\frac{m\gamma^2\left(e^2-1\right)}{2\ell^2}=\frac{|\gamma|\left(e^2-1\right)}{2p} \quad ,$$

e dalle (29.04.17), (29.04.18), (29.04.19) si ricava

$$E=-\frac{|\gamma|}{2a} \qquad \text{nel caso } 0\le e<1\text{; in this case, } \gamma>0 \quad ,$$
$$E=0 \qquad \text{nel caso } e=1 \quad , \quad ,$$
$$E=+\frac{|\gamma|}{2a} \qquad \text{nel caso } e>1 \quad .$$

si ricava l'espressione dell'energia totale:

$$E=E_{\text{MIN}}=-\frac{m\gamma^2}{2\ell^2} \qquad \text{orbita circolare} \quad , \tag{29.04.20}$$

$$E=-\frac{|\gamma|}{2a} \qquad \text{orbita ellittica,} \quad E_{\text{MIN}}\le E<0 \quad , \tag{29.04.21}$$

→ 1586 1594 1624

$$E=0 \qquad \text{orbita parabolica} \quad , \tag{29.04.22}$$

→ 1586

$$E=+\frac{|\gamma|}{2a} \qquad \text{orbita iperbolica, } E>0 \quad .$$

29.04.03
Leggi Di Keplero

Una particella in un campo di forza inversamente proporzionale al quadrato della distanza è soggetta alle leggi di Keplero.

1. La traiettoria è una conica in cui il centro di forza occupa uno dei due fuochi.
2. Il raggio vettore dal centro di forza alla particella copre aree uguali in tempi uguali (costanza della velocità areolare (23.04.03)) con
$$\frac{\mathrm{d}S}{\mathrm{d}t} = \frac{\ell}{2m}$$
→ 1565 1586
This law applies to any central motion.
3. Il periodo dell'orbita è legato al semiasse maggiore
$$\frac{T^2}{a^3} = \frac{4\pi^2}{\mathcal{G}M}$$
dove M è la massa del centro di forza, supposta molto maggiore della massa della particella. Nel caso generale di masse paragonabili, M ed m, l'equazione si generalizza
$$\frac{T^2}{a^3} = \frac{4\pi^2}{\mathcal{G}\,(M+m)}$$

29.04.04.01 Scattering Angle

A particle of mass m is directed towards a fixed scattering center, described by an inverse-square force field, with impact parameter b (equation (30.01.01)).

Assume, for definiteness, that the force is attractive: $\gamma > 0$; the case of repulsive force can be treated in a similar way.

The particle is starting from a very large distance, and it has, therefore, a positive conserved mechanical energy, $E_0 > 0$, and conserved angular momentum with respect to the scattering center, ℓ_0.

One wants to determine, a long time after the interaction, the direction of the particle with respect to the initial direction: the scattering angle.

The orbit is hyperbolic, as the total conserved energy is positive. The equation for attractive hyperbolic orbits, with perihelion at $\varphi = 0$, is equation (29.04.08). The angles of the two asymptotes, φ_{A}, are given by:
$$\boxed{\cos\left[\varphi_{\mathrm{A}}\right] = -\frac{1}{e}} \quad .$$
Define, for simplicity of the formulas only, the auxiliary angle, φ_0, to obtain:
$$\boxed{\varphi_0 \equiv \pi - \varphi_{\mathrm{A}}} \Longrightarrow \boxed{\cos\left[\varphi_0\right] = \cos\left[\pi - \varphi_{\mathrm{A}}\right] = \frac{1}{e}} \quad .$$

DRAFT - IN PROGRESS

The scattering angle, that is the angle between the two asymptotes, is given by:

$$\boxed{\varphi_{\mathrm{S}} = \pi - 2\varphi_0 = \pi + 2\varphi_{\mathrm{A}}} \Longrightarrow \boxed{\frac{\varphi_{\mathrm{S}}}{2} = \frac{\pi}{2} - \varphi_0 \qquad \text{with } 0 \leq \frac{\varphi_{\mathrm{S}}}{2} \leq \frac{\pi}{2}} \quad .$$

On then has:

$$\boxed{\sin\left[\varphi_{\mathrm{S}}/2\right] = \cos\left[\varphi_0\right] = \frac{1}{e}}$$

From the initial conditions at large distance,

$$E = E_0 = \frac{p_{\mathrm{I}}^2}{2m} = \text{constant} \quad ,$$
$$\ell = \ell_0 = p_{\mathrm{I}} b = \text{constant} \quad ,$$
$$\text{while the linear momentum } p \text{ is not conserved} \quad ,$$

it follows, noting that $0 \leq \dfrac{\varphi_{\mathrm{S}}}{2} \leq \dfrac{\pi}{2}$ implies $\sin\left[\varphi_{\mathrm{S}}/2\right] > 0$ and $\cos\left[\varphi_{\mathrm{S}}/2\right] > 0$,

$$\cot\left[\varphi_{\mathrm{S}}/2\right] = \frac{\cos\left[\varphi_{\mathrm{S}}/2\right]}{\sin\left[\varphi_{\mathrm{S}}/2\right]} = \frac{\sqrt{1-\sin^2\left[\varphi_{\mathrm{S}}/2\right]}}{\sin\left[\varphi_{\mathrm{S}}/2\right]} = \sqrt{e^2-1} = \boxed{\sqrt{\frac{2E\ell^2}{m\gamma^2}} = \frac{2E_0 b}{|\gamma|} = \frac{\ell_0^2}{m|\gamma|b} = \cot\left[\varphi_{\mathrm{S}}/2\right]} \quad ,$$

(29.04.23) → 1564 1566

showing how the scattering angle can be expressed either in terms of the energy (plus impact parameter) or angular momentum (plus impact parameter).

In case of a repulsive potential the above result (29.04.23) is unchanged. In fact, in case of a repulsive force, at the same center of force, corresponding to the other branch of the same hyperbola, one has:

$$\boxed{\cos\left[\varphi_{\mathrm{A}}\right] = +\frac{1}{e} \qquad \varphi_{\mathrm{S}} = \pi - 2\varphi_0 = \pi + 2\varphi_{\mathrm{A}}} \quad ,$$

and all goes on the same way.

29.04.04.02 Gravitational Slingshot Effect (Gravity Assist)

This § is referenced at pages:
[1547]

Una sonda spaziale di massa m viene diretta verso un pianeta (ad esempio Giove), che ha massa M, con $m \ll M$, in modo che la sua orbita, a seguito dell'interazione con Giove, venga accelerata e deviata opportunamente per dirigerla in una direzione voluta aumentando (ovvero diminuendo) al tempo stesso l'energia cinetica della sonda rispetto al Reference Frame solidale con il Sole.

1. Determinare la variazione del modulo della velocità della sonda a seguito del suo incontro ravvicinato con Giove, sia rispetto al Reference Frame solidale con Giove (velocità relativa a Giove $\mathbf{v}'$) sia rispetto al Reference Frame solidale con il Sole (velocità relativa al Sole $\mathbf{v}$).
2. Calcolare, nel Reference Frame solidale con Giove, l'angolo di scattering (deviazione) φ_{S} della sonda in funzione della sua velocità iniziale, $\mathbf{v}'_{\mathrm{I}}$, e del parametro di impatto b rispetto a Giove.
3. Calcolare l'angolo di deviazione della sonda nel Reference Frame solidale con il Sole.

Read also § 29.04.04.

As the potential is attractive we have: $\gamma > 0$. Nel caso gravitazionale il potenziale è sempre attrattivo, mentre nel caso Coulmbiano può essere anche repulsivo.

Moreover, by hypotesis, $m \ll M$, and therefore we can neglect the reduction of the two-body problem to a one-body problem and consider Jupiter a fixed scattering center. Si assuma che quando la sonda si trova nei pressi di Giove risenta solo dell'attrazione gravitazionale del pianeta in modo da poter descrivere l'interazione come un semplice problema a due corpi (sonda entro la sfera di influenza di Giove). Si trascuri la variazione di quantità di moto di Giove durante l'interazione (essendo $M \gg m$). Si supponga il tempo di interazione così breve da poter trascurare il moto di Giove nella sua orbita durante il tempo di interazione. Sotto tali ipotesi il moto visto dal Reference Frame inerziale solidale con Giove è descritto

DRAFT - For Proofreading

CC BY NC ND

dal problema gravitazionale dei due corpi e l'energia totale della sonda sarà positiva in quanto non è gravitazionalmente legata con Giove.

Nel caso specifico in questione sono solo rilevanti le orbite iperboliche, corrispondenti ad energia meccanica totale positiva:

$$r[\varphi] = \frac{p}{+1 + e\cos[\varphi]} = \frac{a\left(e^2-1\right)}{+1+e\cos[\varphi]} \qquad \text{orbita iperbolica, } e>1\text{, potenziale attrattivo, perielio a } \varphi = 0. \tag{29.04.24}$$

$$r[\varphi] = \frac{p}{+1 - e\cos[\varphi]} = \frac{a\left(e^2-1\right)}{-1-e\cos[\varphi]} \qquad \text{orbita iperbolica, } e>1\text{, potenziale attrattivo, perielio a } \varphi = \pi \quad .$$

Si ha

$$\boxed{p = \frac{\ell^2}{m|\gamma|} \geq 0} = a\left|e^2-1\right| \qquad \text{nel caso } 0 \leq e \neq 1 \tag{29.04.25}$$

→ 1565

e

$$\boxed{e^2 = 1 + \frac{2E\ell^2}{m\gamma^2}} \quad . \tag{29.04.26}$$

→ 1565

Dalle (29.04.25), (29.04.26), (2) si ricava l'energia totale

$$E = +\frac{|\gamma|}{2a} \qquad \text{orbita iperbolica, } E>0 \quad .$$

La relazione che lega le velocità nel Reference Frame solidale con il Sole, $\mathbf{v}$, e in quello solidale con Giove, $\mathbf{v}'$, denotando con $\mathbf{V}$ la velocità di Giove, sono

$$\begin{aligned} \mathbf{v}_{\mathrm{F}} &= \mathbf{V} + \mathbf{v}'_{\mathrm{F}} \quad , \\ \mathbf{v}_{\mathrm{I}} &= \mathbf{V} + \mathbf{v}'_{\mathrm{I}} \quad , \\ \Delta\mathbf{v} &\equiv \mathbf{v}_{\mathrm{F}} - \mathbf{v}_{\mathrm{I}} \quad , \\ \Delta\mathbf{v}' &\equiv \mathbf{v}'_{\mathrm{F}} - \mathbf{v}'_{\mathrm{I}} \quad , \\ \boxed{\Delta\mathbf{v}' = \Delta\mathbf{v}} & \end{aligned}$$

→ 1566

e nel Reference Frame solidale con Giove le velocità iniziale e finale della sonda sono invariate in modulo

$$\boxed{\left|\mathbf{v}'_{\mathrm{F}}\right| = \left|\mathbf{v}'_{\mathrm{I}}\right|} \quad ,$$

cioè il processo è elastico (energia cinetica immutata) nel Reference Frame solidale con il pianeta. Ne segue

$$\boxed{\frac{\Delta \mathtt{k}}{m} \equiv \frac{1}{2}\left(v_{\mathrm{F}}^2 - v_{\mathrm{I}}^2\right) = \mathbf{V}\cdot\mathbf{v}'_{\mathrm{F}} - \mathbf{V}\cdot\mathbf{v}'_{\mathrm{I}} = \mathbf{V}\cdot\mathbf{v}_{\mathrm{F}} - \mathbf{V}\cdot\mathbf{v}_{\mathrm{I}} = \mathbf{V}\cdot\Delta\mathbf{v}' = \mathbf{V}\cdot\Delta\mathbf{v}} \quad .$$

Ne segue che, a seconda della relazione tra il vettore velocità di Giove e la variazione di velocità, che è la stessa nel Reference Frame solidale con il Sole e in quello solidale con Giove, il modulo della velocità della sonda può aumentare o diminuire. In particolare dalla relazione sopra è evidente come, per una fissata velocità iniziale, la massima velocità finale si ottiene quando la velocità finale è parallela a quella di Giove. L'energia guadagnata dalla sonda è sottratta al pianeta. Il metodo può essere usato sia per accelerare che per rallentare la sonda.

Gli asintoti dell'orbita iperbolica sono determinati dall'equazione

$$\cos[\varphi_{\mathtt{A}}] = -\frac{1}{e} \quad ,$$

scegliendo sempre per $\varphi = 0$ il punto del perielio. Conviene introdurre l'angolo ausiliario

$$\varphi_0 = \pi - \varphi_{\mathtt{A}} \implies \cos[\varphi_0] = \frac{1}{e} \quad .$$

In tal modo l'angolo di deviazione, $\varphi_{\mathtt{S}}$, che risulta è

$$\varphi_{\mathtt{S}} = \pi - 2\varphi_0 \quad ,$$

da cui segue

$$\boxed{\cos[\varphi_{\mathtt{S}}] = -\cos[2\varphi_0] = 1 - 2\cos^2[\varphi_0] = 1 - \frac{2}{e^2}} \quad . \tag{29.04.27}$$

→ 1566 1613

DRAFT - IN PROGRESS

L'espressione dell'eccentricità dell'orbita è

$$\boxed{e^2 = 1 + \frac{2E\ell^2}{m\gamma^2}} \quad ,$$

dove $\gamma = \mathcal{G}Mm$.

Note that the result in equation (29.04.23) can be cast in the form of result of equation (29.04.27) using a trigonometric identity:

$$t \equiv \tan\left[\varphi_S/2\right] \Longrightarrow \cos\left[\varphi_S\right] = \frac{1-t^2}{1+t^2} \Longrightarrow \frac{1}{t^2} = \frac{1+\cos\left[\varphi_S\right]}{1-\cos\left[\varphi_S\right]} = e^2 - 1 \quad ,$$

$$\boxed{\frac{2E\ell^2}{m\gamma^2} = \left(\frac{2Eb}{\gamma}\right)^2 = \left(\frac{\ell^2}{m\gamma b}\right)^2 = \frac{1}{t^2} = \cot^2\left[\varphi_S/2\right]} \quad .$$

I parametri iniziali dell'orbita sono, nel Reference Frame di Giove,

$$\ell'_0 = mbv'_I \quad ,$$

$$E'_0 = \frac{1}{2}m{v'_I}^2 \quad ,$$

determinati dalla trasformazione della velocità della sonda dal Reference Frame eliocentrico a quello solidale con Giove, secondo la (29.04.04.02).

In termini dei parametri iniziali questa si scrive

$$e^2 = 1 + \left(\frac{m{v'_I}^2 b}{\gamma}\right)^2 \geq 1 \quad .$$

This equation allows to determine the eccentricity as a function of b and v'_I. Moreover, from v'_I one can determine the mechanical energy E and from that one can find the major axis of the hyperbola, thus determining the geometry of the hyperbola.

Moreover, one can write the expression for the module of the velocity change:

$$\boxed{\left|\Delta\mathbf{v}'\right| = 2\left|\mathbf{v}'_F\right|\sin\left[\varphi_S/2\right] = 2\left|\mathbf{v}'_I\right|\sin\left[\varphi_S/2\right]} \quad .$$

L'espressione per l'angolo di deviazione φ_S fornisce i seguenti casi limite.

- Nel caso $e \longrightarrow 1$, $\varphi_S \longrightarrow \pi$; questo caso si ottiene per $v'_I \longrightarrow 0$ oppure $b \longrightarrow 0$. La sonda punta molto vicino a Giove, oppure ha una energia cinetica all'infinito molto piccola.
- Nel caso $e \longrightarrow \infty$, $\varphi_S \longrightarrow 0$; questo si ottiene per $v'_I \longrightarrow \infty$ oppure $b \longrightarrow \infty$. La sonda punta molto lontano da Giove, oppure ha una energia cinetica all'infinito molto grande.

Il calcolo dell'angolo di deviazione nel Reference Frame solidale permette di calcolare anche la deviazione nel Reference Frame solidale con il Sole dalla legge di trasformazione delle velocità (29.04.04.02).

Note that, even if $b \longrightarrow 0$, the spacecraft does not fall on the center of force, in principle, but it may fall onto the planet surface in a realistic case. It will never end orbiting Jupiter, whenever the mechanical energy is conserved.

The relative velocity of the spacecraft with respect to the planet is unchanged in absolute value, but its direction changes. Therefore the velocity of the spacecraft with respect to the Sun may change in absolute value.

In the limiting case $E\ell^2 \longrightarrow 0$ the scattering angle is maximal: $\varphi_S \longrightarrow \pi$. Therefore the velocity of the spacecraft relative to the planet is reversed:

$$\mathbf{v}'_F = -\mathbf{v}'_I \Longrightarrow \Delta\mathbf{v}' = +2\mathbf{v}'_F = -2\mathbf{v}'_I \quad .$$

Depending on the direction of $\mathbf{v}'_F = -\mathbf{v}'_I$ with respect to $\mathbf{V}$ the change of kinetic energy with respect to the Sun can be positive or negative and it reaches its maximum absolute value when $\mathbf{v}'_F = -\mathbf{v}'_I$ has the same direction of $\mathbf{V}$.

©|H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...|3.9||
©|WEB - URL |Mysteries of the gravitational 2-body problem|*John Baez*|

It applies to both gravitational and electric forces.
The equation is:

$$m\ddot{\mathbf{r}} = -\gamma\frac{\mathbf{r}}{r^3} \quad , \tag{29.04.28}$$

→ 1567

with the convention that the constant γ is positive for attractive forces and negative for repulsive forces.
Equation (29.04.28) can be also written in the following way:

$$\frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}t} = -\dot{\varphi}\widehat{\mathbf{e}}_r \longrightarrow \frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}\varphi} = -\widehat{\mathbf{e}}_r \longrightarrow m\ddot{\mathbf{r}} = +\frac{\gamma}{r^2\dot{\varphi}}\frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}t} \quad . \tag{29.04.29}$$

The previous equation can be integrated by introducing the angular momentum:

$$\ddot{\mathbf{r}} = \frac{\gamma}{mr^2\dot{\varphi}}\frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}t} = \frac{\gamma}{\ell_z}\frac{\mathrm{d}\widehat{\mathbf{e}}_\theta}{\mathrm{d}t} \longrightarrow \mathbf{v} = \mathbf{w} + \frac{\gamma}{\ell_z}\widehat{\mathbf{e}}_\theta \longrightarrow \mathbf{w} = \mathbf{v} - \frac{\gamma}{\ell_z}\widehat{\mathbf{e}}_\theta \quad , \tag{29.04.30}$$

where $\mathbf{w}$ is a constant vector.
The following vector is therefore a constant of motion:

$$\boxed{\mathbf{w} \equiv \mathbf{v} - \frac{\gamma}{\ell_z}\widehat{\mathbf{e}}_\theta} \quad .$$

The dimensionless vector eccentricity is defined from $\mathbf{w}$ as:

$$\boxed{\mathbf{e} \equiv -\mathbf{w}\frac{\ell_z}{\gamma} = -\mathbf{v}\frac{\ell_z}{\gamma} + \widehat{\mathbf{e}}_\theta} \quad .$$

Its module is the eccentricity of the orbit.
The Runge-Lenz vector, a constant vector lying in the plane of the orbit, is defined from the two constant of motion $\boldsymbol{\ell}$ and $\mathbf{w}$, as:

$$\boxed{\mathbf{A} \equiv \frac{\mathbf{w}\wedge\boldsymbol{\ell}}{\gamma} = \frac{\mathbf{v}\wedge\boldsymbol{\ell}}{\gamma} - \widehat{\mathbf{e}}_r} \quad . \tag{29.04.31}$$

→ 1567 1568

Note that different definitions can be found in the literature. The one used here, for instance, differs by an overall factor $m\gamma$ with respect to the one used in [1]. The present definition is such that the vector is dimensionless.
By its very definition $\mathbf{A} \perp \boldsymbol{\ell}$ that is $\mathbf{A}$ lies in the plane of the orbit. As the vector is constant it can be calculated at any suitable point along the orbit, for instance at the perihelion or aphelion. It can be seen that its direction lies along the major axis of the conic.
Note that from the constancy of the vector it is immediate to demonstrate that for $\boldsymbol{\ell} = 0$ the motion is rectilinear (see problem § 29-003). In fact:

$$\boldsymbol{\ell} = 0 \implies \mathbf{r}/r = \mathbf{A} = \text{constant} \quad .$$

When $\mathbf{e} = 0$ it follows, from equation (29.04.31), by expressing $\mathbf{v}$ in terms of $\widehat{\mathbf{e}}_r$ and $\widehat{\mathbf{e}}_\theta$, that $\dot{r} = 0$ and the orbit is circular.

[1] H.Goldstein *et al.*, *Classical Mechanics*, 2014, Pearson Education, 3rdEd., ...

DRAFT: IN PROGRESS

Take the dot product of equation (29.04.31) with $m\mathbf{r}$ to obtain:

$$\cos[\varphi] = \frac{\mathbf{r}\cdot\mathbf{A}}{rA} \Longrightarrow r[\varphi] = \frac{\ell^2}{m\gamma}\left(\frac{1}{1+A\cos[\varphi]}\right) \quad ,$$

from which the interpretation of $|\mathbf{A}|$ as the eccentricity is manifest. The vector $\mathbf{A}$ points from the center of the ellipse to the perihelion as long as φ is the angle between $\mathbf{A}$ and the line from the focus to the perihelion.

The Kepler problem, in the plane, is a fourth order problem, requiring four constants of motion for the integration. It is in fact a 2-dimensional problem in the plane of the orbit, whose absolute orientation is determined by the direction of the angular momentum vector $\boldsymbol{\ell}$. By considering the motion in space one would have seven constants of motion $\boldsymbol{\ell}$, E, $\mathbf{A}$. They are linked by two equations:

$$\mathbf{A}\cdot\boldsymbol{\ell} = 0 \quad ,$$

$$A^2 = 1 + \frac{2E\ell^2}{m\gamma^2} \quad .$$

Only five constants are then independent, the exact number required by a six-degrees of freedom motion. As all the constants of motion have been found it was possible to determine the orbit equation by using algebraic methods only. The constants do not depend explicitly on time.

As we have been able to find four constants of motion the orbit can be found exclusively by algebraic methods.

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|1-6.4.2||

Let us study the gravitational potential produced by an arbitrary mass distribution at point $\mathbf{r}$, a point located at large distance from the mass distribution. The restriction of large distance might be relaxed to consider also points near the mass distribution but in this case some complications might arise on the convergence of the series expansion.

Choose a Coordinate System. The choice of the origin of this Coordinate System is arbitrary, but it is anticipated that it will turn out to be useful to choose the origin at the CM of the mass distribution. Therefore it is easier to choose since the beginning the origin of the orthonormal Cartesian Coordinates Coordinate System at the Center-Of-Mass of the mass distribution, but this is not strictly necessary.

Assume that the mass distribution is bounded inside a sphere of radius r_0. If $\mathbf{x}$ is the variable describing the position of the mass distribution there is therefore an upper limit to $|\mathbf{x}|$: $|\mathbf{x}| \leq r_0$.

Moreover, this hypothesis allows to choose the reference point for the gravitational potential energy at infinity:

$$\lim_{r \longrightarrow \infty} \Phi[\mathbf{r}] = 0 \quad .$$

The following notation will be used: $r \equiv |\mathbf{r}|$ and $x \equiv |\mathbf{x}|$.

Develop the gravitational potential energy at $\mathbf{r}$ up to second-order in (x/r), using

$$(1+w)^{-1/2} = 1 - \frac{1}{2}w + \frac{3}{8}w^2 + \mathcal{O}\left(w\right)^3 \qquad \text{convergent for } w < 1 \quad ,$$

to obtain:

$$\Phi[\mathbf{r}] = -\mathcal{G} \iiint \frac{\rho[\mathbf{x}]}{|\mathbf{r}-\mathbf{x}|}\, \mathrm{d}V_{\mathbf{x}} = -\mathcal{G} \iiint \frac{\rho[\mathbf{x}]}{\sqrt{r^2 + x^2 - 2\,\mathbf{r}\cdot\mathbf{x}}}\, \mathrm{d}V_{\mathbf{x}} = \quad , \qquad \rightarrow 1574$$

$$-\mathcal{G} \iiint \frac{\rho[\mathbf{x}]}{r} \left(1 - 2\frac{\mathbf{r}\cdot\mathbf{x}}{r^2} + \frac{x^2}{r^2}\right)^{-1/2} \mathrm{d}V_{\mathbf{x}} = \quad ,$$

$$-\mathcal{G} \iiint \frac{\rho[\mathbf{x}]}{r} \left(1 + \frac{\mathbf{r}\cdot\mathbf{x}}{r^2} + \frac{3}{2}\left(\frac{\mathbf{r}\cdot\mathbf{x}}{r^2}\right)^2 - \frac{x^2}{2r^2} + \mathcal{O}\left(\frac{x}{r}\right)^3\right) \mathrm{d}V_{\mathbf{x}} \quad .$$

WORK IN PROGRESS

The gravitational potential energy can be written as a sum of three terms, up to second-order:

$$\Phi[\mathbf{r}] = \Phi_0[\mathbf{r}] + \Phi_1[\mathbf{r}] + \Phi_2[\mathbf{r}] + \mathcal{O}\left(\frac{r_0}{r}\right)^3 \quad . \tag{29.05.01}$$

→ 1574

The problem of the convergence of the series expansion is not discussed here.

Developing the calculation one has, in terms of the total mass, M:

$$\boxed{\Phi_0[\mathbf{r}]} = -\frac{\mathcal{G}M}{r} \qquad \text{unipolar contribution} \quad . \tag{29.05.02}$$

→ 1575

$$\boxed{\Phi_1[\mathbf{r}]} = -\frac{\mathcal{G}M}{r^3}(\mathbf{r}\cdot\mathbf{R}_{\text{CM}}) \qquad \text{dipolar contribution: it is zero if the origin is at the CM} \quad . \tag{29.05.03}$$

$$\boxed{\Phi_2[\mathbf{r}]} = -\frac{\mathcal{G}}{r^5}\iiint \rho[\mathbf{x}]\left(\frac{3\,(\mathbf{r}\cdot\mathbf{x})^2 - r^2x^2}{2}\right) \mathrm{d}V_{\mathbf{x}} \qquad \text{quadripolar contribution} \quad . \tag{29.05.04}$$

As a general rule, note that if the term Φ_n in the development of the potential is non zero, then all the terms Φ_k with $k > n$ do depend on the choice of the origin of the Coordinate System. In the gravitational case one always has $M > 0$, therefore all the terms after the monopole do depend on the choice of the origin of the Coordinate System. This is markedly different from the ElectroStatic case, where the total charge, as well as any higher-order moment, might be zero.

The second-order term can be written with explicit tensor indexes, in terms of the **Quadrupole** moment tensor, $Q^{\cdot\cdot}_{jk}$:

$$\boxed{\Phi_2[\mathbf{r}] = -\mathcal{G}\frac{r_j r_k}{2r^5}\iiint \rho[\mathbf{x}]\left(3x_jx_k - x^2\delta^{\cdot\cdot}_{jk}\right)\mathrm{d}V_{\mathbf{x}} = -\mathcal{G}\frac{r_j r_k Q^{\cdot\cdot}_{jk}}{2r^5}} \quad . \tag{29.05.05}$$

→ 1597

The **Quadrupole** moment is obviously a second-order tensor, as it can be demonstrated as for the inertia Matrix|Tensor in section § 26.04.04.01.

The **Quadrupole** moment is a symmetric and traceless tensor:

$$\boxed{Q^{\cdot\cdot}_{jk} \equiv \iiint \rho[\mathbf{x}]\left(3x_jx_k - x^2\delta^{\cdot\cdot}_{jk}\right)\mathrm{d}V_{\mathbf{x}} \qquad \text{with} \qquad \begin{cases} Q^{\cdot\cdot}_{jk} = Q^{\cdot\cdot}_{kj} \\ \sum_i Q^{\cdot\cdot}_{ii} = 0 \end{cases},} \quad .$$

→ 1570 1571

The value of the **Quadrupole** moment tensor, $Q^{\cdot\cdot}_{jk}$, obviously depends on the choice of the origin as well as orientation of the orthonormal Cartesian Coordinates Coordinate System. The dependence on the origin, normally, is not made explicit as one normally choose the Center-Of-Mass of the mass distribution as the origin.

The relation (29.05.01) shows that the gravitational **Quadrupole** moment has only five independent components.

Note that, in presence of mass, $\Phi_0[\mathbf{r}]$ is always different from zero, in contrast to the ElectroMagnetic case where the monopole term might be zero for a globally neutral distribution. Therefore the importance of the successive terms in the expansion is comparatively more limited in the gravitational case with respect to the ElectroMagnetic case because in the gravitational case the monopole contribution is always present and dominant. Higher order terms are sometimes important in the accurate study of the motion of artificial satellites.

DRAFT In Progress

29.05.01.01 Gravitational Quadrupole Moment and Inertia Matrix|Tensor

Consider the origin of the Coordinate System fixed at the Center-Of-Mass, from now on, so that the **Dipole** term is null. The inertia Matrix|Tensor is evaluated with respect to the Center-Of-Mass from equation (26.04.08), with S=CM, which will be assumed implicitly.

From definitions (29.05.01), (26.04.08) the following relation apply:

$$\boxed{Q^{\cdot\cdot}_{ij} + 3I^{\cdot\cdot}_{ij} = \delta^{\cdot\cdot}_{ij}\,\mathrm{Tr}\,\mathbb{I} = \delta^{\cdot\cdot}_{ij}\left(2\iiint x^2\rho[\mathbf{x}]\,\mathrm{d}V_{\mathbf{x}}\right) > 0} \quad .$$

It is obvious that the gravitational **Quadrupole** moment and the inertia Matrix|Tensor are not independent quantities:

$$\boxed{Q^{\cdot\cdot}_{ij} = -3\left(I^{\cdot\cdot}_{ij} - (1/3)\delta^{\cdot\cdot}_{ij}\,\mathrm{Tr}\,\mathbb{I}\right)} \quad . \tag{29.05.06}$$

→ 1572

As the **Quadrupole** tensor is traceless by definition, it has only five independent components.

Furthermore, if we define the unit vector $\widehat{\mathbf{n}} \equiv \mathbf{r}/r$ and let $\mathbb{I}[\widehat{\mathbf{n}}]$ be the moment of inertia along the line joining the Center-Of-Mass to to point where the gravitational field has to be evaluated, that is at $\mathbf{r}$, and define I_{11}, I_{22} and I_{33} the moments of inertia with respect to the principal axes of inertia, we have, exploiting equation (26.04.10):

$$\Phi_2[\mathbf{r}] = -\mathcal{G}\frac{r_j r_k Q^{\cdot\cdot}_{jk}}{2r^5} = -\frac{\mathcal{G}}{2r^5} r_j r_k\left(\delta^{\cdot\cdot}_{jk}\,\mathrm{Tr}\,\mathbb{I} - 3I^{\cdot\cdot}_{jk}\right) = -\frac{\mathcal{G}}{2r^5}\left(r^2\,\mathrm{Tr}\,\mathbb{I} - 3r^2\mathbb{I}[\widehat{\mathbf{n}}]\right) = -\frac{\mathcal{G}}{2r^3}\left(I_{11}+I_{22}+I_{33}-3\mathbb{I}[\widehat{\mathbf{n}}]\right) \quad . \tag{29.05.07}$$

The latter is known as MacCullagh formula.

29.05.01.02 Gravitational Quadrupole Moment for Systems With Cylindrical Symmetry

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|§ 1-6.4.2, 2-5.3.4||

Consider a system with cylindrical symmetry around the z axis: the z axis is then a symmetry axis but the symmetry is stronger than that, as the system is invariant for rotations around the z axis. The z axis, in other words, is an axis of revolution for the system.

Let the Coordinate System be centered on the Center-Of-Mass (lying on the z axis itself). The cylindrical symmetry implies that the mass density is only dependent of z and the distance from the z axis:

$$\rho[\mathbf{r}] \longrightarrow \rho[\sqrt{x^2+y^2}, z] \qquad \text{independent of } \phi \quad .$$

As a corollary every plane passing by the z axis is a plane of symmetry [1].

The **Quadrupole** moment tensor assumes a particularly simple form in this quite common case. In fact, because of the symmetry, all the terms with an odd power of x or y are zero, as both the zx and zy plane are planes of symmetry:

$$Q_{xy} = Q_{yz} = Q_{zx} = 0 \qquad Q_{xx} = Q_{yy} \quad .$$

that is the tensor is diagonal. As the tensor is traceless it follows:

$$0 = Q_{xx} + Q_{yy} + Q_{zz} \qquad \longrightarrow \qquad Q_{xx} = Q_{yy} = -\frac{1}{2}Q_{zz} \neq 0 \quad ,$$

implying that all elements can be expressed in terms of any one of the diagonal elements.

It is common practice to define the **Quadrupole moment** of a distribution with cylindrical symmetry as $Q \equiv Q_{zz}$.

The **Quadrupole** potential becomes:

$$\Phi_2[\mathbf{r}] = -\frac{\mathcal{G}}{2r^5} r_j r_k Q^{\cdot\cdot}_{jk} = -\frac{\mathcal{G}}{2r^5}\left(r_1^2 Q_{11} + r_2^2 Q_{22} + r_3^2 Q_{33}\right) = \quad ,$$

→ 1572

$$-\frac{\mathcal{G}}{4r^5}Q_{33}\left(2r_3^2 - \left(r_1^2+r_2^2\right)\right) = -\frac{\mathcal{G}}{4r^5}Q_{33}\left(3r_3^2 - r^2\right) = -\mathcal{G}\frac{Q\left(3\cos^2[\theta]-1\right)}{4r^3} \quad .$$

[1] Note that for a simple axial symmetry it is not true that every plane passing by the z axis is a plane of symmetry: consider for instance two intersecting planes making an angle different from $\pi/2$, where the intersection line is a symmetry axis but the planes are not planes of symmetry

DRAFT - In Progress

Let $I_\perp \equiv I_{11} = I_{22}$. Equation (29.05.01.02) can be written in terms of the tensor of inertia using equation (29.05.06), giving:

$$\boxed{Q \equiv Q_{33} = 2\left(I_\perp - I_{33}\right)} \quad . \tag{29.05.08}$$

→ 1572

Then

$$\boxed{\Phi_2[\mathbf{r}] = -\mathcal{G}\frac{Q\left(3\cos^2[\theta]-1\right)}{4r^3} = -\mathcal{G}\frac{\left(I_\perp - I_{33}\right)\left(3\cos^2[\theta]-1\right)}{2r^3}} \quad . \tag{29.05.09}$$

The **Quadrupole** moment gravitational field becomes significant, in practice, when the body producing the field is significantly distorted with respect to a spherical shape.

Equation (29.05.08) shows that:

- $Q > 0$ implies that the body mass is closer to the z axis, on average, than a spherically symmetrical distribution: cigar-like shape along the z axis;
- $Q < 0$ implies that the body mass is closer to the xy plane, on average, than a spherically symmetrical distribution: disk-like shape along the xy plane.

The shape of the **Quadrupole** potential can be understood as follows:

- $Q > 0$ implies that on the z axis (that is $|\cos\theta| = 1$), at fixed r: $\Phi_2 < 0$; therefore the total potential is lower than it would be from the pure monopole term; therefore the equipotential surface of the pure monopole term moves at $|z| > r$, and it deforms like the mass distribution;
- $Q < 0$ implies that on the z axis (that is $|\cos\theta| = 1$), at fixed r: $\Phi_2 > 0$; therefore the total potential is higher than it would be from the pure monopole term; therefore the equipotential surface of the pure monopole term moves at $|z| < r$, and it deforms like the mass distribution.

DRAFT - IN-PROGRESS

Forces and Torques Produced by a Cylindrically Symmetrical Mass Distribution

This § is referenced at pages:
[1071]

Consider a main body with cylindrical symmetry around the z axis and let the Coordinate System be centered on its Center-Of-Mass and its large-distance gravitational potential truncated to second-order. A point mass m is located at $\mathbf{r}$. The components, $\{f_r; f_\theta; f_\phi\}$, of the gravitational force, $\mathbf{f}$, acting on the point mass, are calculated by taking the gradient in spherical coordinates of the potential (equation (29.05.01)) and multiplying by the test mass:

$$f_r[\mathbf{r}] \equiv -m\frac{\partial\Phi[\mathbf{r}]}{\partial r} = -\frac{\mathcal{G}Mm}{r^2} - \frac{3\mathcal{G}mQ\left(3\cos^2[\theta]-1\right)}{4r^4} \quad , \qquad \rightarrow 1574$$

$$f_\theta[\mathbf{r}] \equiv -m\frac{1}{r}\frac{\partial\Phi[\mathbf{r}]}{\partial\theta} = -\frac{3\mathcal{G}mQ\sin[2\theta]}{4r^4} \quad , \qquad \rightarrow 1574$$

$$f_\phi[\mathbf{r}] \equiv -m\frac{1}{r\sin[\theta]}\frac{\partial\Phi[\mathbf{r}]}{\partial\phi} = 0 \quad . \qquad \rightarrow 1574$$

The force field is not central with respect to the Center-Of-Mass of the main body, which is taken, since now on, as the origin of the Coordinate System. Actually, the force field is not central at all. As a consequence, **the orbit is not, in general, a plane one**; read § 29.05.03.

The force in the direction of the polar angle, $\mathbf{f}_\theta[\mathbf{r}]$, goes like $\sin[2\theta]$, that is it changes its sign every $\pi/2$ radians. This is because the mass point is attracted, at any point in its orbit, either towards the poles or towards the equator, depending on the sign of Q.

As the system (main body plus the point mass) is isolated, the sum of internal forces and torques is zero.

The (reaction) force exerted by the mass point on the planet is equal but opposite to $\mathbf{f}$ as expressed in equations (29.05.01.02), (29.05.01.02), (29.05.01.02).

While the force exerted on the mass point is just the force $\mathbf{f}$ applied at the mass point itself, the main body is subject to a distributed system of forces originating from the mass point, applied to the different infinitesimal parts of the main body, whose resultant is $-\mathbf{f}$.

The intrinsic torque exerted by the gravitational field on the mass point, $\boldsymbol{\gamma}[\mathbf{r}]$, is assumed to be zero, coherently with the properties of a gravitational field and, in particular, with the isotropy of a mass point. Because the force field acting on the mass point is non central (with respect to the Center-Of-Mass of the main body) the momentum of the force $\mathbf{f}$ on the mass point, with respect to the Center-Of-Mass of the main body, is:

$$\boldsymbol{\Gamma} = \boldsymbol{\gamma} + \mathbf{r}\wedge\mathbf{f} = \mathbf{r}\wedge\mathbf{f} \neq 0 \quad .$$

In order to balance to zero the internal torques of the planet plus satellite system, the mass point must exert an equal but opposite total torque on the planet, $\boldsymbol{\Gamma}'$ given by:

$$\boldsymbol{\Gamma}' + \boldsymbol{\Gamma} = 0 \qquad \boldsymbol{\Gamma}' = -\boldsymbol{\Gamma} \quad .$$

29.05.02
Multipole Development in Terms of Legendre Polynomials

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|4.1, P4.1, P4.2, P4.3, P4.4, P4.5, P4.6 ||

The contribution to the potential of any infinitesimal mass element is (compare with equation (29.05.01)):

$$\mathrm{d}\Phi[\mathbf{r}] = -\mathcal{G}\frac{\mathrm{d}m}{r}\left(1 - 2\frac{\mathbf{r}\cdot\mathbf{x}}{r^2} + \frac{x^2}{r^2}\right)^{-1/2} = -\mathcal{G}\frac{\mathrm{d}m}{r}\left(1 - 2\frac{x}{r}\cos[\Phi] + \frac{x^2}{r^2}\right)^{-1/2} \quad .$$

DRAFT-IN-PROGRESS

The expansion in terms of the Legendre polynomials gives:

$$\text{d}\Phi[\mathbf{r}] = -\mathcal{G}\frac{\text{d}m}{r}\sum_{k=0}^{\infty}\left(\frac{x}{r}\right)^k P_k[\cos[\Phi]] \quad , \tag{29.05.10}$$

→ 1575

where P_k is the Legendre polynomial of order k.

The first four Legendre polynomials are:

$$P_0[s] = 1 \quad ,$$
$$P_1[s] = s \quad ,$$
$$P_2[s] = (1/2)\left(3s^2 - 1\right) \quad ,$$
$$P_3[s] = (1/2)\left(5s^3 - 3s\right)$$

Integrating term by term equation (29.05.10) up to second-order one finds:

$$\Phi[\mathbf{r}] = -\frac{\mathcal{G}M}{r} - \frac{\mathcal{G}}{r^2}\int x\cos[\Phi]\ \text{d}m - \frac{\mathcal{G}}{r^3}\int x^2\frac{\left(3\cos^2[\Phi]-1\right)}{2}\text{d}m + \quad ,$$
$$\ldots - \frac{\mathcal{G}}{r^{n+1}}\int x^n P_n[\cos[\Phi]]\ \text{d}m + \ldots \quad .$$

Let $\mathbf{r} \equiv r\left(\cos[\alpha_1], \cos[\alpha_2], \cos[\alpha_2]\right)$ and $\mathbf{x} \equiv (x_1, x_2, x_3)$. It follows that:

$$\mathbf{x}\cdot\mathbf{r} = xr\cos[\Phi] = r\left(x_1\cos[\alpha_1] + x_2\cos[\alpha_2] + x_3\cos[\alpha_2]\right) \longrightarrow x\cos[\Phi] = \left(x_1\cos[\alpha_1] + x_2\cos[\alpha_2] + x_3\cos[\alpha_2]\right) \quad .$$

The second term of the development is thus zero if the origin of the coordinates is chosen at the Center-Of-Mass of the mass distribution whose gravitational field has to be evaluated.

Consider the origin of the Coordinate System fixed at the Center-Of-Mass, since now on.

The **Quadrupole** term can be re-written, to obtain equation (29.05.02), as:

$$\cos[\Phi] = \frac{\mathbf{r}\cdot\mathbf{x}}{rx} \longrightarrow \quad ,$$
$$\Phi_2[\mathbf{r}] = -\frac{\mathcal{G}}{r^3}\int x^2\frac{\left(3\cos^2[\Phi]-1\right)}{2}\text{d}m = -\frac{\mathcal{G}}{2r^5}\int\left(3\left(x_k x_j r_k r_j\right) - x^2\delta_{kj}^{\cdot\cdot}r_k r_j\right)\ \text{d}m = \quad ,$$
$$-\frac{\mathcal{G}}{2r^5}r_k r_j\iiint\rho[\mathbf{x}]\left(3\left(x_k x_j\right) - x^2\delta_{kj}^{\cdot\cdot}\right)\ \text{d}V_{\mathbf{x}} = -\frac{\mathcal{G}}{2r^5}r_k r_j Q_{kj}^{\cdot\cdot} \quad .$$

29.05.02.01 Development in Terms of Legendre Polynomials for a System With Cylindrical Symmetry

For a system with cylindrical symmetry one can also write:

$$\Phi[\mathbf{r}] = -\frac{\mathcal{G}M}{r}\left(1 - \sum_{k=2}^{\infty}J_k\left(\frac{x}{r}\right)^k P_k[\sin[\phi]]\right) \quad , \tag{29.05.11}$$

→ 1672

where ϕ is the latitude of the point where the potential has to be calculated.

29.06.01
Central Force Fields: Equation of Motion in the Co-Rotating non-Inertial Reference Frame

This § is referenced at pages:
[1553]

Consider a non-Inertial Reference Frame , centered in the center of force, with its $\widehat{\mathbf{e}}_3$ axis oriented parallel to ℓ, and with its $\widehat{\mathbf{e}}_r$ axis always directed from the center of force to the point mass; call it the co-rotating non-Inertial Reference Frame .

Show that the equation of motion in this non-Inertial Reference Frame are the same as (29.03.01), (29.03.01).

Note that the center of force is assumed to be at rest in an Inertial Reference Frame .

In the co-rotating non-Inertial Reference Frame the three inertial forces related to the rotation of the Reference Frame with respect to the non inertial one appear, in addition to the real central force field. Note that the motion of the co-rotating non-Inertial Reference Frame is described by the same angle, φ, describing the motion of the point mass in the inertial Reference Frame.

Moreover:

$$
\begin{aligned}
r' &= r \quad , \\
\widehat{\mathbf{e}}_r &\equiv \mathbf{r}/r \quad , \\
\mathbf{r}' &= r\widehat{\mathbf{e}}_r \quad , \\
\mathbf{v}' &= \dot{r}\widehat{\mathbf{e}}_r \qquad \text{because the motion in co-rotating Reference Frame is along } \widehat{\mathbf{e}}_r \quad , \\
\mathbf{a}' &= \ddot{r}\widehat{\mathbf{e}}_r \qquad \text{because the motion in co-rotating Reference Frame is along } \widehat{\mathbf{e}}_r \quad , \\
\widehat{\mathbf{e}}_3 &\equiv \widehat{\mathbf{e}}_r \wedge \widehat{\mathbf{e}}_\psi \quad .
\end{aligned}
$$

The forces read:

$$
\begin{aligned}
\mathbf{f}[\mathbf{r}'] &= f[r]\widehat{\mathbf{e}}_r \qquad \text{forces are absolute in } \textbf{Galilei-Newton Mechanics} \quad , \\
\mathbf{f}_{\text{CEN}}[\mathbf{r}'] &= m\dot{\varphi}^2 r\widehat{\mathbf{e}}_r \quad , \\
\mathbf{f}_{\text{COR}}[\mathbf{r}'] &= -2m\dot{\varphi}\dot{r}\widehat{\mathbf{e}}_\psi \qquad \text{the Coriolis force is transverse, because the velocity is radial } \mathbf{v}' = \dot{r}\widehat{\mathbf{e}}_r \quad , \\
\mathbf{f}_{\text{ACC}}[\mathbf{r}'] &= -m\ddot{\varphi}r\widehat{\mathbf{e}}_\psi \quad .
\end{aligned}
$$

Equations (29.03.01), (29.03.01) then follow.

29.06.02
Monotonicity of the Angular Position

Show that, for any motion with non zero angular momentum, the angle is a strictly monotonic function of time.

For a non zero angular momentum, one has, from equation

$$\ell = mr^2\dot{\varphi} \neq 0 \quad ,$$

that $\dot{\varphi} \neq 0$ and therefore the angle is a strictly monotonic function of time.

PRELIMINARY-IN-PROGRESS

29.06.03
Behavior of the Force for Power-Law Potentials

Consider the effective potential energy:

$$\Phi_{\text{E}}[r] = -\gamma r^{\alpha} + \frac{\ell^2}{2mr^2} \qquad \text{with} \qquad r \geq 0 \quad , \qquad \alpha \neq 0 \quad .$$

The effective force will be given by:

$$f_{\text{E}}[r] = -\frac{\mathrm{d}\Phi_{\text{E}}[r]}{\mathrm{d}r} \quad ,$$

which has a minimum at

$$r^{(\alpha+2)} = -\frac{\ell^2}{\gamma\alpha m} \qquad \Leftrightarrow \qquad \gamma\alpha < 0 \quad .$$

Note that (from the expression of the force alone, not of the effective force):

- the force is attractive for $\alpha\gamma < 0$;
- the force is repulsive for $\alpha\gamma > 0$.

29.06.04
Behavior of the Effective Potential Energy for Power-Law Potentials

Consider a potential energy of the type:

$$\Phi[r] = -\gamma r^{\alpha} \qquad \text{with} \qquad r \geq 0 \quad , \qquad \alpha \neq 0 \quad .$$

Note that γ will be proportional to the gravitational mass, in case of gravitational forces.

Note that:

- for $\alpha > 0$ the potential energy is attractive for $\gamma < 0$ and repulsive for $\gamma > 0$ and the zero potential energy state cannot be chosen at $r \longrightarrow \infty$ but it is normally chosen at $r = 0$;
- for $\alpha < 0$ the potential energy is attractive for $\gamma > 0$ and repulsive for $\gamma < 0$ and the zero potential energy state is normally chosen at $r \longrightarrow \infty$.

Determine the behavior of $\Phi_{\text{E}}[r]$ for $r \longrightarrow 0$ and for $r \longrightarrow +\infty$.

WORKED SOLUTION

For $0 < \alpha$:

- $\gamma > 0 \implies \lim_{r\longrightarrow 0} \Phi_{\text{E}}[r] = +\infty$;
- $\gamma > 0 \implies \lim_{r\longrightarrow +\infty} \Phi_{\text{E}}[r] = -\infty$;
- $\gamma < 0 \implies \lim_{r\longrightarrow 0} \Phi_{\text{E}}[r] = +\infty$;
- $\gamma < 0 \implies \lim_{r\longrightarrow +\infty} \Phi_{\text{E}}[r] = +\infty$;

For $-2 < \alpha < 0$:

- any $\gamma \implies \lim_{r\longrightarrow 0} \Phi_{\text{E}}[r] = +\infty$;
- any $\gamma \implies \lim_{r\longrightarrow +\infty} \Phi_{\text{E}}[r] = 0$;

For $\alpha < -2$:

- $\gamma > 0 \implies \lim_{r\longrightarrow 0} \Phi_{\text{E}}[r] = -\infty$;
- $\gamma > 0 \implies \lim_{r\longrightarrow +\infty} \Phi_{\text{E}}[r] = 0$;
- $\gamma < 0 \implies \lim_{r\longrightarrow 0} \Phi_{\text{E}}[r] = +\infty$;
- $\gamma < 0 \implies \lim_{r\longrightarrow +\infty} \Phi_{\text{E}}[r] = 0$;

Determine the orbit for an inverse square force law.

29.06.07
Determination of the Orbit for an Elastic Restoring Force Law

This § is referenced at pages:
[1405]

Note: in this case it is easy to start from scratch and just solve the two-dimensional first cardinal law in orthonormal orthonormal Cartesian Coordinates Coordinate System.

WORKED SOLUTION

It is an ellipse whose geometrical center is at the center of force.

DRAFT - IN - PROGRESS

29.06.08
Symmetry of the Orbit With Respect to the Apsidal Vectors

This § is referenced at pages:
[1554, 1556]

The apsidal vectors are defined as the vectors joining the center of force to the points of the orbit such that $\frac{\mathrm{d}r}{\mathrm{d}\varphi} = 0$, including the points of either maximum or minimum distance along the orbit. Choose the origin of the angles in the plane of the orbit in such way that one apsidal vector appears at $\varphi = 0$.

Show that the trajectory is an even function of φ, that is symmetric under the interchange $\varphi \longrightarrow -\varphi$. This means that it is enough to know the equation of the orbit between any two apsidal points, that is the turning points of the orbit, to be able to reconstruct the full orbit.

Solve the Binet equation with initial conditions at $\varphi = 0$. Let $u[\varphi]$ be such a solution (see equation (29.03.09)):

$$u[\varphi] \equiv \frac{1}{r[\varphi]} \quad ,$$

$$u[\varphi = 0] = \frac{1}{r_0} \tag{29.06.01}$$ → 1581

$$\frac{\mathrm{d}u}{\mathrm{d}\varphi}[\varphi = 0] = 0 \qquad \text{because } \frac{\mathrm{d}u}{\mathrm{d}\varphi} = -\frac{1}{r^2}\frac{\mathrm{d}u}{\mathrm{d}r} \text{ implies } \frac{\mathrm{d}u}{\mathrm{d}\varphi} = 0 \quad \Leftrightarrow \quad \frac{\mathrm{d}u}{\mathrm{d}r} = 0 \tag{29.06.02}$$ → 1581

$$\frac{d^2u}{\mathrm{d}\varphi^2} + u = -\frac{m}{u^2\ell^2} f[\frac{1}{u}] \quad .$$

Consider now the function:

$$\hat{u}[\varphi] \equiv u[-\varphi] \quad .$$ → 1581

It is obvious that such a function satisfies both the same Binet equation as $u[\varphi]$, equation (29.06.08), and the same initial conditions as $u[\varphi]$, equations (29.06.01), (29.06.02). In fact,

$$\frac{d^2}{\mathrm{d}\varphi^2}\hat{u}[\varphi] = \frac{d^2}{\mathrm{d}\varphi^2}u[-\varphi] \implies ,$$

$$\frac{d^2}{\mathrm{d}\varphi^2}\hat{u}[\varphi] + \hat{u}[\varphi] = \frac{d^2}{\mathrm{d}\varphi^2}u[-\varphi] + u[-\varphi] = \text{from Binet} = -\frac{m}{u^2\ell^2} f[\frac{1}{u[-\varphi]}] = \text{by definition} = -\frac{m}{u^2\ell^2} f[\frac{1}{\hat{u}[\varphi]}] \quad ,$$

$$\hat{u}[\varphi = 0] = u[\varphi = 0] = \frac{1}{r_0} \quad ,$$

$$\frac{\mathrm{d}\hat{u}}{\mathrm{d}\varphi}[\varphi = 0] = -\frac{\mathrm{d}u}{\mathrm{d}\varphi}[\varphi = 0] = 0 \quad ,$$

as only a second derivative appears in the equation, and the first derivative condition is set to zero (this is where the condition that $\varphi = 0$ be an apsidal vector).

Therefore the unicity of the solution of the equation allows one to conclude that:

$$\hat{u}[\varphi] \equiv u[-\varphi] = u[+\varphi] \quad ,$$

that is the desired result ($u[\varphi]$ is an even function).

Orbite Circolari in Potenziale Centrale

©|Sch, , ..., ..., ...Ed., ...|1.21||

29.06.10
Radial Stability of a Circular Orbit in a Central Force Field

Determine the conditions for the radial stability of a circular orbit in a central force field.

Study the effective potential energy (equation (29.03.03)):

$$\Phi_{\text{E}}[r] = \Phi[r] + \frac{\ell^2}{2mr^2} \quad .$$

Take the first and second derivative with respect to r:

$$\Phi'_{\text{E}}[r] = \Phi'[r] - \frac{\ell^2}{mr^3} = 0 \quad \Longrightarrow \Phi'[r_0] = \frac{\ell^2}{mr_0^3} \qquad \text{at the extremum value } r_0 \quad , \tag{29.06.03}$$

$$\Phi''_{\text{E}}[r] = \Phi''[r] + \frac{3\ell^2}{mr^4} \qquad \Longrightarrow \Phi''_{\text{E}}[r_0] = \Phi''[r_0] + 3\frac{\Phi'[r_0]}{r_0} = \Phi''[r_0] + 3m\omega_0^2 \qquad \text{at the extremum value } r_0 \quad . \tag{29.06.04}$$

■

The extrema condition is the same determined in equation (29.03.13), as it should. 1582

A sufficient condition for the stability of the radial motion is thus:

$$\boxed{\frac{\Phi''_{\text{E}}[r_0]}{m} = \frac{\Phi''[r_0]}{m} + 3\omega_0^2 > 0} \quad .$$

In the case of a power-law potential energy:

$$\Phi[r] = -\gamma r^\alpha \qquad \text{with} \qquad r \geq 0 \quad , \alpha \neq 0 \quad ,$$

the stability condition implies $\alpha > -2$.

29.06.11
Small Radial Oscillations Around a Stable Circular Orbit

This § is referenced at pages:
[1405]

Determine the frequency of the small radial oscillations around a stable circular orbit in a central force field. Study the case of a potential energy

$$\Phi[r] = -\gamma r^\alpha \qquad \text{with} \qquad r \geq 0 \quad , \alpha \neq 0 \quad . \tag{29.06.05}$$

→ 1582

For a one-dimensional motion the frequency of the small oscillations, ω_{R}, around a stable equilibrium position, at $r = r_0$, in the potential energy $\widetilde{\Phi}[r]$, is given by:

$$\boxed{\omega_{\text{R}}^2 \equiv \frac{\widetilde{\Phi}''[r_0]}{m}} \quad .$$

Therefore the result from equation (29.06.04) is:

$$\boxed{\omega_{\text{R}}^2 \equiv \frac{\Phi''_{\text{E}}[r_0]}{m} \Longrightarrow \omega_{\text{R}}^2 = \frac{\Phi''[r_0]}{m} + 3\omega_0^2} \quad . \tag{29.06.06}$$

→ 1583 1584

Consider now the potential energy in equation (29.06.05). One finds, from equation (29.03.15):

$$\omega_0^2 = -\frac{\alpha\gamma}{m} r_0^{\alpha-2} = \frac{1}{m\,(\alpha-1)}\Phi'' \quad ,$$

DRAFT - IN PROGRESS

and therefore, from equation (29.06.06), one finds:

$$\boxed{\omega_{\mathrm{R}}^2 = (\alpha+2)\,\omega_0^2} \quad , \tag{29.06.07}$$

→ 1583

which, implicitly, shows that the equilibrium is stable for $\alpha > -2$.

Note that for $\alpha = 2$ the effective potential is an inverse square potential whose sign is given by the relative magnitude of the two coefficients of the physical potential and centrifugal potential. It is a monotonic function and therefore it does not admit circular orbits.

Note the following cases:

- $\alpha = -1$, the Kepler and Coulomb problem, $\omega_{\mathrm{R}} = \omega_0$;
- $\alpha = +2$, the harmonic oscillator, $\omega_{\mathrm{R}} = 2\omega_0$, that is the radial distance oscillates twice during a $\Delta\varphi = 2\pi$ turn (due to the fact the orbit is always an ellipse centered on the force field).

Equation (29.06.07) shows that the perturbed orbit is closed if and only if $\sqrt{\alpha+2}$ is a rational number. Compare with the statement of the Bertrand theorem, § 29.03.08.

29.06.12
Precession of the Perihelion of a Near Circular Stable Orbit in a Inverse Square Force Field

This § is referenced at pages:
[1585, 1585, 1628]

Consider the potential energy:

$$\Phi[r] = -\frac{\gamma}{r} - \frac{\epsilon}{r^\beta} \equiv \Phi_0[r] + \Phi_1[r] \qquad \text{with} \qquad r \geq 0 \quad , \qquad \gamma > 0 \quad , \qquad \beta > 0 \quad ,$$

→ 1584

$$f[r] = -\frac{\mathrm{d}\Phi}{\mathrm{d}r} = -\frac{\gamma}{r^2} - \frac{\beta\epsilon}{r^{1+\beta}} \quad ,$$

where the $\Phi_1[r]$ term is much smaller than the $\Phi_0[r]$ term at all the points in the orbit:

$$\frac{\epsilon}{r^\beta} \ll \frac{\gamma}{r} \qquad \text{for any } r \text{ along the orbit} \qquad \Longrightarrow \epsilon \ll \gamma r^{\beta-1} \quad . \tag{29.06.08}$$

→ 1584

The potential is therefore broadly attractive, as it is dominated by the Kepler attractive term.

Note that with the above convention the quantity ϵ (the perturbation parameter) is not dimensionless. To avoid complicating the notation one might keep in mind the it might be linked to a truly dimensionless quantity, $\bar{\epsilon}$, by:

$$\epsilon = \bar{\epsilon} r_0^\beta \quad ,$$

where r_0 is any suitable distance, such as the radius of the unperturbed orbit.

Determine the frequency of the small radial oscillations around a circular orbit and, based on it, determine the precession of the perihelion of the orbit due to the perturbation $\Phi_1[r]$, as the pure $\Phi_0[r]$ term will always give closed orbits, that is no precession of the perihelion.

$$\Phi'[r] = \frac{\gamma + \beta\epsilon r^{1-\beta}}{r^2} \quad ,$$

$$\Phi''[r] = -\frac{2\gamma}{r^3} - \frac{\epsilon\beta\,(1+\beta)}{r^{2+\beta}} \quad .$$

Let $r = r_0$ be the radius of the circular orbit (for the given energy and|or angular momentum). Equation (29.03.15) implies that the exact revolution frequency for circular orbits in the perturbed potential is:

$$\boxed{\omega_0^2 = \frac{1}{m}\left(\frac{\gamma}{r_0^3} + \frac{\beta\epsilon}{r_0^{\beta+2}}\right) = \frac{1}{mr_0^2}\left(\frac{\gamma}{r_0} + \frac{\beta\epsilon}{r_0^\beta}\right)} \quad .$$

DRAFT IN PROGRESS

CC BY NC ND

This revolution frequency differs by only a small amount (first-order in the perturbation parameter ϵ) from the revolution frequency of the unperturbed force:

$$\boxed{\omega_0^2\Big|_{\text{non-pert}} = \frac{\gamma}{mr_0^3}} \quad ,$$

thanks to the condition (29.06.08).

If the real orbit is only slightly different from a circular orbit in the exact perturbed potential the precession of perihelion can be calculated by means of the frequency of the radial oscillation around the equilibrium position. Equation (29.06.06) then implies:

$$\boxed{\omega_{\text{R}}^2 = \frac{\Phi''[r_0]}{m} + 3\omega_0^2 = \frac{1}{m}\left(\frac{\gamma}{r_0^3} + \frac{\epsilon\beta\,(2-\beta)}{r_0^{\beta+2}}\right) = \frac{1}{mr_0^2}\left(\frac{\gamma}{r_0} + \frac{\epsilon\beta\,(2-\beta)}{r_0^{\beta}}\right)} \quad .$$

This radial oscillation frequency, also, differs by only a small amount from the radial oscillation frequency of the unperturbed force thanks to the condition (29.06.08).

The approximate perihelion precession, $\Delta\varphi_0$, can be calculated by:

$$\boxed{\Delta\varphi_0 + 2\pi \simeq \omega_0 T_{\text{R}} = 2\pi\frac{\omega_0}{\omega_{\text{R}}} = 2\pi\left(1 + \frac{\beta\epsilon\,(\beta-1)}{2\gamma}r_0^{1-\beta} + \frac{\beta^2\epsilon^2\,(\beta-1)\,(3\beta-7)}{8\gamma^2}r_0^{2-2\beta} + \mathcal{O}\,(\epsilon)^3\right)} \quad .$$

The above expression assumes that the revolution angular velocity can be treated as a constant, ω_0, or, better to say, that the average revolution angular velocity equals ω_0, the revolution angular velocity of the circular orbit. This seems to be a reasonable assumption because the real orbit is, in any case, a slightly perturbed orbit with respect to the circular orbit.

To first-order the azimuthal frequency, $\dot{\varphi}$, (revolution angular velocity) is affected (changed) with respect to the circular orbit one, ω_0, because the angular momentum does not change and therefore, as the distance from the center in a non-circular orbit does actually change, the azimuthal frequency must change. In fact:

$$\ell \equiv mr^2\dot{\varphi} = \ell_0 = mr_0^2\omega_0 \implies \dot{\varphi} = \frac{\ell}{mr^2} \simeq \frac{\ell}{mr_0^2}\left(1 - 2\frac{\Delta r}{r_0}\right) = \omega_0\left(1 - 2\frac{\Delta r}{r_0}\right) \quad .$$

The latter shows that the value of $\dot{\varphi}$, when averaged along a full orbit, gives ω_0. In the small-oscillations approximations used here the potential energy near the minimum is supposed to be a quadratic function (which implies, in particular, that it is symmetrical) and the radial motion is then an harmonic motion. Therefore, in this approximation, the averaging can be done both in time and in the radial position.

In the significant case of $\beta = 2$ it reduces, to first-order in ϵ, to:

$$\boxed{\Delta\varphi_0 = \frac{2\pi\epsilon}{\gamma r_0}} \quad .$$

The result gives the precession of the perihelion due to the presence of the perturbation term, because the pure inverse square law gives no precession and $\omega_{\text{R}}^2 = \omega_0^2$. The additional term implies: $\omega_{\text{R}}^2 \neq \omega_0^2$.

29.06.13

Inverse Cube Law Perturbation to the Inverse Square Law

Consider the force law:

$$f[r] = -\frac{\gamma}{r^2} - \frac{2\epsilon}{r^3} \qquad \text{with } \frac{2|\epsilon|}{r^3} \ll \frac{|\gamma|}{r^2} \text{ for all } r \text{ in the interesting range} \quad , \tag{29.06.09}$$

→ 1584 1585

where an inverse cube law is a perturbation to the inverse square law. Note that the force law corresponds to the potential (29.06.12) with $\beta = 2$, which explains the presence of the factor 2 in the expression (29.06.09).

Determine the equation of the orbit.

The Binet equation gives:

$$u''[\varphi] + \left(1 - \frac{2m\epsilon}{\ell^2}\right)u[\varphi] = \frac{m\gamma}{\ell^2} \quad ,$$

IN PREPARATION

CC BY NC ND

whose general solution is:

$$u[\varphi] = B\cos\left[\alpha\left(\varphi-\varphi_0\right)\right] + \frac{m\gamma}{\ell^2}\left(\frac{1}{1-\dfrac{2m\epsilon}{\ell^2}}\right) \qquad \alpha \equiv \sqrt{1-\frac{2m\epsilon}{\ell^2}} \simeq 1-\frac{m\epsilon}{\ell^2} \quad .$$

The general solution shows that the angular distance (azimuthal distance) between any two successive maxima of u (that is perihelia) or between any two successive minima of u (that is aphelia), that is the period of the function, is:

$$\Delta\varphi = \frac{2\pi}{\alpha} \simeq 2\pi\left(1+\frac{m\epsilon}{\ell^2}\right) \quad .$$

The orbit, as long as the inverse cube law is only a small perturbation to the inverse square law, can be thought as an ellipse (for a bound system) whose perihelion is rotating at every orbit by

$$\Delta\varphi_0 = \frac{2m\pi\epsilon}{\ell^2} \quad . \tag{29.06.10}$$

→ 1585

This expression is generally correct, not only for almost circular orbits, as in § 29.06.12. When can then apply the result (29.06.10) to an almost circular orbit, in the force law (29.06.09):

$$\ell_0 = mr_0^2\omega_0 \quad ,$$
$$m\omega_0^2 r_0 = \frac{\gamma}{r_0^2} + \frac{2\epsilon}{r_0^3} \quad ,$$
$$2\epsilon \ll \gamma r_0 \quad ,$$

to obtain the same result as in § 29.06.12:

$$\Delta\varphi_0 = \frac{2m\pi\epsilon}{\ell^2} = \frac{2m\pi\epsilon}{m^2 r_0^4\omega_0^2} = \frac{2m^2\pi\epsilon r_0}{m^2 r_0^4\left(\dfrac{\gamma}{r_0^2}+\dfrac{2\epsilon}{r_0^3}\right)} = \frac{2\pi\epsilon}{(r_0\gamma+2\epsilon)} \simeq \frac{2\pi\epsilon}{r_0\gamma} \quad .$$

29.06.14
On Bertrand Theorem

It is possible to find closed particular orbits for a general potential law by finding a particular closed orbit for a generic central force field.

In fact, any attractive force field admits circular orbits as a solution.

- Verify using equation (29.03.05), by explicit calculation, the conservation of mechanical energy.

29.06.16
Speed Along a Keplerian Orbit

Consider a mass particle of mass m orbiting around an object of mass M. Show that the velocity along the orbit is as follows.

Elliptic orbit:

$$v^2 = \frac{|\gamma|}{m}\left(\frac{2}{r} - \frac{1}{a}\right) \quad . \tag{29.06.11}$$

→ 1589

Note that γ is necessarily positive.

Parabolic orbit:

$$v^2 = \frac{|\gamma|}{m}\left(\frac{2}{r}\right) \quad . \tag{29.06.12}$$

Note that γ is necessarily positive.

Hyperbolic orbit:

$$v^2 = \frac{|\gamma|}{m}\left(\frac{2}{r} + \frac{1}{a}\right) \quad . \tag{29.06.13}$$

Use the mechanical energy conservation and the relations (29.04.21), (29.04.22), (2).

29.06.17
Third Kepler Law

Derive the third Kepler law.

From the expression of the areolar velocity, $\frac{\mathrm{d}A}{\mathrm{d}t} = \frac{\ell}{2m}$, and the are of the ellipse, $A = \pi ab$, one finds:

$$T = \frac{2m\pi a^2}{\ell}\sqrt{1-e^2} = 2\pi\sqrt{\frac{ma^3}{\gamma}} \quad .$$

29.06.18
Third Kepler Law and the Measurement of the Masses of a Binary Stellar System

©|B.W.Carroll & D.A.Ostlie, *An Introduction To Modern Astrophysics*, ..., ..., 1stEd., ...|||

Show how to use the Third Kepler law for the measurement of the total mass of a binary stellar system.

From the orbital period the sum of the masses is determined. From the relative distance with respect to common Center-Of-Mass the ration of the masses is determined.

This works in principle, in practice the geometry of the system with respect to the line of sight needs to be accounted for.

This § is referenced at pages:
[Never referenced.]

Un satellite di massa m è in orbita circolare attorno alla Terra ad una distanza $r = r_0$ dal centro della Terra. Sul satellite agisce una forza di attrito resistente, dovuta alla resistenza degli strati alti dell'atmosfera, di valore piccolo rispetto alla forza gravitazionale e avente direzione opposta alla sua velocità.

Supponendo che l'orbita sia sempre circolare con raggio lentamente variabile discutere l'evoluzione del moto del satellite in termini della sua energia meccanica e del suo momento angolare.

WORKED SOLUTION

A causa della presenza della forza di attrito resistente $\mathbf{f}$, che ha momento non nullo rispetto al centro della Terra, il momento angolare del satellite non si conserva. Tuttavia l'equazione del moto radiale, per le ipotesi fatte di orbita circolare e forza di attrito $\mathbf{f}$ antiparallela alla velocità $\mathbf{v}$ del satellite, resta la stessa che si ha nel caso in cui $\mathbf{f}$ non è presente

$$\frac{\mathcal{G}Mm}{r^2} = m\frac{v^2}{r} = m\omega^2 r \tag{29.06.14}$$

→ 1587 1588

L'energia meccanica del satellite non è conservata a causa della presenza della forza dissipativa $\mathbf{f}$ e si scrive, in virtù dell'equazione (29.06.14),

$$E = \mathcal{K} + \Phi = \frac{1}{2}mv^2 - \frac{\mathcal{G}Mm}{r} = -\mathcal{K} = \frac{\Phi}{2} < 0 \tag{29.06.15}$$

→ 1587

ed è negativa essendo il satellite gravitazionalmente legato. Denotando con L il lavoro fatto dalla resistenza del mezzo, non conservativa, il bilancio energetico diventa

$$\Delta E = L < 0 \tag{29.06.16}$$

In generale L può includere il lavoro di altre forze, conservative e non. Dalla relazione (29.06.15) si ha

$$\mathrm{d}L = \mathrm{d}E = \frac{1}{2}\,\mathrm{d}\Phi = \frac{\mathcal{G}Mm}{2r^2}\,\mathrm{d}r < 0 \implies \mathrm{d}r < 0 \quad ,$$

$$\mathrm{d}L = \mathrm{d}E = -\,\mathrm{d}\mathcal{K} = -\frac{m}{2}\,\mathrm{d}v^2 < 0 \implies \mathrm{d}v^2 > 0 \quad .$$

da cui si deduce che, essendo $\Delta E < 0$, il raggio dell'orbita diminuisce mentre il modulo della velocità del satellite aumenta. Si noti che il legame inverso tra r e v può essere dedotto già dall'equazione (29.06.14) che da sola non permette però di capire se r aumenti o diminuisca (e di conseguenza l'andamento di v). Le considerazioni energetiche, partendo dal fatto che $\Delta E = L < 0$, permettono di discriminare tra i due casi. In generale quindi se l'energia meccanica totale diminuisce anche il raggio dell'orbita diminuisce mentre se l'energia meccanica totale aumenta (cioè in presenza di una forza non resistente ma che compie lavoro positivo) il raggio dell'orbita aumenta. Le considerazioni energetiche fatte non dipendo dal tipo di forza tangenziale che agisce sul satellite ma solo dal segno del lavoro che questa compie. L'energia dissipata per attrito e quella che va in aumento di energia cinetica sono entrambe ottenute a spese dell'energia potenziale gravitazionale. Infatti si può scrivere dall'equazione (29.06.15),

$$-\,\mathrm{d}\Phi = -2\,\mathrm{d}E = -\,\mathrm{d}L + \,\mathrm{d}\mathcal{K}$$

da cui risulta come l'energia potenziale gravitazionale persa, $-\,\mathrm{d}\Phi > 0$, si ripartisce in parti uguali in aumento di energia cinetica, $\mathrm{d}\mathcal{K} > 0$ ed energia che il satellite cede all'esterno tramite la forza

dissipativa di attrito $-\,\mathrm{d}L > 0$ (L è il lavoro che l'ambiente esterno compie sul satellite, negativo, e $-L$ è il lavoro che il satellite compie sull'ambiente esterno, positivo).
Il momento angolare del satellite vale

$$l = mrv = m\sqrt{\mathcal{G}Mr} = \frac{\mathcal{G}Mm}{v} \quad ,$$

e quindi diminuisce nel caso in cui il raggio dell'orbita diminuisce (in quanto in tal caso il momento della forza resistente è opposto al momento angolare) e aumenta nel caso in cui il raggio dell'orbita aumenta (in quanto in tal caso il momento della forza resistente è concorde al momento angolare).
La legge di variazione del momento angolare fornisce l'equazione differenziale per r

$$\frac{\mathrm{d}r}{\mathrm{d}t} = \frac{2f[v]}{m\sqrt{\mathcal{G}M}}r^{3/2} = -k\frac{2}{m\sqrt{\mathcal{G}M}}r^{3/2}v \quad , \tag{29.06.17}$$

→ 1588

dove, in generale, la forza resistente $\mathbf{f} = -k\mathbf{v}$ dipende dal modulo della velocità che va espressa nell'equazione (29.06.17) in funzione di r, $v = v[r]$, tramite l'equazione (29.06.14).
Ne segue che la proiezione tangenziale dell'equazione del moto risulta

$$m\frac{\mathrm{d}v}{\mathrm{d}t} = f[v] \quad .$$

Un caso di forza concorde con la velocità del satellite è nel problema § 31.04.05.

Una stella a simmetria sferica espelle una parte ΔM della sua massa totale M sotto forma di un sottile guscio sferico a simmetria sferica che si allontana all'infinito in un tempo breve. Un pianeta di massa m orbita inizialmente attorno alla stella su un'orbita circolare a distnza $r = r_0$ dal centro della stella. Si supponga di poter trascurare l'effetto sul pianeta dell'onda d'urto causata dal passaggio del guscio di materia e di poter considerare tale passaggio istantaneo.

1. Determinare l'effetto dell'espulsione della massa sull'orbita del pianeta.
2. Discutere la dinamica del pianeta in coordinate polari.

WORKED SOLUTION

Ammettendo per il problema in questione che il passaggio del guscio sferico alla distanza del pianeta possa essere schematizzato come una variazione, con discontinuità di prima specie, della forza che agisce sul pianeta si ha quindi che la velocità è a priori una funzione non derivabile (in senso stretto) all'istante del passaggio. Si osservi che essendo il pianeta soggetto ad una forza dipendente dal tempo la sua energia non è conservata.
Fatte queste premesse si ha allora che l'energia meccanica totale dopo che la massa ΔM si è allontanata all'infinito è

$$E' = \frac{1}{2}mv_0^2 - \frac{\mathcal{G}\,(M - \Delta M)\,m}{r_0}$$

in cui r_0 e v_0 sono le stesse che si avevano prima del passaggio del guscio sferico. L'energia

CC BY NC ND

meccanica totale è dunque variata e denotando con α la frazione $\Delta M/M$ di massa espulsa si ha

$$E' = E_0 + \frac{\alpha \mathcal{G} M m}{r_0} > E_0$$

Il pianeta guadagna dunque energia a spesa dell'energia meccanica della stella. Essendo l'orbita iniziale circolare si ha poi

$$E_0 = \frac{\Phi_0}{2} = \mathcal{K}_0$$

da cui

$$E' = \frac{\Phi_0}{2} + \frac{\alpha \mathcal{G} M m}{r_0} = \frac{\mathcal{G} M m}{r_0}\left[\alpha - \frac{1}{2}\right]$$

Da questa relazione segue subito che

$$E' > 0 \qquad \Leftrightarrow \qquad \alpha > \frac{1}{2}$$

che è la condizione per cui il pianeta viene espulso dall'orbita. Supponendo $0 < 2\alpha < 1$ in modo che il pianeta resti legato il semiasse maggiore a della nuova orbita ellittica si determina usando la relazione (29.06.11) tra energia meccanica e semiasse per un'orbita Kepleriana

$$E' = -\frac{\mathcal{G} M m\,(1-\alpha)}{2a} = \frac{\mathcal{G} M m}{r_0}\left[\alpha - \frac{1}{2}\right] \qquad \text{per } 0 < 2\alpha < 1$$

Si osservi che l'orbita diventa ellittica perché l'energia del pianeta aumenta ma il momento angolare resta costante. Si ricava allora

$$a = \left[\frac{\alpha - 1}{2\alpha - 1}\right] r_0 > r_0 \qquad \text{per } 0 < 2\alpha < 1$$

e il semiasse maggiore dell'orbita aumenta sempre essendo $E' > E_0$.
In coordinate polari l'equazione del moto radiale del pianeta si scrive

$$\mu\left(\ddot{r} - r\dot{\varphi}^2\right) = -\frac{\mathcal{G} M[t] m}{r^2}$$

in cui la massa della stella è variabile in funzione del tempo. Introducendo la conservazione del momento angolare, giustificata dal fatto che si suppone sempre simmetria sferica della distribuzione di massa della stella e del guscio espulso e quindi il pianeta soggetto ad un campo di forza centrale, si ha

$$\mu\left(\ddot{r} - \frac{l^2}{\mu^2 r^3}\right) = -\frac{\mathcal{G} M[t] m}{r^2}$$

L'energia allora non è conservata essendo la massa della stella dipendente dal tempo e variabile con discontinuità di prima specie all'istante in cui il guscio oltrepassa il pianeta. Si ha allora che $r[t]$ è una funzione continua ma $\ddot{r}$ è discontinua quindi il pianeta acquista un'accelerazione radiale che muta l'orbita da circolare ($\ddot{r} = 0$) in ellittica. Dalla conservazione del momento angolare del pianeta, $l = mr^2\dot{\varphi} = mrv_\varphi$, e dalla continuità di $\dot{r}$ si ha pure la continuità delle componenti tangenziale e radiale della velocità.

29.06.21
Gravitational Quadrupole Moment of the Sun

The gravitational **Quadrupole** moment of the Sun affects the orbit of planets, producing precession. Its exact value is important, for instance, in order to compare the measured precession with the expectation from the theory of general relativity.

29.06.22
Orbits Around a Non-Spherical Cylindrically Symmetric Planet

Consider a point-mass satellite orbiting around a non-spherical cylindrically symmetric planet. Whenever the force is not a central force, the direction of the force on the satellite is not always passing for a fixed point, as for a central force.

On the equatorial plane, the overall force is central but not purely $1/r^2$, in general. Based on the gravitational **Multipole** development, the monopole field, $1/r^2$, can be modified by other power laws.

Outside the equatorial plane, the overall force is not central and not purely $1/r^2$, in general. In order to conserve the total angular momentum of the planet-satellite, assumed to be isolated, the point mass must exert a torque on the planet to compensate the torque the planet exerts on the satellite.

29.06.23
Potential Energy for a Generic Power-Law Force and Long-Range Interactions

This § is referenced at pages:
[2570]

Consider a large homogeneous distribution of identical point particles, whose properties are invariant under rotation, interacting via a potential energy given, at large distances, by:

$$\Phi[r] = -\frac{k}{r^\alpha} \qquad \alpha > 0 \qquad \text{for large } r \quad .$$

Consider a generic particle and calculate its potential energy due to its interaction with all the other particles in a spherical region of radius R. We are only interested in the long-range behavior of the interaction and therefore we set a cut-off at a small distance, $r = e$, to avoid problems with the convergence of the integral at $r = 0$.

Show that for $0 < \alpha < 3$ the contribution to the potential energy of the particle is increasing while R. Therefore, in this case, the contribution of distant particles to the potential energy is dominating the contribution of nearby particles. This interaction is called a long-range interaction.

29-002 Expression of the Areolar Velocity

Demonstrate equation (29.02.03).

WORKED SOLUTION

In fact the area covered by the position vector in the (small) time interval Δt is given by:

$$\Delta\mathbf{S}[t,\Delta t] \simeq \frac{1}{2}|\,\mathbf{r}[t]\wedge\mathbf{r}[t+\Delta t]| = \frac{1}{2}|\,\mathbf{r}[t]\wedge(\mathbf{r}[t]+\Delta\mathbf{r}[t,\Delta t])| = \frac{1}{2}|\,\mathbf{r}[t]\wedge\Delta\mathbf{r}[t,\Delta t]| \quad ,$$

$$\Longrightarrow \lim_{\Delta t\longrightarrow 0}\frac{\Delta A}{\Delta t}[t,\Delta t] = \frac{1}{2}|\,\mathbf{x}\wedge\mathbf{v}| \quad .$$

Using the expression of $\mathbf{r}$ and $\mathbf{v}$ in polar coordinates the result that

$$\boxed{\frac{\mathrm{d}S}{\mathrm{d}t} = \frac{1}{2}r^2\dot{\varphi} \equiv \frac{c}{2}}$$

can be obtained.

29-003 Zero Angular Momentum Orbit in a Central Force Field

This § is referenced at pages:
[1567, 1592]

Show analytically that a zero angular momentum orbit in a Central Force Field is a rectilinear motion.

WORKED SOLUTION

A first solution can be obtained in the following way.
First of all:

$$\boldsymbol{\ell} \equiv \mathbf{r}\wedge\dot{\mathbf{r}} = 0 \longrightarrow \widehat{\mathbf{T}} \parallel \mathbf{r} \quad .$$

Moreover, due the central character of the force, equation (23.03.09) implies

$$\mathbf{r}\wedge\ddot{\mathbf{r}} = 0 \longrightarrow \mathbf{a} = \left(\frac{\mathrm{d}v}{\mathrm{d}t}\widehat{\mathbf{T}} + \frac{v^2}{\rho}\widehat{\mathbf{N}}\right) \parallel \mathbf{r} \longrightarrow \frac{v^2}{\rho}\mathbf{N}\wedge\mathbf{r} = 0 \quad .$$

As $\mathbf{N}\wedge\mathbf{r} \neq 0$, because $\mathbf{N}\wedge\mathbf{T} \neq 0$ by construction and $\widehat{\mathbf{T}} \parallel \mathbf{r}$, the latter equations imply $\rho^{-1} = 0$, that is the trajectory is a straight line.
Moreover, the straight line passes by the pole, because $\mathbf{r} \parallel \mathbf{v} \parallel \mathbf{a}$. In fact $\boldsymbol{\ell} = 0$ implies $\dot{\varphi} = 0$. Therefore $\varphi = \varphi_0$ is a solution and, because of the unicity of the solution, it is the solution.
A second, more formal, method to obtain the same solution is the following.

Consider any vector $\mathbf{u}$:

$$u^2 = \mathbf{u}\cdot\mathbf{u} \implies u\dot{u} = \mathbf{u}\cdot\dot{\mathbf{u}} \quad ,$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathbf{u}}{u}\right) = \frac{\dot{\mathbf{u}}u - \dot{u}\mathbf{u}}{u^2} = \frac{(\mathbf{u}\cdot\mathbf{u})\,\dot{\mathbf{u}} - (\mathbf{u}\cdot\dot{\mathbf{u}})\,\mathbf{u}}{u^3} = \frac{(\mathbf{u}\wedge\dot{\mathbf{u}})\wedge\mathbf{u}}{u^3} \quad .$$

Read also § 29-005.
Applying the relation to $\mathbf{u} = \mathbf{r}$.

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathbf{r}}{r}\right) = \frac{(\mathbf{r}\wedge\dot{\mathbf{r}})\wedge\mathbf{r}}{r^3} = \frac{\mathbf{c}\wedge\mathbf{r}}{r^3} \quad .$$

If $\mathbf{c} = \mathbf{0}$ then the vector $\mathbf{r}/r$ is constant and the motion is thus a straight line through the origin.

29-004 Non Central Force Fields

1. Find an example of a conservative non central force field.
2. Find an example of a conservative non radial force field.
3. Find an example of a non conservative radial force field.

29-005 An Identity

This § is referenced at pages:
[1591]

Demonstrate that:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathbf{r}}{r}\right) \equiv \frac{\mathrm{d}}{\mathrm{d}t}\widehat{\mathbf{e}}_r = \frac{1}{r}(\widehat{\mathbf{e}}_r\wedge(\dot{\mathbf{r}}\wedge\widehat{\mathbf{e}}_r)) \quad . \tag{29.07.01}$$

Read also § 29-003.

29-006 Inverse Cube Force Law

Determine the equation of the orbit in a inverse cube force law.
Use Binet equation, which is easily solved in this case (in fact, also the centrifugal-barrier term is an inverse cube force law).

29-007 Energia Potenziale Gravitazionale Di Una Sfera Omogenea

©|Berkeley Physics Course, in 5 Vol., , ..., McGraw-Hill, ...Ed., ...|||

Data una distribuzione sferica e omogenea di massa, avente massa totale M e raggio R, si calcoli l'energia potenziale gravitazionale.

AEH - IN PROGRESS

WORKED SOLUTION

$$M[r] = \int_0^r \rho[r]\, \mathrm{d}V = \rho \int_0^r \mathrm{d}V = \frac{4\pi}{3}\rho r^3 \qquad M = M[R] \quad ,$$

$$\mathrm{d}m = 4\pi\rho r^2\, \mathrm{d}r \quad ,$$

$$\boxed{\mathrm{d}\Phi = -\frac{\mathcal{G}M[r]}{r}\, \mathrm{d}m} \quad ,$$

$$\mathrm{d}\Phi = -\frac{4\pi\mathcal{G}}{3}\rho r^2\, \mathrm{d}m = -\frac{(4\pi)^2\,\mathcal{G}}{3}\rho^2 r^4\, \mathrm{d}r \quad ,$$

$$\Phi = -\frac{(4\pi)^2\,\mathcal{G}}{3}\rho^2 \int_{r=0}^{R} r^4\, \mathrm{d}r = -\frac{3}{5}\frac{\mathcal{G}M^2}{R} \quad .$$

Result:

$$\Phi = -\frac{3}{5}\frac{\mathcal{G}M^2}{R} \quad .$$

29-008 Effetto Sull'orbita Terrestre Dell'accumulo Di Polvere Interplanetaria

La Terra, nella sua orbita attorno al Sole, raccoglie $m = 1.0{\cdot}10^4$ ton di polvere interplanetaria all'anno. Determinare l'effetto del cambio di massa della Terra sull'orbita. Si considerino due modelli del fenomeno:

- la polvere interplanetaria viene catturata dalla Terra con un processo a distribuzione totalmente isotropa;
- la polvere interplanetaria è stazionaria rispetto al Sole e viene catturata dalla Terra che attraversa questa distribuzione stazionaria.

WORKED SOLUTION

Momento angolare si conserva di certo, sistema isolato. Ma è una assunzione: se la polvere fa drag... non si conserva... e diventa il problema del satellite.
Energia meccanica potrebbe variare ... conversione in energia interna con la caduta della polvere...

29-009 Moto in Campo Di Forza Centrale

Un punto materiale di massa m in un campo di forza centrale è soggetto ad un potenziale

$$V[r] = -\frac{\gamma}{r^\alpha} \qquad \text{con } \alpha = 1/2 \text{ e } \gamma > 0 \quad .$$

1. Determinare il periodo orbitale delle orbite circolari del punto materiale.

   WORKED SOLUTION

   $$\omega^2 = \frac{\alpha\gamma}{m}\frac{1}{r^{\alpha+2}} \longrightarrow \frac{\gamma}{2m}\frac{1}{r^{5/2}} \qquad T = \frac{\pi\sqrt{8m}}{\sqrt{\gamma}} r^{5/4} \quad .$$

2. Da quali parametri dipende il periodo orbitale delle orbite circolari?
3. Disegnare e discutere il grafico del potenziale efficace.
4. Per ogni fissato valore del momento angolare orbitale determinare l'energia meccanica minima possibile.

cc BY NC ND

WORKED SOLUTION

$$E_{\text{MIN}} = \frac{\gamma\,(\alpha-2)}{2}\left(\frac{m\alpha\gamma}{l^2}\right)^{\frac{\alpha}{2-\alpha}} \longrightarrow -\frac{3\gamma}{4\,(2)^{1/3}}\left(\frac{m\alpha\gamma}{l^2}\right)^{1/3} \quad .$$

5. Sono stabili le orbite circolari in tale potenziale?

29-010 Total Energy for an Elliptic Orbit in an Inverse-Square Field

Demonstrate the relation (29.04.21) for the total energy for an elliptic orbit, starting from the equation (29.04.03), applied to the perihelion and aphelion, and using equation (29.04.01.03).

WORKED SOLUTION

As the orbit is elliptic one necessarily has: $\gamma > 0$. The perihelion and aphelion are expressed by (when $B > 0$, that is perihelion at $\varphi = 0$):

$$\frac{1}{r_P} = +B + \frac{m\gamma}{\ell^2} \quad ,$$
$$\frac{1}{r_A} = -B + \frac{m\gamma}{\ell^2} \quad .$$

Therefore:

$$2a = r_P + r_A = \frac{\frac{m\gamma}{\ell^2}}{\frac{m^2\gamma^2}{\ell^4} - B^2} \Longrightarrow E = -\frac{\gamma}{2a} < 0 \quad .$$

29-011 A Circular Orbit

A particle of mass m is moving on a circular orbit of radius $R = 2b$ passing through the center of force of a power-law attractive central force with unknown exponent:

$$\Phi[r] = -\frac{\gamma}{r^\alpha} \qquad \gamma > 0 \quad .$$

- Determine the exponent for which such an orbit exists.
- Find the energy and angular momentum of this orbit.
- Determine the period of the orbit as a function of the radius of the orbit, γ and m.

29-012 A Circular Orbit in the Yukawa Potential

A particle of mass m is moving in the Yukawa potential:

$$\Phi[r] = -\frac{\gamma}{r}\exp\left[r/r_0\right] \qquad \gamma > 0 \qquad r_0 > 0 \quad .$$

- Show that circular orbits exist only if the angular momentum does not exceed a certain value, ℓ_{M}, and determine such a value.
- Show that for any value $\ell < \ell_{\text{M}}$, there exist two circular orbits, at different radii, r_1 and r_2, and that one of them is a stable orbit and the other one is an unstable one. Determine r_1 and r_2.
- Plot $r_1[\ell]$ and $r_2[\ell]$.

DRAFT PROGRESS

CC BY NC ND

WORKED SOLUTION

$$\frac{\mathrm{d}\Phi_{\mathrm{E}}[r]}{\mathrm{d}r} \propto m\gamma r \exp[r/r_0]\,(r+r_0) - r_0\ell^2$$

The first derivative might have either zero or two zeros. In the first case the effective potential energy is always decreasing while in the second case it has one relative maximum and one relative minimum.

The positive zero of the first derivative (flex point) is at:

$$r = r_0\frac{1+\sqrt{5}}{2} \quad ,$$

from which the value of ℓ_{M} follows.

$$\frac{l^2}{2\,m\,r^2} - \frac{\gamma}{\exp\frac{r}{\rho}r} \quad ,$$

$$\left(-\left(\frac{l^2}{m\,r^3}\right) + \frac{\gamma}{\exp\frac{r}{\rho}r^2} + \frac{\gamma}{\exp\frac{r}{\rho}r\,\rho}\right)\left(\frac{l^2}{2\,m\,r^2} - \frac{\gamma}{\exp\frac{r}{\rho}r}\right) \quad ,$$

$$\left(\frac{3\,l^2}{m\,r^4} - \frac{2\,\gamma}{\exp\frac{r}{\rho}r^3} - \frac{\gamma}{\exp\frac{r}{\rho}r\,\rho^2} - \frac{2\,\gamma}{\exp\frac{r}{\rho}r^2\,\rho}\right)\left(\frac{l^2}{2\,m\,r^2} - \frac{\gamma}{\exp\frac{r}{\rho}r}\right) + \quad ,$$

$$\left(-\left(\frac{l^2}{m\,r^3}\right) + \frac{\gamma}{\exp\frac{r}{\rho}r^2} + \frac{\gamma}{\exp\frac{r}{\rho}r\,\rho}\right)^2\left(\frac{l^2}{2\,m\,r^2} - \frac{\gamma}{\exp\frac{r}{\rho}r}\right) \quad .$$

29-013 Orbita in Campo Centrale

Si supponga di sapere che il moto di una particella in un campo di forza centrale ha un'orbita data, in coordinate polari, da:

$$r[\varphi] = r_0 \exp -\alpha\varphi \quad ,$$

con r_0 ed α costanti positive e $-\infty < \varphi < +\infty$.

Note that the symmetry with respect to the apsidal vectors cannot be satisfied because apsidal vectors do not exist for this orbit.

1. Determinare la legge della forza a cui è soggetta la particella e descrivere qualitativamente il moto.
2. Ricavare $r[t]$ e $\varphi[t]$.

29-014 Another Orbita in Campo Centrale

A point mass follows a circular orbit passing by the force center. Determine the force law.

WORKED SOLUTION

Inverse fifth power.

RUGPHYS

29-015 Still Another Orbita in Campo Centrale

A point mass follows a lemniscate orbit: $r^2 = a^2 \cos[2\varphi]$ Determine the force law.

WORKED SOLUTION

Inverse seventh power.

29-016 Still Another Another Orbita in Campo Centrale

Prove that the orbits $r = r_0 \exp -\varphi$ and $r = r_0/\varphi$ are both possible for the case of an inverse cube field of force. Explain physically how this is possible.

29-017 Sonda Spaziale in Interazione Con Giove

Il pianeta Giove ha un periodo di rivoluzione attorno al Sole $T = 11.87$ anni, raggio $r_G = 0.7{\cdot}10^5$ km e massa $M_G = 1.9{\cdot}10^{27}$ kg. A fini del presente problema l'orbita si può supporre circolare (eccentricità pari a 0.05) e la velocità orbitale, $\mathbf{V}$, costante. Una sonda spaziale si trova inizialmente a distanza da Giove pari a $r \simeq 50 r_G$ e si avvicina a Giove inseguendolo con velocità, $\mathbf{v} = \alpha \mathbf{V}$ ($\alpha = 2$), nel sistema di riferimento solidale con il Sole, parallela a quella di Giove, concorde in verso. Il parametro di impatto della sonda con Giove è b. La massa del Sole vale $M_S = 2.0{\cdot}10^{30}$ kg e la distanza di Giove dal Sole vale: 778330000 km.

1. Dimostrare che in tali condizioni l'effetto dell'attrazione gravitazionale del Sole sulla sonda può essere trascurato rispetto all'effetto dell'attrazione gravitazionale di Giove.

   WORKED SOLUTION

   $$\frac{F_S}{F_G} \approx \frac{M_S}{M_G}\left(\frac{r}{a}\right)^2 = 0.02 \quad .$$

2. Quale deve essere il parametro di impatto, b, per ottenere un angolo di deviazione della sonda pari a $\Delta\varphi = \pi/2$ nel sistema di riferimento solidale con il Sole?
3. Quanto vale la variazione di energia cinetica nel sistema di riferimento solidale con il Sole e nel sistema di riferimento solidale con Giove?
4. Quale è la velocità, nel sistema di riferimento solidale con Giove, della sonda al perielio?
5. Tenendo conto del raggio finito di Giove quale è, idealmente, la massima deviazione della traiettoria che si può ottenere, con la sonda, cioè, che viene rispedita quasi all'indietro?

29-018 Escape Speed From the Earth and From Solar System

©|Berkeley Physics Course, Vol. 1, *Mechanics*, 1965, McGraw-Hill, ...Ed., ...|§ 5||

Determine the minimum velocity necessary to a spaceship starting from the Earth to escape: the Earth; the Solar System.

DRAFT - IN-PROGRESS

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|||

Collision (also know as scattering processes) is the term used to refer to very fast interactions between two or more moving bodies that form, usually, an isolated system. During collisions very large Force|Torque|Interaction take place, usually of short range. A lot of information can be obtained about the results of collisions even without a precise knowledge of the interaction by using general principles, such as the exchange of energy, linear momentum, angular momentum.

Only collisions among point masses will be considered.

DRAFT-IN-PROGRESS

30.01 Introduction

At the microscopic level all interactions are conservative: therefore assuming conservation of the total energy is not a real limitation.

It is assumed that the interaction potential energy tends to zero at infinity.

The only real limitation of the classical treatment is the non-relativistic assumption, that is low velocities. This excludes from the treatment mass-less particles, (for instance photons), that are always relativistic particles. However, in **Galilei-Newton Mechanics** , massless particles cannot exist; if they existed, thanks to the **Cardinal Equations** , they are not affected by external forces nor torques.

The collision processes are supposed to take place starting from some time ($t \to -\infty$) when the particles are very distant between each other, and ending at a time ($t \to +\infty$) when they are again very distant between each other, after the interaction. In other words, one studies the initial and final state and forgets about any intermediate state.

30.01.01 Conservation Laws

In **Galilei-Newton Mechanics** , **Galilei-Invarian*** and linear momentum conservation implies mass conservation, read § 24.10.04.

In many cases the kinematic conservation laws, that is the laws of conservation of linear momentum, angular momentum and energy, alone, can be used to obtain useful results concerning the properties of various processes, including possibly showing that some specific process is forbidden, without information about the details of the interaction. These properties are independent of the particular type of interaction between the particles involved.

Also, the laws of conservation of electric charge and other charges, such as baryonic and leptonic numbers, whenever applicable, can be used to constrain the collision processes.

30.01.02 Elastic and Non Elastic Collisions

An elastic collision between two generic isolated systems is a collision such that the total kinetic energy remains constant. This definition is independent from Reference Frame. In fact, **Koënig theorem** for kinetic energy implies that the variation of the kinetic energy during the collision is expressed in terms of the velocities relative to the Center-Of-Mass of the system, as the kinetic energy of the motion of the Center-Of-Mass remains constant for the conservation of linear momentum. The kinetic energy relative to the Center-Of-Mass, being expressed in terms of relative velocities, is independent of the choice of Reference Frame.

As the collision processes are supposed to take place starting from some time ($t \to -\infty$) when particles are very distant and ending at a time ($t \to +\infty$) when they are very distant again, the potential energy of interaction is negligible both at the beginning and at the end of the process. Moreover, the potential energy from external fields is often supposed to be negligible.

Under these conditions the scattering process is elastic if and only if the identity (and masses) of the particles do not change, because this condition is necessary and sufficient to ensure the conservation of kinetic energy.

A inelastic collision between particles is characterized by the change in kinetic energy of the system, quantified by the so-called Q-value, Q:

$$\Delta\mathcal{K} = \mathcal{K}_{\mathrm{F}} - \mathcal{K}_{\mathrm{I}} \equiv -Q \qquad \begin{cases} \Delta\mathcal{K} > 0 \text{exo-energetic reaction} \\ \Delta\mathcal{K} < 0 \text{endo-energetic reaction} \end{cases} ,$$

DRAFT - IN PROGRESS

It possibly includes the change in number and | or mass of the particles, as classically the constraint on masses is that the sum of the masses before the collision is equal to the sum of the masses after the collision, read § 24.10.04.

Types of inelastic collisions:

- $Q = 0$ elastic collision;
- $Q > 0$ inelastic (endothermal) collision: kinetic energy is converted into internal energy of the collision partners (excitation of the collision partners);
- $Q < 0$ inelastic (exothermal) collision: internal energy is converted into kinetic translational energy (de-excitation of the collision partners).

The Q-value is Galilei invariant (read § 30-001).

30.01.03
Impact Parameter

This § is referenced at pages:
[Never referenced.]

The impact parameter, for a generic collision with two point particles in the initial state, is defined as follows.

Assume that, at the beginning, the particles are far-away and their interaction is negligible, and are far-away from any other source of interaction, and move with constant velocity in some Inertial Reference Frame .

The impact parameter is defined as the geometrical distance between the two straight lines giving the trajectories of the particles before the interaction. This is, by definition, the minimum distance of the two straight lines. It is calculated as discussed in section § 15-015.

In **Galilei-Newton Mechanics** , as particles must have positive mass, one can always choose the Rest Frame of one particle. In this Reference Frame, usually defined as the Reference Frame of the **target** particle, the (scalar) impact parameter is defined as:

$$b \equiv \left| \frac{\mathbf{r} \wedge \mathbf{v}_\infty}{v_\infty} \right| \quad , \tag{30.01.01}$$

→ 1563

in terms of the velocity of the projectile particle at large distance, $\mathbf{v}_\infty$: it is the distance between the target particle and the line of flight, at large distances, of the projectile particle.

Note that it is not in general possible to find a Inertial Reference Frame such that the impact parameter is zero.

One distinguishes two-body collisions by their kinematics.

- Central/straight-line collisions: the impact parameter is zero; the colliding point-masses move along their connecting lines both before and after the collision; one coordinate is sufficient to describe the collision.
- Non-central collisions: the impact parameter is greater than zero; in the Rest Frame of any one of the two particles the position of the particles and the linear trajectory of the other define a plane, the plane of collision; for a given incident energy the impact parameter determines the orbital angular momentum of the relative motion of the two point-masses.

DRAFT - IN PROGRESS

30.02 Fixed-Target - Relation Between Laboratory and Center-Of-Mass System

Fixed target of mass M; projectile of mass m.

The kinematics of the elastic non-relativistic collision between two pint-particles is better discussed in the Center-Of-Mass Reference Frame.

La relazione tra angolo di scattering nel Reference Frame del laboratorio e nel Reference Frame del centro di massa è data da

$$\tan[\theta] = \frac{\sin[\theta^\star]}{\cos[\theta^\star] + (m/M)} \qquad 0 \leq \theta^\star \leq \pi \qquad 0 \leq \theta \leq \pi \quad , \tag{30.02.01}$$

completamente definita dal rapporto delle masse.

However, to make easier the choice of the quadrant of the angle in the Laboratory frame it is better to separate the sinus and cosinus:

$$\sin[\theta] = \sin[\theta^\star] \qquad \cos[\theta] = \cos[\theta^\star] + (m/M) \quad , \tag{30.02.02}$$

The angle in the Lab versus angle in the Center-Of-Mass for different values of the projectile to target masses ratio, ρ, is shown in figure 30.11.

Nel Reference Frame del Center-Of-Mass l'angolo non è vincolato (dai principi di conservazione), ma potrebbe esserlo dalla dinamica.

Se $m \gg M$ allora $|\tan[\theta]| \ll 1$: cioè se la massa del proiettile è grande rispetto a quella del bersaglio il proiettile viene poco deviato.

Se $m \ll M$ allora $\tan[\theta] \simeq \tan[\theta^\star]$: se la massa del proiettile è piccola rispetto a quella del bersaglio l'angolo di deflessione nel Reference Frame del Laboratorio diventa uguale a quello nel Reference Frame del centro di massa.

Esperimento di Rutherford: l'osservazione di eventi con scattering a grande angolo implica che ci siano dei bersagli di massa molto maggiore di quella dell'elettrone.

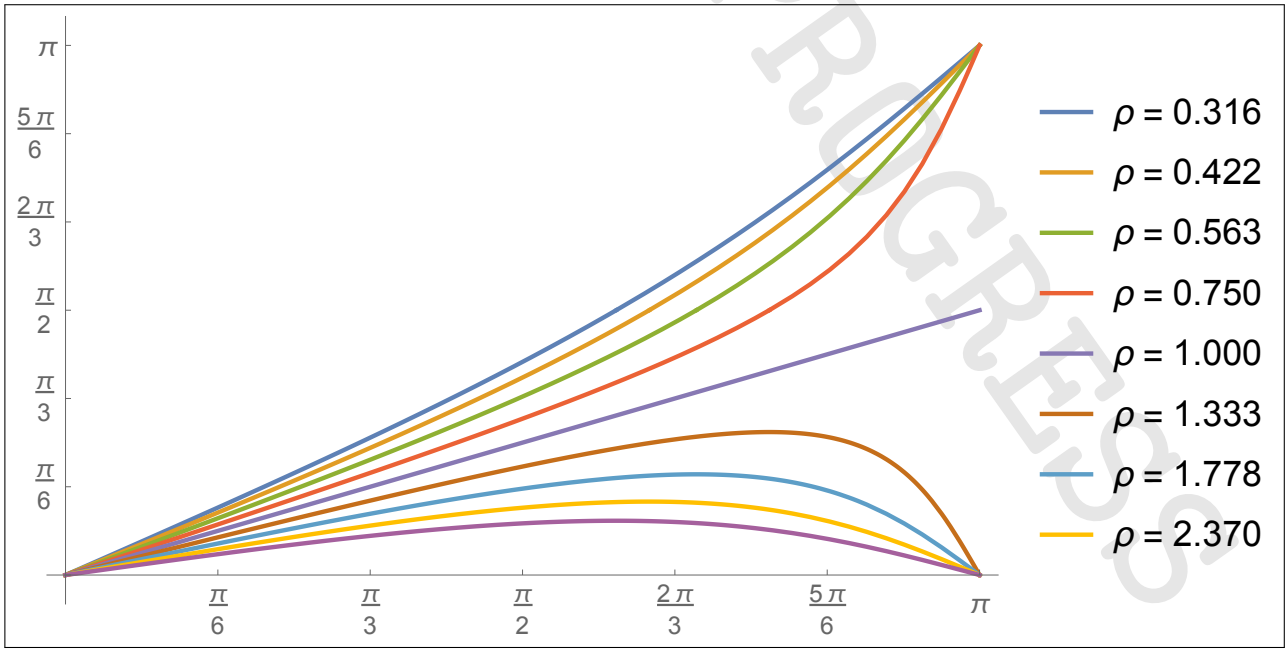

Figure 30.11: fixed target: angle in the Lab versus angle in the Center-Of-Mass for different values of the projectile to target masses ratio, ρ.

DRAFT IN PROGRESS

30.03 Two-Body Elastic Collisions

This § is referenced at pages:
[Never referenced.]

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|14||

Read § ?? for the relativistic treatment.

30.03.01 Classical Kinematics of Two-Particles Collisions

Consider a two-to-two particles elastic collision, between the two particles, A_1 and A_2:

$$A_1[m_1, \mathbf{p}_1] + A_2[m_2, \mathbf{p}_2] \longrightarrow A_1[m_1, \mathbf{p}'_1] + A_2[m_2, \mathbf{p}'_2] \quad ,$$

in the Laboratory frame.

As the collision is elastic, the identity and mass of each particle is unchanged by the collision.

Let θ_k be the scattering angle of the two particles, $(k = 1, 2)$, in the laboratory frame:

$$\cos[\theta_k] = \frac{\mathbf{p}'_k \cdot \mathbf{p}_k}{|\mathbf{p}'_k||\mathbf{p}_k|} \quad .$$

The relative position of the two particles is, by definition:

$$\mathbf{r} \equiv \mathbf{r}_2 - \mathbf{r}_1 \quad .$$

The relative velocity of the two particles is, by definition:

$$\mathbf{v} \equiv \mathbf{v}_2 - \mathbf{v}_1 \quad .$$

30.03.01.01 SdRCM

The [glo:CMRF]Center-of-Momenta Reference Frame is defined as the non inertial (in general) Reference Frame frame whose origin is fixed at the Center-Of-Mass of the system and which is translating with respect to the inertial Laboratory frame.

30.03.01.02 CM and Positions

The position of the [glo:CMRF]Center-of-Momenta Reference Frame, as seen by the Laboratory frame, is:

$$\mathbf{R} \equiv \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{M} = \mu\frac{\mathbf{r}_1}{m_2} + \mu\frac{\mathbf{r}_2}{m_1} \qquad M \equiv m_1 + m_2 \qquad \mu \equiv \frac{m_1 m_2}{M} \quad .$$

The relation between Center-Of-Mass ($\mathbf{r}^\star_k$) and Laboratory frame ($\mathbf{r}_k$) positions is:

$$\mathbf{r}_k \equiv \mathbf{r}^\star_k + \mathbf{R} \Longrightarrow \mathbf{r}^\star_k = \mathbf{r}_k - \mathbf{R} = m_j\left(\frac{\mathbf{r}_k - \mathbf{r}_j}{M}\right) \begin{cases} \text{if } k = 1 \text{ then } j = 2\text{, no sum on the indexes} & , \quad , \\ \text{if } k = 2 \text{ then } j = 1\text{, no sum on the indexes} & , \end{cases} \quad .$$

Equivalentely:

$$\mathbf{r}_k \equiv \mathbf{r}^\star_k + \mathbf{R} \Longrightarrow m_k\mathbf{r}^\star_k = m_k\mathbf{r}_k - m_k\mathbf{R} = \mu\left((\mathbf{r}_k - \mathbf{r}_j)\right) \begin{cases} \text{if } k = 1 \text{ then } j = 2\text{, no sum on the indexes} & , \quad , \\ \text{if } k = 2 \text{ then } j = 1\text{, no sum on the indexes} & , \end{cases} \quad .$$

The following relation apply, by definition of Center-Of-Mass:

$$m_1\mathbf{r}_1{}^\star + m_2\mathbf{r}_2{}^\star = 0 \quad .$$

DRAFT - IN PROGRESS

30.03.01.03 CM and Velocities/momenta

The velocity of the [glo:CMRF]Center-of-Momenta Reference Frame, as seen by the Laboratory frame, is:

$$\mathbf{V} \equiv \frac{\mathrm{d}\mathbf{R}}{\mathrm{d}t} = \frac{m_1\mathbf{v}_1 + m_2\mathbf{v}_2}{m_1+m_2} \equiv \frac{\mathbf{P}}{M} \quad .$$

The relation between Center-Of-Mass ($\mathbf{v}_k^\star$) and Laboratory frame ($\mathbf{v}_k$) velocities is:

$$\mathbf{v}_k \equiv \mathbf{v}_k^\star + \mathbf{V} \implies \mathbf{v}_k^\star = \mathbf{v}_k - \mathbf{V} = m_j\left(\frac{\mathbf{v}_k - \mathbf{v}_j}{M}\right) \begin{cases} \text{if } k=1 \text{ then } j=2\text{, no sum on the indexes} & , \quad , \\ \text{if } k=2 \text{ then } j=1\text{, no sum on the indexes} & , \end{cases} .$$

Equivalently:

$$\mathbf{p}_k \equiv m_k\mathbf{v}_k^\star + m_k\mathbf{V} \implies \mathbf{p}_k^\star \equiv m_k\mathbf{v}_k - m_k\mathbf{V} = \mu\left(\mathbf{v}_k - \mathbf{v}_j\right) \begin{cases} \text{if } k=1 \text{ then } j=2\text{, no sum on the indexes} & , \quad , \\ \text{if } k=2 \text{ then } j=1\text{, no sum on the indexes} & , \end{cases} .$$

30.03.01.04 Expression of the Dynamical Quantities With Respect to the Center-Of-Mass

This § is referenced at pages:
[1605]

The following relation apply, by definition of Center-Of-Mass:

$$\mathbf{p}_1^\star + \mathbf{p}_2^\star = 0 \quad .$$

The linear momentum relative to the Center-Of-Mass, expressed in terms of the reduced mass of the pair of particles as follows:

$$\mathbf{p}_k^\star \equiv m_k\mathbf{v}_k^\star = \frac{m_1m_2}{m_1+m_2}\left(\mathbf{v}_k - \mathbf{v}_j\right) \equiv \mu\left(\mathbf{v}_k - \mathbf{v}_j\right) \begin{cases} \text{if } k=1 \text{ then } j=2\text{, no sum on the indexes} & , \quad , \\ \text{if } k=2 \text{ then } j=1 & , \end{cases} .$$

The linear momentum relative to the Center-Of-Mass, can be also expressed in terms of the relative velocity of the two particles, which is invariant under transformation between different inertial frames, as:

$$\begin{aligned} \mathbf{v} &\equiv \mathbf{v}_2 - \mathbf{v}_1 \qquad \text{relative velocity of particle 2 with respect to particle 1} \quad , \\ \mathbf{p}_1^\star &= -\mu\mathbf{v} \quad , \\ \mathbf{p}_2^\star &= +\mu\mathbf{v} \quad , \\ \mathbf{p}^\star &\equiv +\mu\mathbf{v} = +\mu\left(\mathbf{v}_2 - \mathbf{v}_1\right) \quad . \end{aligned}$$

The kinetic energy can be decomposed by means of the **Koënig theorem** : equation (24.11.05).

$$\mathcal{K} = \mathcal{K}_{\mathrm{CM}} + \mathcal{K}^\star = \frac{1}{2}MV^2 + \frac{1}{2}\left(m_1\mathbf{v}_1^{\star 2} + m_2\mathbf{v}_2^{\star 2}\right) = \frac{1}{2}MV^2 + \frac{1}{2}\mu v^2 = \frac{P^2}{2M} + \frac{p^{\star 2}}{2\mu} \quad .$$

The orbital angular momentum can be decomposed by means of the **Koënig theorem** : equation (24.11.02).

In the case of a two-particle system the angular relative to the Center-Of-Mass can be expressed (equation (24.11.02)), as:

$$\mathbf{L}^\star \equiv \mathbf{r}_1^\star \wedge \mathbf{p}_1^\star + \mathbf{r}_2^\star \wedge \mathbf{p}_2^\star = \mathbf{r}_1 \wedge \mathbf{p}_1^\star + \mathbf{r}_2 \wedge \mathbf{p}_2^\star = \mathbf{r} \wedge \mathbf{p}^\star = \mu\,\mathbf{r} \wedge \mathbf{v} \quad . \tag{30.03.01}$$

→ 1605

Conservazione dell'energia significa conservazione dell'energia cinetica in un processo di scattering tale che l'energia potenziale è nulla prima e dopo la interazione, e, dalla espressione dell'energia cinetica scritta sopra, questo significa conservazione dell'energia cinetica relativa e cioè del modulo dell'impulso nel Reference Frame del Center-Of-Mass (la quantità di moto si conserva). Therefore elastic scattering means:

$$\left|\mathbf{p}_k^{\star\prime}\right| = \left|\mathbf{p}_k^\star\right| \quad .$$

La massima energia che può essere persa dal sistema è data dal termine di energia cinetica relativa: $p^{\star 2}/(2\mu)$. Read § 30.04.

30.03.01.05 Urto Elastico Contro Bersaglio Fermo: Sistema Del Laboratorio

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|||

The kinematics of the elastic non-relativistic collision between a particle and a fixed target will be discussed in the laboratory Reference Frame. It is not a great kinematic limitation as for any collision one can stay in the Reference Frame of one of the two particles which is always possible because, in classical physics, all particles have a non-zero mass. The requirement of elastic collision is a limitation for macroscopic bodies but it is not a limitation at the microscopic level, where energy is always conserved.

Note that a different, and simplified, notation is used with respect to the general notation of section § 30.03.01.04. In that section the two particles are considered at the same level and therefore the notation $\{...\}_1$ and $\{...\}_2$ is used. On the other hand in this section there is a clear asymmetry between the two particles, as one of them is initially at rest: therefore the quantities related to the particle at rest will be denoted with upper-case letters while quantities related to the particle in motion (the projectile) will be denoted with lower-case letters.

The choice of a fixed target is not a real limitation, because one can always use as a Reference Frame the Reference Frame where the target is at rest.

Particella di massa m, velocità $\mathbf{v}$ e impulso $\mathbf{p}$ che incide su un bersaglio di massa M e impulso $\mathbf{P} = 0$ (bersaglio fermo). Gli impulsi e velocità dopo l'urto sono rispettivamente $\mathbf{p}'$, $\mathbf{P}'$ e $\mathbf{v}'$, $\mathbf{V}'$.

L'angolo di deflessione della prima particella è θ, l'angolo con cui parte la seconda particella, rispetto alla direzione originale dell'impulso $\mathbf{p}$ è α. That is:

$$\cos[\theta] \equiv \frac{\mathbf{p}'\cdot\mathbf{p}}{|\mathbf{p}'||\mathbf{p}|} \qquad \cos[\alpha] \equiv \frac{\mathbf{P}'\cdot\mathbf{p}}{|\mathbf{P}'||\mathbf{p}|} \quad .$$

Note that the impact parameter need not be zero.

If the orbital angular momentum in conserved (as it is the case, for instance, for isolated systems made of particles without intrinsic spin angular momentum), the motion is a plane motion, both before and after the collision, thanks to the expression (30.03.01) and the plane of motion does not change.

The plane defined by the linear momentum $\mathbf{p}$ of the incoming particle and the position of the fixed target defines the plane of motion before the interaction. The plane defined by the momenta, $\mathbf{p}'$ and $\mathbf{P}'$, of the outgoing particles defines the plane of motion after the interaction. The two planes need not to be coincident, in general, but they are coincident if the orbital angular momentum is conserved.

It will be assumed that the kinetic energy is just translational kinetic energy, as it is normally appropriate for elementary particles, while it is not for macroscopic bodies.

Applicando la conservazione dell'impulso e dell'energia cinetica si deduce

$$k \equiv M/m > 0 \quad ,$$

$$p = p'\cos[\theta] + P'\cos[\alpha] \qquad (30.03.02) \quad \rightarrow 1605$$

$$p'\sin[\theta] = P'\sin[\alpha] \qquad (30.03.03) \quad \rightarrow 1605$$

$$\frac{p^2}{2m} = \frac{p'^2}{2m} + \frac{P'^2}{2M} \qquad p^2 = p'^2 + \frac{P'^2}{k} \quad . \quad \rightarrow 1605$$

Ci sono tre equazioni e quattro incognite in quanto la dinamica non è del tutto determinata dai soli principi di conservazione.

Note that both the orientation of the final plane and the angles θ and α might be influenced by a possible intrinsic spin of the two particles and by the dynamics of the interaction. Moreover, the conservation of angular momentum, and|or other conservation laws, might add additional constraints. However, the three constraints given the linear momentum and energy conservation, equations (30.03.02), (30.03.03), (30.03.01.05), must always be obeyed. In other worlds: no matter possible additional constraints, imposed by either the properties of the particles or the dynamics of the interactions, the three constraints (30.03.02), (30.03.03), (30.03.01.05) are always valid. Once one of the four variables, (p', P', θ, α) is known the other three are determined. The determination of at least one of the four variables, (p', P', θ, α), as well as the determination of the final plane of motion, require additional information.

IN PROGRESS

Si possono ricavare p', P' e α in funzione di θ. Eliminando α dalle prime due equazioni si esplicita p' che poi si sostituisce nella terza equazione da cui si ricava p' in funzione di θ e p. Sostituendo si ricava poi P' in funzione di θ e p. Si trova

$$k \equiv M/m > 0 \qquad p > 0 \qquad p' \geq 0 \qquad P' \geq 0 \qquad p' \leq p \qquad P' \leq p\sqrt{k} \quad ,$$
$$0 \leq \theta \leq \pi \qquad 0 \leq \alpha \leq \pi \quad ,$$
$$\frac{p'}{p} = \frac{\cos\theta \pm \sqrt{\cos^2\theta + k^2 - 1}}{1+k} = \frac{\cos\theta \pm \sqrt{k^2 - \sin^2\theta}}{1+k} \quad ,$$
$$\frac{P'}{p} = \sqrt{k\left(1 - \frac{p'^2}{p^2}\right)} = \frac{\sqrt{2k}}{k+1}\sqrt{1 + k - \cos^2\theta \mp \cos\theta\sqrt{\cos^2\theta + k^2 - 1}} = \frac{\sqrt{2k}}{k+1}\sqrt{k + \sin^2\theta \mp \cos\theta\sqrt{k^2 - \sin^2\theta}} \quad ,$$
$$\cos[\alpha] = \frac{p - p'\cos[\theta]}{P'} \quad .$$

Note that the above equations are always valid non matter the final plane of motion is different from the initial plane of motion.

Le caratteristiche fondamentali, indipendenti dalle specificche proprietà delle particelle e dalla dinamica seguono, solo solggette alla limitazione di urto elastico non-relativistico su bersagio fermo con energia cinetica solo traslazionale:

- la soluzione mostra che P' è sempre automaticamente tale che $P' \leq p\sqrt{k}$; per P' occorre quindi solo accertarsi che risulti non negativo, ma per questo è sufficiente che sia soddisfatta la condizione $p' \leq p$; è quindi sufficiente verificare le condizioni su p' ($0 \leq p' \leq$) perchè quelle su P' siano automaticamente soddisfatte;
- per $k > 1$ ($M > m$) la sola soluzione accettabile è quella a segno positivo, perché l'altra fornirebbe un valore negativo di p', mentre si può verificare anche che la soluzione a segno positivo fornisce una soluzione tale che $0 \leq p' \leq p$;
- per $0 \leq k < 1$ ($M < m$) entrambe le soluzioni sono accettabili, e si hanno quindi due possibili valori di p', P' e α per ogni valore di θ;
- per $0 \leq k < 1$ ($M < m$) si ha necessariamente $|\sin[\theta]| \leq k < 1$: il proiettile, pesante, ha una deviazione massima possibile e risulta tanto più indirizzato in avanti quanto più la sua massa è grande rispetto a qualla del bersaglio;
- in entrambi i casi limite, $k \longrightarrow +\infty$ ($M \gg m$) e $k \longrightarrow 0$ ($M \ll m$), si ha $p' \longrightarrow p$ e $P' \longrightarrow 0$, cioè in entrambi i casi il bersaglio non acquista energia cinetica e il proiettile prosegue senza perdita di energia;
- nel caso limite $k \longrightarrow 0$ ($M \ll m$), si ha $|\sin[\theta]| \leq k \longrightarrow 0$, cioè il proiettile pesante prosegue diritto e senza perdita di energia;

The following relations are used to build a geometrical interpretation of the scattering in the Laboratory frame, the so-called scattering diagram.

Note that the relative velocity between the projectile and the target is:

$$\mathbf{v}_{\mathrm{R}} \equiv \mathbf{v} - \mathbf{V} = \mathbf{v} \qquad \text{because:} \qquad \mathbf{V} = \mathbf{0} \quad .$$
$$|\mathbf{p}^\star| = |\mathbf{P}^\star| = |\mathbf{p}^{\star\prime}| = |\mathbf{P}^{\star\prime}| = \mu|\mathbf{v}_{\mathrm{R}}|\mu|\mathbf{v}| \quad ,$$
$$\mathbf{p}' \equiv m\mathbf{v}' = m\left(\mathbf{v}^{\star\prime} + \mathbf{V}_{\mathrm{CM}}\right) = \mathbf{p}^{\star\prime} + m\frac{m\mathbf{v}}{m+M} = \mathbf{p}^{\star\prime} + \frac{m}{M}\mu\mathbf{v} \quad ,$$
$$\mathbf{P}' = -\mathbf{p}^{\star\prime} + \mu\mathbf{v} \quad .$$

30.04 Two-Body Inelastic Collisions

This § is referenced at pages:
[1604]

©|J.P.Pérez *et al.*, *Mécanique*, ..., DUNOD, ...Ed., WEB - URL.|14||

DRAFT - IN-PROGRESS

30.04.01 Types of Inelastic Two-Body Collisions

Types of inelastic two-body collisions include, as extreme cases:

- Capture Reaction: the two particles move as a whole after the collision.
- Particle Decay: a single particle decays into two different particles.

30.04.02 Examples of Inelastic Two-Body Collisions

A collisions between two particles such that one of the two particles breaks into two parts is certainly endo-energetic, because part of the kinetic energy must be used to break the particle.

An exo-thermal chemical reaction between two molecules is exo-energetic.

30.04.03 Coefficient of Restitution in Two-Body Collisions

The coefficient of restitution is defined as:

$$\epsilon \equiv \sqrt{\frac{\mathcal{K}^\star_{\mathrm{F}}}{\mathcal{K}^\star_{\mathrm{I}}}} = \frac{|\mathbf{v}'_2 - \mathbf{v}'_1|}{|\mathbf{v}_2 - \mathbf{v}_1|} \,.$$

Note that sometimes other similar definitions are used.

For $\epsilon = 0$ the loss of kinetic energy is maximal.

For $\epsilon = 1$ the collision is elastic.

Note that some of the total kinetic energy can never disappear, as dictated by **Koënig theorem** , because the kinetic energy of the Center-Of-Mass motion must remain constant for an isolated system whose linear momentum is conserved. This is the reason why the coefficient of restitution is defined in terms of the kinetic energy relative to the CM.

30.05 N-Body Collision Processes

The two-body problem can be, in general, reduced to two one-body problem and thus generally solved.

The N-body problem cannot be, in general, reduced to N one-body problems and no general solution is known.

The Center-Of-Mass position is defined as:

$$\mathbf{R} \equiv \frac{\sum_{k=1}^{N} m_k \mathbf{r}_k}{\sum_{k=1}^{N} m_k} \equiv \frac{\sum_{k=1}^{N} m_k \mathbf{r}_k}{M} \quad .$$

The Center-Of-Mass velocity is defined as:

$$\mathbf{V} \equiv \frac{\mathrm{d}\mathbf{R}}{\mathrm{d}t} = \frac{\sum_{k=1}^{N} m_k \mathbf{v}_k}{\sum_{k=1}^{N} m_k} \equiv \frac{\sum_{k=1}^{N} m_k \mathbf{v}_k}{M} \quad .$$

The Center-Of-Mass-coordinates are defined as:

$$\mathbf{r}_k^\star = \mathbf{r}_k - \mathbf{R} \qquad \text{with} \qquad \sum_{k=1}^{N} m_k \mathbf{r}_k^\star = \mathbf{0} \quad .$$

The Center-Of-Mass-velocities are defined as:

$$\mathbf{v}_k^\star \equiv \frac{\mathrm{d}\mathbf{r}_k^\star}{\mathrm{d}t} = \mathbf{v}_k - \mathbf{V} \qquad \text{with} \qquad \sum_{k=1}^{N} m_k \mathbf{v}_k^\star = \mathbf{0} \quad .$$

The linear momentum is given by:

$$\mathbf{P} = \sum_{k=1}^{N} m_k \mathbf{v}_k = M\mathbf{V} \quad .$$

The angular momentum with respect to a pole O is given by the first **Koënig theorem** (read § 24.11.02):

$$\mathbf{L}_0 = M\,(\mathbf{R} - \mathbf{x}_0) \wedge \mathbf{V} + \sum_{k=1}^{N} m_k\, \mathbf{r}_k^\star \wedge \mathbf{v}_k^\star \quad . \tag{30.05.01}$$

The kinetic energy is given by the second **Koënig theorem** (read § 24.11.03):

$$\mathcal{K} = \frac{1}{2} M V^2 + \frac{1}{2} \sum_{k=1}^{N} m_k \mathbf{v}_k^{\star 2} \quad . \tag{30.05.02}$$

DRAFT - IN PROGRESS

30.06 Cross-Section

This § is referenced at pages:
[1103, 2078, 2328, 2726]

The only known way to investigate matter at a microscopic level is to used known microscopic projectiles to bombard the target to study and try to deduce properties of the target from the study of its interaction properties with the know projectiles. This method of investigation is usually employed to study particles, atoms, molecules but also bulk matter and surface properties. The projectiles are different types of particles, most often photons. The properties of the projectiles must be chosen so that their interaction with the target allows to draw interesting conclusions.

This explains the importance of the study of the interaction of a beam of projectiles with some target and the introduction of the concept of cross-section.

Si abbia un processo in cui un certo numero di particelle **bersaglio** sono bombardate da un fascio di particelle **proiettile** e si osservi il risultato di tale processo.

La sezione d'urto, σ, del generico processo si definisce, in termini del numero di eventi che interessano per unità di tempo, $\frac{\mathrm{d}N_S}{\mathrm{d}t}$, come:

$$\boxed{\frac{\mathrm{d}N_S}{\mathrm{d}t} \equiv \mathcal{N}\sigma\mathcal{F} \qquad \mathcal{F} \equiv \frac{d^2 N_0}{\mathrm{d}A\ \mathrm{d}t}} \quad , \tag{30.06.01}$$

→ 1610

dove $\mathcal{N}$ è il numero di bersagli ed $\mathcal{F}$ è il flusso delle particelle proiettile, cioé il numero di particelle incidenti per unità di superficie per unità di tempo.

Con tale definizione ci si libera dagli effetti non dinamici, intensità del fascio e numero di centri diffusori, ottenendo una grandezza fisica, la sezione d'urto σ, che dipende solo dalle proprietà dell'interazione tra una particella proiettile ed una particella bersaglio.

Note that the flux (or intensity) of incident particles, $\mathcal{F}$, is actually a current density of particles:

$$\boxed{\mathbf{j}_P = \eta_{\mathcal{N}}\mathbf{v} \equiv \rho_{\mathcal{N}}\mathbf{v}} \quad , \tag{30.06.02}$$

that is a number of particles per unit time per unit area perpendicular to the direction of motion (compare with the definition of current density of charge, the usual current density of ElectroMagnetism, read section ADD REFERENCE). In a similar way one can calculate the current of particles that is the total number of particles crossing any surface Σ:

$$\boxed{\frac{\mathrm{d}N}{\mathrm{d}t} = \iint_{\Sigma} \mathbf{j}_P \cdot \mathrm{d}\mathbf{S}} \quad .$$

The cross-section has dimension of an area. A typical unit of measure used and appropriate for microscopic physics is the barn:

$$\boxed{\mathrm{barn} = 10^{-28}\ \mathrm{m}^2} \quad . \tag{30.06.03}$$

Nei calcoli espliciti può essere necessario considerare i due casi distinti di un fascio più grande del bersaglio oppure di un fascio più piccolo del bersaglio. Nel seguito si assumerà sempre implicitamente che la sezione A di cui si parla è la sezione del bersaglio, nel primo caso, e la sezione del fascio, nel secondo caso.

Con riferimento alla definizione (30.06.01) si assume quanto segue.

- The spatial distribution of both the projectiles inside the incoming beam and the particles inside the target are random and homogeneous.
- Il numero di bersagli è così piccolo che la probabilità che un proiettile abbia più di una interazione, nell'attraversare il bersaglio, è trascurabile: assenza di scattering multiplo. Questo significa che, per ogni proiettile, il numero di bersagli potenziali deve essere sufficientemente piccolo.
- La lunghezza d'onda di De Broglie dei proiettili è piccola rispetto alle distanze tra i bersagli, in

WORK IN PROGRESS

modo che gli effetti di interferenza dovuti allo scattering con diversi bersagli siano trascurabili. In altre parole i diversi bersagli devono agire come centri di scattering indipendenti e devono mancare effetti di interferenza/diffrazione.
This means that wave-properties must be negligible and that it should be possible to treat the projectiles as particles/corpuscles. The appropriate factor to discriminate between particle-like and wave-like behavior is, in general,

$$\frac{\lambda}{D} \qquad D\text{: characteristics dimensions involved in the processes} \quad .$$

- Finally the involved interaction forces should be short-range forces. Long range forces might require a special, more complex, treatment. However, short-range forces are rather common, with the exception of gravitational forces. Electric forces among charges, in fact, are in principle long-range forces as well but electric field are most often screened in conductive materials.

La sezione d'urto differenziale in angolo solido, $\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}$, del generico processo si definisce dal numero di particelle diffuse ad una certa direzione definita dagli angoli polare ed azimuthale θ e ϕ, $\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t}[\theta,\phi]$:

$$\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t}[\theta,\theta+\mathrm{d}\theta;\phi,\phi+\mathrm{d}\phi] \equiv \frac{d^2\mathsf{N}_\mathsf{S}}{\mathrm{d}\Omega\,\mathrm{d}t}[\theta;\phi]\,\mathrm{d}\Omega \equiv \mathcal{N}\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta,\phi]\,\mathrm{d}\Omega\mathcal{F} \quad ,$$

$$\Longrightarrow \quad \boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta,\phi] \equiv \frac{1}{\mathcal{N}\mathcal{F}}\frac{d^2\mathsf{N}_\mathsf{S}}{\mathrm{d}\Omega\,\mathrm{d}t}[\theta;\phi]} \quad ,$$

$$\boxed{\sigma = \iint \frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta,\phi]\,\mathrm{d}\Omega} \quad .$$

It depends, a priori, on the polar and azimuthal angles, θ and ϕ. In case the system is invariant by rotation around the axis of the incident beam the differential cross-section in angle does not depend on the azimuthal angle ϕ.

In a simpler way:

$$\boxed{\mathrm{d}\sigma \equiv \frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta,\phi]\,\mathrm{d}\Omega} \quad .$$

In generale la sezione d'urto, $\sigma = \sigma[\varepsilon,\alpha]$, dipende dall'energia e da altri parametri, α.

Note that the number of targets, $\mathcal{N}$, is strictly liked to the cross section used. As a typical example if one is studying photon-matter interactions and uses a photon-electron cross-section the number of targets, $\mathcal{N}$, is the number of electrons; if, on the other hand, one uses the photon-atom cross-section the number of targets, $\mathcal{N}$, is the number of atoms.

30.06.01
Cammino Libero Medio E Sezione D'urto

This § is referenced at pages:
[2077, 2726, 2727]

Incident beam of projectiles of sectional area $\mathrm{d}\mathbf{S}$ crossing a thin sheet of targets of thickness $\mathrm{d}z$. The area of the target is assumed to be very much larger than the sectional area $\mathrm{d}\mathbf{S}$ of the beam.

First introduce the volume, $\delta V \equiv \mathrm{d}\mathbf{S}\,\mathrm{d}z$, of the region of intersection between the beam of particles and the target is introduced. This is assumed to be the region where interactions happen and the number of involved targets is thus the number of targets inside this volume.

DRAFT - IN PROGRESS

One can write:

$$\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t} = \sigma \eta_\mathbb{N}\, \delta V\, \mathcal{F} \quad ,$$

$$\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t} = \sigma\, \delta\mathcal{N}\, \mathcal{F} = \frac{\mathrm{d}\mathsf{N}_0}{\mathrm{d}t}\frac{\delta\mathcal{N}}{\delta V}\sigma\, \mathrm{d}z \quad ,$$

$$\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t} = \sigma\, \delta\mathcal{N}\, \mathcal{F} = \sigma\frac{\delta\mathcal{N}}{\mathrm{d}\mathbf{S}\, \mathrm{d}z}\, \mathrm{d}\mathbf{S}\, \mathrm{d}z \frac{d^2\mathsf{N}_0}{\mathrm{d}A\, \mathrm{d}t} = \frac{\mathrm{d}\mathsf{N}_0}{\mathrm{d}t}\frac{\delta\mathcal{N}}{\delta V}\sigma\, \mathrm{d}z \quad ,$$

$$\frac{\left(\frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}t}\right)}{\left(\frac{\mathrm{d}\mathsf{N}_0}{\mathrm{d}t}\right)} = \frac{\mathrm{d}\mathsf{N}_\mathsf{S}}{\mathrm{d}\mathsf{N}_0} = \frac{\mathcal{N}}{V}\sigma\, \mathrm{d}z \quad ,$$

$$N[z] \Longrightarrow \frac{\mathrm{d}N[z]}{N[z]} = -\frac{\mathcal{N}}{V}\sigma\, \mathrm{d}z \equiv -\frac{\mathrm{d}z}{\lambda} \quad ,$$

$$\frac{1}{\lambda} \equiv \frac{\mathcal{N}\sigma}{V} \quad ,$$

where

Dato un processo con una certa sezione d'urto σ il libero cammino medio per l'interazione corrispondente al processo vale dunque

$$\boxed{\frac{1}{\lambda[\varepsilon,\alpha]} \equiv \frac{\mathcal{N}\sigma[\varepsilon,\alpha]}{V} \equiv \eta_\mathbb{N}\sigma[\varepsilon,\alpha]} \tag{30.06.04}$$

→ 2078

dove $\eta_\mathbb{N} \equiv (\mathcal{N}/V)$ è il numero di bersagli per unità di volume. In generale, così come $\sigma = \sigma[\varepsilon,\alpha]$ dipende dall'energia e da altri parametri α, anche il cammino libero medio, $\lambda = \lambda[\varepsilon,\alpha]$, ne dipende.

Il numero medio di interazioni attese in un percorso $[z, z+\ \delta z\ ]$ è dunque:

$$\mathsf{N}_\mathsf{S}[z, z+\ \delta z\ ] = \frac{\delta z}{\lambda}\mathsf{N}_0[z] \quad .$$

Il numero di interazioni attese in un percorso $[z, z+\ \delta z\ ]$ ha dunque una distribuzione di Poisson con valore medio:

$$\boxed{\langle \mathsf{N}_\mathsf{S}[z, z+\ \delta z\ ]\rangle = \frac{\delta z}{\lambda}\mathsf{N}_0[z]} \quad .$$

In generale un fascio di particelle incidenti su un bersaglio viene attenuato dalle interazioni: le particelle possono essere assorbite o semplicemente diffuse in una direzione diversa. Il numero di particelle eliminate dal fascio, nell'intervallo infinitesimo $\mathrm{d}z$, è proporzionale al numero di particelle nel fascio e all'intervallo $\mathrm{d}z$:

$$-\frac{\mathrm{d}\mathcal{F}}{\mathcal{F}} = \frac{\mathrm{d}z}{\lambda} \tag{30.06.05}$$

da cui segue

$$\boxed{\mathcal{F}[z] = \mathcal{F}_0 \exp\left[-z/\lambda\right]} \quad .$$

DRAFT - IN PROGRESS

30.06.02
Differential Cross-Section and Impact Parameter

Assume that the system is invariant by rotation around the axis of the incident beam: the differential cross-section in angle does not depend on the azimuthal angle ϕ.

There exist a well defined relation between the impact parameter and the scattering angle θ:

$$\boxed{b = b[\theta]} \quad ,$$

determined by the interaction.

The number of particles scattered in the angular interval of polar angle $[\theta, \theta + \mathrm{d}\theta]$ and azimuthal angle $[\phi, \phi + \mathrm{d}\phi]$ is expressed in terms of the impact parameter, $b[\theta]$, as it is given by the particles passing through an infinitesimal circular corona of radius $b[\theta]$:

$$\mathrm{d}\mathsf{N}_\mathsf{S}[\theta, \theta + \mathrm{d}\theta; \phi, \phi + \mathrm{d}\phi] = \mathcal{N}\mathcal{F} b \, \mathrm{d}b \, \mathrm{d}\phi \, \mathrm{d}t = b\mathcal{N}\mathcal{F}\left|\frac{\mathrm{d}b}{\mathrm{d}\theta}\right| \mathrm{d}\theta \, \mathrm{d}\phi \, \mathrm{d}t \quad .$$

Finally:

$$\boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta] = \frac{1}{\mathcal{N}\mathcal{F}}\frac{d^2\mathsf{N}_\mathsf{S}}{\mathrm{d}\Omega \, \mathrm{d}t}[\theta] = \frac{1}{\mathcal{N}\mathcal{F}}\frac{\left(b\mathcal{N}\mathcal{F}\left|\frac{\mathrm{d}b}{\mathrm{d}\theta}\right| \mathrm{d}\theta \, \mathrm{d}\phi \, \mathrm{d}t\right)}{\mathrm{d}\Omega \, \mathrm{d}t} = \frac{b\left|\frac{\mathrm{d}b}{\mathrm{d}\theta}\right| \mathrm{d}\theta \, \mathrm{d}\phi \, \mathrm{d}t}{\sin[\theta] \, \mathrm{d}\theta \, \mathrm{d}\phi \, \mathrm{d}t} = \frac{b}{\sin[\theta]}\left|\frac{\mathrm{d}b}{\mathrm{d}\theta}\right|} \quad .$$

30.06.02.01 Angular Differential Cross-Section for a Rigid Sphere

Consider the elastic scattering of a mass point particle from a rigid sphere of radius R.

One finds, from geometrical considerations:

$$b = R\sin[\theta_0] \quad ,$$
$$2\theta_0 + \theta = \pi \quad ,$$
$$b[\theta] = R\sin\left[\frac{\pi - \theta}{2}\right] = R\cos\left[\frac{\theta}{2}\right] \quad .$$

It follows:

$$\boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta] = \frac{R^2}{4} \qquad \sigma = \iint \frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta] \, \mathrm{d}\Omega = \pi R^2} \quad .$$

Therefore the total cross-section for a rigid sphere is just the geometrical area of the **shadow** presented by the sphere to the incident beam.

30.06.02.02 Angular Differential Cross-Section for Kepler/Rutherford Scattering

The relation between scattering angle and impact parameter for scattering from an inverse-square force law (Kepler/Rutherford scattering) is given by equation (29.04.27):

$$\boxed{b = \frac{\gamma}{2E}\cot[\theta/2] \qquad \left|\frac{\mathrm{d}b}{\mathrm{d}\theta}\right| = \frac{\gamma}{4E}\frac{1}{\sin^2[\theta/2]}} \quad .$$

It follows:

$$\boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}[\theta] = \frac{\frac{\gamma}{2E}\cot[\theta/2]}{\sin[\theta]}\frac{\gamma}{4E}\frac{1}{\sin^2[\theta/2]} = \frac{\gamma^2}{16E^2}\frac{1}{\sin^4[\theta/2]}} \quad .$$

The divergence at $\theta = 0$ is not a problem. It just means that, if there is a beam of infinite extension and therefore an infinite number of incident particles, there are infinite scattered particles. Moreover, for any real beam of finite extension the impact parameter cannot be integrated to infinity, and therefore the scattering angle is not integrated down to zero.

For any beam of finite extension the impact parameter is to be integrated to less than infinity, and therefore the scattering angle should not be integrated down to zero !!!!!!

WORK-IN-PROGRESS

30.07.01
Jacobi Identity

Consider an arbitrary system made of N point particles, that is made of systems with no, or negligible, internal degrees of freedom. The particles can be complex systems themselves as long as the internal degrees of freedom can be ignored and only the translational degrees of freedom are relevant. In particular, the kinetic energy must be the translational kinetic energy only. More complex systems may led to different formulations. Note, however, that for small pieces of matter, assumed at fixed density, the rotational kinetic energy, goes to zero as the fifth power of size, due to the inertia moments, while the translational kinetic energy goes to zero as the third power of the size, due to mass.

Assume, therefore, that the kinetic energy of any particle is just given by the translational kinetic energy:

$$\mathtt{k} \equiv \frac{1}{2} m v^2 \quad .$$

If any particle has additional significant contributions to the kinetic energy the following derivations must be modified accordingly.

Starting from the total translational kinetic energy of the system of N point particles one can re-write it as follows:

$$\mathcal{K} \equiv \frac{1}{2}\sum_{i=1}^{N} m_i v_i^2 = \frac{1}{2}\sum_{i=1}^{N} \mathbf{p_i}\cdot\mathbf{v_i} = \frac{1}{2}\sum_{i=1}^{N} \frac{\mathrm{d}}{\mathrm{d}t}(\mathbf{p_i}\cdot\mathbf{r_i}) - \frac{1}{2}\sum_{i=1}^{N}(\mathbf{r_i}\cdot\dot{\mathbf{p}}_\mathbf{i}) = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\sum_{i=1}^{N}(\mathbf{p_i}\cdot\mathbf{r_i}) - \frac{1}{2}\sum_{i=1}^{N}(\mathbf{r_i}\cdot\mathbf{F_i}) = \quad ,$$

$$\frac{1}{4}\frac{d^2}{\mathrm{d}t^2}\sum_{i=1}^{N} m_i(\mathbf{r_i}\cdot\mathbf{r_i}) + \Omega = \quad ,$$

$$\frac{1}{4}\ddot{I}_0 + \Omega \quad ,$$

where the **virial**, Ω, has been defined as

$$\boxed{\Omega \equiv -\frac{1}{2}\sum_{k=1}^{N}(\mathbf{r_k}\cdot\mathbf{F_k})} \quad ,$$

and I_0, the polar moment of inertia with respect to the origin, have been introduced.

The result is the so called Jacobi identity:

$$\boxed{\mathcal{K} = \frac{1}{4}\ddot{I}_0 + \Omega} \quad . \tag{30.07.01}$$

→ 1616

For continuous systems, with only surface forces normal to the surface (normal stresses), the virial is:

$$\Omega = -\frac{1}{2}\iint_{\Sigma} p[\mathbf{x}]\,\mathbf{r}\cdot\,\mathrm{d}\mathbf{A} \qquad \text{provided } p[\mathbf{x}]\,\mathrm{d}\mathbf{S} \text{ has the same oriented direction as the force} \quad .$$

CC BY NC ND

For continuous systems, with volume forces the virial is:

$$\Omega = -\frac{1}{2}\iiint_V \mathbf{r}\cdot\mathbf{f}_V[\mathbf{x}]\ \mathrm{d}V \quad .$$

30.07.02
Virial Theorem

The virial theorem derives from Jacobi identity when, as sufficient conditions:

- either the motion of the system is finite (that is both coordinates and velocities are limited functions);
- or the system is in a macroscopically steady state.

The virial theorem provides the mean value in time of the kinetic energy.

For any given sufficiently well-behaved time-dependent function, $\xi[t]$, defined for $0 \le t \le \infty$, the average value in time is defined as:

$$\boxed{\langle \xi \rangle \equiv \lim_{T\longrightarrow\infty} \frac{1}{T}\int_0^T \xi[t]\ \mathrm{d}t}$$

In general, the coordinates, velocities and accelerations of the point particles building up the system are time-dependent. However, we may content ourselves with average values of macroscopic quantities when the number of particles is very large.

- Assume that the system is contained in a finite volume, that is the coordinates are limited functions at any time. Assume that also velocities are limited functions of time. The latter assumption is normally verified due to energy conservation, unless there is the possibility that the potential energy goes to $-\infty$ for some actual configuration. In any case relativity implies that the speeds cannot exceed the speed of light, and, if speeds increase close to the speed of light the current classical framework is not applicable anymore.
  It follows:
  $$\langle \ddot{I}_0 \rangle = \lim_{T\longrightarrow\infty} \frac{1}{T}\int_0^T \ddot{I}_0\ \mathrm{d}t = \lim_{T\longrightarrow\infty} \frac{1}{T}\Big(\dot{I}_0[T] - \dot{I}_0[0]\Big) = 0 \quad ,$$
  as the quantity $\Big(\dot{I}_0[T] - \dot{I}_0[0]\Big)$ is limited at any time. In fact,
  $$\dot{I}_0 \equiv 2\sum_{i=1}^{N} m_i\,(\mathbf{r_i}\cdot\mathbf{v_i}) \quad ,$$
  and, by hypothesis, position and velocities are limited functions.
  The virial theorem follows:
  $$\boxed{\langle \mathcal{K} \rangle = \langle \Omega \rangle} \quad . \qquad (30.07.02)$$
- Another sufficient condition for the validity of the virial theorem (30.07.02) is that the configuration of the system is steady from a thermodynamical, that is macroscopic, point of view. In this case all macroscopic quantities are constant in time, including I_0, and therefore the result
  $$\langle \ddot{I}_0 \rangle = 0 \quad ,$$
  follows again.
  The virial theorem follows:
  $$\boxed{\langle \mathcal{K} \rangle = \langle \Omega \rangle} \quad .$$

→ 1615

The quantity $\langle \Omega \rangle$ is called **virial** as well. Note, however, that sometimes the virial is defined without the factor $-1/2$; this is the original definition from Clausius.

DRAFT - In PROGRESS

The virial can be written splitting the contribution from external and internal forces:

$$\boxed{\langle\Omega\rangle = -\frac{1}{2}\langle\sum_{i=1}^{N}\left(\mathbf{r_i}\cdot\mathbf{F}_\mathbf{i}^{I}\right)\rangle - \frac{1}{2}\langle\sum_{i=1}^{N}\left(\mathbf{r_i}\cdot\mathbf{F}_\mathbf{i}^{E}\right)\rangle \equiv \langle\Omega^{\mathrm{I}}\rangle + \langle\Omega^{\mathrm{E}}\rangle} \quad ,$$

where F_i^I and F_i^E are, respectively, the resultant on particle i of all the internal and external forces.

Note that the formulation of the virial theorem is based on time averages of infinite length. If the virial theorem is applied to systems (with finite motion) which are either expanding or contracting, then one must be careful in the calculation of time averages and compare the finite length of time of the averaging with the typical time-scales of the system changes.

The time average is often replaced, in systems made of a large number of constituents, by the ensemble average over all the constituents of the system.

30.07.03
Virial for a Homogeneous Function Potential Energy

Assume that the interaction potential energy among the particles only depends on the position of all the N particles,

$$\Phi = \Phi[\mathbf{r}_i] \equiv \Phi[\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_N] \quad ,$$

and that it is an homogeneous function of degree n (read § 14.04.03).

It follows:

$$\Omega = -\frac{1}{2}\sum_{i=1}^{N}\left(\mathbf{r_i}\cdot\mathbf{F}_\mathbf{i}\right) = +\frac{1}{2}\sum_{i=1}^{N}\left(\mathbf{r_i}\cdot\frac{\partial\Phi}{\partial\mathbf{r}_i}\right) = \frac{n}{2}\Phi[\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_N] \quad .$$

Note that the sum over all particles is actually the gradient of the potential energy function, which is a function of all the $\mathbf{r}_i$.

Jacobi identity (30.07.01) then implies:

$$\boxed{\frac{1}{2}\ddot{I}_0 = (n+2)\,\mathcal{K} - nE} \quad .$$

30.07.03.01 Newton and Coulomb Interactions

In the most relevant case of either newtonian or coulombian forces:

$$\Phi = -\frac{\mathcal{G}}{2}\sum_{a=1,b=1,a\neq b}^{a=N,b=N}\frac{m_a m_b}{|\mathbf{r}_a - \mathbf{r}_b|} \qquad n=-1 \implies \Omega = -\frac{1}{2}\Phi \qquad \frac{1}{2}\ddot{I}_0 = \mathcal{K} + E \qquad \langle\mathcal{K}\rangle = \langle\Omega\rangle = -\frac{1}{2}\langle\Phi\rangle \quad .$$

(30.07.03) → 1618

Note that it is a polar moment of inertia and not an axial moment of inertia.

DRAFT - IN - PROGRESS

30.07.03.02 Harmonic Interactions

In the case of harmonic interactions one finds:

$$n = +2 \implies \Omega = \Phi \implies \langle \mathcal{K} \rangle = \langle \Phi \rangle \quad .$$

30.07.04 Some Applications of the Jacobi Identity and the Virial Theorem

30.07.04.01 Dark Matter in a Cluster of Galaxies

©|B.W.Carroll & D.A.Ostlie, *An Introduction To Modern Astrophysics*, ..., ..., 1stEd., ...|25.3, pag 1127||

The following method can be used to roughly estimate the total mass M of a cluster of galaxies with linear dimension of the order of R whose galaxies have an average squared velocity $\langle v^2 \rangle$.

The total kinetic and total potential energy is:

$$\Phi \approx -\mathcal{G}\frac{M^2}{R} \qquad \mathcal{K} = \frac{1}{2}M\langle v^2 \rangle \quad .$$

The virial theorem can be applied by assuming that the time average can be replaced by the average on the large number of elements making up the cluster of galaxies. If that is the case one can write, for the cluster of galaxies in a steady configuration, neglecting factors of the order of unity,

$$\langle \mathcal{K} \rangle = -\frac{\langle \Phi \rangle}{2} \implies M = \frac{R\langle v^2 \rangle}{\mathcal{G}} \quad .$$

The two quantities R and $\langle v^2 \rangle$ can both be estimated and therefore the total mass of the cluster can be estimated.

On the other hand the total mass of the cluster can be also estimated from the well known mass-luminosity relations for stars and by applying the necessary corrections for absorption and possibly other effects.

The mass estimated from the luminosity turns out to be invariably lower than the mass estimated from gravitational effect via the virial theorem. This points to the existence of dark matter in the universe.

The real estimation can be much more refined and needs to take into account geometrical and other effects.

30.07.04.02 Equation of State of a Ideal Molecular Gas

This § is referenced at pages:
[2754]

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|13.4.3||

A ideal gas is a model for a system for which the constituting particles are assumed to be point particles and the particle-particle interactions are negligible while the interactions with the walls are always present and are responsible for thermalization the gas; that is, particle-wall interactions are not elastic on a event-by-event basis, but only on average, and the wall, on average, does not change energy but just catalyses the thermalization of the gas.

An equivalent, more realistic, model of ideal gas is a model for a system for which the constituting particles are assumed to be almost point particles and the particle-particle interactions are elastic contact collisions, while the interactions with the walls are always present and elastic interactions.

Consider a ideal gas inside a closed fixed container at rest and assume the pressure is uniform.

The virial of internal forces is null. In fact at any contact interaction between any pair of point particles the two particles have the same positions, the forces are equal and opposite and the total virial of the pair is null.

We are only interested in the mean values and we can therefore calculate the virial of the external forces, given by the walls of the container, by introducing the pressure that is exactly the physical quantity describing the effect of collisions averaged in time, the impulse transferred per unit time per unit surface.

DRAFT - UNDER REVIEW

One finds, passing to the integral on the surface of the container,

$$\langle \Omega^{\mathrm{E}} \rangle = -\frac{1}{2}\langle \sum_{i=1}^{N} \left(\mathbf{r}_{\mathrm{i}} \cdot \mathbf{F}_{\mathrm{i}}^{E} \right) \rangle \implies \langle \Omega^{\mathrm{E}} \rangle = +\frac{1}{2} p \oiint \mathbf{r} \cdot \mathrm{d}\mathbf{S} \quad ,$$

as the pressure is uniform and the unit vector is oriented towards the exterior of the surface. Note that one can change the sum over the particles to the integral on the surface of the container thanks to the large number of particles. However, the time-average implied by the virial theorem is required to use the concept of pressure, that is the time-averaged force per unit area.

By applying the **divergence theorem** :

$$\boxed{\langle \Omega^{\mathrm{E}} \rangle = \frac{3}{2} pV \implies \langle \mathcal{K} \rangle = \frac{3}{2} pV} \quad .$$

From the kinetic theory interpretation of the kinetic energy one finds the equation of state of ideal gases:

$$\boxed{pV = \frac{2}{3}\langle \mathcal{K} \rangle = N k_{\mathrm{B}} T} \quad .$$

The virial theorem is the main tool in classical kinetic theory to handle non-ideal gases.

30.07.04.03 Virial for a Set of Charged Particles in a Magnetic Field

Consider a set of charged particles in a uniform and constant magnetic field $\mathbf{B}$.

If all the particles have the same charge-to-mass ratio, $g \equiv q/m$ the virial is:

$$\Omega = -\frac{g}{2} \mathbf{L} \cdot \mathbf{B} \quad ,$$

as a function of the total orbital angular momentum $\mathbf{L}$.

30.07.04.04 Virial Theorem in Presence of Forces Depending Linearly on the Velocity

Show that the virial of viscous forces, proportional to the velocity of each particle, is zero.

30.07.04.05 A Proto-Star Collapse

©|Berkeley Physics Course, in 5 Vol., , ..., McGraw-Hill, ...Ed., ...|||

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|T22||

©|D.V.Schroeder, *Thermal Physics*, 1999, Addison-Wesley, ...Ed., ...|problem 1.55||

Consider a system made of particles subject to gravitational forces only in quasi-static equilibrium. Assume the internal energy is just given by translational kinetic energy and gravitational potential energy.

According to equation (30.07.03) if the system loses mechanical energy, (that is, by hypotesis, total energy), for instance by radiation (as a in collapsing proto-star) or by friction (as in the satellite paradox), $\Delta E < 0$ implies that its kinetic energy increases by the same amount, $\Delta \mathcal{K} = -\Delta E > 0$. These energies are supplied by the potential energy, which changes by, $\Delta \mathcal{U} = 2\Delta E < 0$. This normally implies that the system is shrinking in size.

Consider the protostar as composed of a ideal gas. The temperature is normally so high that molecules do not exist and atoms are largely ionized. The kinetic energy of the plasma is then:

$$\mathcal{K} = \frac{3}{2} N k_{\mathrm{B}} T \quad ,$$

with N total number of particles, that is assume that the total internal energy is just given by the translational kinetic energy only. In a high-temperature plasma all molecules and atoms are ionized so this is consistent. Therefore:

$$\Delta E = -\Delta \mathcal{K} = -\frac{3}{2} N k_{\mathrm{B}} \Delta T < 0 \quad .$$

Therefore while the system shinks and loses total energy it increases its temperature.

However, in real cases, also conservation of angular momentum plays a role

We want to determine the effect of a small arbitrary perturbing force, $\mathbf{f}_{\text{P}}[\mathbf{r}]$, on the unperturbed conic orbit of a point particle in a pure and fixed inverse-square force field.

Assume that the interaction on a point particle of mass m is fully described by the total force, $\mathbf{f}_{\text{T}}$,:

$$\boxed{\mathbf{f}_{\text{T}} = -\frac{\gamma}{r^3}\mathbf{r} + \mathbf{f}_{\text{P}}[\mathbf{r}] \qquad \text{with } |\mathbf{f}_{\text{P}}| \ll \frac{|\gamma|}{r^2} \text{ at any point on the orbit}} \quad , \tag{31.01.01}$$

→ 1622

with no other external interaction, no intrinsic torques, for instance. Note that the perturbing force, $\mathbf{f}_{\text{P}}[\mathbf{r}]$, is not necessarily a central force.

In the presence of the small perturbation the orbit can be considered as a slowly changing conic. The case of the ellipse, that is a bound system, will be mostly considered, but the approach would be that same for parabolic and hyperbolic orbits, when using the appropriate equations. The osculating orbit is defined as the conic orbit which would be followed by the point particle if the perturbation would suddenly vanish.

The problem necessarily becomes a three-dimensional problem. Choose a Coordinate System in a Inertial Reference Frame such that its origin lies in the center of the inverse square force, at $\mathbf{r} = \mathbf{0}$, according to (31.01.01).

Define the line of nodes as the line defined by the crossing of the xy plane with the instantaneous orbit plane, that is the plane defined, at any instant, by the osculating ellipse (conic). Define the ascending node as the point where the osculating ellipse (conic) crosses the xy plane going in the direction of increasing z.

An unperturbed elliptical orbit will be only considered from now on. Therefore, in the current case,

$$\boxed{\gamma > 0} \quad .$$

See the figures 31.11, 31.12 for a graph and definition of variables. Note that with respect to the figures some notation in the text differ:

- we call φ the anomaly (called θ in the figure), because we must reserve θ for the polar angle in later applications;
- we call ν the eccentric anomaly (called ϵ in the figure);
- we call ℓ the orbital angular momentum of the mass point (called $\mathbf{H}$ in the figure).

Note finally that m and M in the figure refer to the mass of the two bodies while we will not use M as it is buried in our definition of γ. On the other hand we will later use M for the mean anomaly, as it is usually done in celestial mechanics.

See the text for comments on the notation

See the text for comments on the notation

The reference orbit equation (ellipse) in the plane of motion is:

$$\boxed{r[\varphi] = \frac{p}{1 + e\cos[\varphi - \omega]} \equiv \frac{p}{1 + e\cos[f]}} \quad , \tag{31.01.02}$$

→ 1623 1624

WORK IN PROGRESS

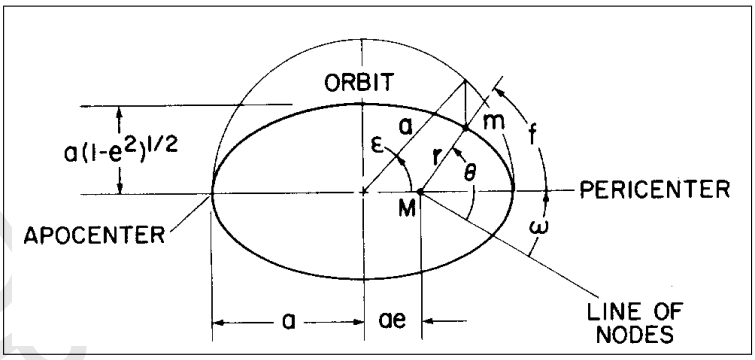

Figure 31.11: FIGURE

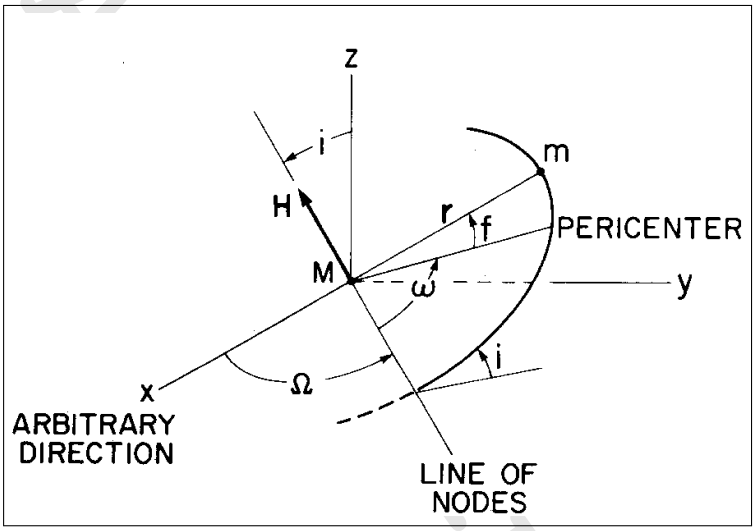

Figure 31.12: FIGURE

where φ is measured from the ascending node, such that it is increasing with time, and ω is the azimuth of the pericenter, measured in the plane of the osculating ellipse starting from the ascending node. The argument of the cosine term is called the true anomaly:

$$\boxed{f \equiv \varphi - \omega} \quad ,$$

and it represents the azimuth of the point particle from the pericenter.

One can show that an equivalent equation can be written in terms of the eccentric anomaly, ν:

$$\boxed{r[\varphi] = a\,(1 - e\cos[\nu])} \quad , \tag{31.01.03}$$

→ 1623 1640

with the following relation between the true and eccentric anomaly:

$$\boxed{\cos[\nu] = \frac{e + \cos[f]}{1 + e\cos[f]}} \quad , \tag{31.01.04}$$

→ 1640

which can be straightforwardly derived by comparing equations (31.01.02), (31.01.03).

See the references for the geometrical interpretation of the eccentric anomaly.

The eccentric anomaly allows one to solve the time dependence of the Kepler problem, via the mean anomaly M, defined in terms of the average angular velocity, which lacks a simple geometrical interpretation.

The time dependence is solved by the Kepler equations, which read:

$$M[t] \equiv \frac{2\pi}{T}(t - \tau) = e\,\mathrm{sih}\,[\nu[t]] - \nu[t] \qquad \text{for } e \geq 1 \tag{31.01.05}$$

$$M[t] \equiv \frac{2\pi}{T}(t - \tau) = \nu[t] - e\sin[\nu[t]] \qquad \text{for } 0 \leq e \leq 1 \quad , \tag{31.01.06}$$

→ 1641

cc BY NC ND

where T is the orbital period. Kepler equations allows to determine the time-dependence of the motion, as their solution is unique. Kepler equations are transcendental equations and therefore have no closed form solutions. Solutions via numerical methods is However, trivial and approximate methods have been developed to solve then in an approximate way.

The following expressions, which can be derived in a straightforward way by taking the time derivative of equation (31.01.02) and using the definition of the orbital angular momentum, will be necessary:

$$\boxed{\dot{r} = \frac{e\ell}{mp}\sin[f]} \qquad (31.01.07) \quad \rightarrow 1640$$

$$\boxed{r\dot{\varphi} = \frac{\ell}{mp}(1 + e\cos[f])} \quad . \qquad \rightarrow 1640$$

A useful expression for the forthcoming derivations is the time derivative of the anomaly expressed in terms of the distance only:

$$\boxed{\dot{\varphi} \equiv \frac{\mathrm{d}f}{\mathrm{d}t} = \frac{\ell}{mr^2} = \frac{1}{r^2}\sqrt{\frac{|\gamma|a\left(1-e^2\right)}{m}}} \quad , \qquad (31.01.08) \quad \rightarrow 1627\ 1640$$

derived from equation (29.04.17).

We need now a set of equation relating the geometrical parameters of the ellipse in space to the constant of motions, in such a waxy that we can consider how the two sets are related for small changes.

Equation (29.04.21) implies ($\gamma > 0$, by hypothesis):

$$\boxed{E = -\frac{\gamma}{2a} \equiv \frac{1}{2}mv^2 - \frac{\gamma}{r} \equiv K + \Phi_g} \quad .$$

The eccentricity is given by equation (29.04.16):

$$\boxed{e = \sqrt{1 + \frac{2E\ell^2}{m\gamma^2}}} \quad .$$

Two equations are required to describe the orientation of the orbit in space, which can be derived from the geometry, one giving the inclination of the plane of the osculating ellipse with respect to the xy plane,

$$\boxed{\cos[i] = \frac{\ell_z}{\ell}} \quad , \qquad (31.01.09) \quad \rightarrow 1640$$

and another one giving the angle between the line of nodes and the x axis,

$$\boxed{\tan[\Omega] = -\frac{\ell_x}{\ell_y}} \quad . \qquad (31.01.10) \quad \rightarrow 1640$$

Note that the three angles i, Ω and ω actually resemble Euler angles.

The two quantities i and Ω fix the orientation of the orbit plane in space.

Consider a small perturbing force:

$$\boxed{\mathbf{f}_{\mathrm{P}} = R\mathbf{e}_{\mathrm{R}} + T\mathbf{e}_{\mathrm{T}} + N\mathbf{e}_{\mathrm{N}}} \quad ,$$

in terms of the radial unit vector, $\mathbf{e}_{\mathrm{R}}$, the transverse unit vector in the plane of the orbit, positive in the direction of motion of the particle, $\mathbf{e}_{\mathrm{T}}$, and the unit vector normal to the osculating orbit plane, $\mathbf{e}_{\mathrm{N}} = \mathbf{e}_{\mathrm{R}} \wedge \mathbf{e}_{\mathrm{T}}$, given, in terms of the reference Coordinate System, by:

$$\begin{aligned} \mathbf{e}_{\mathrm{R}} &= \sin[\theta]\cos[\phi]\,\hat{\mathbf{e}}_1 + \sin[\theta]\sin[\phi]\,\hat{\mathbf{e}}_2 + \cos[\theta]\,\hat{\mathbf{e}}_3 \quad , \\ \mathbf{e}_{\mathrm{T}} &= \ldots \quad , \\ \mathbf{e}_{\mathrm{N}} &= \ldots \end{aligned} \qquad (31.01.11)$$

We will write the mechanical energy balance in terms of the work done by the perturbing force, in order to allow for possibly non conservative perturbing forces. The mechanical energy is defined as the sum of the kinetic energy plus the gravitational potential energy.

DRAFT WORK IN PROGRESS

The power balance then, at any instant of time, reads:

$$\boxed{\frac{\mathrm{d}E}{\mathrm{d}t}=\frac{\mathrm{d}K}{\mathrm{d}t}+\frac{\mathrm{d}\Phi_g}{\mathrm{d}t}=\frac{\mathrm{d}W_{\mathrm{P}}}{\mathrm{d}t}=\mathbf{v}\cdot\mathbf{f}_{\mathrm{P}}=R\dot{r}+Tr\dot{\varphi}} \quad . \tag{31.01.12}$$

→ 1625

The second **Cardinal Equation** applied to the point, with pole at the center of force, gives:

$$\boxed{\frac{\mathrm{d}\boldsymbol{\ell}}{\mathrm{d}t}=\mathbf{r}\wedge\mathbf{f}_{\mathrm{P}}=rT\mathbf{e}_{\mathrm{N}}-rN\mathbf{e}_{\mathrm{T}}} \quad . \tag{31.01.13}$$

→ 1625

Moreover

$$\frac{\mathrm{d}\ell^2}{\mathrm{d}t}=2\ell\frac{\mathrm{d}\ell}{\mathrm{d}t}=2\,\boldsymbol{\ell}\cdot\frac{\mathrm{d}\boldsymbol{\ell}}{\mathrm{d}t}=2\ell\,(rT\mathbf{e}_{\mathrm{N}}-rN\mathbf{e}_{\mathrm{T}})\cdot\mathbf{e}_{\mathrm{N}}=2\ell rT \quad ,$$

implies

$$\boxed{\frac{\mathrm{d}\ell}{\mathrm{d}t}=rT} \quad . \tag{31.01.14}$$

→ 1625 1627 1628

The three equations (31.01.12), (31.01.13), (31.01.14) provide the relation between the force and the change in the basic constants of motion of the problem.

DRAFT - IN PROGRESS

CC BY NC ND

One should note that equations (31.01.17), (31.01.18) can be derived without any reference to the Kepler natuare of the problem.

It should be noted that equation (31.02.00.02) contains explicitly the time, which causes practical problems with this equations since the right-hand term grows with time.

It is clear from the previous equations that:

- R affects: E;
- T affects: E and, in addition, both $\boldsymbol{\ell}$ and ℓ;
- N affects: $\boldsymbol{\ell}$ (but not ℓ).

As far as the orbit parameters are concerned, it is clear from the previous equations that:

- R affects: a, e, ω and τ;
- T affects: a, e, ω and τ;
- N affects: Ω, ω and i.

31.01.01.01 Secular Perturbations From Lagrange Planetary Equations

In many cases the disturbing forces are very small with respect to the main Kepler force and therefore also the changes of the orbital elements are very small during the change of the true anomaly by 2π, the periond of the particle orbit. In this case one need not calculate perturbation equations exactly but one can average during one period.

The use of equations from (31.01.15) to (31.02.00.02) to obtain the secular (that is non-periodic) perturbation effects must go as follows. The right-hand side of equations (31.01.15) to (31.02.00.02) must be time-averaged over one period of the unperturbed orbit in order to obtain the change in the parameters during one unperturbed orbit. Next the updated parameters are used to build the new orbit with the new parameters. This means, in particular, that during the integration the parameters a, e, i, Ω, ω and τ, appearing in the right-hand sides of equations (31.01.15) to (31.02.00.02), must be kept constant in the averaging. The procedure is, obviously, an approximate one, but this is the core of the perturbation method. In fact the exact procedure would require to evaluate the effects on the orbit by using the real orbit, instead of the unperturbed one. As the real orbit is unknown, and it is what we need to determine, it is only possible to evaluate the approximate effect on the unperturbed orbit.

DRAFT - IN PROGRESS

CC BY NC ND

31.02 Examples and Physical Applications

The following general comments apply.

Whenever the perturbing force is given by external static gravitational fields the mechanical energy is conserved,

as the perturbing field is conservative. Therefore the major axis of the osculating ellipse does not change (secularly). In general the presence of dissipative effects (for instance drag or deformation of extended bodies) will make the mechanical energy not conserved.

When the initial orbit is a circumference the application might be tricky. In fact the eccentricity function (29.04.16) is not differentiable for a zero value of the eccentricity, due to the presence of the square-root function. Moreover, the present method is slightly perverse in the case the initial orbit is a circumference, because the method would amount to approximate a circumference with an ellipse at any time. This would imply that the particle is always at the periastron (or apoastron) of the osculating ellipse, because its velocity is purely transverse.

Note that averaging of equations from (31.01.15) to (31.02.00.02) must be done in time and not in anomaly. Therefore in the present context when one talks about average the meaning is that one is taking the average on an integer number of periods of the unperturbed orbit. The use of equation (31.01.08) is useful to change the variable time to anomaly and vice-versa.

One should make sure to avoid confusion between the transverse component of the force and the component of the force parallel to the velocity, as they are, in general, different. Moreover, one has to be very careful not to confuse the transverse and normal components with respect to the osculating orbit with the $\mathbf{e}_\phi$ and $\mathbf{e}_z$ components with respect to the axis of symmetry of the field, if any.

Finally one should keep in mind the meaning of the osculating orbit: it is the Keplerian orbit which would be followed by the mass m in case one might suddenly switch off the perturbation.

31.02.00.01 Non-Spherical Static Gravitational Field With Cylindrical Symmetry

Introduce a cylindrical Coordinate System, (r, ϕ and z) with the z axis along the axis of cylindrical symmetry.

Energy is conserved and therefore the semi-major axis is constant. Note that this implies that the averaging of equation (31.01.15) will give zero.

The component of the angular momentum along the axis of symmetry (the z axis), ℓ_z, is conserved because the field is axisymmetric and therefore there is no component of $\mathbf{f}_\mathrm{P}$ in the ϕ direction. However, in general, neither the angular momentum nor its module are conserved. In fact (see equation (31.01.14)) the tangential component of the force is not zero in general. This can be easily shown when one considers that the field has, in general, a non null component in the meridional planes (planes passing by the z axis). As the orbit is in general inclined this component has in general a non null projection along the transverse direction to the orbit.

It can be shown that the both the eccentricity and inclination stay constant on average (that is they have no secular changes). However, they both have short period periodic changes.

On the other hand both the periastron and the line of nodes will show secular changes.

Some more conclusions can be easily found in some special cases.

DRAFT in PROGRESS

Circular Orbits

Some more conclusions can be easily drawn when the orbit is circular. In this case the averaging can be done also in the anomaly as this is equivalent to averaging in time.

The absolute value of the angular momentum does not change on average as equation (31.01.14) shows when it is averaged on a period of a circular orbit, due to the fact that the transverse component of the prturbing force, T, is periodic in the anomaly with period π.

The normal component of the perturbing force is an odd function of φ, changing its sign at $\varphi = 0, \pm\pi$ and therefore Δi will be zero during one period, as equation (31.01.17) shows (no secular term), beacuse the absolute value of the angular momentum does not change, on average. On the other hand, for the same reason, the line of nodes will precess, as it follows from (31.01.18), when the normal component of the force is an odd function of φ, beacuse the absolute value of the angular momentum does not change, on average.

In the case of a circular orbit the longitude of the perihelion and the time of passage at perihelion have non meaning.

Elliptic Orbit in the Equatorial Plane

Some more conclusions can be easily drawn when the orbit is elliptic in the equatorial plane. The case of elliptic orbits in the equatorial plane gives a central force given by an inverse square plus an inverse quartic force.

The angular momentum and the z component of it are conserved. As both energy and angular momentum are conserved the eccentricity does not change.

The orbit plane stays the same, because there is no force normal to the orbital plane.

The periastron precesses, as explained in section § 29.06.12.

Elliptic Orbit above the POles

31.02.00.02 Atmospheric Drag

Assume an atmospheric drag force of type:

$$\mathbf{f}_{\text{D}} = -k[r]v^{\alpha}\mathbf{v} \qquad k[r] > 0 \quad ,$$

→ 1626 1627

where the dependence $k[r]$ comes from the changing of the density of the atmosphere. Note that a special case of drag due to ElectroMagnetic waves absorption and emission, the method discussed in present section is applicalbe to, is givne by the Poynting-Robertson effect (read § 61.09.12).

The mechanical energy is dissipated and therefore the size of the orbit shrinks.

The drag force has both a radial and a transverse component, in general. Both $\boldsymbol{\ell}$ and ℓ change, and in particular ℓ_z changes.

It can be shown, from equation (31.01.16), that the eccentricity decreases down to zero.

It can be shown that for large eccentricities the decrease of the aphelion distance is larger than the decrease of the perihelion distance.

In case of a circular orbit the orbit will stay circular because if any perturbation would make it rise above zero it will go back to zero again.

As the normal component is zero the inclination and lines of nodes do not change, that is the orbit plane is fixed in space.

DRAFT-IN-PROGRESS

31.02.00.03 Tides

Assume that the rotational angular velocity of the primary (planet) and the orbital angular velocity of the secondary (satellite) are parallel (along the z axis), and that both have a common sense of rotation and consider the common case when the former is larger than the latter.

In this case the tidal deformation provides a positive tangential component of the force on the satellite plus a radial component but no normal component of the force exist.

Therefore both the mechanical energy of the satellite alone and the angular momentum component along z increase.

The plane of the orbit does not change (inclination and line of nodes).

31.04.01 Gravitational Attraction Between Spherically Symmetric Finite-Size Bodies

We want to demonstrate that the gravitational attraction between two spherically symmetric finite-size bodies can be calculated by assuming the mass of the two bodies of finite size is concentrated at their centers. This is not evident a priori because, even if the field produced by one body is given by the field produced by a point mass at the center, this field is applied to a finite-size body and the total force is given by the sum of all the forces acting on the different infinitesimal masses making up the body. The forces on the different infinitesimal masses are, in general, different.

First consider an isolated system made of one spherically symmetric finite-size body and one external point mass. The force on the point mass is given by Newton law of gravitation for the two equivalent point masses, because the body is spherically symmetrical. Therefore, as the sum of internal forces is zero, also the force exerted by the mass point on the finite size body is given by Newton law for the two equivalent point masses. Therefore the total force of a point mass applied to a spherically symmetrical body can be calculate from Newton law of gravitation for the two equivalent point masses.

It then follows that also the gravitational attraction between two spherically symmetric finite-size bodies can be calculated from Newton law of gravitation for the two equivalent point masses because the field produced externally by each of them is the same as the field of a point charge.

31.04.02 Roche Limit

This § is referenced at pages:
[1634, 1634]

Consider a satellite of mass m and radius d revolving around a central planet of mass M on a circular orbit of radius R. Assume that the angular velocities of rotation and revolution of the satellite are parallel vectors. Assume that the satellite is co-rotating, that is its rotation period is equal to the period of revolution around the planet, just like the Moon around the Earth. Let the radial axis, r, be directed in the radial direction, starting from the center of the planet towards the center of the satellite. Assume that both the satellite and planet have a spherically symmetrical mass distribution.

Consider a small mass μ at the surface of the satellite, just along the line joining the center of the planet to the center of the satellite (radial axis r). Consider both cases when the small mass lies on the side of the planet, in one case, and when the small mass lies on the opposite side with respect to the planet, in the other case. A constraint force, $\mathbf{N}$, directed along the line joining the center of the planet to the center of the satellite, acts on the mass, a radial force, oriented towards the exterior of the satellite as long as the small mass is just lying on the land; this is just the normal force keeping the small mass in equilibrium with respect to the gravitational attraction of the satellite. In this case, for the convention chosen, when we consider the case of the small mass lying on the side of the planet, the projection of $\mathbf{N}$ along the radial axis originating from the satellite center will be negative. This force might even have a positive component, in the case a contribution of a cohesion force exists capable to keep the mass from escaping. In the other case of the small mass lying on the opposite side with respect to the planet, the forces will be inverted. With this convention we will denote by N the component of the force $\mathbf{N}$ radial with respect to the center of the satellite. This is positive if and only if the small mass is just lying on the satellite surface while it will be negative if there is a cohesion force keeping the small mass from escaping high on the satellite surface.

We want to study the equilibrium condition of the small mass and show under which conditions a cohesive force is required to keep the mass from escaping from the satellite. This problem is related to the breaking of a satellite due to the tidal force of a planet.

DRAFT-N-PROGRESS

Assume: $\mu \ll m \ll M$ and $d \ll R$. The simplifying hypothesis $m \ll M$ is done in order to simplify the dynamics of the problem, as it allows one to assume that the small satellite is just revolving around the center of the large planet.

Let ω be the angular velocity of the revolution of the satellite around the planet. The orbit of the satellite around the planet satisfies, according to the **Cardinal Equations** :

$$\omega^2 R = \frac{\mathcal{G}M}{R^2} \quad .$$

Study the problem from the non-Inertial Reference Frame co-rotating with the satellite. The projection of the first **Cardinal Equation** on the r axis, applied to the small mass μ at equilibrium, in the non-Inertial Reference Frame co-rotating with the satellite, reads:

$$-N + \frac{\mathcal{G}m\mu}{d^2} - \frac{\mathcal{G}M\mu}{(R-d)^2} + \mu\omega^2 (R-d) = 0 \qquad \text{if the mass lies on the side of the planet} \qquad (31.04.01)$$

→ 1632

$$+N - \frac{\mathcal{G}m\mu}{d^2} - \frac{\mathcal{G}M\mu}{(R+d)^2} + \mu\omega^2 (R+d) = 0 \qquad \text{if the mass lies on the opposite side with respect to the planet} \quad .$$

(31.04.02)

→ 1632

The unknown constrain force **N** reads:

$$N = +\frac{\mathcal{G}m\mu}{d^2} - \frac{\mathcal{G}M\mu}{(R-d)^2} + \mu\omega^2 (R-d) \qquad \text{if the mass lies on the side of the planet} \qquad (31.04.03)$$

$$N = +\frac{\mathcal{G}m\mu}{d^2} + \frac{\mathcal{G}M\mu}{(R+d)^2} - \mu\omega^2 (R+d) \qquad \text{if the mass lies on the opposite side with respect to the planet} \quad .$$

(31.04.04)

Note that:

- $N > 0$, force oriented towards the exterior of the satellite, implies that the surface of the satellite is just sustaining the weight of the mass;
- $N < 0$ force oriented towards the interior of the satellite, implies that the surface of the satellite must keep the mass from getting high over the satellite surface (a cohesion force is required).

One can develop equations (31.04.01), (31.04.02), to first-order in d/R, by exploiting the fact that $d \ll R$:

$$\begin{aligned} N &= +\frac{\mathcal{G}m\mu}{d^2} \pm \frac{\mathcal{G}M\mu}{(R \pm d)^2} \mp \mu\omega^2 (R \pm d) \quad , \\ N &\simeq +\frac{\mathcal{G}m\mu}{d^2} \pm \frac{\mathcal{G}M\mu}{R^2}\left(1 \mp 2\frac{d}{R}\right) \mp \mu\omega^2 \left(1 \pm 2\frac{d}{R}\right) = \quad , \\ &+ \frac{\mathcal{G}m\mu}{d^2} \pm \frac{\mathcal{G}M\mu}{R^2}\left(1 \mp 2\frac{d}{R}\right) \mp \frac{\mathcal{G}M\mu}{R^2}\left(1 \pm 2\frac{d}{R}\right) = \quad , \\ &+ \frac{\mathcal{G}m\mu}{d^2} + \frac{\mathcal{G}M\mu}{R^2}\left(-3\frac{d}{R}\right) \quad . \end{aligned} \qquad (31.04.05)$$

→ 1632

The first term in equation (31.04.05) is just the weight due to the satellite, and the second one is a correction factor, going in the opposite direction with respect to the weight, that is tending to lift the mass μ from the satellite surface. This is true in both locations of the test mass μ as the equations show that the different signs cancel.

Coherently with the chosen conventions N is dominated by a positive term, to counteract the gravitational attraction of the satellite. However, the second term is negative, decreasing the effective weight of the test mass. Under appropriate conditions, the corrective term can exceed the first term, showing that a cohesion force is required to keep the small mass from escaping from the gravitational attraction of the satellite.

The condition of weightlessness is $N < 0$:

$$N \leq 0 \implies \boxed{\frac{R}{d} \leq \left(\frac{3M}{m}\right)^{1/3} \text{ for zero cohesion force}} \quad . \qquad (31.04.06)$$

DRAFT - IN PROGRESS

CC BY NC ND

The overall effect is to deform the satellite in the direction of the line joining the centers of the planet and satellite.

In a real case one should also account for:

- the rotation of the satellite, if not geo-synchronous;
- the real geometry of the orbits (elliptic orbits, non parallel angular velocities of rotation and revolution of the satellites);
- tidal deformations of the planet and satellite, and effect on the tidal bulge of the rotation of the planet;
- the real cohesion force.

Note finally that the analysis is a purely static one, assuming that the satellite is co-rotating.

The problem has applications in astrophysics (dynamics of binary stars) as well as in planetary mechanics (tidal disruption of a satellite).

$$N = +\frac{\mathcal{G}m\mu}{r_0^2} + \frac{\mathcal{G}M\mu}{(D-r_0)^2} - \mu\omega^2(r+r_0) \qquad \text{if the mass lies on the opposite side with respect to the planet} \quad . \qquad (31.04.10)$$

$$\begin{aligned} N = &+\frac{\mathcal{G}m\mu}{r_0^2} - \frac{\mathcal{G}M\mu}{(D-r_0)^2} + \mu\omega^2(r-r_0) \simeq \quad , \\ &+\frac{\mathcal{G}m\mu}{r_0^2} - \frac{\mathcal{G}M\mu}{D^2}\left(1+2\frac{r_0}{D}\right) + \frac{\mathcal{G}M\mu}{D^2}\left(1-\frac{r_0}{r}\right) = \quad , \\ &+\frac{\mathcal{G}m\mu}{r_0^2} - \frac{\mathcal{G}M\mu}{D^2}\left(\frac{r_0}{r}+2\frac{r_0}{D}\right) \end{aligned} \qquad (31.04.11)$$

$$\begin{aligned} N = &+\frac{\mathcal{G}m\mu}{r_0^2} + \frac{\mathcal{G}M\mu}{(D-r_0)^2} - \mu\omega^2(r+r_0) \simeq \quad , \\ &+\frac{\mathcal{G}m\mu}{r_0^2} + \frac{\mathcal{G}M\mu}{D^2}\left(1-2\frac{r_0}{D}\right) - \frac{\mathcal{G}M\mu}{D^2}\left(1+\frac{r_0}{r}\right) = \quad , \\ &+\frac{\mathcal{G}m\mu}{r_0^2} - \frac{\mathcal{G}M\mu}{D^2}\left(\frac{r_0}{r}+2\frac{r_0}{D}\right) \quad . \end{aligned} \qquad (31.04.12)$$

In the limit $m \ll M$ the latter results reduce to the results of problem § 31.04.02.

31.04.04

Tidal Potential

This problem represents the generalisation of problem § 31.04.02.

We want to determine the tidal effects at the surface of a first small spherically symmetrical body (conventionally called the satellite), with mass m and radius r, caused by a second far-away spherically symmetrical body (conventionally called the planet) with mass M; the distance between the centers the two bodies is D.

Assume that the satellite is spinning with angular velocity perpendicular to the plane of the two orbits.

Assume, for simplicity, $m \ll M$. Assume $r \ll D$.

Thanks to the hypotheses the planet can be considered just as a distant point mass. We are going to calculate the effects of the fact that the field produced by the planet is not uniform on the whole volume of the satellite, because the satellite has finite dimensions.

Assume that the planet is at rest with respect to some Inertial Reference Frame , with a Coordinate System centered at the center of the planet. Let $\mathbf{D}$ be the position vector from the center of the planet to the center of the satellite. Let $\mathbf{r}$ be the position vector from the center of the satellite. Let $\mathbf{d} \equiv \mathbf{D} + \mathbf{r}$ be the location of a small mass μ ($\mu \ll m$ and $\mu \ll M$) with respect to the center of the planet. Even if it is not strictly necessary we might assume, for concreteness, that the mass lies at the surface of the satellite. Let us assume that the tidal deformation is very small with respect to the radius of the satellite, that is consider the satellite spherical even if it is subject to the tidal force we are going to calculate.

DRAFT-IN-PROGRESS

The two bodies are rotating around the common Center-Of-Mass with an angular angular frequency given by:

$$\frac{Mm}{m+M}\omega^2 D = \frac{\mathcal{G}Mm}{D^2} \Longrightarrow \omega^2 = \frac{\mathcal{G}(m+M)}{D^3} \simeq \frac{\mathcal{G}M}{D^3} \quad .$$

The equation of motion of the small mass μ with respect to the center of mass of the satellite can be written directly from equation (24.12.01), taking into account that the reduced mass of the pair satellite and small mass is just μ:

$$\mu\ddot{\mathbf{r}} = -\frac{\mathcal{G}\mu m}{r^3}\mathbf{r} + \mathbf{N} + \mu\left(-\frac{\mathcal{G}M}{d^3}\mathbf{d} + \frac{\mathcal{G}M}{D^3}\mathbf{D}\right) \Longrightarrow \ddot{\mathbf{r}} = -\frac{\mathcal{G}m}{r^3}\mathbf{r} + \frac{\mathbf{N}}{\mu} + \mathcal{G}M\left(-\frac{\mathbf{d}}{d^3} + \frac{\mathbf{D}}{D^3}\right) \quad .$$

The force $\mathbf{N}$ is the force constraining the small mass at the surface of the satellite, a constraint force to be determined from the equation of motion. At equilibrium $\ddot{\mathbf{r}} = 0$.

Note that the above equation is the equation for the relative coordinate $\mathbf{r}$ of the small mass with respect to the center of the satellite, and not the equation of motion of the small mass itself. This is indeed the correct expression to use, as we are intereted in the motion of the small mass with respect to the satellite. Moreover, we want to understand the change in the total force acting on the small mass when the third body (the planet) is present, with respect to the satellite-generated weight of the small mass alone.

The resulting force on the small mass μ is thus dominated by its weight and by the constraint force $\mathbf{N}$, plus a correction term taking into account the gravitational effects of the distant planet and the overall gravitational force of the planet on the satellite. The corrective term tends to elongate the satellite along the direction of the line connecting the centers of the planet and satellite, producing two tidal bulges.

The equation is the equation for the relative coordinate $\mathbf{r}$ of the small mass with respect to the center of the satellite. It shows that the forces on the small mass are, firstly, the weight of the mass and the constraint force $\mathbf{N}$. However, the presence of a third body manifests itself via two new additional terms, as it is shown by the fact that the two additional terms are proportional to the mass M of the third body (the planet). The two additional terms are the direct force on the small mass by the third body (the planet), $-\mathcal{G}M\frac{\mathbf{d}}{d^3}$, plus the direct force on the satellite by the planet with reversed sign, $\mathcal{G}M\frac{\mathbf{D}}{D^3}$, affecting the motion of the Center-Of-Mass of the satellite itself. As the force applied by the small mass on the satellite is negligible with respect to the latter force applied by the planet on the satellite, the latter term is just the acceleration of the satellite with respect to same Inertial Reference Frame . It is recognised that the acceleration of the satellite, when carried on the left side and summed to the relative acceleration of the small mass with respect to the Center-Of-Mass of the satellite, gives the absolute acceleration of the small mass with respect to same Inertial Reference Frame , thus expressing the first **Cardinal Equation** applied to the small mass. In case the mass of the planet is much large than the mass of the satellite and the planet is fixed with respect to some Reference Frame the aforementioned acceleration can be taken as the acceleration with respect to the center of the planet. In the additional simplifying assumption of a circular orbit the centripetal acceleration can be expressed as $-\omega^2\mathbf{D} = \mathcal{G}M\frac{\mathbf{D}}{D^3}$.

As long as tidal forces are small with respect to gravitational forces and the distance to the external force center, the planet, is large with respect to the satellite radius the result can be cast in an approximate form. In fact

$$\frac{\mathbf{d}}{d^3} - \frac{\mathbf{D}}{D^3} = \frac{\mathbf{D}+\mathbf{r}}{d^3} - \frac{\mathbf{D}}{D^3} = \mathbf{D}\left(\frac{1}{d^3} - \frac{1}{D^3}\right) + \frac{\mathbf{r}}{d^3} \quad ,$$

and

$$d \equiv |\mathbf{r}+\mathbf{D}| = D\left(1 + 2\frac{\mathbf{r}\cdot\mathbf{D}}{D^2} + \frac{r^2}{D^2}\right)^{1/2} = D\left(1 + \frac{\mathbf{r}\cdot\mathbf{D}}{D^2}\right) + \mathcal{O}\left(\frac{r}{D}\right)^2 \simeq D\left(1 + \frac{\mathbf{r}\cdot\mathbf{D}}{D^2}\right) \quad .$$

The binomial approximation gives, to first-order in $\frac{r}{D}$:

$$\mathbf{D}\left(\frac{1}{d^3} - \frac{1}{D^3}\right) + \frac{\mathbf{r}}{d^3} \simeq \frac{\mathbf{D}}{D^3}\left(-3\frac{\mathbf{r}\cdot\mathbf{D}}{D^2}\right) + \frac{\mathbf{r}}{d^3} = -3\frac{(\mathbf{r}\cdot\mathbf{D})\,\mathbf{D}}{D^5} + \frac{\mathbf{r}}{D^3} \quad .$$

DRAFT - Do Not Distribute

Note that the term $\frac{\mathbf{r}}{d^3}$ is already a first-order term in $\frac{r}{D}$ and therefore only the zero order approximation for d is used in developing it.

Note that the result has the functional expression of a **Dipole** field calculated at the position **D** produced by a Dipole moment proportional to **r**.

It follows:

$$\ddot{\mathbf{r}} \simeq -\frac{\mathcal{G}m}{r^3}\mathbf{r} + \frac{\mathbf{N}}{\mu} - \mathcal{G}M\left(\frac{\mathbf{r}}{D^3} - 3\frac{(\mathbf{r}\cdot\mathbf{D})\,\mathbf{D}}{D^5}\right) \quad .$$

Note that the tidal force changes the value of the constraint force **N** required to keep the body in equilibrium.

The potential at the surface of the satellite is thus:

$$\Phi[\mathbf{r}] = -\frac{\mathcal{G}m}{r} + \frac{\mathcal{G}M}{2D^3}\left(r^2 - 3\frac{(\mathbf{r}\cdot\mathbf{D})^2}{D^2}\right) \quad .$$

Note that this potential assumes that the satellite is of spherical shape, that is its deformation due to the tidal forces is negligible. As a successive approximation one should calcolate the deformation of the satellite due to the tidal force and after that one should calcolate the change of the potential produced by the satellite due to the deformation. Also note that the expression for the potential is not limited to the surface of the satellite.

As a fluid body will tend to reach an equilibrium situation such that its free surface is an equipotential surface a fluid satellite will tend to change its shape accordingly.

Choose the z axis perpendicularly to the plane where the orbits of the planet and satellite lies, that is along the rotation axis of the planet. Choose the x axis pointing to the center of the planet. Introducing a spherical Coordinate System the potential can be re-written as:

$$\Phi[\mathbf{r}] = -\frac{\mathcal{G}m}{r} + \frac{\mathcal{G}M}{2r}\frac{r^3}{D^3}\left(1 - 3\frac{(\mathbf{r}\cdot\mathbf{D})^2}{r^2D^2}\right) = -\frac{\mathcal{G}m}{r} - \frac{\mathcal{G}M}{r}\left(\frac{r}{D}\right)^3\left(\frac{3\sin^2[\theta]\cos^2[\phi] - 1}{2}\right) \quad .$$

The equilibrium shape of ideal planet covered by an ocean would be given by a constant potential.

Note, finally, that the tidal force is given by the gradient of the gravitational force exerted by the planet, and therefore it goes as an inverse-cube force. Therefore it rises at short distances more than the gravity force. Tides generated by different bodies must thus be compared by comparing the gradient of the force, not the force itself.

31.04.05
Tidal Evolution of the Earth-Moon System

This § is referenced at pages:
[1587]

©|Lim Yung-Kuo, *Problems And Solutions On Mechanics*, 1994, World Scientific, ...Ed., ...|1176||

The Earth-Moon system can be considered, to a first approximation, as subject to a small overall torque due to external bodies, at least on average. Thus the total angular momentum is nearly constant. Note that the same argument does not apply equally well to the overall force due to external bodies, because that is driven by the Sun gravitational force and therefore the linear momentum is not conserved, not even in an approximate way.

To study the evolution of the system one can use a number of simplifying assumptions, useful to simplify the calculations while giving, at the same time, a clear identification of the physical mechanisms coming into play.

- Describe the situation from a Reference Frame tied to the Earth center, which is assumed to be approximately inertial.
- The Moon orbits around the Earth center on a circular orbit of radius r in the ecliptic plane.

DRAFT - IN PROGRESS

- The circular orbit of the Moon is slowly changing its radius, on a very long time scale compared to the orbital period.
- The spin angular momentum of the Earth, $\mathbf{S} = I\boldsymbol{\omega}$, is assumed to be parallel to the orbital angular momentum of the Moon around the Earth, $\mathbf{L}$. Moreover, one should keep in mind that the angular velocity of the Moon rotation is equal to the angular velocity of its revolution around the Earth. These assumptions are justified by the fact that the Earth spin precesses about the normal to the ecliptic plane with a period of about $2.5{\cdot}10^5$ years while the plane of the Moon orbit precesses similarly with a period of about 19 years. Therefore, on the long-time average, both $\mathbf{S}$ and $\mathbf{L}$ are perpendicular to the ecliptic plane.
- The total angular momentum, $\mathbf{J}$ is constant (we are neglecting the Solar tidal drag) and the spin angular momentum of the Moon is negligible with respect to $\mathbf{L}$ and $\mathbf{S}$. Thus: $\mathbf{J} = \mathbf{L} + \mathbf{S}$.

We want to determine the evolution of the Earth-Moon system due to the effect of the tidal drag.

Let the Earth mass be M, its momentum of inertia with respect to its rotation axis be I, the Moon mass be m and the velocity of the Moon Center-Of-Mass be $\mathbf{v}$. The following numerical data are useful.

Earth Radius: $R = 6.3781{\cdot}10^6$ m.
Earth Mass: $M = 5.974{\cdot}10^{24}$ kg.
Moon Mass: $m = 7.353{\cdot}10^{22}$ kg.
Earth-Moon distance: $r = 3.841{\cdot}10^8$ m.
Earth rotation sidereal period: $T_{\mathtt{E}} = 86164$ s.
Moon revolution and rotation sidereal period: $T_{\mathtt{M}} = 2.361{\cdot}10^6$ s.

Moment of inertia of the Earth with respect to its rotation axis: $I = 0.3335MR^2 \neq (2/5)\,MR^2$. Note the significant difference with respect to the calculated value for a homogeneous spherical mass distribution: it is smaller than expected because the Earth density increases going towards the center of the Earth.

Let us use an Inertial Reference Frame with the Earth at rest and let z be the axis perpendicular to the Moon orbit. Let $\omega \equiv \omega_z$ be the component of the spin angular velocity of the Earth on the z axis (which might have any sign). Let $\Omega \equiv \Omega_z$ be the component of the orbital angular velocity of the Moon on the z axis (which might have any sign). Let $L \equiv L_z$ be the component of the orbital angular momentum of the Moon on the z axis (which might have any sign).

The total mechanical energy of the Earth-Moon system relative to the Center-Of-Mass of the Earth is:

$$E = \frac{1}{2}mv^2 - \frac{\gamma}{r} + \frac{1}{2}I\omega^2 \qquad \gamma \equiv \mathcal{G}Mm \quad ,$$

neglecting the spin energy of the Moon. Note that thanks to the hypothesis that the Moon orbits around the Earth center on a circular orbit this is actually the mechanical energy in the [glo:CMRF]Center-of-Momenta Reference Frame of the Earth-Moon system, following **Koënig theorem** for kinetic energy. Moreover, the kinetic energy of the motion of the Center-Of-Mass of the Earth-Moon system is driven by the external forces as it just depends on the total linear momentum of the Earth-Moon system, which is determined by the first **Cardinal Equation** .

From the first **Cardinal Equation** applied to the Moon one finds:

$$-m\frac{v^2}{r} \equiv -m\Omega^2 r = -\frac{\gamma}{r^2} \equiv -\frac{\gamma}{r^2} \quad , \tag{31.04.13}$$

→ 1637 1638

in terms of the angular velocity of the revolution of the Moon around the Earth, Ω.

It follows that:

$$\left\{L \equiv mrv \neq \text{constant} \qquad \text{and} \qquad mrv^2 = \gamma = \text{constant}\right\} \Longrightarrow \left\{v = \frac{\gamma}{L} \qquad r = \frac{L^2}{m\gamma}\right\} . \tag{31.04.14}$$

→ 1637 1638

As a consequence of (31.04.13), (31.04.14) we can express both Ω and ω as a function of either r alone or as a function of L alone:

$$\Omega = \frac{2\pi}{T_{\mathtt{M}}} = 2.66170{\cdot}10^{-6}\ \text{rad/sec} \quad ,$$

$$\Omega[r] = \sqrt{\frac{\gamma}{mr^3}} = \qquad \Omega[L] = \frac{m\gamma^2}{L^3} \quad ,$$

→ 1638

DRAFT IN PROGRESS

CC BY NC ND

and:

$$\omega = \frac{2\pi}{T_{\mathrm{E}}} = 7.29212{\cdot}10^{-5}\ \mathrm{rad/sec} \quad ,$$
$$\omega[L] = \frac{J-L}{I} \qquad \omega[r] = \frac{J-\sqrt{m\gamma r}}{I} \quad ,$$

→ 1638 1639

all these equations being ready for later use.

Moreover, as a consequence of (31.04.13), (31.04.14), the mechanical energy can be rewritten, by eliminating r, v and ω in favour of the angular momenta, as:

$$E[L] = -K + \frac{S^2}{2I} = +\frac{\Phi}{2} + \frac{S^2}{2I} = -\frac{1}{2}mv^2 + \frac{S^2}{2I} = -\frac{\gamma}{2r} + \frac{S^2}{2I} = -\frac{m\gamma^2}{2L^2} + \frac{S^2}{2} = -\frac{m\gamma^2}{2L^2} + \frac{(J-L)^2}{2I} \quad . \tag{31.04.15}$$

→ 1638

The expression (31.04.15) allows one to rewrite the mechanical energy as a function of either the Moon distance or the Moon velocity, by using equation (31.04.14).

If tidal friction is present the mechanical energy is not constant and it is dissipated into internal energy of the system. Moreover, only **J** is constant, not **L** nor **S** separately. The system will continue to dissipate the mechanical energy until this is compatible with the conservation of angular momentum. The ultimate state will feature the lowest possible mechanical energy compatible with the constraints (**J** constant). Therefore we look for the minimum of the energy:

$$\frac{\mathrm{d}E[L]}{\mathrm{d}L} = \frac{m\gamma^2}{L^3} - \frac{J-L}{I} = \Omega - \omega \quad ,$$
$$\frac{d^2E[L]}{\mathrm{d}L^2} = -\frac{3m\gamma^2}{L^4} + \frac{1}{I} \quad .$$

The extrema of the mechanical energy at fixed total angular momentum are thus characterized by co-rotation of the Moon: $\Omega = \omega$. The result is actually a very general theorem, stating that at thermal equilibrium a system must rotate as a rigid-body.

Using the dependence of the angular velocities on the distance, equations (31.04.05), (31.04.05), one can solve the equation for the distance of minimum energy.

The study of the function (31.04.15), defined for $L > 0$, shows the following. The limits at the boundary of the domain are:

$$\lim_{L\longrightarrow 0^+} E[L] = -\infty \qquad \lim_{L\longrightarrow +\infty} E[L] = +\infty \quad .$$

The limits at the boundary of the domain of the first derivative are:

$$\lim_{L\longrightarrow 0^+} \frac{\mathrm{d}E[L]}{\mathrm{d}L} = +\infty \qquad \lim_{L\longrightarrow +\infty} \frac{\mathrm{d}E[L]}{\mathrm{d}L} = +\infty \quad .$$

However, the second derivative has one and only one zero, as it is apparent from its expression, at $L_f = \left(3m\gamma^2 I\right)^{1/4}$ (flex point). It should be checked, by using the actual values of the physical parameters, that the minimum of the first derivative, $\frac{\mathrm{d}E}{\mathrm{d}L}[L = L_f]$, is negative in such a way that the function is not monotonically increasing but has one relative maximum at small L and one relative minimum at large L.

The plot of the total mechanical energy of the Earth-Moon system versus the Moon orbital angular momentum is shown in figure 31.14. Note that as $r \propto L^2$, as from equation (31.04.14), the qualitative behavior of $E[r]$ is similar to the qualitative behavior of $E[L]$.

One finds the following numerical values:

$$L_{\mathtt{today}} = 2.887{\cdot}10^{34}\ \mathrm{kg\cdot m^2/s} \quad ,$$
$$L_{\mathtt{MAX}} = 0.438{\cdot}10^{34}\ \mathrm{kg\cdot m^2/s} \quad ,$$
$$L_{\mathtt{MIN}} = 3.472{\cdot}10^{34}\ \mathrm{kg\cdot m^2/s} \quad ,$$
$$E[L_{\mathtt{today}}] = 3.931{\cdot}10^{29}\ \mathrm{J} \quad ,$$
$$E[L_{\mathtt{MIN}}] = -2.615{\cdot}10^{28}\ \mathrm{J} \quad .$$

In all the cases when $\Omega > \omega$ the Moon is orbiting faster than the Earth is rotating, therefore the tidal bulge is delayed with respect to the Moon position and it tends to decrease the orbital angular mo-

DRAFT IN PROGRESS

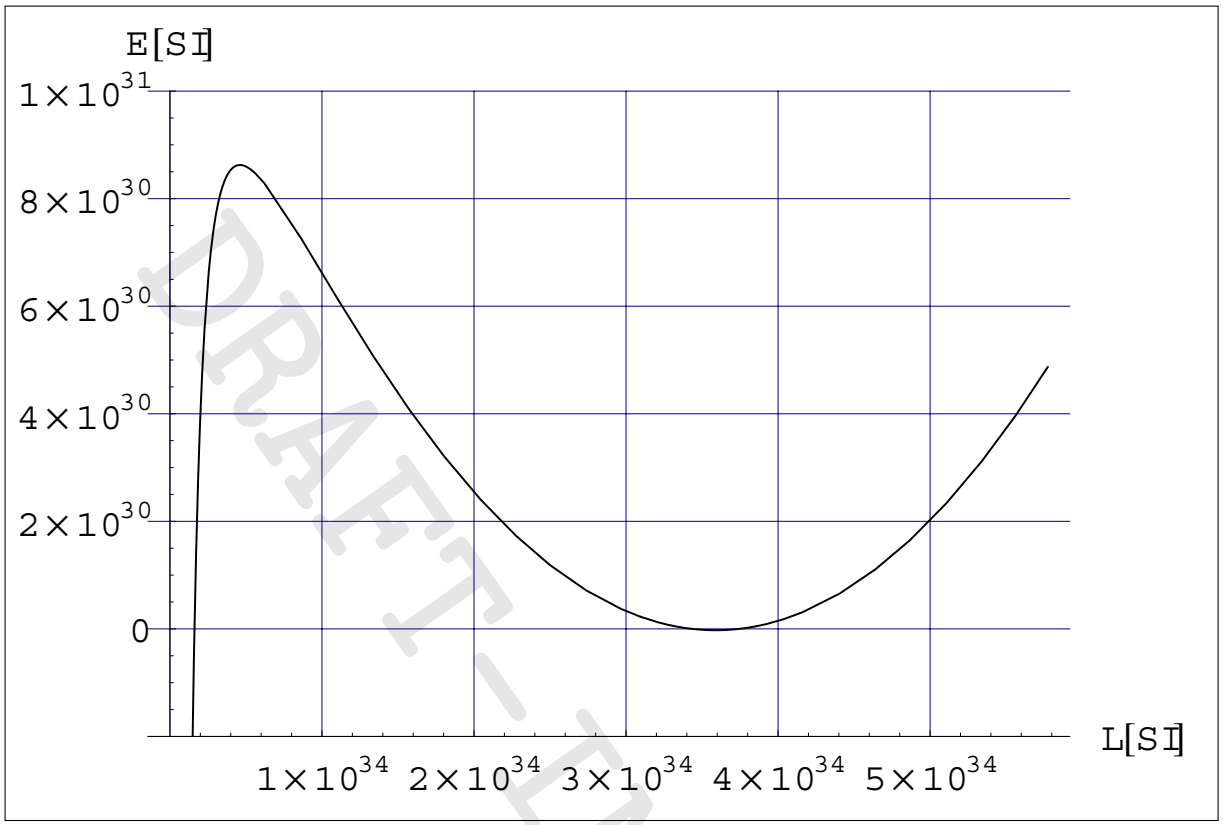

Figure 31.14: Total mechanical energy of the Earth-Moon system versus the Moon orbital angular momentum.

mentum of the Moon:

$$\Omega > \omega \implies \frac{\mathrm{d}L}{\mathrm{d}t} < 0 \implies \frac{\mathrm{d}r}{\mathrm{d}t} < 0 \quad .$$

In all the cases when $\Omega < \omega$ the Moon is orbiting slower than the Earth is rotating, therefore the tidal bulge is advanced with respect to the Moon position and it tends to increase the orbital angular momentum of the Moon:

$$\Omega < \omega \implies \frac{\mathrm{d}L}{\mathrm{d}t} > 0 \implies \frac{\mathrm{d}r}{\mathrm{d}t} > 0 \quad .$$

The extremum of the mechanical energy the at the smallest L is a relative maximum, such that the bulk of mechanical energy is in the spin of the Earth, because J is conserved. The extremum of mechanical energy at the largest L is a relative minimum, such that the bulk of mechanical energy is in the orbital angular momentum of the Moon, because J is conserved.

At the extrema, as they are characterized by co-rotation, both the Moon tidal drag on the Earth and the Earth tidal drag on the Moon will vanish. From then on the solar tidal drag (which is neglected in our model) will drive the system.

The minimum is obviously a stable configuration while the maximum is not.

From the current measured value of the lengthening of the Earth day length, $\dot{\omega} = -0.85 \cdot 10^{-21}\ \mathrm{rad/s^2}$, we can derive the value of the rate at which the Moon is receding from the Earth. In fact by taking the time deirvative of equation (31.04.05) and dividing the resulting equiation by r one finds:

$$\dot{S} = I\dot{\omega} = -\sqrt{\frac{m\gamma}{r}}\frac{\dot{r}}{2} \quad ,$$

$$\frac{\dot{r}}{r} = -2\frac{I\dot{\omega}}{\sqrt{m\gamma r}} = -2\frac{I\dot{\omega}}{L} = -2\frac{S\dot{\omega}}{L\omega} \quad .$$

The numerical result gives:

$$\dot{r} \simeq 0.058\ \mathrm{m/year} \quad .$$

DRAFT - IN - PROGRESS

31-001 Perturbed Orbit Equation in Terms of the Intrinsic Unit Vectors

Express the perturbed orbit equation of § 31.01.01 in terms of the intrinsic unit vectors: **tangent**, **normal** and **binormal**. Note that the **normal** unit vector does not correspond to the $\mathbf{e}_N$ unit vector, which is normal to the orbit plane, of § 31.01. On the other hand the **binormal** unit vector corresponds to the $\mathbf{e}_N$ unit vector of § 31.01.

31-002 Equation Derivation

Derive equation (31.01.03) and equation (31.01.04).

31-003 Equation Derivation

Derive equation (31.01.07) and equation (31.01).

31-004 Equation Derivation

Derive equation (31.01.08).

31-005 Equation Derivation

Derive equation (31.01.09) and equation (31.01.10).

31-006 Magnitude of the Quadrupole Moment

Consider a point at a certain distance R from the Center-Of-Mass of an arbitrary mass distribution of total mass M, assumed for simplicity with cylindrical symmetry. Determine the condition on Q ensuring that the **Quadrupole** potential is negligible with respect to the monopole potential at the point.

31-007 Satellite Around an Oblate Planet

Determine the period of rotation T of a satellite in a circular orbit of radius a on the equatorial plane of a planet of mass M, radius R and **Quadrupole** moment Q.

31-008 True and Eccentric Anomaly

Show that the following relation links the true and eccentric anomaly for hyperbolic motion:

$$\tan\left[\frac{f}{2}\right] = \sqrt{\frac{1+e}{1-e}}\tanh\left[\frac{\nu}{2}\right] \quad .$$

Show that the following relation links the true and eccentric anomaly for elliptic motion:

$$\tan\left[\frac{f}{2}\right] = \sqrt{\frac{1+e}{1-e}}\tan\left[\frac{\nu}{2}\right] \quad .$$

32.01 Lagrangian and Eulerian Approaches

This § is referenced at pages:
[1517, 1645]

Lagrangian approach: describe all quantities as a function of the space coordinates at some reference configuration of the continuous medium, $\mathbf{x}$. That is: follow the motion of each macroscopically infinitesimal volume of the continuum. Consider any reference configuration of the continuous medium and label each macroscopically infinitesimal volume of the continuum with its position at the reference configuration. In case of a solid use, for instance, the position of any particle at equilibrium.

Eulerian approach: describe all quantities as a function of the space coordinates of the point where the quantity is to be evaluated: $\mathbf{X}$. That is: fix a point in space a look at the properties there. Consider each point in space and describe what happens at that point irrespectively of which macroscopically infinitesimal volume of the continuum is passing there. It is most suitable for fluids, for which a reference configuration cannot be usually introduced.

DRAFT – IN-PROGRESS

32.02 Deformations of a Continuous Medium

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|7||

DRAFT IN PROGRESS

32.02.01 Geometry of Deformation

Consider a continuous medium, either solid or fluid, in a reference configuration, for instance, but not necessarily, when it is unstrained and at rest in some Inertial frame. Each point of the medium, when it is in the reference configuration, is labeled by its position vector $\mathbf{x}$.

Its position at time t, $\mathbf{X}[\mathbf{x}, t]$, is given by the function:

$$\boxed{\mathbf{X}[\mathbf{x}, t] \equiv \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}, t] \qquad \mathbf{x} \text{ does not depend on time}} \quad . \tag{32.02.01}$$

→ 1647

The displacement vector is thus:

$$\boxed{\boldsymbol{\xi}[\mathbf{x}, t] \equiv \mathbf{X}[\mathbf{x}, t] - \mathbf{x}} \quad .$$

Note that the dynamical variable is either $\boldsymbol{\xi}[\mathbf{x}, t]$, the displacement vector, or $\mathbf{X}[\mathbf{x}, t]$, the actual position, while $\mathbf{x}$ just labels any point on the continuous medium via its position in the reference configuration.

The Jacobian of the transformation, which is supposed to be locally invertible, is given by:

$$\boxed{\frac{\partial \xi_j}{\partial x_k} \neq 0} \quad .$$

Every function defined for the continuous medium can be expresses either in terms of the initial coordinates $\mathbf{x}$ (the Lagrangian formulation) or in terms of the instantaneous coordinates $\mathbf{X}$ (the Eulerian formulation). Read § 32.01.

32.02.02 Infinitesimal Deformations and the Strain Tensor

Consider either a solid or a fluid continuous medium undergoing infinitesimal deformations. Use as a reference configuration, a configuration where the solid/fluid is unstrained at rest in an Inertial Reference Frame .

Then consider a situation outside equilibrium, under a small strain, such that the linear approximation can be applied. If this is not the case the much more complex theory for finite deformations must be used. Small displacements are always assumed since now on and therefore the linear approximation is always used.

The displacement from the equilibrium position of a point, whose position at equilibrium is at $\mathbf{x}$, is given by the function $\boldsymbol{\xi}[\mathbf{x}]$ (compare with the elementary introduction in section § 27.02).

Refer to figure 32.11.

Consider, at equilibrium, two nearby points $\mathbf{x}$ and $\hat{\mathbf{x}}$, separated by a displacement $\Delta\mathbf{x}$. One must look for the transformed vector of $\Delta\mathbf{x}$, that is $\Delta\mathbf{X}$, in order to understand how locally the continuous medium is deformed. This can be found as follows (the time dependence is omitted for brevity):

$$\mathbf{x} \longrightarrow \mathbf{X}[\mathbf{x}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] \qquad \mathbf{X}[\mathbf{x}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] \longrightarrow \mathbf{X}[\mathbf{x}] - \mathbf{x} = \boldsymbol{\xi}[\mathbf{x}] \quad ,$$

$$\hat{\mathbf{x}} \equiv \mathbf{x} + \Delta\mathbf{x} \longrightarrow \begin{cases} \mathbf{X}[\hat{\mathbf{x}}] = (\mathbf{x} + \boldsymbol{\xi}[\mathbf{x}]) + \Delta(\mathbf{x} + \boldsymbol{\xi}[\mathbf{x}]) \\ \mathbf{X}[\hat{\mathbf{x}}] = (\mathbf{x} + \Delta\mathbf{x}) + \boldsymbol{\xi}[\mathbf{x} + \Delta\mathbf{x}] \end{cases} , \qquad \mathbf{X}[\hat{\mathbf{x}}] = \mathbf{x} + \Delta\mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] + \Delta\boldsymbol{\xi}[\mathbf{x}] \longrightarrow \mathbf{X}[\hat{\mathbf{x}}] - \hat{\mathbf{x}} = \boldsymbol{\xi}[\mathbf{x}] + \Delta\boldsymbol{\xi}[\mathbf{x}]$$

with the last equation showing two different, but equivalent, ways to obtain the displacement for $\hat{\mathbf{x}}$.

The basic result for equation (32.02.02) is thus:

$$\boxed{\mathbf{X}[\mathbf{x}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] \qquad \mathbf{X}[\hat{\mathbf{x}}] = \mathbf{x} + \Delta\mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] + \Delta\boldsymbol{\xi}[\mathbf{x}]}$$

→ 1645 1647

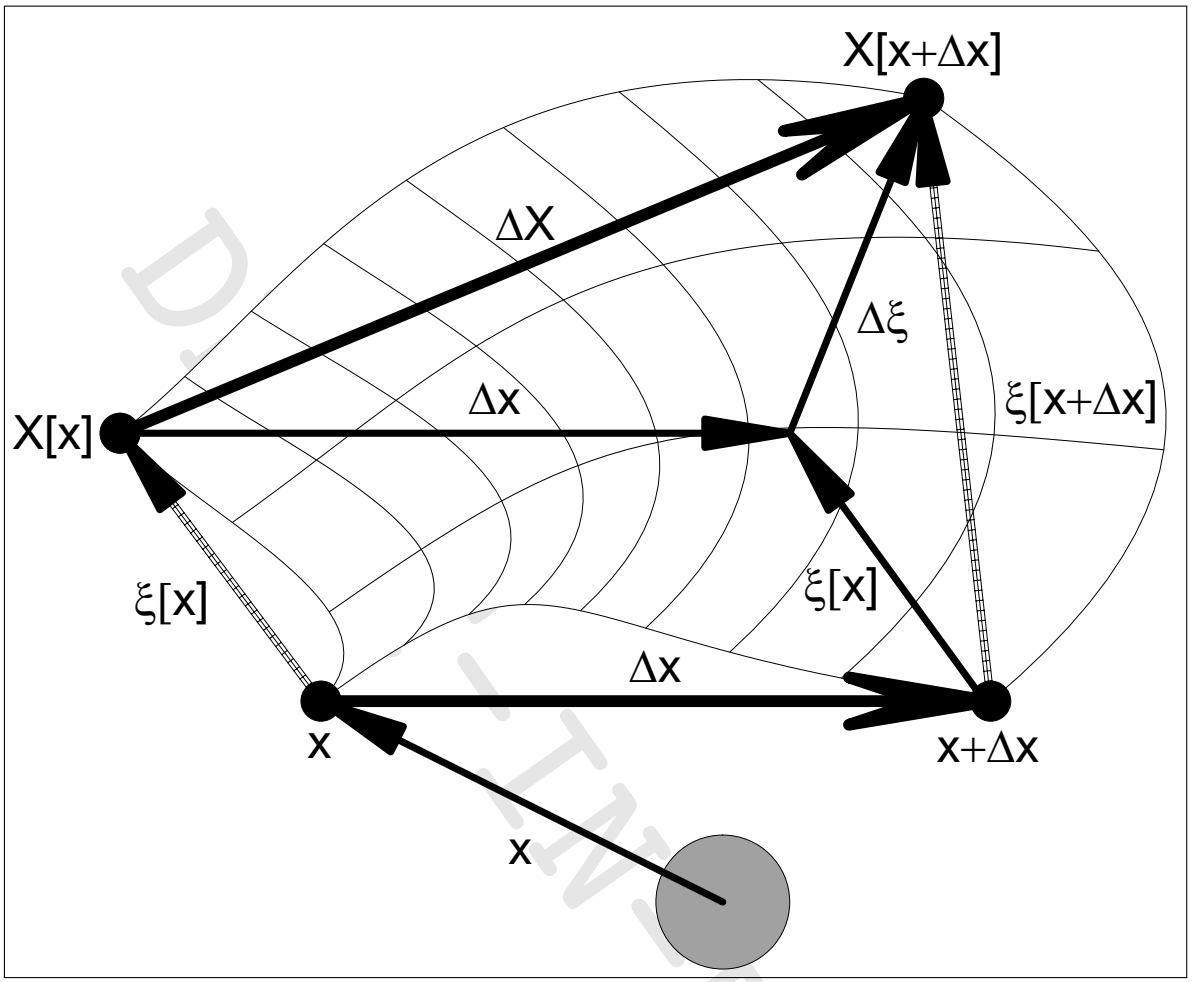

Figure 32.11: Sketchof the geometry of the displacement; the real displacements are in three dimensions

The displacement inside the medium is obtained by:

$$\Delta\mathbf{X} - \Delta\mathbf{x} = (\mathbf{X}[\hat{\mathbf{x}}] - \mathbf{X}[\mathbf{x}]) - (\hat{\mathbf{x}} - \mathbf{x}) = (\Delta\boldsymbol{\xi}[\mathbf{x}] + \Delta\mathbf{x}) - (\Delta\mathbf{x}) = \Delta\boldsymbol{\xi}[\mathbf{x}] \quad .$$

Alternatively:

$$\boxed{\Delta\mathbf{X} = \Delta\mathbf{x} + \Delta\boldsymbol{\xi}[\mathbf{x}]} \quad . \tag{32.02.02}$$

→ 1647

Note that, as long as we treat with $\Delta\mathbf{x}$ and $\Delta\mathbf{X}$, we cannot describe any translation of the medium. The translation, on the other hand, is described by the function $\boldsymbol{\xi}[\mathbf{x}]$ itself.

Therefore:

- the translation of the medium at $\mathbf{x}$ is described by $\boldsymbol{\xi}[\mathbf{x}]$;
- the deformation at $\mathbf{x}$ of an infinitesimal segment of medium $\Delta\mathbf{x}$ is described by $\Delta\mathbf{x} + \Delta\boldsymbol{\xi}[\mathbf{x}]$.

The linearization, assuming small strains, gives:

$$\boxed{\mathrm{d}\xi_k[\mathbf{x}] = \mathrm{d}x_j \frac{\partial \xi_k}{\partial x_j}[\mathbf{x}] + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2 = \mathrm{d}x_j \left(\partial_j \xi_k[\mathbf{x}]\right) + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2 \equiv F^{\cdot\cdot}_{kj}[\mathbf{x}]\,\mathrm{d}x_j + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2} \quad , \tag{32.02.03}$$

which can be written without explicit tensor indexes as:

$$\boxed{\mathrm{d}\boldsymbol{\xi}[\mathbf{x}] = \mathrm{d}x_j \left(\frac{\partial \boldsymbol{\xi}[\mathbf{x}]}{\partial x_j}\right) + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2 = \left(\,\mathrm{d}\mathbf{x}\cdot\boldsymbol{\nabla}\right)\boldsymbol{\xi}[\mathbf{x}] + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2 \equiv \mathbb{F}[\mathbf{x}]\cdot\,\mathrm{d}\mathbf{x} + \mathcal{O}\left(|\,\mathrm{d}\mathbf{x}|\right)^2} \quad , \tag{32.02.04}$$

where the strain tensor $\mathbb{F}$ has been introduced:

$$\boxed{\mathbb{F} \longrightarrow F^{\cdot\cdot}_{kj}[\mathbf{x}] \equiv \frac{\partial \xi_k}{\partial x_j}[\mathbf{x}]} \quad . \tag{32.02.05}$$

→ 1647

D. TW. PROGRESS

The order of the indexes in $\mathbb{F}$ is such that the matrix formed by $\mathbb{F}$ transforms the column vector $\mathrm{d}\mathbf{x}$ into $\mathrm{d}\boldsymbol{\xi}[\mathbf{x}]$ by normal matrix multiplication on the right of the matrix.

The strain tensor is defined as in (32.02.05) in orthonormal Cartesian Coordinates Coordinate System and it is defined in arbitrary coordinates starting from definition (32.02.05).

We have, in the linearised form, in terms of the matrix $\mathbb{F}$ with elements $F^{\cdot\cdot}_{kj}$:

$$\boxed{\mathrm{d}\mathbf{X} = \mathrm{d}\mathbf{x} + \mathrm{d}\boldsymbol{\xi}[\mathbf{x}] = \mathrm{d}\mathbf{x} + \mathbb{F}\ \mathrm{d}\mathbf{x} + \mathcal{O}\left(|\ \mathrm{d}\mathbf{x}|\right)^2 \simeq (\mathbb{I} + \mathbb{F})\ \mathrm{d}\mathbf{x}} \quad . \tag{32.02.06}$$

→ 1648

We will only be interested in the linear theory of elasticity, applicable to small deformations. The theory for finite deformations exists but it is obviously considerably more complex. Along this line we will always consider the linearised equations, neglecting terms of order higher than one.

32.02.03
Invariant Decomposition of the Strain Tensor

Equations (32.02.01), (32.02.02) show that the general infinitesimal deformation around any infinitesimal region around the point $\mathbf{x}$ is given by an overall translation by the amount $\boldsymbol{\xi}[\mathbf{x}]$ (described by equation (32.02.01)) plus a change in length and direction of every oriented line element originating at $\mathbf{x}$ (described by equation (32.02.02)).

In fact from equations (32.02.02), (32.02.02) we have:

$$\boxed{\mathbf{X}[\hat{\mathbf{x}}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] + \Delta\mathbf{x} + \Delta\boldsymbol{\xi}[\mathbf{x}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] + \Delta\mathbf{X}} \quad .$$

For an infinitesimal region:

$$\boxed{\mathbf{X}[\hat{\mathbf{x}}] = \mathbf{x} + \boldsymbol{\xi}[\mathbf{x}] + (\mathbb{I} + \mathbb{F})\ \mathrm{d}\mathbf{x}} \quad .$$

The general strain is thus defined, in orthonormal Cartesian Coordinates Coordinate System, in terms of the quantity

$$\boxed{F^{\cdot\cdot}_{kj}[\mathbf{x}] \equiv \frac{\partial \xi_k}{\partial x_j}[\mathbf{x}]} \quad , \tag{32.02.07}$$

→ 1647

the strain, a second-order tensor. That the strain is a Cartesian tensor is clear form its definition, equation (32.02.07), in terms of two vectors: ξ_k and x_j.

32.02.03.01 Trace of the Strain Tensor

The diagonal elements of the strain tensor represent the relative change of length in the corresponding direction. Its non diagonal elements, $F^{\cdot\cdot}_{kj}$, represent the shear deformations.

The trace of the strain tensor gives the relative volume dilatation of the element:

$$\frac{\Delta V}{V} = \mathrm{Tr}\,\mathbb{F} = F^{\cdot\cdot}_{jj} \quad .$$

In fact:

$$\frac{\Delta V}{V} = \frac{\Delta l_x}{l_x} + \frac{\Delta l_y}{l_y} + \frac{\Delta l_z}{l_z} \quad ,$$

becomes, in terms of the strain tensor,

$$\frac{\Delta V}{V} = \frac{\Delta \xi_x}{\Delta x} + \frac{\Delta \xi_y}{\Delta y} + \frac{\Delta \xi_z}{\Delta z} \qquad \lim_{\Delta x \Delta y \Delta z \longrightarrow 0} \frac{\Delta V}{V} = \frac{\partial \xi_x}{\partial x} + \frac{\partial \xi_y}{\partial y} + \frac{\partial \xi_z}{\partial z} \equiv \mathbf{div}\boldsymbol{\xi} \quad .$$

Alternatively one can note that:

$$\boxed{\delta V = \oiint_{\partial V} \boldsymbol{\xi} \cdot \mathrm{d}\mathbf{S} = \iiint_{V} \mathbf{div}\boldsymbol{\xi}\ \mathrm{d}V} \quad .$$

DRAFT IN PROGRESS

32.02.03.02 Shear Tensor

The strain tensor is not symmetric but, as any tensor with two indexes, it can be always decomposed in its symmetric and anti-symmetric parts:

$$F_{kj}^{\cdot\cdot} = \frac{1}{2}\left(F_{kj}^{\cdot\cdot} + F_{jk}^{\cdot\cdot}\right) + \frac{1}{2}\left(F_{kj}^{\cdot\cdot} - F_{jk}^{\cdot\cdot}\right) \equiv F^{\mathtt{S}}{}_{kj}^{\cdot\cdot} + F^{\mathtt{A}}{}_{kj}^{\cdot\cdot} \qquad \Leftrightarrow \qquad \mathbb{F} \equiv \mathbb{F}^{\mathtt{S}} + \mathbb{F}^{\mathtt{A}} \quad . \tag{32.02.08}$$

The symmetric part can be additionally decomposed by extracting the traceless, $\mathbb{F}_0^{\mathtt{S}}$, part as:

$$\mathbb{F}^{\mathtt{S}} = \left(\mathbb{F}^{\mathtt{S}} - \frac{\operatorname{Tr} F}{3}\mathbb{I}\right) + \frac{\operatorname{Tr} F}{3}\mathbb{I} \equiv \mathbb{F}_0^{\mathtt{S}} + \frac{\operatorname{Tr} F}{3}\mathbb{I} \quad .$$

This shows that an arbitrary strain deformations, described by a symmetrical strain, can be expressed as the sum of a pure shear plus an isotropic dilatation/compression, because the term proportional to $\mathbb{I}$ is an isotropic tensor and it is multiplied by the trace of the strain tensor, that is the relative change of volume, having the same overall structure as an hydrostatic pressure stress tensor.

Principal Strains

As the pure shear tensor is symmetrical it can be diagonalized via an orthogonal matrix, that is a suitable rotation of the coordinates.

The eigenvalues are called the principal strains. Note that the pure shear tensor is not necessarily positive definite, and the eigenvalues may have any sign.

32.02.03.03 Anti-Symmetrical Part of the Strain Tensor

The anti-symmetric part can be written as a vector product, in terms of the vector $\boldsymbol{\Omega}$ as follows:

$$\mathrm{d}\boldsymbol{\xi}^{\mathtt{A}} = \mathbb{F}^{\mathtt{A}} \cdot \mathrm{d}\mathbf{x} = \boldsymbol{\Omega} \wedge \mathrm{d}\mathbf{x} \quad , \tag{32.02.09}$$

with

$$\Omega_q = +\frac{1}{2}\epsilon_{irq}^{\cdots} F^{\mathtt{A}}{}_{ri}^{\cdot\cdot} = -\frac{1}{2}\epsilon_{qri}^{\cdots} F^{\mathtt{A}}{}_{ri}^{\cdot\cdot} \qquad F^{\mathtt{A}}{}_{ri}^{\cdot\cdot} = \epsilon_{irq}^{\cdots}\Omega_q \quad . \tag{32.02.10}$$

→ 1648 1649

Therefore it describes a pure rotation around the direction of the vector $\boldsymbol{\Omega}$ by an amount described by the module of the vector $\boldsymbol{\Omega}$ itself.

Moreover, one has:

$$\Omega_q = \frac{1}{2}\epsilon_{irq}^{\cdots} F^{\mathtt{A}}{}_{ri}^{\cdot\cdot} = \frac{1}{2}\epsilon_{irq}^{\cdots}\left(F^{\mathtt{A}}{}_{ri}^{\cdot\cdot} + F^{\mathtt{S}}{}_{ri}^{\cdot\cdot}\right) = \frac{1}{2}\epsilon_{irq}^{\cdots} F_{ri}^{\cdot\cdot} = \frac{1}{2}\epsilon_{irq}^{\cdots}\frac{\partial \xi_r}{\partial x_i} = \frac{1}{2}\mathbf{e}_q \cdot \mathbf{rot}\boldsymbol{\xi} \quad . \tag{32.02.11}$$

→ 1648

Therefore a deformation is without rotation if and only if the rotor of the displacement is zero.

One should be careful with the signs from equations (32.02.10), (32.02.11).

32.02.03.04 General Deformation

The general state of strain can thus be described as a translation, plus a rotation, plus a pure deformation (described by the symmetric traceless part of the tensor) plus a dilatation (described by the trace of the tensor).

Starting from equation (32.02.06) one can write:

$$\mathrm{d}\mathbf{X} = \mathrm{d}\mathbf{x} + \mathrm{d}\boldsymbol{\xi}[\mathbf{x}] = (\mathbb{I} + \mathbb{F})\ \mathrm{d}\mathbf{x} = \left(\mathbb{I} + \mathbb{F}^{\mathtt{S}} + \mathbb{F}^{\mathtt{A}}\right)\ \mathrm{d}\mathbf{x} = \left(\mathbb{I} + \mathbb{F}^{\mathtt{S}}\right)\ \mathrm{d}\mathbf{x} + \mathbb{F}^{\mathtt{A}}\ \mathrm{d}\mathbf{x} \quad .$$

Consider a infinitesimal vector $\mathrm{d}\mathbf{x}$, originating at $\mathbf{x}$. The head of this infinitesimal vector describes a sphere centered at $\mathbf{x}$.

After the most general deformation the center of this sphere is translated by $\boldsymbol{\xi}[\mathbf{x}]$, any infinitesimal vector $\mathrm{d}\mathbf{x}$ is mapped into a direction rotated as described by $\mathbb{F}^{\mathtt{A}}$ and the heads of the mapped infinitesimal vectors describe the surface of ellipsoid whose center is at $\mathbf{x} + \boldsymbol{\xi}[\mathbf{x}]$. The fact that the sphere is mapped into an ellipsoid comes from the fact that $\mathbb{I} + \mathbb{F}^{\mathtt{S}}$ is a real, symmetrical positive definite matrix, as the elements of the strain tensors are, by definition of small strains, small with respect to one. The matrix $\mathbb{F}^{\mathtt{S}}$ can then be diagonalized and its eigenvalues (principal strains) can have any sign but the sum with one is positive. The matrix $\mathbb{I} + \mathbb{F}^{\mathtt{S}}$ is thus positive definite.

DRAFT - IN PROGRESS

CC BY NC ND

32.02.03.05 Types of Motion of Continuous Media

The decomposion of the strain tensor shows that the general motion of continuous media can be kinematicly descibed as follows.

Motions in which the trace of the strain tensor is null are solenoidal (zero-divergence) motions with no change in volume (iso-volumetric).

Motions in which the anti-symmetrical part of the strain tensor is null are irrotational (zero rotor) motions with no rotation at any point.

Motions in which the symmetrical part of the strain tensor is null are rigid motions.

32.02.04
Non-Diagonal Elements of the Strain Tensor

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||

Consider the plane finite deformation:

$$\boldsymbol{\xi}[\mathbf{x}] = \{y \tan[\theta], 0, 0\} \quad ,$$

shown in figure 32.12.

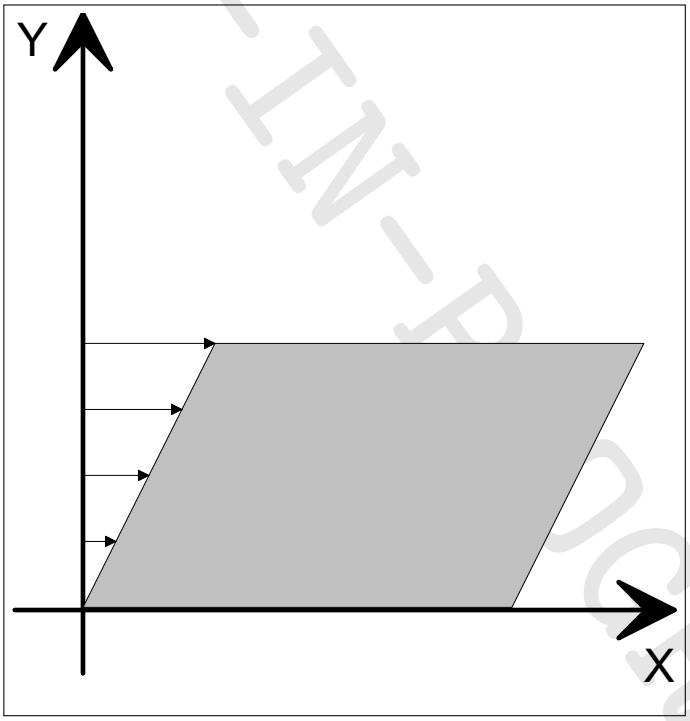

Figure 32.12: FIGURE

This corresponds to the deformation used in defining the shear modulus, G, see section § 27.02.02.

If we limit to infinitesimal deformations we can write the infinitesimal strain matrix, as a function of the infinitesimal angle $\mathrm{d}\theta$, as:

$$F^{\cdot}_{kj}[\mathbf{x}] \equiv \frac{\partial \xi_k}{\partial x_j}[\mathbf{x}] = \begin{pmatrix} 0 & \mathrm{d}\theta & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & +\mathrm{d}\theta/2 & 0 \\ +\mathrm{d}\theta/2 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & +\mathrm{d}\theta/2 & 0 \\ -\mathrm{d}\theta/2 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad .$$

The strain matrix is traceless and therefore the deformations preserves the volume. The strain is made of a pure strain (the symmetric traceless matrix) plus a rotation by an angle $-\theta/2$ (clockwise direction). In fact equation (32.02.10) gives

$$\boldsymbol{\Omega} = \{0, 0, -\mathrm{d}\theta/2\} \quad .$$

DRAFT - IN-PROGRESS

If one considers a square figure in the xy plane the complete deformation can be decomposed into a pure deformation of the square, such that the square becomes a rhombus with its diagonals parallel to the diagonals of the original square followed by a clock-wise rotation by an angle $|\,\mathrm{d}\theta|/2$

The interpretation of the non-diagonal elements of the strain matrix coming from this particular case is valid in general: the non-diagonal elements (r, s) of the strain matrix represent one half of the decrease of the angle between the two initially orthogonal directions r and s.

32.03.01
Volume and Surface Forces and Moments/Couples

This § is referenced at pages:
[1514]

Consider a continuous medium and an arbitrary ideal volume inside it, Ω, whose boundary is made by the closed surface, $\mathcal{A} \equiv \partial\Omega$, delimiting the system we are studying. Let $\hat{\mathbf{n}}$ denote the normal vector exiting the surface, a function of the point at the surface.

32.03.01.01 Volume (Body) Forces and Moments/Couples

Volume (body) forces and volume (body) moments/couples, which are forces and moments/torques acting at a distance on the volume, due either to external fields or to long range forces internal to the medium, need to be included as well.

In the following, except when specificed otherwise, the body moments/torques will be assumed to be zero, as it is done in the classical theory of elasticity.

Notable examples of body forces include: gravitational, centrifugal and Coriolis forces.

Notable examples of body moments include: Polarized material in an external electric field Magnetized material in an external magnetic field and material made of dipolar-molecules.

DRAFT - IN PROGRESS

32.03.01.02 Surface Forces and Moments/Couples

The classical force-stress and torque-stress tensors measure the internal forces and torques that parts of a medium exert on other parts (even though there may be zero net force and zero net moment at each point).

The description of the contact interaction between the material external to the surface and the material internal to the surface (which constitutes the system under study) as well as the description of the contact interactions between the system and external objects in contact with the system can be carried on as follows.

As the system is the part of material internal to the surface all the forces and torques are to be interpreted as the external forces and torques acting on the system.

Consider a small surface $\mathrm{d}\mathbf{S} \equiv \hat{\mathbf{n}}\,\mathrm{d}S$, oriented with its normal exiting the surface. Actually it might be noted that it is the unit vector $\hat{\mathbf{n}}$ which defines the internal and external parts to the system, in an unambiguous way, as the surface is closed.

The part of the material external to the surface applies to the internal part, that is the system, a set of contact forces and torques, whose extent depends on the area $\Delta\mathbf{S}$.

Consider the system of forces applied to the surface $\Delta\mathbf{S}$.

It is known, read § 15.04, that any system of applied forces is equivalent to a system composed of the total force (call it $\Delta\mathbf{F}$), applied at any point (pole) of the small area $\Delta\mathbf{S}$, plus a torque (call it $\Delta\mathbf{\Gamma}$), equal to the resultant momentum of the applied forces with respect to the same point (pole) of the small area $\Delta\mathbf{S}$. Note that, as we are dealing with torques, the choice of the pole is not relevant for them, that is their momentum is the same with respect to any pole. This decomposition is always implicitly assumed, except when specified otherwise.

For an alternative decomposition, read § 15.04, the concept of central axis can be used.

One should remember that the Force|Torque in the following discussion are the forces and torques applied to the system by the external world.

It is assumed that the following limits (which depend on $\hat{\mathbf{n}}$) exists as finite vectors:

$$\lim_{\Delta\mathbf{S}[\hat{\mathbf{n}}]\longrightarrow 0} \frac{\Delta\mathbf{F}}{\Delta\mathbf{S}[\hat{\mathbf{n}}]} = \frac{\mathrm{d}\mathbf{F}}{\mathrm{d}A} \equiv \mathbf{S}[\hat{\mathbf{n}}] \qquad (32.03.01)$$

$$\lim_{\Delta\mathbf{S}[\hat{\mathbf{n}}]\longrightarrow 0} \frac{\Delta\mathbf{\Gamma}}{\Delta\mathbf{S}[\hat{\mathbf{n}}]} = \frac{\mathrm{d}\mathbf{\Gamma}}{\mathrm{d}A} \equiv \mathbf{M}[\hat{\mathbf{n}}] \quad .$$

→ 1651 1652

It is obvious, from its very definition, that the objects defined by equations (32.03.01), (32.03.02.01) are, for any fixed point at the surface (which determines in a unique way $\hat{\mathbf{n}}$ and $\mathrm{d}\mathbf{S}$), vectors. More generally: it is obvious, from its very definition, that the objects defined by equations (32.03.01), (32.03.02.01) are, for any fixed point and $\hat{\mathbf{n}}$ (which determines in a unique way $\mathrm{d}\mathbf{S}$), vectors. Later on one should ask what happens to the force when one changes $\hat{\mathbf{n}}$ at a fixed point.

The action of the two vectors, $\mathbf{S}[\hat{\mathbf{n}}]$, the force-stress, and $\mathbf{M}[\hat{\mathbf{n}}]$, the torque-stress, on the infinitesimal surface $\mathrm{d}\mathbf{S} = \hat{\mathbf{n}}\,\mathrm{d}S$, is equipollent to the action of the set of external forces applied on $\mathrm{d}\mathbf{S} = \hat{\mathbf{n}}\,\mathrm{d}S$.

Note that the previous assumptions are fundamental assumptions of the theory, or, in other words, they are constitutive equations for the material. Note in particular that in the theory of classical elastic materials one assumes that the limit in equation (32.03.02.01) is zero, that is absence of surface couples: $\mathbf{M}[\hat{\mathbf{n}}] = 0$.

The force-stress, $\mathbf{S}[\hat{\mathbf{n}}]$, and the torque-stress, $\mathbf{M}[\hat{\mathbf{n}}]$, describe the effect of contact interaction, acting across the surface $\mathrm{d}\mathbf{S} = \hat{\mathbf{n}}\,\mathrm{d}S$.

In the following, except when specificed otherwise, the torque-stress will be assumed to be zero.

DRAFT IN PROGRESS

32.03.01.03 Some Comments

Note that many authors define the interaction of the material with the external world in terms of the forces exerted by the material system on the external world, thus obtaining definitions of the quantities with the opposite sign. In fact the generalized Newton third law ensures that the two set of forces have equal and opposite total force and total torque. With the chosen convention the component of the force in the definition of equation (32.03.01) is positive whenever it is a traction force. It is, in fact, often called **traction**. With the chosen convention the component of the moment of the moments/torques in the definition of equation (32.03.02.01) is positive if it tends to rotate the material of the system in the counter-clockwise direction (right-hand rule) with respect to the local normal unit vector $\widehat{\mathbf{n}}$.

Cases when torque-stresses and body torques intervene include, for instance, Polarized material in an external electric field Magnetized material in an external magnetic field and material made of dipolar-molecules.

32.03.02
Forces: The Force-Stress Tensor and Volume (Body) Forces

This § is referenced at pages:
[Never referenced.]

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|7.3||
©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.31||

32.03.02.01 Force-Stress Tensor

From the force-stress, $\mathbf{S}[\widehat{\mathbf{n}}]$, one can introduce the force-stress tensor, usually just called the stress tensor, because in the theory of classical elastic materials the torque-stress tensor, $\mathbf{M}[\widehat{\mathbf{n}}]$, is zero.

The $S^{\cdot\cdot}_{jk}$ component of stress tensor is defined as the j component of the force across a unit area perpendicular to the k axis:

$$S^{\cdot\cdot}_{jk} \equiv \frac{\mathrm{d}F_j}{\mathrm{d}A_k} \quad , \qquad \rightarrow \text{1651 1652}$$

in terms of the j component of the force acting on the surface $\mathrm{d}\mathbf{S}_k$ perpendicular to the k axis.

Note the convention that the first index of $S^{\cdot\cdot}_{jk}$ gives the component of the force.

It can be shown that the force per unit area (the stress) acting on an arbitrary unit surface perpendicular to the unit vector $\widehat{\mathbf{n}}$ has a j component given by:

$$\frac{\mathrm{d}F_j}{\mathrm{d}A[\widehat{\mathbf{n}}]} \equiv \mathbf{e}_j \cdot \mathbf{S}[\widehat{\mathbf{n}}] = S^{\cdot\cdot}_{jk} n_k \quad . \qquad (32.03.02) \qquad \rightarrow \text{1652 1653}$$

Since both n_k and $\mathbf{e}_j \cdot \mathbf{S}[\widehat{\mathbf{n}}]$ are components of vectors, equation (32.03.02) demonstrates that $\mathbf{S}$ is actually a tensor, thanks to the **Quotient Law** § 20.03.07.

It was born as a native second rank tensor, in contrast to most of the other second-order tensor arising as coefficients in relating one vector to another.

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...- 2.31

It follows that the force per unit area (the stress) along the direction of the unit vector $\mathbf{u}$ acting on a surface defined by the unit vector $\widehat{\mathbf{n}}$ is given by:

$$\mathbf{u} \cdot \frac{\mathrm{d}\mathbf{F}}{\mathrm{d}A[\widehat{\mathbf{n}}]} \equiv S[\widehat{\mathbf{n}}, \mathbf{u}] = S^{\cdot\cdot}_{jk} n_k u_j \quad . \qquad (32.03.03)$$

DRAFT - In Progress

As the tensor $S^{\cdot\cdot}_{jk}$ is sufficient to calculate the force at any point in the direction perpendicular to any surface it completely describes the internal state of stress of the continuous medium.

The stress tensor, in general, depends on the point, and therefore it defines a tensor field (as the strain).

It can be shown that the stress tensor is actually symmetric in most common cases, but this is an assumption of the theory, valid as long as no body torques nor torque-stresses are present. That is the symmetry of the stress tensor is a constitutive equation of the material considered.

R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...- 2.31

As long as S is represented by a real symmetric matrix in Cartesian Coordinates it can be diagonalized to find the principal stress axes. For surfaces perpendicular to those three axes the stresses are particularly simple as they corresponds to push or pulls along these axes. There are no shear forces along those the surfaces perpendicular to the principal axes of inertia. For any stress one can choose the axes in such a way that shear components are zero.

In the case there is no isotropy the mean pressure is defined as the invariant:

$$\overline{p} \equiv -\frac{1}{3}\operatorname{Tr} S = -\frac{1}{3}(S_{11} + S_{22} + S_{33}) \quad .$$

Note the sign. Hydrostatic pressure gives a force that a piece of matter exerts on the surroundings, resisting compression, exiting from its boundary. Due to the convention used for the stress energy tensor this is a negative stress. The minus sign thus makes the average pressure positive.

Therefore in a similar way as the decomposition of the symmetrical part of the strain tensor into a traceless symmetrical tensor plus a tensor proportional to the unit tensor, also the stress tensor can be separated in a similar way.

Example: The Stress Tensor of a Fluid at Rest

The stress tensor of any fluid at rest:

$$S^{\cdot\cdot}_{kj} = -p\delta^{\cdot\cdot}_{kj} \quad .$$

Example: The Stress Tensor of an Ideal Fluid

The stress tensor of an ideal fluid, under any conditions, is:

$$S^{\cdot\cdot}_{kj} = -p\delta^{\cdot\cdot}_{kj} \quad .$$

32.03.02.02 Force-Stress Tensor and the Spatial Part of the Energy-LinMomentum Tensor

This § is referenced at pages:
[1929]

The force-stress tensor thus defined can be obviously introduced, by means of its definition (32.03.02) for any system, possibly by making use of the description of the force as change of linear momentum per unit time. When carrying on the relativistic generalisation (section § 60.03) the force-stress tensor becomes the spatial part of the Energy-LinMomentum four-tensor.

In order to show the relation between the stress tensor and the linear momentum flux one should note that if we refer to the linear momentum flux exiting the volume, as it is usually done when dealing with the Energy-LinMomentum tensor (read § 60.03), this represents the force per unit area applied by the system inside the volume to the external world. Therefore, based on our conventions, the stress tensor has the opposite sign with respect to the spatial components of the Energy-LinMomentum tensor. This can be also expressed by saying that the linear momentum flux described by the stress tensor is the flux of linear momentum entering the volume, that is given to the system inside the volume.

DRAFT - PROOFREAD

The force per unit area on a surface is equivalent to the flux of linear momentum, that is linear momentum crossing the surface per unit area and per unit time:

$$-S^{\cdot\cdot}_{jk} \equiv \frac{\mathrm{d}F_j[\text{IN} \longrightarrow \text{OUT}]}{\mathrm{d}A_k} = \frac{d^2 p_j[\text{IN} \longrightarrow \text{OUT}]}{\mathrm{d}A_k \, \mathrm{d}t} \equiv T^{\cdot\cdot}_{jk} \quad .$$

32.03.02.03 Principal Stresses

As long as the force-stress tensor is symmetrical it can be diagonalized via an orthogonal matrix, that is a suitable rotation of the coordinates.

The eigenvalues are called the principal stresses. Note that the force-stress tensor is not necessarily positive definite, and the eigenvalues may have any sign.

32-001 Von Mises Stress

Von Mises stress is often used as a measure of the total state of stress at a point, especially in cases related to the maximum allowables stress for a real material. It is defined as:

$$S_{\text{VM}} \equiv \sqrt{\frac{3}{2} S^{\cdot\cdot}_{jk} S^{\cdot\cdot}_{jk}} \quad . \tag{32.03.04}$$

Show that it can be written, in terms of the principal stresses, σ_1, σ_2 and σ_3, as:

$$S_{\text{VM}} = \sqrt{\frac{1}{2}\Big((\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2\Big)} \quad . \tag{32.03.05}$$

32.03.02.04 Examples of Stress Tensor: Fluids

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|41.2||

A fluid is a continuous system which does not keep any shear stress without starting to flow. That is a fluid at equilibrium with respect to any one Coordinate System has not shear stresses. In other words a fluid moving as a rigid-body has no shear stresses.

Ideal Fluid

An ideal fluid is totally isotropic, therefore its stress tensor must be proportional to the identity tensor, the only isotropic tensor with two indexes:

$$S^{\cdot\cdot}_{ij} = -p\delta^{\cdot\cdot}_{ij} \qquad \text{ideal fluid} \quad .$$

Note the minus sign coming from the convention that the stress tensor is the **traction** of the external world on the system.

Real Fluid

A real fluid is isotropic at equilibrium but it is not necessarily isotropic outisde equilibrium, due to the presence of viscosity which trasnfers shear stresses.

Therefore, for a real fluid at rest, one has:

$$S^{\cdot\cdot}_{ij} = -p\delta^{\cdot\cdot}_{ij} \qquad \text{real fluid at rest} \quad .$$

However, in general for a real fluid an additional non isotropic term, $\Pi^{\cdot\cdot}_{ij}$, arises:

$$S^{\cdot\cdot}_{ij} = -p\delta^{\cdot\cdot}_{ij} + \Pi^{\cdot\cdot}_{ij} \qquad \text{generic real fluid} \quad .$$

DRAFT-IN-PROGRESS

Real Newtonian Fluids

A Newtonian fluid is a fluid such that the stress tensor for an infinitesimal parcel of fluid in the local Reference Frame of the parcel of fluid is:

$$S_{ij}^{\cdot\cdot} = -p\delta_{ij}^{\cdot\cdot} + \eta'\delta_{ij}^{\cdot\cdot}\mathbf{div}\,\mathbf{v} + \eta\left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}\right) = -p\delta_{ij}^{\cdot\cdot} + \eta'\delta_{ij}^{\cdot\cdot}\mathbf{div}\,\mathbf{v} + 2\eta\partial_t F^{\mathrm{S}\,\cdot\cdot}_{ij} \qquad \text{real Newtonian fluid} \quad .$$

That is the shear stresses in a Newtonian fluid, by definition, are linear in the gradient of the velocity.

Read § 32.08.03.

32.03.02.05 Volume (Body) Forces

This § is referenced at pages:
[Never referenced.]

Volume forces are forces whose intensity is proportional to the volume Ω of the material included inside the closed surface $\mathcal{A} \equiv \partial\Omega$, that is the volume of the system:

$$\mathbf{F}_{\mathrm{V}} = \iiint_{\Omega} \frac{\mathrm{d}\mathbf{F}}{\mathrm{d}V}\,\mathrm{d}V \equiv \iiint_{\Omega} \mathbf{f}\,\mathrm{d}V \quad .$$

32.03.02.06 First Cardinal Equation for Continuous Media

For any arbitrary part of the material medium, defined by a small volume Ω with a surface boundary $\partial\Omega$ and located at $\mathbf{r}$ we can write the first **Cardinal Equation** of motion:

$$\iiint_{\Omega} f_k\,\mathrm{d}V + \oiint_{\partial\Omega} S_{kj}^{\cdot\cdot}\,\mathrm{d}\mathbf{S}_j = \iiint_{\Omega} \partial_t p_k\,\mathrm{d}V = \frac{\mathrm{d}P_k}{\mathrm{d}t} \quad . \qquad (32.03.06)$$

→ 1662

It can be written in local form as:

$$f_k + \partial_j S_{kj}^{\cdot\cdot} = \partial_t p_k \quad . \qquad (32.03.07)$$

→ 1655 1657 1660

It can be written in local form also emphasising the linear momentum balance:

$$\partial_t p_k - \partial_j S_{kj}^{\cdot\cdot} = f_k \qquad \partial_t p_k + \partial_j T_{kj}^{\cdot\cdot} = f_k \quad . \qquad (32.03.08)$$

→ 1655

Equation (32.03.08) has the standard form of a balance (or continuity) equation.

Note that the derivation of equation (32.03.07) shows that surface forces can be expressed equivalently as volume forces, via the divergence theorem:

$$f_k^S \equiv \frac{\mathrm{d}F_k^S}{\mathrm{d}V} = \partial_j S_{kj}^{\cdot\cdot} \quad .$$

For material with symmetrical force-stress tensor the second **Cardinal Equation** does not provide additional informations besides those provided by the first **Cardinal Equation** . It is actually dependent of the first one.

$$\partial_t p_k = \rho_0 \frac{\partial^2 \xi}{\partial t^2} \quad .$$

32.03.03 Moments: The Torque-Stress Tensor and Volume (Body) Torques

This § is referenced at pages:
[Never referenced.]

Most of the common materials are adequately modeled without the use of couple-stresses and volume (body) torques. The classical theory of elastic bodies do not account for them.

However, there exists significant cases where couple-stresses and volume (body) torques do need to be included. In such cases it is mandatory to account for the second **Cardinal Equation** , which is independent of the first one in such cases.

32.03.03.01 Torque-Stress Tensor

The torque exerted by the external world onto a small surface

32.03.03.02 Volume (Body) Moments/couples

This § is referenced at pages:
[Never referenced.]

Volume moments/torques are moments/torques whose intensity is proportional to the volume Ω of the material included inside the closed surface $\mathcal{A} \equiv \partial\Omega$, that is the volume of the system:

$$\boldsymbol{\Gamma}_{\mathrm{V}} = \iiint_{\Omega} \frac{\mathrm{d}\boldsymbol{\Gamma}}{\mathrm{d}V} \, \mathrm{d}V \equiv \iiint_{\Omega} \boldsymbol{\gamma} \, \mathrm{d}V \quad .$$

32.03.03.03 Second Cardinal Equation for Continuous Media

For any arbitrary part of the material medium, defined by a small volume Ω with a surface boundary $\partial\Omega$ and located at $\mathbf{r}$ we can write the second **Cardinal Equation** of motion:

$$\iiint_{\Omega} \left(\gamma_k + \epsilon_{kab}^{\cdot\cdot\cdot} x_a f_b\right) \, \mathrm{d}V + \oiint_{\partial\Omega} \left(M_{kj}^{\cdot\cdot} + \epsilon_{kab}^{\cdot\cdot\cdot} x_a S_{bj}^{\cdot\cdot}\right) \, \mathrm{d}\mathbf{S}_j = \iiint_{\Omega} \partial_t j_k \, \mathrm{d}V = \frac{\mathrm{d}J_k}{\mathrm{d}t} \quad . \tag{32.03.09}$$

It can be written in local form as:

$$\gamma_k + \epsilon_{kab}^{\cdot\cdot\cdot} x_a f_b + \partial_j \left(M_{kj}^{\cdot\cdot} + \epsilon_{kab}^{\cdot\cdot\cdot} x_a S_{bj}^{\cdot\cdot}\right) = \partial_t j_k \quad . \tag{32.03.10}$$

→ 1656

It can be written in local form also emphasizing the angular momentum balance:

$$\partial_t j_k - \partial_j \left(M_{kj}^{\cdot\cdot} + \epsilon_{kab}^{\cdot\cdot\cdot} x_a S_{bj}^{\cdot\cdot}\right) = \gamma_k + \epsilon_{kab}^{\cdot\cdot\cdot} x_a f_b \quad . \tag{32.03.11}$$

→ 1656

Equation (32.03.11) has the standard form of a balance (or continuity) equation.

For material with symmetrical force-stress tensor the second **Cardinal Equation** does not provide additional informations besides those provided by the first **Cardinal Equation** . It is actually dependent of the first one.

Note that the derivation of equation (32.03.10) shows that surface moments can be expressed equivalently as volume moments, via the divergence theorem:

$$\gamma_k^S \equiv \frac{\mathrm{d}\Gamma_k^S}{\mathrm{d}V} = \partial_j M_{kj}^{\cdot\cdot} \quad .$$

Draft - Do Not Distribute

32-003 Acoustic Waves in Fluids/solids

Derive the equation for the acoustic waves in fluids/solids, as in section § 45.02.03, using the concept of stress tensor, instead of pressure, and assuming a linear relation (Hooke law) between the normal stress and the longitudinal strain.

Show that this is consistent with the local form of first **Cardinal Equation** for continuous media, equation (32.03.07).

WORKED SOLUTION

Equation (45.02.03) of section § 45.02.03, the first **Cardinal Equation** , can be re-written as:

$$\mathrm{d}F_z = -\left(S_{zz}[z] - S_{zz}[z+\Delta z_0]\right) \simeq \frac{\partial S_{zz}}{\partial z} A\Delta z_0 = \rho_0 A\Delta z_0 \frac{\partial^2 \xi_z}{\partial t^2} \quad .$$

It should be noted the negative sign, due to the different sign conventions between pressure and stress tensor.

The linear relation (Hooke law) implies:

$$S_{zz} = Y\frac{\partial \xi_z}{\partial z} \Longrightarrow \frac{\partial S_{zz}}{\partial z} = Y\frac{\partial^2 \xi_z}{\partial z^2} \quad ,$$

which, after substitution in the first **Cardinal Equation** , gives:

$$\frac{\partial S_{zz}}{\partial z} = \boxed{Y\frac{\partial^2 \xi_z}{\partial z^2} = \rho_0 \frac{\partial^2 \xi_z}{\partial t^2}} \quad .$$

The above expression

$$\frac{\partial S_{zz}}{\partial z} = \rho_0 \frac{\partial^2 \xi_z}{\partial t^2} \quad ,$$

is actually the local form of first **Cardinal Equation** for continuous media, equation (32.03.07):

$$f_k^V + \partial_j S_{kj}^{\cdot\cdot} = \partial_t p_k = \rho_0 \frac{\partial^2 \xi_k}{\partial t^2} \quad .$$

This shows, in this particular case, that the equation of motion of an elastic solid is a wave equation. Note that the signs are consistent with the expression of the stress tensor for an ideal fluid (and with the expression of the stress tensor for a real fluid at rest):

$$S_{kj}^{\cdot\cdot} = -p[\mathbf{x}]\delta_{kj}^{\cdot\cdot} \quad .$$

32.03.04
Statics of Continuous Media

Statics of continuous media is based on the elementary priciple that when the entire system is in equilibrium any portion of it must be in equilibrium as well.

32.04 Tensor of Elasticity and Hooke Law for Homogeneous and Isotropic Materials

This § is referenced at pages:
[1032, 1664]

©|W.C.Elmore & M.A.Heald, , ..., ..., ...Ed., ...|7||

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.39.2||

The case of materials with symmetrical stress tensor only will be considered. Read also § 32.

Consider homogeneous, isotropic and linear materials. The generalized Hooke law is expressed as:

$$\boxed{S^{\cdot\cdot}_{ij} = E^{\cdot\cdot\cdot\cdot}_{ijkl} F^{\cdot\cdot}_{kl}} \quad , \tag{32.04.01}$$

→ 1658

in terms of the fourth-rank tensor of elasticity $\mathbb{E}$.

Note that the genralized Hooke law (32.04.01) implies that the symmetrcal part of the strain tensor only intervene. The anti-symmetrical part of the strain tensor does not intervene in Hooke law, as it is appropriate because the anti-symmetrical part of the strain tensor describes a pure rotation and therefore no elastic effect is involved. In this section it is therefore implicitly assumed that the strain tensor is symmetrical.

A priori $\mathbb{E}$ has $3^4 = 81$ independent elements. However, at a closer inspection the number of independent components turn out to be much less than that. In fact both $\mathbb{S}$ and $\mathbb{F}$ are symmetric second rank tensors with six independent components and therefore there can be almost 36 independent components. There are actually much less. It can be shown that there are at most 21 independent components in the fourth-rank tensor of elasticity $\mathbb{E}$. In fact if one considers the six independent components of both $\mathbb{S}$ and $\mathbb{F}$ and the six times six matrix linking them. The latter is a symmetrical matrix, which has 21 independent components.

If the material is homogeneous the elasticity tensor does not depend on the position, that is its values are uniform.

If the material is isotropic many more additional constraints exist. In fact isotropy implies that the components of the elasticity tensor must be unchanged under any arbitrary rotation of the Coordinate System: the elasticity tensor of an isotropic medium must be and isotropic tensor, that is one whose components do not change under any arbitrary rotation of the Coordinate System. Therefore the stress tensor must be expressed in terms of the strain tensor via isotropic tensors only, that includes scalars as well as all the isotropic fourth-rank tensors with the correct symmetry properties. Read § 20.05.08.

The relation we are looking for is a linear one, as we are looking for a generalisation of Hooke law.

Therefore two possibilities arise:

$$S^{\cdot\cdot}_{ij} \propto F^{\cdot\cdot}_{ij} \qquad S^{\cdot\cdot}_{ij} \propto \delta^{\cdot\cdot}_{ij} F^{\cdot\cdot}_{kk} \quad .$$

Therefore the stress-strain relation for a isotropic (non necessarily homogeneous) medium can be written as:

$$\boxed{S^{\cdot\cdot}_{ij}[\mathbf{x}] = 2\mu[\mathbf{x}] F^{\cdot\cdot}_{ij} + \lambda[\mathbf{x}] \operatorname{Tr} F \delta^{\cdot\cdot}_{ij}} \quad ,$$

where the two constants are called Lamé constants.

It turns out that the Lamé constants relate to the constants Y, Σ, G and B in the following way:

$$\boxed{\mu = G \qquad \lambda = B - \frac{2}{3} G} \quad .$$

Finally the stress-strain relation for a homogeneous and isotropic medium, Hooke law, can be written as:

$$\boxed{S^{\cdot\cdot}_{ij} = 2\mu F^{\cdot\cdot}_{ij} + \lambda \operatorname{Tr} F \delta^{\cdot\cdot}_{ij} = 2G F^{\cdot\cdot}_{ij} + \left(B - \frac{2}{3} G \right) \operatorname{Tr} F \delta^{\cdot\cdot}_{ij}} \quad . \tag{32.04.02}$$

→ 1659 1660

In tensor terms one can write:

$$\mathbb{S} = 2\mu[\mathbf{x}]\mathbb{F} + \lambda[\mathbf{x}]\,\mathrm{Tr}\,F\mathbb{I} = 2\mu[\mathbf{x}]\mathbb{F}^{\mathrm{S}} + \lambda[\mathbf{x}]\,\mathrm{Tr}\,F\mathbb{I} = 2\mu[\mathbf{x}]\mathbb{F}_0^{\mathrm{S}} + \left(\lambda[\mathbf{x}] + \frac{2}{3}\mu[\mathbf{x}]\right)\mathrm{Tr}\,F\mathbb{I} = 2G[\mathbf{x}]\mathbb{F}_0^{\mathrm{S}} + B[\mathbf{x}]\,\mathrm{Tr}\,F\mathbb{I} \quad , \tag{32.04.03}$$

→ 1659

where the traceless part of the strain tensor has been made explicit.

The latest expressions can be also written as:

$$\mathbb{S} = 2G[\mathbf{x}]\mathbb{F}_0^{\mathrm{S}} + B[\mathbf{x}]\,\mathrm{Tr}\,F\mathbb{I} \quad , \tag{32.04.04}$$

→ 1659

which shows the decomposition into a pure shear part, given by $\mathbb{F}_0^{\mathrm{S}}$ with coefficient is $2G[\mathbf{x}]$, and a pure compression/dilatation part, given by $\mathrm{Tr}\,F$ with coefficient $B[\mathbf{x}]$. This is consistent with the definition of the coefficients G and B.

32-004 Elasticity Tensor

Find the expression of the elasticity tensor $\mathbb{E}$ for the Hooke law, equation (32.04.02).

32-005 Decomposition of Hooke Law

Equation (32.04.04) expresses each side of Hooke law as a symmetrical traceless term plus an isotropic term. Hooke law is now separated in an invariant manner into two equations, one involving the pure shear, the other one for pure hydrostatic compression/dilatation.

Show that this separation leads to one relation between Y, G and Σ and one relation between Y, B and Σ.

32-006 Hooke Law

Compare the elementary derivation of the effects of uniform stresses on a homogeneous and isotropic parallelepiped block in section § 27.07.06 with the general expression of Hooke law in equation (32.04.02).

32-007 Alternative Forms of the Hooke Law

Show that Hooke law (equation (32.04.03)), for homogeneous and isotropic materials, can be written in the alternative but equivalent form:

$$Y\mathbb{F} = (1+\Sigma)\,\mathbb{S} + 3\Sigma\langle p\rangle\mathbb{I} \quad , \tag{32.04.05}$$

→ 1659

in terms of the average pressure, $\langle p\rangle$.

Use the relations of § 27.02.04.

Note that the above expression (32.04.05) decomposes the strain tensor into a diagonal (that is isotropic) part plus a non diagonal part.

Show that equation (32.04.05) can be written as:

$$\mathbb{S} = \frac{Y}{1+\Sigma}\left(\mathbb{F} + \frac{\Sigma}{Y}\mathrm{Tr}\,S\mathbb{I}\right) \quad . \tag{32.04.06}$$

→ 1659

Show that equation (32.04.06) gives a relation among Y, Σ and G as well as a relation among Y, Σ and B. Show that these relations are the same relations of § 27.02.04.

DRAFT IN PROGRESS

32.05 Equation of Motion of an Homogeneous and Isotropic Elastic Body

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|39.3||

Consider an homogeneous and isotropic elastic body whose constitutive relation is given by Hooke law, equation (32.04.02), of infinite extent (unbounded).

Determine the equation of motion.

WORKED SOLUTION

Equation (32.03.07) implies (Lagrangian approach), for a pure deformation, that is ignoring translations and rotations,

$$\partial_t p_k = \rho_0 \frac{\partial^2 \xi_k}{\partial t^2} = f_k + \frac{\partial S_{kj}^{\cdot\cdot}}{\partial x_j} = \quad ,$$

$$f_k + \frac{\partial}{\partial x_j}\left(2\mu F_{kj}^{\cdot\cdot} + \lambda F_{rr}^{\cdot\cdot}\delta_{kj}^{\cdot\cdot}\right) = f_k + \frac{\partial}{\partial x_j}\left(\mu\left(\frac{\partial \xi_k}{\partial x_j} + \frac{\partial \xi_j}{\partial x_k}\right) + \lambda \frac{\partial \xi_r}{\partial x_r}\delta_{kj}^{\cdot\cdot}\right) = \quad ,$$

$$\boxed{f_k + \mu \nabla^2 \xi_k + (\mu + \lambda)\frac{\partial}{\partial x_k}\mathbf{div}\boldsymbol{\xi} = \rho_0 \frac{\partial^2 \xi_k}{\partial t^2}} \quad ,$$

$$\boxed{f_k - \mu\, \mathbf{e}_k \cdot (\mathbf{rotrot}\boldsymbol{\xi}) + (2\mu + \lambda)\frac{\partial}{\partial x_k}\mathbf{div}\boldsymbol{\xi} = \rho_0 \frac{\partial^2 \xi_k}{\partial t^2}} \quad .$$

In vector form the two equivalent equation of motion can be written as:

$$\boxed{\mathbf{f} + \mu \boldsymbol{\nabla}^2 \boldsymbol{\xi} + (\mu + \lambda)\,\mathbf{graddiv}\boldsymbol{\xi} = \rho_0 \frac{\partial^2 \boldsymbol{\xi}}{\partial t^2}} \quad , \qquad (32.05.01)$$

→ 1661

which is equivalent to:

$$\boxed{\mathbf{f} + (2\mu + \lambda)\,\boldsymbol{\nabla}^2 \boldsymbol{\xi} + (\mu + \lambda)\,\mathbf{rotrot}\boldsymbol{\xi} = \rho_0 \frac{\partial^2 \boldsymbol{\xi}}{\partial t^2}} \quad . \qquad (32.05.02)$$

→ 1661 1662

Note that it is in fact often easier to write the equation of motion in terms of $\boldsymbol{\xi}$ than in terms of $\mathbb{F}$.

32.06 Waves in an Unbounded Homogeneous and Isotropic Elastic Body

This § is referenced at pages:
[2034]

Assume no volume forces: $\mathbf{f} = 0$.

32.06.01 Shear Waves (Solenoidal Waves)

Assume that the deformation in the medium is such that no change in volume takes place, that is $\mathbf{div}\boldsymbol{\xi} = 0$. These solenoidal waves can be described by a vector potential (in any two-connected domain) and their wave equation is easily deduced from equation (32.05.01).

$$\mu\boldsymbol{\nabla}^2\boldsymbol{\xi} = \rho_0\frac{\partial^2\boldsymbol{\xi}}{\partial t^2} \Longrightarrow c_{\mathrm{T}}^2 = \frac{\mu}{\rho_0} = \frac{G}{\rho_0} \quad .$$

These waves are also called iso-voluminous waves.

32.06.01.01 Rotations Associated With an Arbitrary Deformation

Taking the rotor equation (32.05.01), for $\mathbf{f} = 0$, one obtains ($\mathbf{rotgrad}() = 0$):

$$\mu\boldsymbol{\nabla}^2\mathbf{rot}\boldsymbol{\xi} = \rho_0\frac{\partial^2}{\partial t^2}\mathbf{rot}\boldsymbol{\xi} \quad .$$

This is actually a wave equation for the rotor of the deformation, $\mathbf{rot}\boldsymbol{\xi}$, which propagates at the same speed as shear waves.

32.06.02 Dilatational Waves (Irrotational Waves)

Assume that the deformation in the medium is such that no rotation takes place, that is $\mathbf{rot}\boldsymbol{\xi} = 0$. These irrotational waves can be described by a scalar potential (in any one-connected domain) and their wave equation is easily deduced from equation (32.05.02).

$$(2\mu+\lambda)\,\boldsymbol{\nabla}^2\boldsymbol{\xi} = \rho_0\frac{\partial^2\boldsymbol{\xi}}{\partial t^2} \Longrightarrow c_{\mathrm{L}}^2 = \frac{2\mu+\lambda}{\rho_0} = \frac{B+\frac{4}{3}G}{\rho_0} = \frac{Y\,(1-\Sigma)}{(1+\Sigma)\,(1-2\Sigma)} \quad .$$

This result shows that irrotational waves in an unbounded homogeneous and isotropic elastic body have a different velocity than purely longitudinal waves along a bar (section § 45.02.02). The case of section § 45.02.02 is recovered by setting $\Sigma = 0$, as it was implicit in the derivation in that section.

Even if these waves are called dilatational waves note that the deformation is not a pure dilatation as the shear module appears in addition to the bulk modulus.

These waves feature two independent states of Polarizarion.

DRAFT-IN-PROGRESS

32.06.02.01 Dilatations Associated With an Arbitrary Deformation

Taking the divergence of equation (32.05.02), for $\mathbf{f} = 0$, one obtains ($\mathbf{divrot}() = 0$):

$$(2\mu + \lambda)\, \boldsymbol{\nabla}^2 \mathbf{div}\boldsymbol{\xi} = \rho_0 \frac{\partial^2}{\partial t^2} \mathbf{div}\boldsymbol{\xi} \quad .$$

This is actually a wave equation for the divergence of the deformation, $\mathbf{div}\boldsymbol{\xi}$, which propagates at the same speed as dilatational waves.

32.06.03
Properties of Solenoidal and Irrotational Waves

Helmholtz theorem, read § 16.07.05, states that any vector field can be decomposed uniquely (apart from additive constants) into the sum of a solenoidal and an irrotational vector fields. Moreover, if both rotor and divergence vanish in a certain region of space the vector field may be taken to be zero.

As a consequence of the above properties any deformation can be decomposed into into the sum of a solenoidal and an irrotational wave and the two waves propagate independently of one another with different speeds.

The different speeds have an impact on the kinematics, for instance via Snell law.

32.08 Examples and Physical Applications

32.08.01
An Ideal Fluid at Equilibrium

Consider a system at rest. If the ellipsoid describing the force-stress tensor is a sphere there are only normal forces in any direction. This corresponds to hydrostatic pressure (either positive or negative). In this case, a totally isotropic system, the tensor is diagonal and all three components equal to the pressure p:

$$S^{\cdot\cdot}_{jk} = -p\delta^{\cdot\cdot}_{jk} \quad ,$$

in the Reference Frame where the system is at rest. The system is a ideal fluid.

Note that this shows that pressure, normally introduced as a scalar quantity, is actually a tensor.

Apply equation (32.03.06) to consider an equilibrium situation:

$$\iiint_\Omega f_k \, \mathrm{d}V - \delta^{\cdot\cdot}_{kj} \oiint_{\partial\Omega} p \, \mathrm{d}\mathbf{S}_j = 0 \longrightarrow \iiint_\Omega f_k \, \mathrm{d}V - \delta^{\cdot\cdot}_{kj} \iiint_\Omega \partial_j p \, \mathrm{d}V = 0 \longrightarrow \mathbf{f} = \mathbf{grad} p \quad .$$

The result shows that at equilibrium the volume forces must equal the gradient of the pressure (Archimedes' principle). Read also § 16.12.15.

DRAFT - IN PROGRESS

32.08.02
Pressure Waves in an Ideal Fluid

This § is referenced at pages:
[2027, 2029]

A fluid (read § 28.01) is defined as a system such that at equilibrium no shear stress exist. Outside equilibrium shear stress may exist, if viscosity is not negligible. An ideal fluid is such that viscosity is negligible.

Consider an ideal fluid at equilibrium. Let $p_0[\mathbf{x}]$ be the pressure field at equilibrium. Define the differential pressure, that is the variation of pressure at any point with respect to the equilibrium state. In terms of the absolute pressure, $p[\mathbf{x},t]$, we thus define:

$$p[\mathbf{x},t] \equiv P[\mathbf{x},t] - p_0[\mathbf{x}] \quad .$$

The three pressure fields are scalar fields. The displacement vector $\boldsymbol{\xi}[\mathbf{x},t]$ is a vector field. It is therefore easier to describe the situation using the pressure, a scalar field, than with the displacement, a vector field.

Consider a small parallelepiped with sides Δx, Δy and Δz. Assume that the sides are small, one will take the limit for the sides going to zero in the end. Assume that volume forces have a volume density $\mathbf{g}[\mathbf{x},t]$. Along the z axis we have:

$$\mathbb{d}F_z \simeq \left(P[x,y,z,t] - P[x,y,z+\Delta z,t]\right)\Delta x\Delta y + \rho g[x,y,\widetilde{z}]\Delta x\Delta y\Delta z + \mathcal{O}\left(\Delta z\right)^2 \qquad \text{with } z \leq \widetilde{z} \leq z+\Delta z \quad , \quad ,$$

$$\mathbb{d}F_z = \left(g - \frac{\partial P}{\partial z}\right)\Delta x\Delta y\Delta z = \rho_0 \frac{\partial^2 \xi_x}{\partial t^2} \quad .$$

The equation of motion follows, by putting together the three dimensions:

$$\boxed{\rho_0 \mathbf{g} - \mathbf{grad}\, P = \rho_0 \frac{\partial^2 \boldsymbol{\xi}}{\partial t^2}} \quad ,$$

where ρ_0 may or may not depend on the position.

At equilibrium:

$$\rho_0 \mathbf{g} - \mathbf{grad} p_0 = 0 \quad ,$$

and then

$$\boxed{-\mathbf{grad} p = \rho_0 \frac{\partial^2 \boldsymbol{\xi}}{\partial t^2}} \quad .$$

The latter is the equation to use in order to study wave propagation in a ideal fluid, as, in this case, only pressure differences with respect to the equilibrium configuration are relevant. With the differential pressure the (constant) gravity force disappears.

Assume that ρ_0 does not depend on the position. The equation of motion can be written entirely in terms of the pressure by taking the divergence of both sides:

$$-\nabla^2 p = \rho_0 \frac{\partial^2}{\partial t^2}(\mathbf{div}\,\boldsymbol{\xi}) = -\frac{\rho_0}{B}\frac{\partial^2 p}{\partial t^2} \quad ,$$

in terms of the bulk modulus and exploiting the fact that the divergence of $\boldsymbol{\xi}$ is the relative volume change.

The speed of sound follows:

$$\boxed{c^2 = \frac{B}{\rho_0}} \quad .$$

32.08.03.01 General Definition of Viscosity in the Local Rest Frame

A fluid is, by definition, a continuous medium which which does not keep any shear stress when it is at rest with respect to any Coordinate System. In the case shear stresses are present the fluid flows, even if it might flow with a very slow speed. This means, in particular, that a fluid moving as a rigid-body does not suffer shear stresses.

The stress tensor of a fluid at rest is thus symmetrical, due to the lack of shear stresses, but also isotropic, that is proportional to the identity matrix, thanks to Pascal Principle: The stress tensor of any fluid at rest:

$$\boxed{S^{\cdot\cdot}_{kj} = -p\delta^{\cdot\cdot}_{kj}} \quad .$$

In the case a real fluid is not at rest shear stresses appear, giving rise to an additional non isotropic term, the symmetrical rank-two tensor $\Pi^{\cdot\cdot}_{ij}$. Consider the comoving rest frame of the fluid, that is the local Rest Frame of the infinitesimal volume of fluid, moving at the velocity of the Center-Of-Mass of the infinitesimal volume of fluid; in this frame the bulk flow vanishes. In the comoving rest frame of the fluid the stress tensor is thus generalized to:

$$\boxed{S^{\cdot\cdot}_{ij} = -p\delta^{\cdot\cdot}_{ij} + \Pi^{\cdot\cdot}_{ij} \qquad \text{generic real fluid}} \quad .$$

Shear stresses are cause by viscous forces, giving rise to linear momentum transfer.

Note in the comoving Rest Frame convection terms are missing. Also note that in the comoving Rest Frame the gradient is meaningful: even if the velocity of the Center-Of-Mass is zero in the comoving Rest Frame the gradient can be non zero.

Viscous forces depend on the different velocities at neighboring points inside the fluid, that is they depend on the gradient of the velocity field. Newtonian fluids, by definitions, are fluids such that the viscosity tensor, $\Pi^{\cdot\cdot}_{ij}$, depends linearly on the gradient of the velocity. This is typically a good model for a real fluid only in the case the gradient of the velocity is small:

$$\eta\left|\frac{\partial v_j}{\partial x_k}\right| \ll p \qquad \eta'\left|\frac{\partial v_j}{\partial x_k}\right| \ll p \quad .$$

Note that as $\Pi^{\cdot\cdot}_{ij}$ contains the gradient of the velocity it is in general non null in the comoving rest frame (velocities with respect to the Center-Of-Mass).

The tensor $\dfrac{\partial v_j}{\partial x_k}$ is called the gradient velocity tensor or rate of strain tensor.

One should only consider the symmetrical part of the gradient velocity tensor because the anti-symmetrical part gives rise to a rigid rotation which produces no shear stresses.

Let

$$v^{\cdot\cdot}_{ij} \equiv \frac{1}{2}\left(\frac{\partial v_j}{\partial x_i} + \frac{\partial v_i}{\partial x_j}\right) = \partial_t F^{\mathtt{s}\,\cdot\cdot}_{ij} \qquad \text{Lagrangian approach, x is a label not a variable} \quad .$$

In the comoving Rest Frame the fluid is isotropic. Therefore the same arguments used in section § 32.04 for isotropic elastic media lead to conclude that the only possible terms are a term proportional to the gradient velocity tensor plus a isotropic term proportional to the trace of the gradient velocity tensor.

WORK IN PROGRESS

Therefore, for a real Newtonian fluid in the comoving Rest Frame, one has:

$$\Pi^{\cdot\cdot}_{ij} = \eta' \delta^{\cdot\cdot}_{ij} \mathbf{div}\mathbf{v} + 2\eta v^{\cdot\cdot}_{ij} = \eta' \delta^{\cdot\cdot}_{ij} \mathbf{div}\mathbf{v} + \eta \left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) = \eta' \delta^{\cdot\cdot}_{ij} \mathbf{div}\mathbf{v} + 2\eta \partial_t {F^{\mathrm{s}}}^{\cdot\cdot}_{ij} \qquad \text{real Newtonian fluid} \quad .$$

Here η and η' are known as first and second coefficient of viscosity.

The important case of incompressible fluids implies:

$$\eta' = 0 \qquad \text{for incompressible fluids} \quad .$$

Finally one has for a real Newtonian fluid in the comoving Rest Frame:

$$S^{\cdot\cdot}_{ij} = -p\delta^{\cdot\cdot}_{ij} + \eta' \delta^{\cdot\cdot}_{ij} \mathbf{div}\mathbf{v} + \eta \left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) = -p\delta^{\cdot\cdot}_{ij} + \eta' \delta^{\cdot\cdot}_{ij} \mathbf{div}\mathbf{v} + 2\eta \partial_t {F^{\mathrm{s}}}^{\cdot\cdot}_{ij} \quad . \tag{32.08.01}$$

The force volume density is calculated from:

$$f_k = \frac{\partial}{\partial x_j} S^{\cdot\cdot}_{kj} \implies \mathbf{f} = \eta \boldsymbol{\nabla}^2 \mathbf{v} + (\eta + \eta') \, \mathbf{graddiv}\mathbf{v} \quad . \tag{32.08.02}$$

→ 1665

The use of equation (32.08.02) in the first **Cardinal Equation** gives rise to Navier-Stokes equations.

The force volume density for incompressible fluids is:

$$f_k = \frac{\partial}{\partial x_j} S^{\cdot\cdot}_{kj} \implies \mathbf{f} = \eta \boldsymbol{\nabla}^2 \mathbf{v} \quad . \tag{32.08.03}$$

Note that even if elasticity and viscosity are formally described in a very similar way they are actually very different phenomena.

32.08.07
Torsional Vibrations of a Cylindrical Round Homogeneous and Isotropic Elastic Bar

This § is referenced at pages:
[2033]

Consider a cylindrical, round, homogeneous and isotropic elastic bar of radius R, density ρ_0 and shear modulus G. Write the wave equation for torsional waves, neglecting the presence of volume forces, and show that the wave velocity is:

$$c_T^2 = \frac{G}{\rho_0} \tag{32.08.04}$$

WORKED SOLUTION

Assume that each section of the bar perpendicular to the bar axis will just rotate around the bar axis as a rigid sheet.
See problem § 27.07.12 for the derivation of the internal torques in a static situation. Let the z axis be coincident with the axis of the cylinder, let its origin located at one of the ends and let its orientation be such that the bar is defined by $0 \leq z \leq L$.
When a torsional wave is present the section of the bar at z, $\mathcal{S}[z]$, is rotated, with respect to the equilibrium position, by an angle $\phi[z]$, while the section at $z+\Delta z$, $\mathcal{S}[z+\Delta z]$, is rotated, with respect to the equilibrium position, by an angle $\phi[z+\Delta z]$.
Use the same notations as in problem § 27.07.12, with the time dependence always implicit, and let O be a point on the axis of the bar. The piece of the bar lying between $\mathcal{S}[z]$ and $\mathcal{S}[z+\Delta z]$ is subject to the two torques $\Gamma_O^-[z]$ and $\Gamma_O^+[z+\Delta z]$ on its two ends. Moreover, according to the generalized third Newton law we know that:

$$\Gamma_O^-[z+\Delta z] + \Gamma_O^+[z+\Delta z] = 0 \quad .$$

It follows that the second **Cardinal Equation** of dynamics, written in terms of the momentum of inertia of the piece of the bar, I, applied to the piece of bar, using the theorem of the average value for the integral, gives:

$$\Gamma_O^-[z] + \Gamma_O^+[z+\Delta z] = \Gamma_O^-[z] - \Gamma_O^-[z+\Delta z] = \frac{\mathrm{d}L_z}{\mathrm{d}t} \quad ,$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_z^{z+\Delta z} \frac{\rho_0 \pi R^4}{2}\omega[z']\,\mathrm{d}z' = \frac{\rho_0 \pi R^4}{2}\Delta z\,\partial_t\omega[z+\tilde{z}] \qquad \text{with} \qquad z \leq \tilde{z} \leq z+\Delta z \quad .$$

The expression of the angular momentum L_z of the piece of the bar has been obtained by integrating over the finite length of the piece of the bar, Δz, whose infinitesimal momentum of inertia is given by

$$\mathrm{d}I = \frac{\rho_0 \pi R^4}{2}\,\mathrm{d}z' \quad .$$

This is motivated by the fact that, by definition, the angular momentum is an additive quantity.
Dividing by Δz and taking the limit for $\Delta z \longrightarrow 0$ we get:

$$-\frac{\partial \Gamma_O^-[z]}{\partial z} = \frac{\rho_0 \pi R^4}{2}\partial_t\omega[z] \tag{32.08.05}$$

→ 1667

The expression for $\Gamma_O^-[z]$ is known from equation (27.07.12):

$$\Gamma_O^-[z] = \frac{\pi G}{2L}\left(r_2^4 - r_1^4\right)\phi \quad .$$

The latter equation must be adapted to the notation and setup of the present problem. Consider equation (27.07.12) applied to the current piece of bar lying between $\mathcal{S}[z]$ and $\mathcal{S}[z+\Delta z]$ and having length Δz (taking the place of the length L of the bar under uniform torsion). The torsion of the

cc BY NC ND

piece is measured by the angle:

$$\Delta\phi \equiv \phi[z+\Delta z] - \phi[z] \quad .$$

The linear momentum acting on the piece from the left of section $\mathcal{S}[z]$ and its limit for $\Delta z \longrightarrow 0$ are given by:

$$\Gamma^-_O[z;\Delta z] = -\frac{\pi G R^4}{2}\frac{\Delta\phi}{\Delta z} \qquad \Gamma^-_O[z] = \lim_{\Delta z \longrightarrow 0} \Gamma^-_O[z;\Delta z] = -\frac{\pi G R^4}{2}\frac{\partial\phi}{\partial z} \quad . \tag{32.08.06}$$

→ 1667

In fact in the formula (27.07.12) the torsion angle ϕ represents the overall torsion of the bar of length L under uniform torsion. In fact in the current framework the torsion angle of the piece of bar of length Δz is $\Delta\phi$. Note the minus sign, deriving from the fact that a positive torque $\Gamma^-_O[z]$ would produce a negative $\Delta\phi$ because it would tend to rotate the section $\mathcal{S}[z]$ in the positive angular direction more than it rotates the section $\mathcal{S}[z+\Delta z]$ thus producing a negative $\Delta\phi$.
The equation of motion follows from equations (32.08.05), (32.08.06):

$$\frac{\partial^2\phi}{\partial z^2} = \frac{\rho_0}{G}\frac{\partial^2\phi[z]}{\partial t^2} \qquad c_T^2 = \frac{G}{\rho_0} \quad .$$

Note that no approximation has been done within the elastic behavior.
Because of the relation (27.02.06) the speed of torsional waves is always less than the speed of longitudinal waves.

32.08.08
Hydrostatic Equilibrium of a Non-Rotating Gravitating Fluid Mass

This § is referenced at pages:
[1534]

©|R.Blandford & K.Thorne, *Applications Of Classical Physics*, ..., ..., ...Ed., WEB - URL, WEB - URL.|||

Read also § 28.07.14.

Consider a spherically symmetrical non rotating fluid mass (for instance a star) at equilibrium. Equilibrium is given by the balance between gravity and pressure. Let the mass density be $\rho[r]$ and and the radius R (that is $\rho[r] = 0$ for $r > R$). Assume also that $p[R] = 0$.

The equilibrium conditions (first **Cardinal Equation**) is:

$$f_k + \frac{\partial s_{kj}^{\cdot\cdot}}{\partial x_j} = 0 \quad .$$

In the present case the equilibrium condition becomes:

$$-\mathbf{grad}p[r] + \rho[r]g[r] = -\mathbf{grad}p[r] - \rho[r]\mathbf{grad}\phi[r] = 0 \quad ,$$

$$\mathbf{g}[r] = -\frac{\mathcal{G}M[r]}{r^2}\hat{\mathbf{e}}_r \quad ,$$

$$M[r] = \iiint_{V[r]} \rho[r]\, \mathbb{d}V = \int_{r=0}^{r} \rho[s] 4\pi s^2\, \mathbb{d}s \quad ,$$

$$\frac{\mathbb{d}M[r]}{\mathbb{d}r} = 4\pi\rho[r]r^2 \quad .$$

From the expression of the gradient in spherical coordinates, taking into account that there is only radial dependence, by assumption, one finds:

$$\frac{\mathbb{d}p[r]}{\mathbb{d}r} = -\rho[r]\frac{\mathcal{G}M[r]}{r^2} = -\frac{\mathbb{d}M[r]}{\mathbb{d}r}\frac{1}{4\pi r^2}\frac{\mathcal{G}M[r]}{r^2} < 0 \quad .$$

In general it is necessary to know a relation between pressure and density, that is the equation of state of the medium, to be able to solve the equation. The equation of state of the medium in general, will involve the temperature, too. Therefore the problem is a thermodynamical problem.

IN PROGRESS

However, regardless of the equation of state some general results can be derived.

One obvious conclusion is that the pressure is a decreasing function, that is the maximum pressure is a $r = 0$.

Another conclusion can be drawn by observing that the basic hydrostatic equilibrium equation can be re-written as:

$$\frac{\mathrm{d}p[r]}{\mathrm{d}r} = -\frac{\mathcal{G}}{4\pi}\left(\frac{\mathrm{d}}{\mathrm{d}r}\left(\frac{M^2[r]}{2r^4}\right) + 2\frac{M^2[r]}{r^5}\right) \Longrightarrow \frac{\mathrm{d}}{\mathrm{d}r}\left(p[r] + \frac{\mathcal{G}}{8\pi}\frac{M^2[r]}{r^4}\right) = -\frac{\mathcal{G}}{2\pi}\frac{M^2[r]}{r^5} \leq 0 \quad .$$

The result implies that the function $p[r] + \dfrac{\mathcal{G}}{8\pi}\dfrac{M^2[r]}{r^4}$ is decreasing.

$$\frac{\mathrm{d}}{\mathrm{d}r}\left(p[r] + \frac{\mathcal{G}}{8\pi}\frac{M^2[r]}{r^4}\right) \leq 0 \quad .$$

Moreover, the term added to pressure goes to zero for small r:

$$\frac{\mathcal{G}}{8\pi}\frac{M^2[r]}{r^4} \sim 0 \qquad \text{for } r \sim 0 \qquad \text{as } M^2[r] \sim r^6 \quad .$$

Therefore:

$$p[r=0] > p[r] + \frac{\mathcal{G}}{8\pi}\frac{M^2[r]}{r^4} > p[R] + \frac{\mathcal{G}}{8\pi}\frac{M^2[R]}{R^4} \Longrightarrow \boxed{p[r=0] > \frac{\mathcal{G}M^2[R]}{8\pi R^4} \equiv p_1 \qquad \text{exact}} \quad .$$

This limit is independent of the equation of state of the medium.

Note that the above equations, in fact, are a good approximation for solid planets, as well as for stars and liquid planets. In fact at the enormous stresses encountered in the interior of a solid planet, the strains are so large that plastic flow will occur, that is the limiting shear stresses are much smaller than the isotropic part of the stress tensor.

Note that this derivation of the static equilibrium solution does not give insight into the stability of the solution. In order to study oscillation of stars one should consider small motions around the stable equilibrium solution. In order to accomplish this task one must reintroduce the time derivative term in the first **Cardinal Equation** and then consider small time-dependent motion around the stable equilibrium solution.

32.08.08.01 Molecular Gas - the Polytropic Model for the Equation of State

One often used approximation is the polytropic one, describing a family of equations of state:

$$\boxed{p \propto \rho^{\frac{n+1}{n}}} \quad ,$$

where n is the polytropic index, defining the equation of state.

- The giant planets, Jupiter and Saturn mainly comprise a fluid made of Hydrogen and Helium which is well approximated by $n = 1$; the density of a small planets, like Mercury, is very roughly constant, $n = 0$.
  - $n = 0$: the density is constant; often used for small planets where the small gravity might allow to neglect the change in density due to the change in pressure.
  - $n = 1$: used for big planets.
- $n = (1.5 \div 3.0)$: used for stars.
  Low mass white dwarf stars are well approximated by $n = 1.5$; red giant stars are well approximated by $n = 3.0$.

DRAFT-IN-PROGRESS

32-008 Solution for Uniform Density

Solve the equation of hydrostatic equilibrium for uniform density.

32.08.08.02 Photon Gas - Radiation Pressure

For a gas of thermal photons with vanishing chemical potential (that is an isotropic, black-body distribution) the radiation pressure is proportional to the fourth power of the absolute temperature. In fact, in terms of the radiation constant a, the energy per unit volume, $\rho \equiv u$ and pressure are given,

$$\rho \equiv u = aT^4 \qquad p = \rho/3 \qquad a \equiv \frac{8\pi^5}{15}\frac{k^4}{h^3c^3} = 7.56{\cdot}10^{-16}\ \mathrm{Jm^{-3}K^{-4}} \quad . \tag{32.08.07}$$

→ 1669

Equation (32.08.07) is in fact the equation of state for a gas of photons. When the Universe was younger than about 10^5 years, its energy density and pressure were predominantly due to thermal photons and neutrinos, contributed roughly the same amount, so its equation of state was given by equation (32.08.07) with a slight different coefficient.

In the case of stars a relevant role is played by radiation pressure: in addition to the pressure produced by matter there is the pressure produced by radiation (photons). Radiation pressure must be summed to the pressure produced by matter. In some cases it might exceed the pressure of matter.

32.08.08.03 Some Applications

Estimation of the Central Pressure

$$\frac{\mathrm{d}p[r]}{\mathrm{d}r} = -\rho[r]\frac{\mathcal{G}M[r]}{r^2} \quad ,$$

$$\frac{\Delta r}{\Delta R} \approx -\frac{p_0}{R} \, ,$$

$$\frac{\Delta r}{\Delta R} \approx -\langle\rho\rangle\frac{\mathcal{G}M}{R^2} \, ,$$

$$p_0 \approx \frac{\mathcal{G}M\langle\rho\rangle}{R} = \frac{3\mathcal{G}M^2}{4\pi R^4} \qquad \text{approximate} \quad .$$

$$p_0 \approx \frac{\mathcal{G}M\langle\rho\rangle}{R} = \frac{3\mathcal{G}M^2}{4\pi R^4} > p_1 \quad .$$

Estimations for the Sun

Assume for the Sun: $M = 2{\cdot}10^{30}$ kg; $R = 6.95{\cdot}10^5$ km; $\langle\rho\rangle = 1.42{\cdot}10^3$ kg/m^3.

$$p_0 \approx \frac{\mathcal{G}M\langle\rho\rangle}{R} = 2.7{\cdot}10^{14}\ \mathrm{Pa} \quad .$$

The inequality above gives: $p_1 > 4.5{\cdot}10^{13}$ Pa.

The accurate calculation gives: $p_0 = 2.5{\cdot}10^{14}$ Pa.

The surface acceleration of gravirty is:

$$g = \frac{\mathcal{G}M}{R^2} = 2.8{\cdot}10^2\ \mathrm{m/s^2} \quad .$$

The estimate of the central temperature of the Sun using the law of perfect gases gives: $T_0 = 10^7$ K.

The accurate calculation gives: $T_0 = 1.6{\cdot}10^7$ K.

PRELIMINARY - IN PROGRESS

Neutron Stars

Assume for a typical neutron star: $M = 2{\cdot}10^{30}$ kg; $R = 10$ km; $\langle\rho\rangle = 4.8{\cdot}10^{17}$ kg/m^3.

$$p_0 \approx \frac{\mathcal{G}M\langle\rho\rangle}{R} = 6.4{\cdot}10^{33}\ \text{Pa} \quad .$$

The inequality above gives: $p_1 > 1.1{\cdot}10^{33}$ Pa.

The surface acceleration of gravity is:

$$g = \frac{\mathcal{G}M}{R^2} = 1.3{\cdot}10^{12}\ \text{m/s}^2 \quad .$$

The gravitational potential energy (assuming uniform density) is:

$$\Phi_g \simeq -\frac{3}{5}\frac{\mathcal{G}M^2}{R} = -2{\cdot}10^{46}\ \text{J} \quad .$$

The number of nucleons is: $N = M/m_N = 1.2{\cdot}10^{57}$.

The average distance among neutrons is 1.5 fm.

Given the typical binding energy of nuclear matter, $U_b = 8$ MeV/nucleon, one can estimate the nuclear interaction energy: $U_n = NU_b = -1.5{\cdot}10^{45}$ J.

The gravitational potential energy increases with decreasing radius.

32.08.09

Hydrostatic Equilibrium of a Rotating Self-Gravitating Liquid Mass Body

Consider a mass of liquid of constant and uniform density ρ, mass M, self-gravitating and rotating with angular velocity Ω. Determine the shape of equilibrium in case of small Ω.

Neglect to a first approximation the effect on the gravitational field of the change of shape. This approximation can be justified in the case most of the mass is concentrated near the center of the liquid mass. As a second approximation include the effect of the change of the gravitational field by developing the gravitational potential to second-order.

WORKED SOLUTION

Let θ be the latitude and ϕ be the colatitude measured from the north-pole, such that $\theta + \phi = \pi/2$. Let the z axis be coincident with the rotation axis of the body, oriented as the angular velocity and with its origin at the center of the body. The body will assume a shape which is a revolution figure around the rotational axis. Assume that the body is rotating like a rigid-body, that is the steady state when internal viscous forces have dissipated the kinetic energy with respect to the Center-Of-Mass. Use a Reference Frame rotating with the body. At equilibrium the free surface of the body will be an equipotential surface, that is perpendicular to the volume forces, because a liquid at rest cannot resist shear stresses. The shape of the equipotential surfaces must be sought for, in particular the one corresponding to the surface of the body. This will be described by a function:

$$r[\theta] = a + \delta r\,[\theta] \quad , \tag{32.08.08}$$

→ 1671 1672 1673

where a is some reference, constant, radius, typically the equatorial radius or the polar radius. In any case $\delta r\,[\theta]$ will describe the deviation from a spherical shape.

The centrifugal potential, expressed in polar coordinates, is given by:

$$V_{\text{CEN}}[r,\theta] = -\frac{1}{2}\Omega^2 r^2\cos^2[\theta] = -\frac{1}{2}\Omega^2 r^2\sin^2[\phi] \quad .$$

Note that the requirement of small angular velocity implies that the centrifugal potential is small with respect to the gravitational potential. Take for instance a to be either the equatorial radius. The condition, in terms of the q parameter, the ration between the centrifugal and gravitational force at the equator, becomes:

$$\boxed{q \equiv \frac{\Omega^2 a^3}{2\mathcal{G}M} \ll 1} \quad \Longrightarrow \quad \frac{\Omega^2 a^3}{2\mathcal{G}M}\cos^2[\theta] \ll 1 \quad , \tag{32.08.09}$$

→ 1673

CC BY NC ND

where the condition $q \ll 1$ is a sufficient condition in order that the centrifugal potential is small with respect to the gravitational potential at any latitude. It is also obvious that is th condition is satisfied near the surface it will be valid at any interior point because the centrifugal to gravitational force ratio increases with the distance.

32.08.09.01 First Approximation: Neglect the Change of Gravitational Field Due to the Flattening

In this approximation one neglects the gravitational feedback due to the flattening of the body while rotating. The total (gravitational plus centrifugal) potential is thus:

$$V_{\text{TOT}}[r,\theta] = V_{\text{GRA}}[r,\theta] + V_{\text{CEN}}[r,\theta] = -\frac{\mathcal{G}M}{r} - \frac{1}{2}\Omega^2 r^2 \cos^2[\theta] \quad . \tag{32.08.10}$$

→ 1671

The expression (32.08.08) must be put into equation (32.08.10). All the constant terms must be set apart, inglobing them into a constant K, because in general we are looking for all the equipotential surfaces. In the non-constant terms, that is the terms containing either r or θ, the approximation

$$|\,\delta r\,[\theta]| \ll a$$

is to be done.
The result is:

$$V_{\text{TOT}}[r,\theta] = -\frac{\mathcal{G}M}{a} + \frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] - \frac{1}{2}\Omega^2\cos^2[\theta]\left(a^2 + 2a\,\delta r\,[\theta] + (\,\delta r\,[\theta])^2\right) \simeq \quad ,$$

$$K + \frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] - \frac{1}{2}\Omega^2 a^2\cos^2[\theta] \quad .$$

In order to have a constant potential one must then have:

$$\frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] - \frac{1}{2}\Omega^2 a^2\cos^2[\theta] = \text{constant} \qquad \Longrightarrow \qquad \boxed{\delta r\,[\theta] = K' + \frac{\Omega^2 a^4}{2\mathcal{G}M}\cos^2[\theta]}$$

The value of the constant K' will depend on the value chose for a in equation (32.08.08). If one chooses the equatorial radius for a one has:

$$\delta r\,[\theta = \pm\pi/2] = 0 \qquad \Longrightarrow \qquad K' = -\frac{\Omega^2 a^4}{2\mathcal{G}M} \qquad \Longrightarrow \qquad \boxed{\delta r\,[\theta] = \frac{\Omega^2 a^4}{2\mathcal{G}M}\left(\cos^2[\theta] - 1\right) = -\frac{\Omega^2 a^4}{2\mathcal{G}M}\sin^2[\theta]} \quad .$$

The flattening, f, and the q parameter are thus:

$$f \equiv \frac{r_{\text{EQ}} - r_{\text{PO}}}{r_{\text{EQ}}} \simeq \frac{\Omega^2 a^3}{2\mathcal{G}M} \equiv \frac{q}{2} \quad .$$

Note that a rough estimate of the maximum allowed angular velocity for the body, before braking apart due to the effect of the centrifugal forces, is:

$$q \approx 1 \qquad \Longrightarrow \qquad \Omega_{\text{MAX}} \approx \left(\frac{\mathcal{G}M}{a^3}\right)^{1/2} \approx a\,(\mathcal{G}\langle\rho\rangle)^{1/2} \quad . \tag{32.08.11}$$

→ 1671

In the case of Jupiter, for instance, the actual orbital period is $T_J = 9.9$ hours with a $T_{J|MIN} = 2.9$ hours.
Equation (32.08.11) giving a rough estimate of the angular velocity such the a rotating object without internal cohesion breaks apart can also roughly explain the breaking apart of a collapsing proto-star giving rise to a proto-planetary system.

32.08.09.02 Second Approximation: Account for the Change of Gravitational Field Due to the Flattening

As a second approximation one can try to account for or the change of gravitational field due to the flattening. Planets, but not always asteroids, compare with § 32.08.05, can be approximated as oblate spheroids, that is an ellipsoid with two identical axes, and with the equatorial radius greater than the polar radius the latter acting as the axis of symmetry of the system.

CC BY NC ND

The potential external to any body with an axis of symmetry can be developed in terms of terms of the spherical harmonics (see equation (29.05.11)):

$$V_{\text{GRA}}[r,\theta] = -\frac{\mathcal{G}M}{r}\left(1 - \sum_{k=2}^{\infty} J_k \frac{R^k}{r^k} P_k[\cos[\phi]]\right) \quad \text{with } R \text{ the equatorial radius} \quad . \tag{32.08.12}$$

→ 1672

Note that $J_1 = 0$ if, as usual, the origin is chosen at the Center-Of-Mass of the body. In order to make sure to stay outside the mass distribution one can use the equatorial radius for R and The potential thus obtained, when all terms are summed, is the exact potential externally to the mass distribution. If one wants the potential far and far away the potential can be calculated by truncating the series to a smaller and smaller number of terms. If one is close to the distribution all the terms, in principle, should be used. However, if one knows that the coefficients J_k are sufficiently small one can truncate the series accordingly and estimate the error. Note that the coefficients J_k can be calculated by the gravitational field far away.
Read also § 29-019.
The expression (32.08.12) can be used to calculate the gravitational potential at the surface of the body in order to study the equilibrium condition for the liquid at the surface.
The Legendre polynomials of second degree is:

$$P_2[s] = \frac{1}{2}\left(3s^2 - 1\right) \quad .$$

The centrifugal potential is given by:

$$V_{\text{CEN}}[r,\theta] = \frac{1}{3}\Omega^2 r^2 \left(P_2[\cos[\phi]] - 1\right) \quad .$$

The total potential, up to second-order in the development of the gravitational field, is:

$$V_{\text{TOT}}[r,\theta] = V_{\text{GRA}}[r,\theta] + V_{\text{CEN}}[r,\theta] = -\frac{\mathcal{G}M}{r} + \left(\frac{\mathcal{G}Ma^2}{r^3}J_2 + \frac{1}{3}\Omega^2 r^2\right) P_2[\cos[\phi]] - \frac{1}{3}\Omega^2 r^2 \quad . \tag{32.08.13}$$

→ 1672

One could immediately say that the term $\frac{1}{3}\Omega^2 r^2$, as well as its changes, is negligible with respect to the term $\frac{\mathcal{G}M}{r}$, as well as its changes. Both terms only depend on r only and have no angular dependence. The angular dependence in the centrifugal potential term is elsewhere. The centrifugal term could be then immediately dropped. However, we can keep it to show at the end that it has no impact.
The expression (32.08.08) must be put into equation (32.08.13). All the constant terms must be set apart, inglobing them into a constant K, because in general we are looking for all the equipotential surfaces. In the non-constant terms, that is the terms containing either r or θ, the approximation

$$|\,\delta r\,[\theta]| \ll a$$

is to be done.

CC BY NC ND

One then finds:

$$V_{\text{TOT}}[r,\theta] = -\frac{\mathcal{G}M}{a} + \frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] + \quad ,$$

$$\left(\frac{\mathcal{G}Ma^2}{a^3}J_2\left(1 - 3\frac{\delta r\,[\theta]}{a} + \mathcal{O}\left(\delta r\,[\theta]\right)^2\right) + \frac{1}{3}\Omega^2a^2\left(1 + 2\frac{\delta r\,[\theta]}{a} + \mathcal{O}\left(\delta r\,[\theta]\right)^2\right)\right)P_2[\cos[\phi]] - \quad ,$$

$$\frac{1}{3}\Omega^2a^2\left(1 + 2\frac{\delta r\,[\theta]}{a} + \mathcal{O}\left(\delta r\,[\theta]\right)^2\right) \simeq \quad ,$$

$$K + \frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] + \left(\frac{\mathcal{G}Ma^2}{a^3}J_2 + \frac{1}{3}\Omega^2a^2\right)P_2[\cos[\phi]] - \frac{2}{3}\Omega^2a\,\delta r\,[\theta] = \quad ,$$

$$K + \left(\frac{\mathcal{G}M}{a^2} - \frac{2}{3}\Omega^2a\right)\,\delta r\,[\theta] + \left(\frac{\mathcal{G}Ma^2}{a^3}J_2 + \frac{1}{3}\Omega^2a^2\right)P_2[\cos[\phi]] \simeq \quad ,$$

$$K + \frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] + \left(\frac{\mathcal{G}Ma^2}{a^3}J_2 + \frac{1}{3}\Omega^2a^2\right)P_2[\cos[\phi]] \quad ,$$

where the last passage follows from equation (32.08.09).
In order to have a constant potential one must then have:

$$\frac{\mathcal{G}M}{a^2}\,\delta r\,[\theta] + \left(\frac{\mathcal{G}Ma^2}{a^3}J_2 + \frac{1}{3}\Omega^2a^2\right)P_2[\cos[\phi]] = \text{constant} \quad ,$$

$$\Longrightarrow \quad \boxed{\delta r\,[\theta] = K' - \left(J_2 + \frac{\Omega^2a^3}{3\mathcal{G}M}\right)aP_2[\cos[\phi]]} \quad .$$

The value of the constant K' will depend on the value chose for a in equation (32.08.08). If one chooses the equatorial radius for a one has:

$$\delta r\,[\theta = \pm\pi/2] = 0 \qquad \Longrightarrow \qquad ,$$

$$K' = -\frac{a}{2}\left(J_2 + \frac{\Omega^2a^3}{3\mathcal{G}M}\right) \qquad \Longrightarrow \qquad ,$$

$$\boxed{\delta r\,[\theta] = -\frac{a}{2}\left(3J_2[\,\delta r\,[\theta]] + \frac{\Omega^2a^3}{2\mathcal{G}M}\right)\cos^2[\phi]} \quad .$$

The result is consistent with the result obtained with the previous approximation, equivalent to setting $J_2 = 0$.
Note, as emphasised in the relation (32.08.09.02) itself, the relation is actually an implicit equation for $\delta r\,[\theta]$ because J_2 is actually a function of $\delta r\,[\theta]$ itself.

33.01 Constants of Motion and Integrals of Motion

©|L.D.Landau *et al.*, *Mechanics*, ..., ..., ...Ed., WEB - URL - ISBN: 978-0-7506-2896-9.|§ 3, 13||

Consider a generic system with n degrees of freedom, defined by generalized coordinates and momenta,

$$q_i \qquad p_i \qquad i = 1, \ldots n \quad .$$

Mathematically, the equations of motion constitute

- either a set of n second-order equations for n unknown functions $q_i[t]$;
- or a set of $2n$ first-order equations for $2n$ unknown functions $q_i[t]$ and $p_i[t]$.

The general solution contains in either case $2n$ arbitrary constants. To determine these constants and to define uniquely the motion of the system, it is necessary to know the initial conditions, which specify the state of the system at some given instant.

Constants of motion are functions of phase-space coordinates and time which are constant along orbits:

$$C[q_i[t], p_i[t], t] = \text{constant} \quad ,$$

where $q_i[t]$ and $p_i[t]$ are a solution to the equations of motion.

The function $C[q_i[t], p_i[t], t]$ must be constant along every trajectory, with a value which may depend on the trajectory. In a phase-space of $2n$ dimensions there are always $2n$ independent constants of motion. For example, the $2n$ initial conditions of a trajectory can serve as constants of motion. Once the phase-space coordinates at time t are given one can integrate the orbit backwards to $t = 0$ and read off the initial conditions.

Integrals of motion are functions of phase-space coordinates alone which are constant along orbits:

$$I[q_i[t], p_i[t]] = \text{constant} \quad ,$$

where $q_i[t]$ and $p_i[t]$ are a solution to the equations of motion.

An integral of motion can't depend on time. Thus all integrals of motions are constants of motion, but not all constants are integrals. Integrals of motions are important because they constrain the shapes of orbits. In fact, in a phase-space of $2n$ dimensions, the condition $I[q_i[t], p_i[t]] = \text{constant}$ defines a hyper-surface of $2n - 1$ dimensions. Thus if there are N independent integrals of motion then each orbit is confined to a sub-space of $2n - N$ dimensions.

GO TO AFTER included File

§6. Energy

DURING the motion of a mechanical system, the $2s$ quantities q_i and $\dot{q}_i$ ($i = 1, 2, ..., s$) which specify the state of the system vary with time. There exist, however, functions of these quantities whose values remain constant during the motion, and depend only on the initial conditions. Such functions are called *integrals of the motion*.

The number of independent integrals of the motion for a closed mechanical system with s degrees of freedom is $2s-1$. This is evident from the following simple arguments. The general solution of the equations of motion contains $2s$ arbitrary constants (see the discussion following equation (2.6)). Since the equations of motion for a closed system do not involve the time explicitly, the choice of the origin of time is entirely arbitrary, and one of the arbitrary constants in the solution of the cquations can always be taken as an additive constant t_0 in the time. Eliminating $t+t_0$ from the $2s$ functions $q_i = q_i(t+t_0, C_1, C_2, ..., C_{2s-1})$, $\dot{q}_i = \dot{q}_i(t+t_0, C_1, C_2, ..., C_{2s-1})$, we can express the $2s-1$ arbitrary constants $C_1, C_2, ..., C_{2s-1}$ as functions of q and $\dot{q}$, and these functions will be integrals of the motion.

Not all integrals of the motion, however, are of equal importance in mechanics. There are some whose constancy is of profound significance, deriving from the fundamental homogeneity and isotropy of space and time. The quantities represented by such integrals of the motion are said to be *conserved*, and have an important common property of being additive: their values for a system composed of several parts whose interaction is negligible are equal to the sums of their values for the individual parts.

It is to this additivity that the quantities concerned owc their especial importance in mechanics. Let us suppose, for example, that two bodies interact during a certain interval of time. Since each of the additive integrals of the whole system is, both before and after the interaction, equal to the sum of its values for the two bodies separately, the conservation laws for these quantities immediately make possible various conclusions regarding the state of the bodies after the interaction, if their states before the interaction are known.

33.02 Additional Exercises Problems and Physical Applications

33-001 ...

Si risolva il seguente problema usando esclusivamente l'algebra vettoriale.
Sia data una piramide retta a base quadrata di lato l e altezza h e si consideri una delle sue facce laterali.

1. Si determini l'angolo θ formato, al vertice della piramide, tra i due spigoli della faccia della piramide.
2. Verificare che il risultato ottenuto è corretto nei casi limite:
   a) $h \to +\infty$;
   b) $h \to 0$;
   c) $l \to +\infty$;
   d) $l \to 0$.

33-002 ...

Siano dati i due vettori

$$\mathbf{a} = a_1\widehat{\mathbf{e}}_1 + a_2\widehat{\mathbf{e}}_2 \qquad \mathbf{b} = b_1\widehat{\mathbf{e}}_1 + b_3\widehat{\mathbf{e}}_3 \ ,$$

dove a_1, a_2, b_1 e b_3 sono costanti. Calcolare $\mathbf{a}\wedge\mathbf{b}$.

33-003 ...

Siano dati i due vettori

$$\mathbf{a} = a_1\widehat{\mathbf{e}}_1 + a_2\widehat{\mathbf{e}}_2 \qquad \mathbf{b} = x\widehat{\mathbf{e}}_1 + b_2\widehat{\mathbf{e}}_2 \quad .$$

Determinare il valore di x per cui $\mathbf{a}$ e $\mathbf{b}$ sono perpendicolari.

33-004 ...

Si consideri un moto lungo una linea retta (asse x) per cui l'accelerazione soddisfa alla:

$$a[v] = g - kv^2 \qquad v[t=0] = 0 \qquad x[t=0] = 0 \qquad ,$$

dove g e k sono costanti. Determinare $v = v[t]$ e $x = x[t]$.

33-005 ...

Si consideri un punto materiale la cui equazione del moto è data da:

$$x[t] = x_0\cos\omega t \qquad y[t] = y_0\sin\omega t \qquad z[t] = kt \qquad ,$$

con x_0, y_0, ω e k costanti opportune. Si calcoli l'accelerazione del punto materiale e si verifichi che è sempre perpendicolare all'asse z.

33-006 ...

Si consideri un punto materiale la cui equazione del moto piano è data da:

$$x[t] = x_0\cos\omega t \qquad y[t] = y_0\sin\omega t$$

con x_0, y_0 ed ω costanti opportune e positive. Si calcoli:

1. la componente tangenziale e quella normale dell'accelerazione;
2. la componente radiale e quella trasversale dell'accelerazione.

DRAFT - IN-PROGRESS

33-007 ...

Un cannone spara lungo un pendio in salita. Se il cannone spara con alzo α e se il pendio forma un angolo β con l'orizzontale (con $\beta < \alpha$) si determini:

1. quanto deve valere il modulo v_0 della velocità iniziale del proiettile affinché questo colpisca un punto posto a distanza L lungo il pendio;
2. per una velocità iniziale fissata, v_0, determinare per quale valore dell'alzo α il proiettile cade alla massima distanza possibile dal cannone lungo il pendio.

33-008 ...

Un punto materiale si muove nel piano $x - y$ con equazione del moto:

$$x[t] = A \qquad y[t] = k\,(t - t_0)$$

con $A > 0$, $k > 0$ e t_0 costanti opportune.

- Determinare la velocità angolare e l'accelerazione angolare con cui il moto del punto materiale è visto da un osservatore posto nell'origine.
- Determinare la velocità radiale e quella tangenziale.

33-009 ...

Un'auto percorre una strada rettilinea in pianura. C'è del vento che soffia lungo la stessa direzione della strada e nello stesso verso del moto dell'auto. Per questo la pioggia che cade con velocità di modulo v_0 fa un certo angolo θ con la verticale. Se l'auto si muove con legge oraria

$$x[t] = At\,(1 - \exp(-t/\lambda))$$

con $A > 0$ e $\lambda > 0$ costanti opportune.

Determinare, in funzione del tempo, l'angolo con la verticale che fanno le tracce delle gocce di pioggia sui finestrini laterali dell'auto.

33-010 ...

Un aereo viaggia di moto rettilineo uniforme, velocità $\mathbf{v}_0$, ad una quota costante. Ad un certo istante passa esattamente sopra la verticale del centro di una giostra che ruota con velocità angolare Ω costante attorno ad un asse verticale.

1. Determinare l'accelerazione con cui il moto dell'aereo è visto da un osservatore che si trova al centro della giostra e ruota solidalmente con essa (componenti radiale e trasversale).

33-011 ...

Un blocchetto di massa m giace su un piano orizzontale. I coefficienti di attrito statico e cinetico tra il blocchetto e il piano sono μ_s e μ_c, con $\mu_s > \mu_c$. Una fune è collegata al blocchetto e viene tirata formando un angolo θ con l'orizzontale.

1. Determinare per quale angolo θ il modulo della forza necessario per mantenere il blocchetto in moto rettilineo uniforme è minimo.
2. Se $\theta = 0$, il blocchetto è inizialmente fermo e il modulo della forza applicata dipende dal tempo secondo la relazione $F(t) = kt^2$, con $k > 0$ costante, determinare il moto del blocchetto in funzione del tempo.

DRAFT - IN PROGRESS

33-012 ...

Due blocchetti di masse m_1 ed m_2 sono collegati da una fune ideale. Il blocchetto 1 è poi collegato ad una seconda fune ideale e, tramite questa fune, il tutto viene appeso ad un soffito.

1. Determinare le tensioni delle due funi
2. Se le due funi sono identiche e l'esperimento viene ripetuto con masse di valore progressivamente crescente quale delle due funi è piu probabile che si rompa per prima ? Perché' ?

33-013 ...

Una puleggia ideale ha un peso di massa m che pende ad un estremo della sua fune ideale. All'altro capo della fune c'è un uomo di massa M.

1. Se l'uomo si arrampica sulla fune con accelerazione costante A rispetto alla puleggia (verso l'alto) determinare il moto della massa m.
2. Se $M = m$ e l'uomo si arrampica sulla fune con velocità costante V determinare il moto della massa m.

WORKED SOLUTION

1. $a = (g(M - m) - aM)/m$.
2. $v = V$

33-014 ...

Una moneta è sistemata a $r = 13$ cm dall'asse del piatto di un giradischi. Si osserva che la moneta non si muove quando il giradischi ruota alla velocità angolare di 33.3 giri/s mentre scivola via quando il giradischi ruota alla velocità angolare di 45.0 giri/s.

1. Determinare entro quali limiti è compreso il coefficiente di attrito statico tra la moneta e il piatto del giradischi.
2. La moneta cade fuori dal piatto del giradischi e resta ferma a terra. Descrivere la dinamica della moneta rispetto ad un sistema di riferimento solidale con il piatto del giradischi.

33-015 ...

Si dimostri che il teorema lavoro-energia per un punto materiale è covariante, cioè che la legge assume la stessa forma per tutti i Sistemi di Riferimento Inerziali. Si ricordi che, in meccanica classica, le forze sono assolute, cioè sono le stesse in ogni Sistema di Riferimento Inerziale. Si usi la forma infinitesimale:

$$m\mathbf{v} \cdot \frac{\mathrm{d}\mathbf{v}}{\mathrm{d}t} = \mathbf{F} \cdot \mathbf{v}$$

33-016 ...

Un campo di forze nel piano ha componenti:

$$F_x = y \qquad F_y = -x$$

1. Disegnare le linee di forza del campo.
2. Dimostare che il campo non è conservativo.

DRAFT-IN-PROGRESS

36.01 Introduction

this section deals with the basic laws of ElectroMagnetism. The laws discussed in this section are always valid, as they are expressed in terms of the basic ElectroMagnetic fields **E** and **B**.

The effect of the presence of matter will be considered explicitly in sections § 37, § 38, § 39 where, in addition to the Polarization, **P**, and Magnetization, **M**, fields, the auxiliary fields **D** and **H** are introduced as useful, but optional, tools to describe ElectroMagnetism in presence of matter.

36.01.01 ElectroMagnetism

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|||

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|Introduction||

- Once upon a time electricity and magnetism were two different subjects. Later it become clear that they are different aspects of the same thing: ElectroMagnetism. Later on it was found that optics was also one additional aspect of ElectroMagnetism. Today, Electricity, Magnetism and Optics are unified.
- As far as we know today universe is governed by four forces: gravity, ElectroMagnetism, whose effects are relevant at the macroscopic level, as well as the strong and the weak forces, whose effects are only important at the femto-meter level and below.
- ElectroMagnetism, together with gravity, governs all macroscopic phenomena (all physical and chemical properties of matter).
- Classical ElectroMagnetism survived both relativistic physics and quantum physics revolutions: it is compatible with relativity and it is ok with quantum physics down to pico-meters.
- Electric charges come in two species, distinguished by attraction/repulsion. In fundamental physics this duality becomes the duality between particle and anti-particles (that is matter and anti-matter). Other types of **charges** do exist as well, at the fundamental level: flavor charges in QCD, electroweak charges in the electro-weak model, for instance.
- Electric charge is conserved: the total electric charge in an isolated system, that is the algebraic sum of the positive and negative charge present at any time, never changes.
- Electric charge is Lorentz-invariant: observers in different inertial frames, measuring the charge of any system, obtain the same number. In other words the total electric charge of a system is a relativistically invariant number.
- Electric charge is quantised (as first shown by Millikan): particle and anti-particle have charges $\pm e$; electrons-protons have identically opposite charges; quarks and anti-quarks have $\pm 2/3e$ and $\pm 1/3e$ charges; leptons and anti-leptons have $\pm e$ charges. This is an experimental fact.

  see WEB - URL

- ElectroMagnetism is a field theory: charges and currents produces fields in space and other charges and currents feel the fields. Fields carry energy, linear momentum and angular momentum. The concept of field invites us to regard the fields as real dynamical entities in their own right.
- ElectroMagnetism is often described by different systems of units of measure. SI will be used (read § B).

36.02 Names Notation Symbols and Conventions

As in any field of physics, names, notation, symbols and conventions change from author/teacher to author/teacher and there is no hope for universal agreement. Therefore one must always check names, notation, symbols and conventions at the beginning. Moreover, for this same reason, it is important to look at formulas as linking concepts, not symbols.

36.02.01 EM Fields

According to the modern point of view that the fields **E** and **B** are the fundamental ElectroMagnetic fields, the following names will be used in these notes:

- the electric field **E** is simply called **the electric field**;
- the magnetic field **B** is simply called **the magnetic field**;
- the field **D** is just called **the (auxiliary electric) field D** and it is often called, in the literature, the **electric excitation field**;
- the field **H** is just called **the (auxiliary magnetic) field H** and it is often called, in the literature, the **magnetic excitation field**.

Read § 38.05, § 39.05 for further details on the auxiliary fields.

Also note that **Maxwell Equations** written in terms of the fundamental fields **E** and **B** are often called **Maxwell Equations** in vacuum. Actually they are always valid, either in vacuum or in matter: they are just fundamental laws of physics: they are **the Maxwell equations**.

Finally, while the Electric|Magnetic field has a well-defined operational definition, from the Lorentz force, for instance, or from Coulomb|Biot-Savart laws.

36.02.01.01 EM Fields Versus Auxiliary Fields

While the electric field **E** has always been considered the fundamental field for electric phenomena, in contrast to **D**, the roles of **B** as the fundamental field for magnetic phenomena, has often been stolen by **H**.

Several facts support the idea of **B** begin the fundamental magnetic field, justifying naming it **the magnetic field**.

Read § 41.03.05.02.

36.02.02
Real and Ideal Point Charges

As far as we know today there exist elementary particles that we can consider as point particles, in the sense that we are not able to measure any radius greater than zero with today instruments and technology.

In practice every charge distribution can be considered, to a first approximation, as a point charge as long as all the distances involved are much larger than the size of the particle. This statement is made quantitative via the **Multipole** expansion (read § 36.14).

36.02.03
Real and Ideal Dipoles

As far as **Dipoles** are concerned the following names will be used:

- real or physical **Dipole** will refer to the realistic object made of:
  - two point charges of equal and opposite charge, that is: the dimensions of the two charges are much smaller than their distance;
  - a closed plane thin current loop, that is: the dimensions of the section of the current carrying wire are much smaller than the dimensions of the current loop;
- pure or ideal **Dipole** will refer to the mathematical point-like abstraction:
  - electric: limiting case when the absolute value of the charge tends to infinity and distance tends to zero so that their product stays constant;
  - magnetic: limiting case when the absolute value of the current tends to infinity and the area of the plane circuit tends to zero in such a way that their product stays constant.

On the Meaning of Field

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.15.4, 2.15.5||

© - QUOTE

.....

First we should say that the phrase **a real field** is not very meaningful. For one thing, you probably don't feel that the magnetic field is very real anyway, because even the whole idea of a field is a rather abstract thing. You cannot put out your hand and feel the magnetic field. Furthermore, the value of the magnetic field is not very definite; by choosing a suitable moving Coordinate System, for instance, you can make a magnetic field at a given point disappear.

What we mean here by a real field is this: a real field is a mathematical function we use for avoiding the idea of action at a distance. If we have a charged particle at the position P, it is affected by other charges located at some distance from P. One way to describe the interaction is to say that the other charges make some condition - whatever it may be - in the environment at P. If we know that condition, which we describe by giving the electric and magnetic fields, then we can determine completely the behavior of the particle - with no further reference to how those conditions came about.

In other words, if those other charges were altered in some way, but the conditions at P that are described by the Electric|Magnetic field at P remain the same, then the motion of the charge will also be the same. A real field is then a set of numbers we specify in such a way that what happens at a point depends only on the numbers at that point. We do not need to know any more about what's going on at other places.

36.03 Kinematics of Charge Motion

This § is referenced at pages:
[Never referenced.]

©|J.P.Pérez *et al.*, *Électromagnétisme*, ..., DUNOD, ...Ed., WEB - URL.|6.1|*Excellent and detailed introduction and ...*

Charges and currents give rise to ElectroMagnetic fields and are affected by ElectroMagnetic fields.

Let us consider point charges of mass m_k, charge q_k and velocity $\mathbf{v}_k$ and describe the situation from a fixed Reference Frame.

36.03.01 Charge Densities

36.03.01.01 Volume Charge Density

Consider electric charges with a three-dimensional distribution.

The macroscopic volume charge density at $\mathbf{x}$, a point in the volume of interest, is defined by considering a macroscopically small but microscopically large volume around $\mathbf{x}$, having volume $\widetilde{\Delta V}$, as:

$$\rho \equiv \lim_{\widetilde{\Delta V}\to 0} \frac{1}{\widetilde{\Delta V}} \sum_{\text{charges in } \widetilde{\Delta V}} q \quad . \tag{36.03.01}$$

If the charges can be grouped in different subsets with the same charge, q_α, and number volume density, n_α, one can write:

$$\rho_\alpha = n_\alpha q_\alpha \qquad \rho = \sum_\alpha \rho_\alpha \quad . \tag{36.03.02}$$

Note that n_α in the relation above is a number of charges per unit volume.

36.03.01.02 Surface Charge Density

Consider electric charges with a bi-dimensional distribution, distributed on a regular surface. Read § 36.03.02.02 for a more detailed prescription of the meaning of surface density.

The macroscopic surface charge density at $\mathbf{x}$, a point on the surface, is defined by considering a macroscopically small but microscopically large surface around $\mathbf{x}$, having area $\widetilde{\Delta S}$, as:

$$\rho_{\mathrm{S}} \equiv \lim_{\widetilde{\Delta S}\to 0} \frac{1}{\widetilde{\Delta S}} \sum_{\text{charges in } \widetilde{\Delta S}} q \quad . \tag{36.03.03}$$

If the charges can be grouped in different subsets with the same charge, q_α, and number surface density, n_α, one can write:

$$\rho_{\mathrm{S}\alpha} = n_\alpha q_\alpha \qquad \rho_{\mathrm{S}} = \sum_\alpha \rho_{\mathrm{S}\alpha} \quad . \tag{36.03.04}$$

Note that n_α in the relation above is a number of charges per unit surface.

DRAFT - IN PROGRESS

36.03.01.03 Line Charge Density

Consider electric charges with a one-dimensional distribution, distributed on a regular curve. Read § 36.03.02.03 for a more detailed prescription of the meaning of line density.

The macroscopic surface charge density at $\mathbf{x}$, a point on the curve, is defined by considering a macroscopically small but microscopically large segment around $\mathbf{x}$, having length $\widetilde{\Delta L}$, as:

$$\rho_{\mathrm{L}} \equiv \lim_{\widetilde{\Delta L}\to 0} \frac{1}{\widetilde{\Delta L}} \sum_{\text{charges in } \widetilde{\Delta L}} q \quad . \tag{36.03.05}$$

If the charges can be grouped in different subsets with the same charge, q_α, and number line density, n_α, one can write:

$$\rho_{\mathrm{L}\alpha} = n_\alpha q_\alpha \qquad \rho_{\mathrm{L}} = \sum_\alpha \rho_{\mathrm{L}\alpha} \quad . \tag{36.03.06}$$

Note that n_α in the relation above is a number of charges per unit length.

36.03.01.04 Relationship Among the Different Charge Densities

Whenever applicable the following obvious relations apply, relating the different charge densities, whenever a volume can be approximated by either a surface or a line:

$$\mathrm{d}q \sim \rho_{\mathrm{L}}\, \mathrm{d}L \sim \rho_{\mathrm{S}}\, \mathrm{d}S \sim \rho\, \mathrm{d}V \quad .$$

The infinitesimal integration element is always, volume, surface or line.

36.03.02 Current Densities

©|J.P.Pérez *et al.*, *Électromagnétisme*, ..., DUNOD, ...Ed., WEB - URL.|6.3.3||

36.03.02.01 Volume Current Density

This § is referenced at pages:
[Never referenced.]

Consider a three-dimensional motion of charges. Consider, for simplicity, the motion of all identical charges, with charge q, moving with velocity $\mathbf{v}$. Consider an infinitesimal plane area, $\mathrm{d}\mathbf{S}$, with normal unit vector $\widehat{\mathbf{n}}$; let θ be the angle between $\widehat{\mathbf{n}}$ and $\mathbf{v}$; let $\mathrm{d}N/\mathrm{d}V$ the number of charges per unit volume. Calculate the charge passing across it in the time Δt:

$$\mathrm{d}I = q\left(\frac{\mathrm{d}N}{\mathrm{d}V}\right)\frac{(v\cos[\theta]\ \mathrm{d}S\Delta t)}{\Delta t} = \rho v\, \mathrm{d}S\cos[\theta] \implies \boxed{\mathrm{d}I = \rho v\cos[\theta]\ \mathrm{d}S \equiv (\mathbf{j}\cdot\widehat{\mathbf{n}})\ \mathrm{d}S \implies \mathbf{j} \equiv \rho\mathbf{v}} \quad . \tag{36.03.07}$$

→ 1702

Therefore the current is the flux of $\mathbf{j}$ across the surface:

$$I \equiv \iint_\Sigma (\mathbf{j}\cdot\widehat{\mathbf{n}})\ \mathrm{d}S \quad . \tag{36.03.08}$$

→ 1089

Unit of measure of $\mathbf{j}$: $\mathrm{A/m^2}$.

DRAFT-IN-PROGRESS

36.03.02.02 Surface Current Density

This § is referenced at pages:
[1100, 1695]

Consider a two-dimensional motion of charges, that is a motion on a surface of maximum thickness h. The concept of surface current is useful any time one studies the effects of the current at a distance, r, very much larger than the sheet maximum thickness: $r \gg h$.

Consider, for simplicity, the motion of all identical charges, with charge q, moving with velocity $\mathbf{v}$ constrained to move on a regular surface. Any regular surface can be locally approximated by its tangent plane at any point. Therefore one can consider a plane motion.

Let $\widehat{\mathbf{n}}$ be the normal unit vector of the surface. Consider a line on the surface and a small line segment, $\mathrm{d}\mathbf{L}$, of the line. Let $\widehat{\mathbf{N}}$ be the unit vector on the surface perpendicular to $\mathrm{d}\mathbf{L}$:

$$\widehat{\mathbf{N}} \equiv \frac{\mathrm{d}\mathbf{L}\wedge\widehat{\mathbf{n}}}{\mathrm{d}L} \quad \Leftrightarrow \quad \left(\widehat{\mathbf{n}}\wedge\widehat{\mathbf{N}}\right)\,\mathrm{d}L = \mathrm{d}\mathbf{L} \quad .$$

Note that, as $\widehat{\mathbf{n}}$ is the normal unit vector of the surface, $\widehat{\mathbf{N}}$ is tangent to the surface, whatever $\mathrm{d}\mathbf{L}$ is.

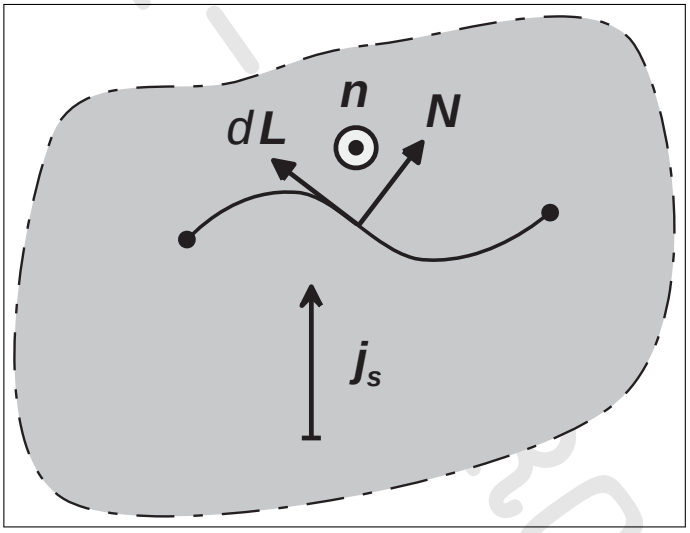

Figure 36.11: Surface current density kinematics

Let θ be the angle between $\widehat{\mathbf{N}}$ and $\mathbf{v}$; let $\mathrm{d}N/\mathrm{d}S$ the number of charges per unit area.

Calculate the current passing across the line in the time Δt:

$$\mathrm{d}I = q\left(\frac{\mathrm{d}N}{\mathrm{d}S}\right)\frac{(v\cos[\theta]\;\mathrm{d}L\Delta t)}{\Delta t} = \rho_{\mathrm{S}} v\;\mathrm{d}L\cos[\theta] \implies \boxed{\mathrm{d}I = \rho_{\mathrm{S}} v\cos[\theta]\;\mathrm{d}L \equiv \left(\mathbf{j}_{\mathrm{S}}\cdot\widehat{\mathbf{N}}\right)\,\mathrm{d}L \implies \mathbf{j}_{\mathrm{S}} \equiv \rho_{\mathrm{S}}\mathbf{v}} \quad .$$

(36.03.09) → 1703

It is understood that the velocity of the surface charges, $\mathbf{v}$, is such that the surface charges stay on the surface, that is $\mathbf{v}$ is tangent to the surface.

Therefore the current is the circulation of $\widehat{\mathbf{n}}\wedge\mathbf{j}_{\mathrm{S}}$ along the line:

$$\boxed{I \equiv \int_C \left(\mathbf{j}_{\mathrm{S}}\cdot\widehat{\mathbf{N}}\right)\,\mathrm{d}L = \int_C (\widehat{\mathbf{n}}\wedge\mathbf{j}_{\mathrm{S}})\cdot\,\mathrm{d}\mathbf{L}} \quad . \qquad \text{(36.03.10)} \quad \rightarrow 1090$$

Unit of measure of $\mathbf{j}_{\mathrm{S}}$: $\mathrm{A/m}$.

PREPRINT PROOFPRESS

36.03.02.03 Line Current Density

This § is referenced at pages:
[1696]

This is the common elementary definition of current, as flow of charges on a thin line.

Consider a tube of flux of a current of maximum section diameter d. The concept is useful any time one studies the effects of the current at a distance, r, very much larger than the wire maximum section diameter: $r \gg d$. If the tube is a thin one (section diameter d very much smaller than its length) it is possible to describe the current as a flow of charges along a line.

Consider, for simplicity, the motion of all identical charges, with charge q, moving with velocity $\mathbf{v}$ constrained to move on a regular curve. Any regular curve can be locally approximated by its tangent unit vector at any point. Therefore one can consider a rectilinear motion. Let $\mathbb{d}\mathbf{L}$ be the infinitesimal element of the curve.

One has:

$$\boxed{I = q\left(\frac{\mathbb{d}N}{\mathbb{d}L}\right)\frac{v\Delta t}{\Delta t} = \rho_{\mathrm{L}} v} \quad . \tag{36.03.11}$$

→ 1703

Note that the above definition can be given a vector character, even this is not usually done, as the direction of motion is dictated by the curve, as:

$$\boxed{\mathbf{I} = \rho_{\mathrm{L}}\mathbf{v} \equiv \mathbf{j}_{\mathrm{L}}} \quad .$$

Therefore, in complete analogy with the case of surface and volume densities, one might equivalently write:

$$\boxed{\mathbf{I}\,\mathbb{d}L \Leftrightarrow I\,\mathbb{d}\mathbf{L}} \quad .$$

It is understood that the velocity of the line charges, $\mathbf{v}$, is such that the line charges stay on the curve, that is $\mathbf{v}$ is tangent to the curve.

36.03.02.04 Relationship Among the Different Current Densities

Whenever applicable the following obvious relations apply, relating the different current densities, whenever a volume can be approximated by either a surface or a line:

$$\boxed{\mathbf{I}\,\mathbb{d}L \equiv I\,\mathbb{d}\mathbf{L} \equiv \mathbf{j}_{\mathrm{L}}\,\mathbb{d}L \sim \mathbf{j}_{\mathrm{S}}\,\mathbb{d}S \sim \mathbf{j}\,\mathbb{d}V} \quad .$$

The infinitesimal integration element is always: volume, surface or line.

Beware the nomenclature:

- volume current density describes a current in three-dimensions, that is a volume current, but is it is fact a current per unit area;
- surface current density describes a current in two-dimensions, that is a surface current, but is it is fact a current per unit length.

Is Current a Vector?

So many people have written to me complaining about my treatment of current as a vector that I have decided to write out my explanation once and for all. Some of what follows may not be relevant to your personal concern, but I hope I have addressed the most common objections. Let me say at the outset that if it bothers you to think of current as a vector, by all means stick with the scalar notation! This is purely a matter of convenience, and most people think it is simpler to do it that way. But for consistency with more advanced work it is (in my opinion) preferable to switch over at some stage to the more general notation.

Let me begin with an analogy: A locomotive on a curving track. Suppose I want to tell someone how fast it is going. Should I specify its *velocity* (magnitude and direction), or just its *speed* (the magnitude)? Obviously it would be simplest to quote the *speed*—after all, the direction of the motion is dictated by the shape of the track, and it seems awkward and unnecessary to say "60 mph due east," and a moment later "60 mph at 37° west of north," and so on—why not just say the train is going 60 mph? In this context it is simpler to use the scalar quantity. But if you are a physics teacher, you know that in the next chapter you will be discussing projectile motion (say), in which the object in question moves in two dimensions, and its direction is *not* constrained by the shape of any track. In this context you might prefer to talk about the *velocity*. Is the rate of change of position a scalar, or a vector? I guess it depends on the context which is the more natural terminology.

In the case of current exactly the same issue arises: If you are talking about current constrained to flow along a wire (the analog to the track), then no doubt it is simpler to treat it as a scalar quantity. But when it comes to surface currents (charge flowing over a 2-dimensional surface) or volume currents (charge flowing through 3-dimensional space), then you *have* to keep track of the directions, and so we adopt the vector notation ($\mathbf{K}$ and $\mathbf{J}$, respectively). Looking back, one asks how come we didn't use a vector for the 1-dimensional case ($\mathbf{I}$). Perhaps, for consistency, we *should* have!

It is a peculiar fact that in almost all formulas (Biot-Savart, Lorentz, etc.) current appears multiplied by an element of displacement along the wire: $I\,d\mathbf{l}$. Because the current (I) and the displacement ($d\mathbf{l}$) are in the same direction, it doesn't matter whether you associate the vector sign with the one or the other—in elementary work everyone attaches it to $d\mathbf{l}$, keeping I a scalar. But again, when you come to surface and volume currents, where the analogous expression is $\mathbf{K}\,da$ and $\mathbf{J}\,d\tau$, you have no choice: here the direction is that of the current ($d\tau$ doesn't even *have* a direction). So if you write $\mathbf{I}\,dl$ for the one-dimensional current, everything is consistent, even though in that case you can do it either way.

Here's another consideration: If you have charges of one sign, with charge density ρ, flowing with velocity $\mathbf{v}$ (in 3-dimensions), this constitutes a volume current density

$$\mathbf{J} = \rho\mathbf{v}.$$

If you have a surface charge σ flowing over a surface with velocity $\mathbf{v}$, the surface current is

$$\mathbf{K} = \sigma\mathbf{v}.$$

What about a line charge λ, flowing down a wire at velocity $\mathbf{v}$? I would like to write the analogous expression

$$\mathbf{I} = \lambda\mathbf{v}.$$

But if you forbid me to treat current as a vector I have to adopt a different notation for the one-dimensional case. Doesn't that seem awkward?

OK: I have told you why I prefer (in appropriate cases) to represent current as a vector. Let me now address the standard objections to this:

- **In high school I was told that current is a scalar.** Sure—so was I. And that is entirely appropriate at that level, where surface and volume currents do not occur. It's not *wrong*, exactly, just limiting. At the college level it is time to liberate yourself from the more constraining notation.

- **Charge is a scalar, and time is a scalar, so $I = dq/dt$ must be a scalar.** To put it another way, the current in a wire is the amount of charge per unit time passing a particular point—there is no reference here to direction. Well, actually there *is*: if positive charge is passing to the right we say the current is positive (say), and if it is going to the left we say the current is negative. Of course, in a wire those are the only two possibilities, so a simple sign suffices to keep track of it. But in general we are talking about charge per unit time flowing in a particular direction—it's just that the direction (up to a sign) is dictated by the shape of the wire. Again, one could run the same argument with the locomotive on the track: distance (traveled) is a scalar, and time is a scalar, so velocity must be a scalar(?)! No: it is not distance we meant, but distance *in a particular direction*, which is to say *displacement*.

- **Currents do not add vectorially.** This is the most subtle objection, because it misconstrues the meaning of vector addition. Kirchhoff's law says that the sum of the currents *into* a junction is zero (counting currents flowing *out* as negative). They do *not* add vectorially—it doesn't matter what direction the wires meet at. Correct, but this is a *law of physics*, not a mathematical case of addition of vectors/scalars. If I say the sum of the momenta of some colliding particles is the same after the collision as before, that is (again) a *law of physics*, not a question of vector addition (though in this case the law says you should add them vectorially). Kirchhoff's law has nothing to do with the vectorial nature of current, since it refers to the *magnitudes*. The number of locomotives entering a junction is equal to the number leaving (in any given time interval)—scalar addition—but this tells me noting about the vectorial nature of velocity, only about the law of conservation of locomotives.

  In point of fact, currents *do* add vectorially. Here's an example. Suppose I have a fat pipe, and inside that pipe there are some wires, each carrying

a current. The wires do not run parallel to the axis of the pipe, but make various angles. When they reach the edge of the pipe, they bend back so as to make the same angle (like light rays reflecting off the surface of a light pipe). If you ask "What is the total current flowing down the pipe?" you would of course have to take into account the direction of each wire. If it happens to run parallel to the pipe, it counts at full value, but if it's going at 45° you'll need to throw in a factor of $1/\sqrt{2}$ (and if it is perpendicular to the pipe it contributes nothing). In other words, you must add the currents *vectorially*—the total current is the *vector* sum of the individual currents.

I hope this helps. But again: if you prefer to think of current as a scalar, that's fine. It won't hurt you; it just isn't very elegant.

David Griffiths

DRAFT IN PROGRESS

36.03.03
Volume Surface and Line Charge|Current Densities

If a surface Charge|Current lies/flows in a thin layer of thickness h, with thickness very much smaller than the linear dimensions of the surface and any other significant dimension, one can write:

$$\boxed{\rho_S \sim h\rho \qquad \mathbf{j}_S \sim h\mathbf{j}} \quad . \tag{36.03.12}$$

→ 1793

The concept of surface Charge|Current is useful any time one studies the effects of the current at a distance, r, very much larger than the layer thickness, $r \gg h$, and any other significant dimension.

If a line Charge|Current lies/flows in a thin wire of cross-sectional area a, with transverse dimension ($\sim \sqrt{a}$) very much smaller than the dimensions of the wire and any other significant dimension, one can write:

$$\boxed{\rho_L \sim a\rho \qquad \mathbf{j}_L \sim a\mathbf{j}} \quad . \tag{36.03.13}$$

→ 1793

The concept of line Charge|Current is useful any time one studies the effects of the current at a distance, r, very much larger than the wire transverse dimension ($\sim \sqrt{a}$), $r \gg\sim \sqrt{a}$, and any other significant dimension.

36.03.04
Current Densities as Charge Transport

In the same way as mass transport is defined by the linear momentum, $\mathbf{p} = m\mathbf{v}$, charge transport can be described by introducing the charge transport quantity $q\mathbf{v}$.

36.03.04.01 Volume Current Density

This § is referenced at pages:
[1103]

One can define the volume density of the charge transport quantity $q\mathbf{v}$, that is the volume current (see (36.03.07)):

$$\mathbf{j} \equiv \lim_{\widetilde{\Delta V}\to 0} \frac{1}{\widetilde{\Delta V}} \sum_{\text{charges in } \widetilde{\Delta V}} q\mathbf{v} \quad .$$

If the charges can be grouped in different subsets with the same charge, $q[i]$, and number volume density, $n[i]$, one can first define the average mean velocity (drift velocity) of each kind of charges, $\mathbf{v}[i]$, and then write:

$$\boxed{\mathbf{j}[i] = n[i]q[i]\mathbf{v}[i] \equiv \rho[i]\mathbf{v}[i] \qquad \mathbf{j} = \sum[i]\mathbf{j}[i]} \quad . \tag{36.03.14}$$

CC BY NC ND

36.03.04.02 Surface Current Density

One can define the surface density of the charge transport quantity $q\mathbf{v}$, that is the surface current (see (36.03.09)):

$$\boxed{\mathbf{j}_{\mathtt{S}} \equiv \lim_{\widetilde{\Delta S}\to 0} \frac{1}{\widetilde{\Delta S}} \sum_{\text{charges in } \widetilde{\Delta \mathtt{S}}} q\mathbf{v}} \quad .$$

If the charges can be grouped in different subsets with the same charge, $q[i]$, and number surface density, $n[i]$, one can first define the average mean velocity (drift velocity) of each kind of charges, $\mathbf{v}[i]$, and then write:

$$\boxed{\mathbf{j}_{\mathtt{S}}[i] = n[i]q[i]\mathbf{v}[i] \equiv \rho_{\mathtt{S}}[i]\mathbf{v}[i] \qquad \mathbf{j}_{\mathtt{S}} = \sum[i]\mathbf{j}_{\mathtt{S}}[i]} \quad . \tag{36.03.15}$$

36.03.04.03 Line Current Density

This is the common elementary definition of current, as flow of charges on a thin line.

One can define the line density of the charge transport quantity $q\mathbf{v}$, that is the line current (see (36.03.11)):

$$\boxed{\mathbf{j}_{\mathtt{L}} \equiv \lim_{\widetilde{\Delta L}\to 0} \frac{1}{\widetilde{\Delta L}} \sum_{\text{charges in } \widetilde{\Delta \mathtt{L}}} q\mathbf{v}} \quad .$$

If the charges can be grouped in different subsets with the same charge, $q[i]$, and number surface density, $n[i]$, one can first define the average mean velocity (drift velocity) of each kind of charges, $\mathbf{v}[i]$, and then write:

$$\boxed{\mathbf{j}_{\mathtt{L}}[i] = n[i]q[i]\mathbf{v}[i] \equiv \rho_{\mathtt{L}}[i]\mathbf{v}[i] \qquad \mathbf{j}_{\mathtt{L}} = \sum[i]\mathbf{j}_{\mathtt{L}}[i]} \quad . \tag{36.03.16}$$

36.03.05
Some Comments About Charge and Current Densities

Note that a globally neutral medium, that is a medium with zero charge density, might be possibly obtained with two big charge densities of equal magnitude and opposite sign.

Note that while all the charges contribute to the charge densities, only the charges with non-zero velocity contribute to the current densities.

Also note that the condition $\mathbf{v}[i] = \mathbf{0}$ for a certain species of charges does not imply that all charges of that species have zero velocity, but it only implies that the velocity distribution has zero average value.

In a thermodynamics/statistical approach one can show that at equilibrium the velocity distribution is isotropic and therefore all partial currents vanish.

On the other hand the total current might be null while the different partial currents are not. In this case compensation among different partial currents occur. This is the case, for instance, when a neutral conductor translates with constant velocity: the total current is zero thanks to the cancellation of the currents due to each subset of charges.

Conducting media are often composed of fixed charges plus mobile charges, such that the total density is

$$\boxed{\rho = \rho_{\mathtt{F}} + \rho_{\mathtt{M}} \qquad \rho_{\mathtt{S}} = \rho_{\mathtt{SF}} + \rho_{\mathtt{SM}}}$$

Note that while **Maxwell Equations** refer to the total charge density, ρ, the equations which describe the charge movement only refer to the mobile charge density, $\rho_{\mathtt{M}}$. Inside neutral conducting media, either $\rho = 0$ or $\rho_{\mathtt{S}} = 0$, the density of mobile charges is often compensated by the density of fixed charges: either $\rho_{\mathtt{M}} = -\rho_{\mathtt{F}}$ or $\rho_{\mathtt{SM}} = -\rho_{\mathtt{SF}}$.

In case the material medium is moving the convection currents have to be included as well.

DRAFT-IN-PROGRESS

36.04 Superposition Principle

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|||

Maxwell Equations in vacuum are linear in the Electric|Magnetic fields: the total field is the linear superposition of the fields produced by all the sources, charges and currents.

The principle of superposition is not obvious at all: if the ElectroMagnetic fields were proportional, for instance, to the square of the total charge (electric field), or to the square of the total current (magnetic field), then the principle of superposition would not hold at all.

The **superposition principle** is not a necessity, it is an experimental fact.

36.05.01.01 Force on Point Charges

In any Inertial Reference Frame , the force acting on an **electrically charged point test particle**, the **test charge** , characterized by an electric charge q and moving with velocity $\mathbf{v}$, is the Lorentz force:

$$\boxed{\mathbf{f} = q\,(\mathbf{E} + \mathbf{v}\wedge\mathbf{B})} \quad , \tag{36.05.01}$$

→ 1335

which actually defines $\mathbf{E}$ and $\mathbf{B}$, the external ElectroMagnetic fields, produced by anything else except the point charge itself.

Physically, **test charge** means that one can neglect the back-action of the test charge on the system of charges|currents that generates the external EM field.

For instance: put a small charge at the point at rest and measure the force to determine $\mathbf{E}$; send a small charge to pass a the point with a known velocity and several directions until the direction such that no force acts on the charge is found, to determine the direction of $\mathbf{B}$ and after do it in a different direction measuring the force to determine the module of $\mathbf{B}$.

36.05.01.02 Torque on Point Charges

It is obviously zero, because it is a spinless particle.

36.05.02 Force|Torque on Point Dipoles

This § is referenced at pages:
[1711, 1947]

36.05.02.01 Force on Point Dipoles

This § is referenced at pages:
[1710, 1711]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|§ 10, § 11||

In case the external ElectroMagnetic fields are homogeneous the total force is zero.

In case the external ElectroMagnetic fields are not homogeneous a force also acts on the **Dipoles** . This is derived in section § 41.05.01.01 and § 41.05.02.01, and results in equations (41.05.01), (41.05.06). The force, in static conditions, when no other charge|current is present at the location of the ideal dipole, is as follows.

UNDER PEER REVIEW

Electric Dipole :

$$\mathbf{f}_e = (\mathbf{p}\cdot\boldsymbol{\nabla})\,\mathbf{E} \qquad \Longrightarrow \; \mathbf{f}_e\Big|_k = p_s^{\cdot}\partial_s^{\cdot}E_k^{\cdot} \quad . \tag{36.05.02}$$

→ 1707 1761 1763 1793

Magnetic Dipole :

$$\mathbf{f}_m = (\mathbf{m}\wedge\boldsymbol{\nabla})\wedge\mathbf{B} \qquad \Longrightarrow \; \mathbf{f}_m\Big|_k = \epsilon_{kpq}^{\cdot\cdot\cdot}\epsilon_{prs}^{\cdot\cdot\cdot}m_r^{\cdot}\partial_s^{\cdot}B_q^{\cdot} \quad . \tag{36.05.03}$$

→ 1707 1793

These expressions can be transformed in many ways, with some additional hypotheses.

In the electric case, in case of irrotational external electric fields and assuming fixed values (rigid dipole) of the **Electric Dipole** moment with respect to the nabla (partial derivative with respect to position) the expression in (36.05.02) is equivalent to:

$$\mathbf{f}_e = \boldsymbol{\nabla}\,(\mathbf{p}\cdot\mathbf{E}) \quad . \tag{36.05.04}$$

→ 1707 1761

Moreover, in the case the external electric fields are also divergence-less and assuming fixed values (rigid dipole) of the **Electric Dipole** moment with respect to the nabla (partial derivative with respect to position) expression (36.05.04) is equivalent to:

$$\mathbf{f}_e = (\mathbf{p}\wedge\boldsymbol{\nabla})\wedge\mathbf{E} \quad . \tag{36.05.05}$$

In the magnetic case, in case of divergence-less external magnetic fields (which is always the case) and assuming fixed values (rigid dipole) of the **Magnetic Dipole** moment with respect to the nabla (partial derivative with respect to position) the expression in (36.05.03) is equivalent to:

$$\mathbf{f}_m = \boldsymbol{\nabla}\,(\mathbf{m}\cdot\mathbf{B}) \quad . \tag{36.05.06}$$

→ 1707 1761

Moreover, in the case the external magnetic fields are also irrotational and assuming fixed values (rigid dipole) of the **Magnetic Dipole** moment with respect to the nabla (partial derivative with respect to position) expression (36.05.06) is equivalent to:

$$\mathbf{f}_m = (\mathbf{m}\cdot\boldsymbol{\nabla})\,\mathbf{B} \quad . \tag{36.05.07}$$

→ 1761 1785

A very common case when all the above formulas are equivalent (a sufficient condition, not a necessary one) is the case when the Charge|Current producing the external fields are outside the region of interest where the **Dipoles** are located, the dipole have fixed values (rigid dipoles) and the situation is a static one.

In all cases when the **Dipole** moment appears inside a nabla in the above expressions, it must be considered as a fixed **Dipole** moment, independent of the position and external fields, even in the case that it depends on the external (applied) field (Polarization|Magnetization) in order for the formulas to be valid.

Read § 41.05.01.01 and § 41.05.02.01.

See also § 41.05.01.02 and § 41.05.02.02.

It is worth recalling a few important facts. In the bare derivation of the force on a dipole, in both the Electric|Magnetic cases, when one moves the $\mathbf{p}|\mathbf{m}$ inside the nabla, it is done assuming $\mathbf{p}|\mathbf{m}$ do not depend on the coordinates.

In fact, the original expression for the force has in any case the $\mathbf{p}|\mathbf{m}$ outside the nabla,

$$\mathbf{p}\cdot\boldsymbol{\nabla} \qquad \mathbf{m}\wedge\boldsymbol{\nabla} \quad , \tag{36.05.08}$$

as the nabla comes from the Taylor series development of the external (applied) field. After that, you can move $\mathbf{p}|\mathbf{m}$ inside nabla, under the condition that it is fixed.

© - QUOTE

D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ... at page 165.
... However, it is safer to stick with the dipole outside the nabla, because we will be applying the formula to materials in which the **Dipole** moment (per unit volume) is itself a function of position and the expression with the dipole inside the nabla would imply (incorrectly) that $\mathbf{p}|\mathbf{m}$ too is to be differentiated. ...

36.05.02.02 Torque on Point Dipoles

This § is referenced at pages:
[1062, 1710, 1711]

In any Inertial Reference Frame a point particle with either **Electric Dipole** moment, $\mathbf{p}$, or **Magnetic Dipole** moment, $\mathbf{m}$, when placed in external ElectroMagnetic fields, $\mathbf{E}$ and $\mathbf{B}$, produced by anything else except the point **Dipoles** themselves, is given a pole-independent torque given by:

$$\boxed{\tilde{\gamma}_{\mathtt{e}}[\mathbf{r}] = \mathbf{p}\wedge\mathbf{E}[\mathbf{r}] \qquad \tilde{\gamma}_{\mathtt{m}}[\mathbf{r}] = \mathbf{m}\wedge\mathbf{B}[\mathbf{r}]} \quad , \tag{36.05.09}$$

The torque acting on a **Dipole** located at $\mathbf{r}$ with respect to any other pole, located at $\mathbf{r}_{\mathtt{P}}$, is obtained by adding to the term $\tilde{\gamma}_{\mathtt{e}}$ and|or $\tilde{\gamma}_{\mathtt{m}}$, the pole-independent torque, the term,

$$\boxed{(\mathbf{r}-\mathbf{r}_{\mathtt{P}})\wedge\mathbf{f}[\mathbf{r}]} \quad , \tag{36.05.10}$$

following the usual law of transformation of the moment when the pole changes:

$$\boxed{\gamma_{\mathtt{P}}[\mathbf{r}] = \tilde{\gamma} + (\mathbf{r}-\mathbf{r}_{\mathtt{P}})\wedge\mathbf{f}[\mathbf{r}]} \quad . \tag{36.05.11}$$

36.05.03 Some Comments on Modeling of Charge|Current Distributions

This § is referenced at pages:
[1922, 1926, 1928, 1930, 2235, 2492]

It might be useful to stress that one might consider point charged particles only, to model the basic components of matter, avoiding to introduce explicitly **Dipoles** and|or higher-order **Multipoles**, from the mathematical point of modeling. In fact any Charge|Current **Multipole** can be always described by a suitable combination of point charges and|or currents of point charges, possibly after a limiting mathematical process. Therefore, in principle, one does not need to introduce explicitly the expressions for **Dipoles** and|or higher-order **Multipoles**.

However, the explicit use of **Dipoles** and|or higher-order **Multipoles** is often a useful shortcut, allowing a much simpler description.

More importantly, today we know elementary (that is point) particles with an intrinsic multipole; at least, the electron, with its magnetic dipole.

Also note that when one considers a generic continuous distribution of Charge|Current, for calculations of integrated properties, such as Force|Torque, one can always model the Charge|Current density of point charges and|or currents of point charges with delta distributions and delta derivatives.

Therefore, modeling the system as a continuous distribution of Charge|Current, is capable to fully describe any **Multipole** distribution.

This § is referenced at pages:
[1062, 1336, 1336]

DRAFT - IN PROGRESS

36.05.05
Forces and Torque on Continuous Distributions

The infinitesimal Lorentz Force|Torque acting on a generic infinitesimal element with Charge|Current density ρ / $\mathbf{j}$ and infinitesimal **Electric Dipole** | **Magnetic Dipole** moment $\mathbb{d}\mathbf{p}$ / $\mathbb{d}\mathbf{m}$, can be written as:

$$\boxed{\mathbb{d}\mathbf{f} = (\rho\mathbf{E} + \mathbf{j}\wedge\mathbf{B})\ \mathbb{d}V + (\ \mathbb{d}\mathbf{p}\cdot\boldsymbol{\nabla})\,\mathbf{E} + (\ \mathbb{d}\mathbf{m}\wedge\boldsymbol{\nabla})\wedge\mathbf{B}} \quad ,$$

$$\boxed{\mathbb{d}\boldsymbol{\gamma}_0 = (\mathbf{r} - \mathbf{r}_0)\wedge\mathbb{d}\mathbf{f} + \ \mathbb{d}\mathbf{p}\wedge\mathbf{E} + \ \mathbb{d}\mathbf{m}\wedge\mathbf{B}} \quad .$$

Note that in this case the Electric|Magnetic field to be used in the above formulas does not need subtraction of the Electric|Magnetic field produced by the infinitesimal element which is subject to the Force|Torque. In fact the infinitesimal element produces an infinitesimal field.

In fact the Electric|Magnetic field produced by the infinitesimal element is proportional to $\mathbb{d}V$ and its contribution goes like the square of the distance, which is internal to the infinitesimal volume element; therefore its contribution goes to zero.

Formally, from Coulomb and Biot-Savart laws, one has:

$$\boxed{\mathbb{d}\mathbf{E}[\ \mathbb{d}q;\widehat{\mathbf{e}}_r] \propto \frac{\mathbb{d}q}{r^2}\widehat{\mathbf{e}}_r = \frac{\rho\ \mathbb{d}V}{r^2}\widehat{\mathbf{e}}_r \xrightarrow[\mathbb{d}V\to 0]{} 0} \qquad \boxed{\mathbb{d}\mathbf{B}[i\ \mathbb{d}\mathbf{L};\widehat{\mathbf{e}}_r] \propto \frac{i}{r^2}\ \mathbb{d}\mathbf{L}\wedge\widehat{\mathbf{e}}_r = \frac{\mathbb{d}V}{r^2}\mathbf{j}\wedge\widehat{\mathbf{e}}_r \xrightarrow[\mathbb{d}V\to 0]{} 0} \quad .$$

36.05.06
Forces and Torques on Real Fixed Electric Dipoles

Read § 41.05.01, § 41.05.01.01, § 41.05.01.02. Read also § 41.02.02.

Consider a static real **Electric Dipole** , a pair of charges $\pm|q|$ separated by $\Delta\mathbf{r}$; afterwards take the limiting case of an ideal **Electric Dipole** : $|\Delta\mathbf{r}| \equiv |\mathbf{r}_+ - \mathbf{r}_-| \to 0$ with $|q||\Delta\mathbf{r}| =$ constant.

It can be shown that the results are those of section § 36.05.01.

36.05.06.01 Total Force

This § is referenced at pages:
[1086]

Uniform and Constant External Field

In a uniform and constant external field the total force is clearly zero.

Generic External Field

In a generic external field, assume a positive charge at $\mathbf{r}_+$ and a negative charge at $\mathbf{r}_-$: the force is

$$\begin{aligned}\mathbf{F}[\mathbf{r}] &= |q|\,(-\mathbf{E}[\mathbf{r}_-] + \mathbf{E}[\mathbf{r}_+]) \quad ,\\ &= |q|\,(-\mathbf{E}[\mathbf{r}_-] + \mathbf{E}[\mathbf{r}_- + \Delta\mathbf{r}]) \quad ,\\ &\simeq |q|\,\Delta\mathbf{r}\cdot\boldsymbol{\nabla}\mathbf{E}[\mathbf{r}_-] \quad ,\\ \mathbf{F}[\mathbf{r}] &\longrightarrow \mathbf{p}\cdot\boldsymbol{\nabla}\mathbf{E}[\mathbf{r}] \quad .\end{aligned}$$

Read § 36.05.02.01, § 36.05.02.02.

36.05.06.02 Total Torque

This § is referenced at pages:
[1086]

Let a positive charge $+|q|$ at $\mathbf{r}_+$ and a negative charge $-|q|$ at $\mathbf{r}_-$. The total torque with respect to the origin of the Coordinate System is calculated as follows.

First method (full and direct calculation):

$$\begin{aligned}\boldsymbol{\Gamma}[\mathbf{r}] &= |q|\,(-\mathbf{r}_-\wedge\mathbf{E}[\mathbf{r}_-] + \mathbf{r}_+\wedge\mathbf{E}[\mathbf{r}_+]) \quad ,\\ &= |q|\,(-\mathbf{r}_-\wedge\mathbf{E}[\mathbf{r}_-] + (\mathbf{r}_- + \Delta\mathbf{r})\wedge\mathbf{E}[\mathbf{r}_- + \Delta\mathbf{r}]) \quad ,\\ &\simeq |q|\,(-\mathbf{r}_-\wedge\mathbf{E}[\mathbf{r}_-] + (\mathbf{r}_- + \Delta\mathbf{r})\wedge(\mathbf{E}[\mathbf{r}_-] + \Delta\mathbf{r}\cdot\boldsymbol{\nabla}\mathbf{E}[\mathbf{r}_-])) \quad ,\\ \boldsymbol{\Gamma}[\mathbf{r}] &\longrightarrow \mathbf{r}\wedge(\mathbf{p}\cdot\boldsymbol{\nabla}\mathbf{E}[\mathbf{r}]) + \mathbf{p}\wedge\mathbf{E}[\mathbf{r}] \quad .\end{aligned}$$

Second method (exploiting the results on the force):

$$\begin{aligned}\boldsymbol{\Gamma}[\mathbf{r}] &= \mathbf{r}_-\wedge\mathbf{F}_- + \mathbf{r}_+\wedge\mathbf{F}_+ \quad ,\\ &= \mathbf{r}_-\wedge\mathbf{F}_- + (\mathbf{r}_- + \Delta\mathbf{r})\wedge\mathbf{F}_+ \quad ,\\ &\simeq \mathbf{r}_-\wedge(\mathbf{F}_- + \mathbf{F}_+) + \Delta\mathbf{r}\wedge\mathbf{F}_+ \quad ,\\ \boldsymbol{\Gamma}[\mathbf{r}] &\longrightarrow \mathbf{r}\wedge\mathbf{F}[\mathbf{r}] + \mathbf{p}\wedge\mathbf{E}[\mathbf{r}] \quad .\end{aligned}$$

In the limiting point case the result is:

$$\boxed{\boldsymbol{\Gamma}[\mathbf{r}] = \mathbf{r}\wedge\mathbf{F}[\mathbf{r}] + \mathbf{p}\wedge\mathbf{E}[\mathbf{r}]} \quad .$$

36.05.07
Forces and Torques on Real Fixed Magnetic Dipoles

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|6.1.2||
©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|§ 11.- ...
©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|||
©|D.J.Griffiths|Dipoles at rest|*Am. J. Phys. 1 November 1992; 60 (11): 979-987.* WEB - URL|

Read § 41.05.02, § 41.05.02.01, § 41.05.02.02.
Read also § 41.02.02.
Consider a static real **Magnetic Dipole** , that is a plane close current loop carrying a steady current I and area $\Delta\mathbf{S}$; afterwards take the limiting case of an ideal **Magnetic Dipole** : $|\Delta\mathbf{S}| \to 0$ with $|I||\Delta\mathbf{S}| =$ constant.
The derivations for the magnetic case are technically more cumbersome: see the references. It can be shown that the results are those of section § 36.05.02.

36.05.07.01 Total Force

Uniform and Constant External Field

In a uniform and constant external field the total force is zero:

$$\mathbf{F} = I \oint \mathrm{d}\mathbf{L} \wedge \mathbf{B} = I \left(\oint \mathrm{d}\mathbf{L} \right) \wedge \mathbf{B} = 0 \quad .$$

Generic External Field

A special instructive case is presented in section § 36.20.61.
In a generic external field, see the references. The result is:

$$\boxed{\mathbf{F}[\mathbf{r}] = (\mathbf{m} \wedge \boldsymbol{\nabla}) \wedge \mathbf{B}[\mathbf{r}]} \quad .$$

Read § 36.05.02.01, § 36.05.02.02.

36.05.07.02 Total Torque

In a generic external field, see the references.
In the limiting point case the result is:

$$\boxed{\boldsymbol{\Gamma}[\mathbf{r}] = \mathbf{r} \wedge \mathbf{F}[\mathbf{r}] + \mathbf{m} \wedge \mathbf{B}[\mathbf{r}]} \quad .$$

A wire current in a uniform magnetic field provides:

$$\boldsymbol{\gamma} = I \oint \mathbf{r} \wedge (\ \mathrm{d}\mathbf{L} \wedge \mathbf{B}) = I \oint ((\mathbf{r} \cdot \mathbf{B})\ \mathrm{d}\mathbf{L} - (\mathbf{r} \cdot \mathrm{d}\mathbf{L})\ \mathbf{B}) = I \oiint (\ \mathrm{d}\mathbf{S} \wedge (\mathbf{grad}\, \mathbf{r} \cdot \mathbf{B})) - 0 \quad , \qquad (36.05.12)$$

where for the last passage come from equation (16.07.07) (left term, with constant $\mathbf{B}$) and (16.07.08) (right term).

DRAFT - IN PROGRESS

36.05.07.03 Summary formulas

36.06 Coulomb|Biot-Savart Laws - ElectroStatics/MagnetoStatics

©|J.P.Pérez *et al.*, *Électromagnétisme*, ..., DUNOD, ...Ed., WEB - URL.|||

©|D.Griffiths, M.Heald|Time-dependent generalizations of the Biot-Savart and Coulomb laws|*Am.J.Phys*, , ..., ..., ...*Ed.*, ...

Stationary charges produce electric fields that are constant in time: ElectroStatics.
Steady currents produce magnetic fields that are constant in time: MagnetoStatics.
Therefore, ElectroStatics/MagnetoStatics:

$$\partial_t \rho = 0 \qquad \partial_t \mathbf{j} = 0 \qquad \text{all places and all times} \quad .$$

The Electric|Magnetic field at $\mathbf{x}$ produced by Static|Steady Charge|Current can be deduced via the Coulomb|Biot-Savart laws from the known static-charge/steady-current distributions at $\mathbf{y}$:

$$\mathbf{u} \equiv \mathbf{u}[\mathbf{x},\mathbf{y}] \equiv \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|} \quad ,$$

$$\mathbb{d}\mathbf{E}[\mathbf{x}] = \frac{1}{4\pi\varepsilon_0}\frac{\mathbb{d}q[\mathbf{y}]\mathbf{u}}{|\mathbf{x}-\mathbf{y}|^2} = \frac{1}{4\pi\varepsilon_0}\frac{\rho[\mathbf{y}]\mathbf{u}}{|\mathbf{x}-\mathbf{y}|^2}\,\mathbb{d}\mathbf{y} \quad , \qquad \rightarrow \text{1335 1756}$$

$$\mathbb{d}\mathbf{B}[\mathbf{x}] = \frac{\mu_0}{4\pi}\frac{i\,\mathbb{d}\mathbf{L}[\mathbf{y}]\wedge\mathbf{u}}{|\mathbf{x}-\mathbf{y}|^2} = \frac{\mu_0}{4\pi}\frac{\mathbf{j}[\mathbf{y}]\wedge\mathbf{u}}{|\mathbf{x}-\mathbf{y}|^2}\,\mathbb{d}\mathbf{y} \quad . \qquad \rightarrow \text{1088 1089 1335 1757}$$

Electric field is generated by superposition of the infinitesimal contributions, $\rho\ \mathbb{d}V$.
Magnetic field is generated by superposition of the infinitesimal contributions, $\mathbf{j}\ \mathbb{d}V$.
In ElectroStatics/MagnetoStatics the above relations are equivalent, respectively, to Gauss law and Ampère law.
It should be noted that both equations are inverse square laws. However, the vector character is very different.
Note that as a moving charge does not constitute a steady current MagnetoStatics cannot be built from the properties of a single charge in motion, while ElectroStatics can be built from the properties of a single stationary charge.
Stationary charges generate constant electric fields: ElectroStatics.
Steady currents generate constant magnetic fields: MagnetoStatics.

DRAFT - IN PROGRESS

36.07 Dipole Fields - ElectroStatics/MagnetoStatics

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|§ eq. 4.20, § eq. 5.64||

The electric field produced by a static electric dipole, read § 16.12.12, is:

$$\mathbf{E}[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(\frac{3\,(\mathbf{p}\cdot\mathbf{r})\,\mathbf{r}}{r^5} - \frac{\mathbf{p}}{r^3}\right) \quad . \tag{36.07.01}$$

→ 1129 1714 1759

It can be also derived from Coulomb law.

The magnetic field produced by a static magnetic dipole, read § 16.12.12, is:

$$\mathbf{B}[\mathbf{r}] = \frac{\mu_0}{4\pi}\left(\frac{3\,(\mathbf{m}\cdot\mathbf{r})\,\mathbf{r}}{r^5} - \frac{\mathbf{m}}{r^3}\right) \quad . \tag{36.07.02}$$

→ 1129 1714

It can be also derived from Biot-Savart law.

A subtle issue arise [1] with the point dipole field. On a closer inspection, it is in fact necessary to add a Dirac delta in equation (36.07.01), (36.07.02), with different signs and coefficients for the electric and magnetic cases. Outside the dipole this additional term is irrelevant.

The corrective term, deriving from § 36.20.03.01, modifies the expression so that the electric field produced by a static electric dipole, located at $\mathbf{r}_0$, equation (36.07.01), becomes:

$$\mathbf{E}[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(\frac{3\,(\mathbf{p}\cdot\mathbf{d})\,\mathbf{d}}{d^5} - \frac{\mathbf{p}}{d^3} - \frac{4\pi}{3}\mathbf{p}\delta^3[\mathbf{r}-\mathbf{r}_0]\right) \qquad \mathbf{d}\equiv\mathbf{r}-\mathbf{r}_0 \quad . \tag{36.07.03}$$

The corrective term, deriving from § 36.20.03.02, modifies the expression so that the magnetic field produced by a static magnetic dipole, located at $\mathbf{r}_0$, equation (36.07.02), becomes:

$$\mathbf{B}[\mathbf{r}] = \frac{\mu_0}{4\pi}\left(\frac{3\,(\mathbf{m}\cdot\mathbf{d})\,\mathbf{d}}{d^5} - \frac{\mathbf{m}}{d^3} + \frac{8\pi}{3}\mathbf{m}\delta^3[\mathbf{r}-\mathbf{r}_0]\right) \qquad \mathbf{d}\equiv\mathbf{r}-\mathbf{r}_0 \quad . \tag{36.07.04}$$

This corrective Dirac-delta term is sometimes called *contact term*.

DRAFT WORK IN PROGRESS

36.08 Maxwell Equations and Charge Conservation in an Inertial Frame

Maxwell Equations unify Electric|Magnetic phenomena showing that electric fields can gives rise to magnetic fields and magnetic fields can gives rise to electric fields so that the two are strictly interconnected.

Moreover, electromagnetism predicts ElectroMagnetic waves, that is optics is an ElectroMagnetic phenomenon as well.

36.08.01 Maxwell Equations in Integral Form With Time-Independent Integration Domains

This § is referenced at pages:
[1717]

Read § 36.10 for the discussion of the case when integration domains are time-dependent.

The **Maxwell Equations** , written in **integral form for arbitrary volumes, surfaces and lines, but fixed in some Inertial Reference Frame** , read:

$$\oiint_{\partial\Omega} \mathbf{E}\cdot \mathbb{d}\mathbf{S} = \frac{1}{\varepsilon_0}\iiint_{\Omega} \rho\, \mathbb{d}V \quad , \tag{36.08.01}$$

→ 1724 2491 2512

$$\oiint_{\partial\Omega} \mathbf{B}\cdot \mathbb{d}\mathbf{S} = 0 \quad , \tag{36.08.02}$$

→ 1724 2512

$$\oint_{\partial\Sigma} \mathbf{E}\cdot \mathbb{d}\mathbf{L} = -\iint_{\Sigma} \partial_t\mathbf{B}\cdot \mathbb{d}\mathbf{S} = -\frac{\mathbb{d}}{\mathbb{d}t}\iint_{\Sigma} \mathbf{B}\cdot \mathbb{d}\mathbf{S} \quad , \tag{36.08.03}$$

→ 1715 1723 1724 2512

$$\oint_{\partial\Sigma} \mathbf{B}\cdot \mathbb{d}\mathbf{L} = \mu_0\iint_{\Sigma} \mathbf{j}\cdot \mathbb{d}\mathbf{S} + \mu_0\varepsilon_0\iint_{\Sigma} \partial_t\mathbf{E}\cdot \mathbb{d}\mathbf{S} = \mu_0\iint_{\Sigma} \mathbf{j}\cdot \mathbb{d}\mathbf{S} + \mu_0\varepsilon_0\frac{\mathbb{d}}{\mathbb{d}t}\iint_{\Sigma} \mathbf{E}\cdot \mathbb{d}\mathbf{S} \quad , \tag{36.08.04}$$

→ 1715 1722 1724 2491 2512

where Ω is an arbitrary fixed volume bounded by the closed surface $\partial\Omega$ and Σ is an arbitrary fixed surface bounded by the closed line $\partial\Sigma$.

The last equality of the last two equations applies **if and only the integration domains are time-independent**. As we are assuming here that all volumes, surfaces and lines are fixed in some Reference Frame, it does not make any difference whether the time derivatives are outside or inside the integral sign. However, the situation changes drastically if one accounts for moving volumes, surfaces and lines (see section § 36.10).

The **Maxwell Equations** must be complemented with the charge conservation law, which is, however, implied by the two **Maxwell Equations** containing Charge|Current:

$$\oiint_{\partial\Omega} \mathbf{j}\cdot \mathbb{d}\mathbf{S} + \frac{\mathbb{d}}{\mathbb{d}t}\iiint_{\Omega} \rho\, \mathbb{d}V_{\mathbf{x}} = 0 \quad . \tag{36.08.05}$$

→ 1715 1716

Note that the charge conservation law, described by the equation of continuity of charge (36.08.05) is a special case of the general balance equations, which includes the more general case of Sources|Sinks of the extensive physical quantity.

Note that Maxwell Equations contain two kinds of generators of ElectroMagnetic fields: charges and currents. However, they are related by the charge continuity equation and, therefore, they are not truly independent. This explains why it is often possible to solve problems by only considering either charge only or current only as the generators of ElectroMagnetic fields.

In the two circulation equations, (36.08.03), (36.08.04), it is implicit, for consistency reasons, that **the quantity on the right-hand side does not depend on the choice of the surface**, for any given closed line

DRAFT In Progress

$\partial\Sigma$. This means that the integrand of surface-integrals at the right-hand side must be solenoidal, that is their integral over any closed surface is null. By using the charge conservation law (36.08.05) one can find:

$$0 = \oiint_{\partial\Omega} \partial_t \mathbf{B} \cdot \mathbb{d}\mathbf{S} \implies \oiint_{\partial\Omega} \mathbf{B} \cdot \mathbb{d}\mathbf{S} = \text{constant in time} \quad ,$$

$$0 = \oiint_{\partial\Omega} (\mathbf{j} + \varepsilon_0 \partial_t \mathbf{E}) \cdot \mathbb{d}\mathbf{S} \implies \oiint_{\partial\Omega} \mathbf{E} \cdot \mathbb{d}\mathbf{S} - \frac{1}{\varepsilon_0} \iiint_{\Omega} \rho[\mathbf{x}] \, \mathbb{d}V_{\mathbf{x}} = \text{constant in time} \quad .$$

This means that if the charge conservation law is assumed the flux equations can be considered as just fixing the initial value at any time of the constant.

Finally note that **when the displacement current is neglected, for instance in steady conditions, the current density vector is solenoidal**:

$$0 = \oiint_{\partial\Omega} \mathbf{j} \cdot \mathbb{d}\mathbf{S} \quad .$$

Note that, **even if the magnetic field is such that its flux across any closed surface is zero, its field lines are not necessarily closed curves**: read § 16.12.19.

36.08.02
Maxwell Equations in Differential Form

This § is referenced at pages:
[1717, 2066]

Maxwell equations is a system of **coupled linear partial differential equations of first order**: **ElectroMagnetism is a linear theory**.

The **Maxwell Equations** , written in differential form and applicable in all the cases when the fields and Charge|Current producing the ElectroMagnetic fields are, from the mathematical point of view, sufficiently well-behaved functions, read:

$$\boxed{\mathbf{div}\mathbf{E} = \rho/\varepsilon_0} \quad , \tag{36.08.06}$$

→ 1736 2066

$$\boxed{\mathbf{div}\mathbf{B} = 0} \quad , \tag{36.08.07}$$

→ 1730 1736 2066 2491

$$\boxed{\mathbf{rot}\mathbf{E} = -\partial_t \mathbf{B}} \quad , \tag{36.08.08}$$

→ 1717 1726 1730 1736 2066 2491

$$\boxed{\mathbf{rot}\mathbf{B} = \mu_0 \mathbf{j} + \mu_0 \varepsilon_0 \partial_t \mathbf{E}} \quad .$$

The **Maxwell Equations** must be complemented with the charge conservation law, which is, however, implied by the two **Maxwell Equations** containing Charge|Current:

$$\boxed{\mathbf{div}\mathbf{j} + \partial_t \rho = 0} \quad . \tag{36.08.09}$$

→ 1716 1953

On the other hand, if the charge conservation law is assumed to hold, one can show that the divergence equations just fix the initial value in time, at any point, of the field divergence itself. In fact it is sufficient to take the divergence of both rotor equations and use equation (36.08.09) to obtain:

$$\partial_t \mathbf{div}\mathbf{B} = 0 \quad ,$$

$$\partial_t \left(\mathbf{div}\mathbf{E} - \frac{\rho}{\varepsilon_0} \right) = 0 \quad .$$

Basically, and very roughly, the applicability range of the **Maxwell Equations** written in differential form extends to all the cases and points in time and space when the written expressions are well defined. In all other cases the integral forms should be used.

Maxwell Equations in differential form show that:

- charge density gives the **sources/sinks** of the electric field: charge density is the same as electric field flux density while no Sources|Sinks exists for magnetic fields;
- current density gives the **vortexes** of the magnetic field: current density is the same as magnetic field circulation density while also changing Electric|Magnetic fields gives rise to magnetic/electric vortexes.

DRAFT-IN-PROGRESS

36.08.03
Number of Independent Variables in Maxwell Equations

©|G.S.Smith, *An Introduction To Classical Electromagnetic Radiation*, 1997, CUP, ...Ed., ...|||

© - QUOTE

The four vector **Maxwell Equations** are equivalent to eight scalar equations. However, the ElectroMagnetic fields, **E** and **B**, have only six independent components. This can be explained by the argument in sections § 36.08.01, § 36.08.02: when taking into account that charges and currents are constrained by the charge conservation equation it can be shown that the two divergence equations are basically initial condition on the values of the divergences (and therefore there are only $6 = 8 - 2$ equations). Note that the actual value of the constant can be assumed to be zero, by assuming as a starting time any time far in the past when charges and fields at the point were zero.

36.08.04
Integral Versus Differential Forms of Maxwell Equations

The integral form can be applied to any continuous field, as a sufficient, but by no means necessary, condition. The integral form is therefore of much broader applicability. The shortcoming of the integral form is the fact that one has one integral equation for each arbitrarily chose volume in space, while the differential form just provides one partial difference equation. Integral equations, in particular, are better suited to deal with discontinuities of the ElectroMagnetic fields.

36.08.05
Some Consequences of Maxwell Equations

As a consequence of Faraday-Neumann-Lenz equation, equation (36.08.08), the line-integral of the electric field between two points depends, in non-static cases, from the path. This is caused by the ElectroMagnetic induction. As a consequence of Faraday-Neumann-Lenz equation an EM-motive force (emf) originating from the electric field is present.

As a consequence of Maxwell-Ampère equation, equation (36.08.02), the line-integral of the magnetic field between two points depends, in non-static cases, from the path. This is caused by the magneto-electric induction, the dual of ElectroMagnetic induction. It also depends on the path in static cases when currents are present.

As discussed in section § 36.20.18 the magneto-electric induction is typically a much smaller effect than ElectroMagnetic induction, this is why it is often neglected, at least for slowly varying fields.

36.08.06
Structure of Maxwell Equations

Two different kinds of structures can be identified in **Maxwell Equations** .

- **Equations 2 and 3 are structural equations for the ElectroMagnetic fields as they only contain the fields** and not the Charge|Current producing the ElectroMagnetic fields. Equations 1 and 4 relate the ElectroMagnetic fields to the Charge|Current producing the ElectroMagnetic fields.
- **The rotor equations (3 and 4) link|mix Electric|Magnetic fields and include a time-dependence**. **The divergence equations (1 and 4) do not link|mix Electric|Magnetic fields and do not include any time-dependence** being identical in static as well as in dynamic conditions.

It is tempting to read the 3rd and 4th Maxwell equations, as: time-varying magnetic fields generate vortexes of the electric field and time-varying electric fields generate vortexes of the magnetic field; currents also generate vortexes of the magnetic field. However, in the relativistic view, Electric|Magnetic

T.U.N.-Progress

fields are parts of the same second-order field tensor, satisfying an inhomogeneous equation with the four-current as the generator, equation (61.05.04).

Therefore, **it seems to be more appropriate to state that the four-current generates the ElectroMagnetic fields (electric plus magnetic fields) at once**.

36.08.07
Maxwell Equations Unify Electric|Magnetic Phenomena

Maxwell Equations quantify to what extent Electric|Magnetic phenomena affect Magnetic|Electric phenomena, via the rotor equations.

36.08.08
On the Existence of Magnetic Monopoles

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|6.11||

©|WEB - URL |||

At present there is no experimental evidence.

The existence of magnetic Monopoles would explain electric charge quantisation.

Some condensed matter systems have a structure superficially similar to a real elementary magnetic monopole, a structure known as a flux tube. The ends of a flux tube form a Magnetic Dipole, but since they move independently, they can be treated for many purposes as independent magnetic monopole quasi-particles.

Consider a smooth surface, separating two different media (media := just two arbitrary distinct portions of space), possibly with different physical properties, a point P at the surface where the normal is $\hat{\mathbf{n}}$, oriented from medium 1 towards medium 2, and define the discontinuity for any vector field $\mathbf{V}$ as:

$$\Delta\mathbf{V} \equiv \mathbf{V}_2 - \mathbf{V}_1 \quad .$$

The ($\perp$) and ($\parallel$) suffixes will refer, in our notation, to the plane tangent at the surface at P, not to the normal vector of the surface at P:

- $\mathbf{V}_\perp \equiv (\hat{\mathbf{n}}\cdot\mathbf{V})\,\hat{\mathbf{n}}$, the component orthogonal to the surface, that is the component having the same direction as the normal at the surface at P, **most often named the normal component**;
- $\mathbf{V}_\parallel \equiv \hat{\mathbf{n}}\wedge(\mathbf{V}\wedge\hat{\mathbf{n}})$, the component parallel to the surface, that is the component lying in the plane tangent at the surface at P, **most often named the tangential component**.

Note that the opposite conventions is often used in the literature! It is therefore important to clarify whether parallel/perpendicular refer to the surface or to the normal.

Surface charges and surface currents must be accounted for, that is a set of charges constrained to move on a smooth surface. Physically speaking, surface charges and surface currents are mathematical limiting cases for charges and currents limited to a very thin sheet whose thickness is much smaller than any other relevant dimension.

The discontinuities of the ElectroMagnetic fields, as derived from the integral forms of the **Maxwell Equations** , are:

$$\hat{\mathbf{n}}\cdot\Delta\mathbf{E}_\perp = \hat{\mathbf{n}}\cdot\Delta\mathbf{E} = \rho_S/\varepsilon_0 \quad , \tag{36.09.01}$$

→ 1723 1745

$$\hat{\mathbf{n}}\cdot\Delta\mathbf{B}_\perp = \hat{\mathbf{n}}\cdot\Delta\mathbf{B} = 0 \quad , \tag{36.09.02}$$

→ 1723 1745

$$\hat{\mathbf{n}}\wedge\Delta\mathbf{E}_\parallel = \hat{\mathbf{n}}\wedge\Delta\mathbf{E} = \mathbf{0} \quad , \tag{36.09.03}$$

→ 1723

$$\hat{\mathbf{n}}\wedge\Delta\mathbf{B}_\parallel = \hat{\mathbf{n}}\wedge\Delta\mathbf{B} = \mu_0\mathbf{j}_S \quad . \tag{36.09.04}$$

→ 1722 1723 2252

The above equations can be summarized in vector form as:

$$\Delta\mathbf{E} = \hat{\mathbf{n}}\rho_S/\varepsilon_0 \qquad \Delta\mathbf{B} = \mu_0\,\mathbf{j}_S\wedge\hat{\mathbf{n}} \quad .$$

Note that in general **the components of the magnetic field parallel to the surface on the two sides may be, in general, not parallel**.

Note that discontinuities in the fields might arise not only in presence of abrupt changes in the physical properties of the medium but **also in presence of moving Charge|Current**, starting/stopping to radiate at some instant.

Read § 36.16.03.

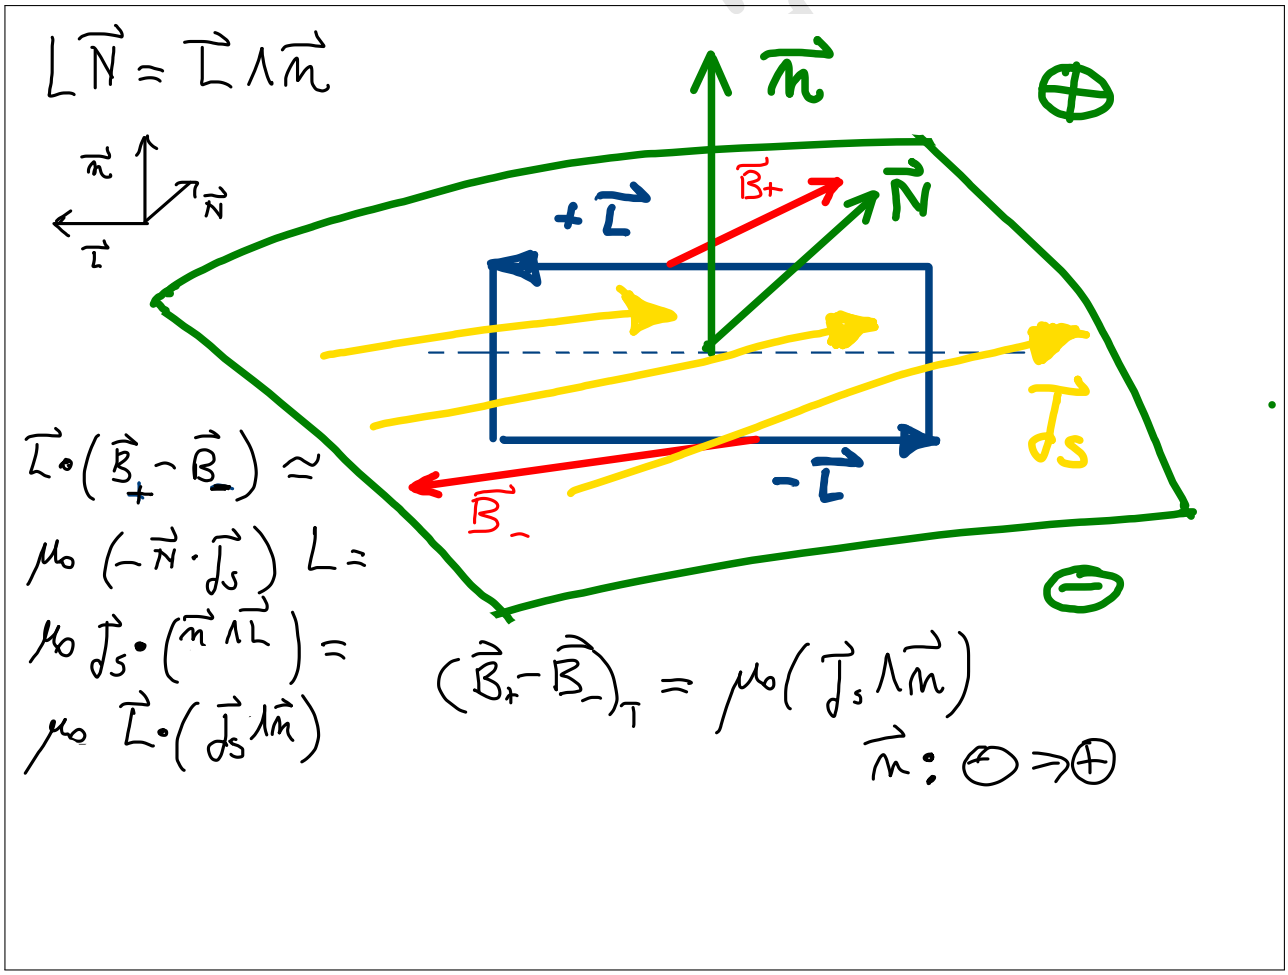
36.09.02
Discontinuity of Tangential Components of fields at a fixed surface

©|G.S.Smith, *An Introduction To Classical Electromagnetic Radiation*, 1997, CUP, ...Ed., ...|1.3||

Note that **the discontinuity relation for the tangential components do not imply at all that the tangential components on the two sides of the surface are parallel vectors: in general they are not collinear. On the other hand, the discontinuity of the normal components are necessarily parallel vectors**. The tangential components on the two sides of the surface can have an arbitrary direction in the tangent plane. In other words the two different tangential components of the fields in the two media are not necessarily in the same plane passing by the normal unit vector $\hat{\mathbf{n}}$.

DRAFT-IN-...

36.09.02.01 Tangential Component of the Magnetic Field



Let us demonstrate equation (36.09.04) starting from the integral form Maxwell equation (36.08.04).

Consider a smooth surface, Σ, separating two different media with different physical properties, a point P at the surface where the normal is $\hat{\mathbf{n}}$, oriented from medium 1 towards medium 2. Consider a small rectangle, S, whose frontier is the rectangular path, $\Gamma \equiv \partial S$, such that the normal vector $\hat{\mathbf{n}}$ is an axis of symmetry of the rectangle and the center of the rectangle is at P. The two sides parallel to $\hat{\mathbf{n}}$ are short and, moreover, the limit to zero will be taken at the end of the derivation. The other two sides, perpendicular to $\hat{\mathbf{n}}$, are short enough that neither the fields nor the Charge|Current, nor the properties of the surface change too much along it. Let $\mathbf{L}$ be the vector defining the oriented side perpendicular to $\hat{\mathbf{n}}$, the one of the two lying inside medium 1. Note that $\mathbf{L}$ will arbitrary but always parallel to the tangent plane.

The other side perpendicular to $\hat{\mathbf{n}}$ is then defined by $-\mathbf{L}$, in medium 2. Let $\widehat{\mathbf{N}}$ be the unit vector perpendicular to the rectangular loop, defined by

$$\boxed{L\widehat{\mathbf{N}} \equiv \mathbf{L}\wedge\hat{\mathbf{n}}} \quad .$$

The surface current concatenated with the path Γ is given by the line integral on the line determined by the intersection of the rectangle S and the surface Σ: $S \cap \Sigma$.

In the limit when the two sides parallel to $\hat{\mathbf{n}}$ tend to zero any contribution to the current concatenated to Γ originating from a volume current and any contribution of the time derivative of the flux of the electric field will tend to zero, because they are both proportional to the surface tending to zero. Any surface current, $\mathbf{j}_S$, will give a non zero contribution, in general, even in the limit when the surface tends to zero.

One can then write:

$$\oint_C \mathbf{B}\cdot \mathrm{d}\mathbf{L} \simeq \mathbf{L}\cdot(\mathbf{B}_1 - \mathbf{B}_2) = \mu_0 I =$$

$$-\mu_0 \int_{S\cap\Sigma} \left(\mathbf{j}_S\cdot\widehat{\mathbf{N}}\right) \mathrm{d}\mathbf{L} = -\frac{\mu_0}{L}\int (\mathbf{j}_S\cdot(\hat{\mathbf{n}}\wedge\mathbf{L})) \mathrm{d}\mathbf{L} \simeq$$

$$\mu_0\, \mathbf{j}_S\cdot(\mathbf{L}\wedge\hat{\mathbf{n}}) = \mu_0\, \mathbf{L}\cdot(\hat{\mathbf{n}}\wedge\mathbf{j}_S) \quad .$$

Finally, as the above relation is valid for any rectangular surface/path (S / Γ), one can conclude:

$$\boxed{\mathbf{L}\cdot(\mathbf{B}_2 - \mathbf{B}_1) = \mu_0\, \mathbf{L}\cdot(\mathbf{j}_S\wedge\hat{\mathbf{n}})} \quad .$$

However, **the relation does not constrain in any way the normal components**. In fact $\mathbf{L}$ is arbitrary but constrained to be in the tangential plane with $\hat{\mathbf{n}}\cdot\mathbf{L} = 0$. Therefore:

$$\mathbf{n}\cdot\mathbf{L} = 0 \implies \mathbf{L}\cdot(\mathbf{B}_2 - \mathbf{B}_1) = \mathbf{L}\cdot(\mathbf{B}_2 - \mathbf{B}_1)_{\parallel} + \mathbf{L}\cdot(\mathbf{B}_2 - \mathbf{B}_1)_{\perp} = \mathbf{L}\cdot(\mathbf{B}_2 - \mathbf{B}_1)_{\parallel} \quad .$$

On the other hand $\mathbf{j}_S\wedge\hat{\mathbf{n}}$ is always in the tangential plane.

One can then only draw conclusions about properties of $(\mathbf{B}_2 - \mathbf{B}_1)$ **in the tangential plane**. Thanks to the arbitrariness of $\mathbf{L}$ in the tangential plane one can then conclude:

$$\boxed{(\mathbf{B}_2 - \mathbf{B}_1)_{\parallel} \equiv \Delta\mathbf{B}_{\parallel} = \mu_0\, \mathbf{j}_S\wedge\hat{\mathbf{n}} \qquad \Longrightarrow \qquad \hat{\mathbf{n}}\wedge\Delta\mathbf{B}_{\parallel} = \mu_0\mathbf{j}_S} \quad , \qquad (36.09.05)$$

→ 1793

as, in fact, the component of $\mathbf{j}_S$ perpendicular to the normal vector is the same as $\mathbf{j}_S$, which is in the tangential plane.

For any material, the concept of **surface current is important because Magnetization of matter gives, in general, a surface Magnetization current**, see section § 39.05.02.

DRAFT - IN - PROGRESS

CC BY NC ND

36.09.02.02 Tangential Component of the Electric Field

In a similar way as the derivation in section § 36.09.02.01 one can demonstrate equation (36.09.03). One starts from the integral form **Maxwell Equation** (36.08.03) and, taking into account that the flux of the magnetic field tends to zero in the limit, one obtains:

$$\boxed{(\mathbf{E}_2 - \mathbf{E}_1)_{\parallel} \equiv \Delta\mathbf{E}_{\parallel} = \mathbf{0} \qquad \Longrightarrow \qquad \widehat{\mathbf{n}}\wedge\Delta\mathbf{E}_{\parallel} = \mathbf{0}} \quad . \tag{36.09.06}$$

→ 1793

36.09.02.03 Equivalent Formulas for Tangential Components

Two different equivalents forms of the equations for the discontinuity of the tangential components are possible:

$$\boxed{\widehat{\mathbf{n}}\wedge\Delta\mathbf{E} = \mathbf{0}} \quad \Leftrightarrow \quad \widehat{\mathbf{n}}\wedge\big(\widehat{\mathbf{n}}\,(\,\widehat{\mathbf{n}}\cdot\Delta\mathbf{E}) - \boldsymbol{\Delta}\mathbf{E}_{\parallel}\big) = \mathbf{0} \quad \Leftrightarrow \quad \boxed{\boldsymbol{\Delta}\mathbf{E}_{\parallel} = \mathbf{0}} \quad , \tag{36.09.07}$$

$$\boxed{\widehat{\mathbf{n}}\wedge\Delta\mathbf{B} = \mu_0\mathbf{j}_S} \quad \Leftrightarrow \quad \widehat{\mathbf{n}}\wedge\big(\widehat{\mathbf{n}}\,(\,\widehat{\mathbf{n}}\cdot\Delta\mathbf{B}) - \boldsymbol{\Delta}\mathbf{B}_{\parallel}\big) = \mu_0\,\widehat{\mathbf{n}}\wedge\mathbf{j}_S \quad \Leftrightarrow \quad \boxed{\boldsymbol{\Delta}\mathbf{B} = \mu_0\,\mathbf{j}_S\wedge\widehat{\mathbf{n}}} \quad . \tag{36.09.08}$$

36.09.03 Discontinuities of the Current Density at a fixed surface

The discontinuity of the current density can be derived from the charge continuity equation in a similar manner to equations (36.09.01), (36.09.02), because they are all based on a flux/divergence equation. One finds:

$$\boxed{\widehat{\mathbf{n}}\cdot\Delta\mathbf{j} = \widehat{\mathbf{n}}\cdot\Delta\mathbf{j}_{\perp} = -\mathbf{div}_S\mathbf{j}_S - \partial_t\rho_S} \quad , \tag{36.09.09}$$

→ 1723

in terms of the surface charge, ρ_S, surface current, $\mathbf{j}_S$ and the surface divergence operator, $\mathbf{div}_S\cdot$, (read § 16.06.02) ■

The physical meaning of the charge discontinuity equation is physically clear: any charge which is not found after crossing the surface must be found either as charge accumulated on the surface or flow as surface current density as leakage current.

In the often encountered case when at the interface there is no surface leakage current and there is a constant surface charge (as it is the case in a steady state) then the normal component of the current density is conserved:

$$\boxed{I_1 = I_2 \implies \widehat{\mathbf{n}}\cdot\Delta\mathbf{j} = \widehat{\mathbf{n}}\cdot\Delta\mathbf{j}_{\perp}} \qquad \text{sufficient condition: steady state and no surface current} \quad . \tag{36.09.10}$$

Note that, when the charge continuity equation is assumed, only three Maxwell equations are truly independent; similarly only three of the five boundary conditions, equations (36.09.01), (36.09.02), (36.09.03), (36.09.04), (36.09.09), are truly independent.

For moving surfaces, read § 36.16.

Equations (36.08.01), (36.08.02) are always valid in any case, even if the integration domain moves.

Equations (36.08.03), (36.08.04) are valid in any case, even if the integration domain moves as long as the form with time derivative inside the integral sign is used. Taking the time derivative sign outside the integral is possible as long as the integration domain is fixed. If it is not fixed, it is clear that the derivative outside the integral sign gives a result which depends on the way the integration domain is changing in time.

In some applications it is useful to use moving integration boundaries. It is therefore necessary to understand how to treat those cases.

It is important to note that studying this problem, in particular the Faraday-Neumann-Lenz law, A.Einstein started to develop the theory of relativity.

36.10.01
Faraday-Neumann-Lenz Law

The most general form of the law of ElectroMagnetic Induction (Faraday-Neumann-Lenz) must take into account that, **in any fixed reference frame, there are two different and distinct physical effects capable to give rise to ElectroMagnetic Induction**:

- **the change, at any point, of the magnetic field**;
- **the movement of a real current-carrying circuit** (that is a **kinematic constraint** to the motion of the charges) inside a magnetic field.

The first effect is totally independent of any real current carrying circuit and it exists in empty space too.

The second effect is closely related to the presence of real current-carrying circuits. **A real current carrying circuit is actually modeled as a set of kinematic constraints to the motion of the charges, a kinematic constraint in the sense of mechanics**.

If the kinematic constraint is one-dimensional, that is a curve, as in the case of a thin wire, the description of ElectroMagnetic induction is relatively easy, as it will be shown below.

If the kinematic constraint is either two-dimensional or three-dimensional, that is either a surface or a volume current, as in the case of either surface or volume conductors, the description is typically much more complex, because the direction of the velocities of the charges are not uniquely determined by the kinematic constraint. In this case, using the law of ElectroMagnetic Induction (Faraday-Neumann-Lenz) in the form of the flux rule is hardly applicable.

We know of no other place in physics where such a simple and accurate general principle requires

WEB-PROOFS

for its real understanding an analysis in terms of two different phenomena. Usually such a beautiful generalization is found to stem from a single deep underlying principle. Nevertheless, in this case there does not appear any such profound implication. We have to understand the rule as the combined effects of two quite separate phenomena. Italics in the original.

In order to avoid mistakes **both two different effects giving rise to EM induction phenomena must always be accounted for** and the physical origin of the EM induction phenomenon must be clearly identified.

A **clear understanding** of the way one passes from/to the **Maxwell Equations** in differential to/from **the flux-rule** is essential to avoid mistakes when applying the flux-rule to peculiar situations.

36.10.02
EM-Motive Force

This § is referenced at pages:
[1726]

The **EM-motive** force is typically introduced **for forces of non-ElectroMagnetic origin as the work done on the unit charge at any fixed time on a closed fixed circuit**:

$$\mathcal{E} \equiv \frac{\mathrm{d}W}{\mathrm{d}q} \equiv \frac{1}{q}\oint_C \mathbf{f}\cdot \mathrm{d}\mathbf{L} \qquad \text{at any fixed time on a closed fixed circuit} \quad . \tag{36.10.01}$$

→ 1725

The term **EM-motive force** is meant to describe the effect of external forces on electric charges (from which the term **EM-motive** originates) but it is by no means a force.

The physical entities responsible for the force f can be any one of many different things: a chemical force, as in a battery; mechanical pressure converted into an electric impulse, as in a piezoelectric crystal; a temperature gradient, as in a thermocouple; light, as in a photo-electric cell; and many others.

Whatever the mechanism, its net effect is quantified by the line integral of **f** around the circuit, that is, **force per unit charge integrated on a closed fixed path at fixed time**

In presence of ElectroMagnetic forces the definition must be generalized to account for and include the Lorentz force. One can therefore write the EM-motive force on a closed loop circuit, C, at any fixed time, for purely ElectroMagnetic forces, starting from its definition, as:

$$\mathcal{E} \equiv \frac{\mathrm{d}W}{\mathrm{d}q} = \oint_C (\mathbf{E} + \mathbf{v}\wedge\mathbf{B})\cdot \mathrm{d}\mathbf{L} \qquad \text{at any fixed time} \quad . \tag{36.10.02}$$

→ 1725 1726

The definition (36.10.02) **generalizes the concept of EM-motive force to the case when the origin of the force is of ElectroMagnetic origin**. The expression (36.10.02) is actually the **force per unit charge integrated on a closed fixed path at fixed time**. Therefore it can be identified with the EM-motive force, with forces of purely ElectroMagnetic origin. The EM-motive force of ElectroMagnetic origin (36.10.02) is thus an extension of the concept of EM-motive force.

In the case of the ElectroStatic field the integral along a closed line is zero.

In the above expression (36.10.02) the velocity **v** is the velocity of the charge, which, in general is the sum of the velocity of the current carrying circuit and the drift velocity of the charge, that is the velocity of the charge with respect to the circuit.

One should be careful that, whenever the real circuit is moving/changing, the definition of **around the closed circuit** requires some care [1]. In fact one should be careful to use the expression (36.10.02) **integrating over the closed loop at a fixed time**. In this sense it might be misleading to think, as suggested by equation (36.10.01), of work done on a specific charge, if the circuit is moving. The correct interpretation, as from equation (36.10.02), is the **circulation of the force vector over the closed path at fixed time per unit charge**. Interpreting the integral as the real work done on a specific charge can give two kinds

[1] D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...

CC BY NC ND

of troubles: if the circuit moves it might be unclear what a closed loop is; if the charges moves slowly with respect to the changes of the ElectroMagnetic fields then the ElectroMagnetic fields might change before the tour of the loop ends.

36.10.03
3rd Maxwell Equation in Differential/Flux-Rule Form

The discussion in this section shows an example where the mathematical modeling needs to be carried on having clearly in mind the physical processes.

In order to be consistent with the following mathematical passages, involving line and surface-integrals, it must be possible to **treat the real current-carrying circuit as an ideal line circuit, that is the kinematic constraint is a one-dimensional constraint**.

In this case it can be shown that it makes no difference to use, in the above expression (36.10.02), either the real velocity of the charge, $\mathbf{v}$, or the velocity of the circuit, $\mathbf{u}$, at the point where the charge is located. In fact the drift velocity, $\mathbf{V}_D$ is parallel to the line element, for a line circuit and therefore, from the law of composition of the velocities:

$$\mathbf{v} = \mathbf{u} + \mathbf{V}_D \implies (\mathbf{v} - \mathbf{u}) = \mathbf{V}_D \parallel \mathbb{d}\mathbf{L} \implies ((\mathbf{v} - \mathbf{u}) \wedge \mathbf{B}) \cdot \mathbb{d}\mathbf{L} = 0 \quad . \tag{36.10.03}$$

→ 1726 1727

The above result means that for a line circuit there is no difference in considering either $\mathbf{v}$ or $\mathbf{u}$ in the expression of the EM-motive force of ElectroMagnetic origin.

Let us start from the 3rd **Maxwell Equation** in differential form (36.08.08) and integrate across any surface, Σ, possibly a moving one. Let the boundary of the surface, $\partial\Sigma$, coincide with a real line current carrying-circuit, acting as a kinematic constraint to the motion of charges. The circuit shall be a fixed constitution circuit, to avoid a discontinuous evolution of the circuit.

For the general case of moving integration domains, Σ and $\partial\Sigma$, one finds, with $\mathbf{u}$ the velocity of any point of $\partial\Sigma$, with a purely mathematical derivation:

$$\oint_{\partial\Sigma} \mathbf{E} \cdot \mathbb{d}\mathbf{L} = \iint_{\Sigma} \mathbf{rot}\mathbf{E} \cdot \mathbb{d}\mathbf{S} = -\iint_{\Sigma} \partial_t \mathbf{B} \cdot \mathbb{d}\mathbf{S} = -\frac{\mathbb{d}}{\mathbb{d}t} \iint_{\Sigma} \mathbf{B} \cdot \mathbb{d}\mathbf{S} - \oint_{\partial\Sigma} (\mathbf{u} \wedge \mathbf{B}) \cdot \mathbb{d}\mathbf{L} \quad ,$$

$$\implies \boxed{\oint_{\partial\Sigma} (\mathbf{E} + \mathbf{u} \wedge \mathbf{B}) \cdot \mathbb{d}\mathbf{L} = -\frac{\mathbb{d}}{\mathbb{d}t} \iint_{\Sigma} \mathbf{B} \cdot \mathbb{d}\mathbf{S}} \quad . \tag{36.10.04}$$

→ 1726

The above relation (36.10.04) is just the **result of mathematical derivations**: **care is required in implementing them into physical laws**.

Following the definition of EM-motive force in section § 36.10.02 and relations (36.10.03) one can write, introducing the shortcut $\Gamma \equiv \partial\Sigma$:

$$\boxed{\mathcal{E}_\Gamma \equiv \mathcal{E}_\Gamma[\text{changing magnetic field}] + \mathcal{E}_\Gamma[\text{motional}] = -\frac{\mathbb{d}\Phi_\Sigma}{\mathbb{d}t}} \quad , \tag{36.10.05}$$

→ 1726

where Φ_Γ is the flux of magnetic field concatenated with the line Γ. Equation (36.10.05) is the **flux-rule** form of the Faraday-Neumann-Lenz law. Note that all quantities are measured in the same Inertial Reference Frame and not in the reference frame at rest (locally) with the moving integration domain.

Alternatively, starting from equation (36.10.04), one can write the total EM-motive force as:

$$\boxed{\mathcal{E}_{\partial\Sigma} = -\iint_{\Sigma[t]} \partial_t \mathbf{B} \cdot \mathbb{d}\mathbf{S} + \oint_{\partial\Sigma[t]} (\mathbf{u} \wedge \mathbf{B}) \cdot \mathbb{d}\mathbf{L}} \quad , \tag{36.10.06}$$

→ 1726 1727 1769

where $\Sigma[t]$ is a generic surface, possibly function of time, and $\partial\Sigma[t]$ is its boundary, which must coincide with the real current-carrying circuit, defined by the lines of current, acting as a one-dimensional kinematic constraint.

In case the circuit is a fixed-constitution one-dimensional circuit (a current line) changing in a sufficiently continuous way, the expression (36.10.06) is totally equivalent to the flux rule:

$$\boxed{\mathcal{E}_{\partial\Sigma} = -\frac{\mathbb{d}\Phi_\Sigma}{\mathbb{d}t}} \quad . \tag{36.10.07}$$

PRELIMINARY PROOFS

CC BY NC ND

The flux-rule law applies if and only if the mathematical integration line, $\Gamma \equiv \partial\Sigma$, whose velocity is $\mathbf{u}$, **is at any instant coincident with the real line current carrying wire and the evolution of the circuit can be modeled as a sufficiently continuous evolution**. In fact in this case the velocity $\mathbf{w}$ in the line integral

$$\oint_{\partial\Sigma[t]} (\mathbf{w}\wedge\mathbf{B})\cdot \mathbb{d}\mathbf{L}$$

can be set, indifferently, to either $\mathbf{w} = \mathbf{v}$, as required by the definition of the EM-motive force, or $\mathbf{w} = \mathbf{u}$, as required by the mathematical theorem.

The mathematical model [1] **used for the demonstration may fail when the conductor is not a line conductor, because it might be not possible to replace the velocity of the charge with the velocity of the circuit based on** (36.10.03).

The mathematical model used for the demonstration may also fail if the real circuit changes in a way that cannot be modeled as a smooth evolution, for instance when the circuit is not a fixed constitution circuit, because the mathematical theorem may not apply.

In fact, the troubles with the well-known flux rule are that, in many examples, either the current spreads out over a whole two-dimensional surface or three-dimensional volume and in in many such cases it is not even clear what the flux through the circuit would mean, or the line circuit varies in a non smooth-enough way.

In the most general case the use of the form (36.10.06) ensures the correct treatment.

Actually the presence of the two terms is related to the invariance of the ElectroMagnetic theory by **Lorentz Transformation** , because under **Lorentz Transformation** Electric|Magnetic fields can mix. Read § 61.

36.10.04

4th Maxwell Equation in Differential/Flux-Rule Form

The same considerations apply to (36.08.02), but in this case they are not very useful on the practical side.

UNDER-LINE-IN-PROGRESS

36.11 Modeling of Conductors and Insulators

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|7||

DRAFT PRELIMINARY

36.11.01 Conductivity and Resistivity

The **conductivity** , σ, is defined as the linear coefficient relating the current density with the applied force per unit charge, $\mathbf{f}/q$.

In the simple case of an isotropic material the **conductivity** is a scalar (possibly depending on the position) as the force and the current density must be parallel.

$$\boxed{\mathbf{j} \equiv \sigma \mathbf{f}/q} \quad . \tag{36.11.01}$$

In the simple case of an homogeneous material the **conductivity** is independent on the position (possibly depending on the direction of the fields)

$$\boxed{j_k \equiv \sigma_{ki}^{\cdot\cdot} f_i/q} \quad . \tag{36.11.02}$$

In the general case of a non-homogeneous and non-isotropic material the **conductivity** is a second-order tensor, relating the force and current density vectors:

$$\boxed{j_k \equiv \sigma_{ki}^{\cdot\cdot}[\mathbf{x}] f_i/q} \quad . \tag{36.11.03}$$

→ 1728

In reality the perfect insulator/conductor commonly used model is just an abstraction to simplify the modeling of very good insulators/conductors. The intermediate cases, as usual, are more difficult to deal with.

For steady currents and uniform **conductivity** in a Ohmic conductor the charge volume density inside the conductor is zero and any unbalanced charge must reside on the surface. This property reminds the case of stationary charges, which can only exist at the surface of a conductor.

36.11.02 Conductors

Note that the relation (36.11.03) is not Ohm law which is the following statement: **a Ohmic conductor is defined as a conductor whose conductivity , σ, is independent of the applied force per unit charge**, $\mathbf{f}/q$:

$$\boxed{\mathbf{j} = \sigma\,(\mathbf{f}/q) \qquad \text{with a fixed } \textbf{conductivity } \sigma\text{, independent of } \mathbf{f}} \quad . \tag{36.11.04}$$

A **perfect conductor** is defined as a Ohmic conductor having zero resistivity, that is: $\sigma \to \infty$. The model of a perfect conductor is used, for instance, in magneto-hydrodynamics, the study of perfectly conductive fluids, and in circuit theory when the connections between different components is modeled by a wire with no resistivity (but in real circuits the potential drop along wires can be significant, requiring wires with a large enough cross-section, also to reduce the power dissipation).

In case only ElectroMagnetic forces are acting on the charges the relation for Ohmic conductors becomes:

$$\boxed{\mathbf{j} = \sigma\,(\mathbf{E} + \mathbf{v}\wedge\mathbf{B}) \qquad \text{with a fixed } \textbf{conductivity } \sigma} \quad . \tag{36.11.05}$$

→ 1728

Note that in many practical cases in (36.11.05) the magnetic term is negligible with respect to the electric term because velocity and|or magnetic field are small. In fact, for general ElectroMagnetic fields (that is ElectroMagnetic waves) typically: $E \approx cB$.

It follows that, in order to have a finite current, **the electric field inside an perfect conductor must be zero**. The 3rd **Maxwell Equation** then implies that **the magnetic field is independent on time**.

Therefore if the magnetic field is zero inside a conductor at a certain time it will remain zero forever. In other words the magnetic field does not penetrate inside a perfect conductor.

Moreover, it can be shown that Ohmic conductors might carry a surface currents if and only if they are perfect conductors, read § 36.20.22.

Summarizing, a perfect Ohmic conductor has the following properties:

perfect Ohmic conductor ($\sigma \to \infty$): $\{ \quad \mathbf{E} = \mathbf{0} \quad \mathbf{B} = \text{constant} \quad \mathbf{j}_s \,/\, \rho_s \text{ might be non zero} \quad \}$.

(36.11.06) → 1729

Note that while the electric field is zero in a generic conductor at equilibrium it is always zero inside a perfect conductor.

In case additional forces of non ElectroMagnetic origin exist, described by a force field per unit charge, $\mathbf{f}/q$, the constitutive relation for a Ohmic conductor becomes:

$$\mathbf{j} = \sigma\,(\mathbf{E} + \mathbf{v}\wedge\mathbf{B} + \mathbf{f}/q) \quad . \tag{36.11.07}$$

→ 1729

Forces of non ElectroMagnetic origin might be, for instance, inertial forces, like in the so-called Nichols disk.

It must be emphasized that the equation (36.11.07) is not a fundamental law of nature but is a constitutive relation, which defines a class of material media having the property that the current density is a linear function of the Electric|Magnetic fields as well as of any other EM-motive field, $\mathbf{f}/q$.

36.11.02.01 Perfect Conductors and Super-Conductors

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|problem 7.42, 7.43||

A **perfect conductor** is characterized by the constitutive relation (36.11.06).

In a perfect conductor, the **conductivity** is infinite and any net charge resides at the surface, just as it does for any non-perfect conductor in static conditions.

A loop made of a perfect-conductor wire has constant concatenated magnetic field flux. In fact the circulation of the electric field is zero, because the electric field is zero, so that the concatenated magnetic field flux does not change.

A superconductor has the additional property that the constant magnetic field inside is zero, that is they are also **perfect diamagnets**. This is the **flux exclusion** effect, which is known as the Meissner effect.

The current in a superconductor is confined to the surface. In fact, from the 4th **Maxwell Equation** , zero electric field and zero magnetic field imply zero current density.

36.11.03 Insulators

36.11.03.01 Perfect Insulators

A perfect insulator is defined as a Ohmic conductor having zero **conductivity** , that is: $\sigma = 0$.

They will be called dielectrics.

Pure vacuum is a perfect dielectric.

36.12 ElectroMagnetic Potentials

This § is referenced at pages:
[2489]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.15.4, 2.15.5||

In this section the short-hand notation:

$$\frac{1}{c^2} \equiv \varepsilon_0 \mu_0 \quad ,$$

will be often used, where c is the speed of light in vacuum. The relation will be derived later, when discussing ElectroMagnetic waves § 46.

Maxwell Equations consist of a set of four coupled first-order partial differential equations relating the Electric|Magnetic fields to their Sources|Sinks, charges and currents. **Maxwell Equations** can be solved directly only in simple situations. In general it is useful to introduce the ElectroMagnetic potentials, in order to obtain two uncoupled second-order partial differential equations. The 2nd and 3rd **Maxwell Equations** are identically satisfied thanks to the definition of the potentials themselves.

From the practical point of view, in ElectroStatics, **the use of the scalar potential allows a considerable simplification of the calculations** with respect to the use of the electric field (a scalar field against a vector field). On the other hand, in MagnetoStatics, **the use of the vector magnetic potential does not allow, usually, simplifications of the calculations** with respect to the use of the magnetic field (a vector field against a vector field), but it allows considerable advances in the development of the ElectroMagnetism. Moreover, since magnetic forces do no work, **the vector potential does not admit a simple physical interpretation as the scalar electric potential in terms of potential energy per unit charge**.

From the structure of the ElectroMagnetic fields, that is Maxwell equations (36.08.07), (36.08.08), the Electric|Magnetic fields can be expressed as a function of the potentials of the ElectroMagnetic fields, provided the conditions described in section § 16.09.03 on the domain of definition of the ElectroMagnetic fields are met:

$$\mathbf{div}\,\mathbf{B} = 0 \implies \mathbf{B} = +\mathbf{rot}\,\mathbf{A} \tag{36.12.01}$$

$$\mathbf{rot}\,\mathbf{E} + \partial_t \mathbf{B} = 0 \implies \mathbf{E} = -\mathbf{grad}\,\Phi - \partial_t \mathbf{A} \quad .$$

→ 1731 1735 1743
→ 1731 1735 1743

In order to use the **ElectroMagnetic potentials** a sufficient condition on the domain is that it is both 1-connected and 2-connected, which will be implicitly assumed in the rest of the section.

36.12.01 Gauge Invariance and Choice of a Gauge

This § is referenced at pages:
[1734]

©|J.D.Jackson|From Lorenz to Coulomb and other explicit gauge transformations|*Am.J.Phys*, , ..., ..., ...Ed., ... *70, 917* ...

©|J.A.Heras|How the potentials in different gauges yield the same retarded electric and magnetic fields|*Am.J.Phys*, , ..., ..., ...

The **ElectroMagnetic potentials** are not uniquely defined. In fact there exist infinitely many possible choices of the potentials giving rise to the same Electric|Magnetic fields.

In classical ElectroMagnetism only the ElectroMagnetic fields have a well-defined physical meaning, as they are ultimately defined from the Lorentz force law, while the **ElectroMagnetic potentials** do not, as

they are not uniquely defined. The fact that the **ElectroMagnetic potentials** are not uniquely defined does not pose any problem to the physics. On the other hand the freedom to choose a set of **ElectroMagnetic potentials** can lead to a considerable simplification of some equations.

The Electric|Magnetic fields do not change under the gauge transformations:

$$\Phi \longrightarrow \Phi' = \Phi - \partial_t \Lambda \tag{36.12.02}$$

→ 1731 1735 2489

$$\mathbf{A} \longrightarrow \mathbf{A}' = \mathbf{A} + \mathbf{grad}\,\Lambda \quad , \tag{36.12.03}$$

→ 1731 1735 2489

that is: $\mathbf{E}$ and $\mathbf{B}$ calculated from equations (36.12.01), (36.12) are the same when using either the pair of **ElectroMagnetic potentials** Φ, $\mathbf{A}$ or the pair of **ElectroMagnetic potentials** Φ', $\mathbf{A}'$.

The freedom in the choice of the potentials which is provided by gauge invariance (equations (36.12.02), (36.12.03)) is used to simplify the developments.

Actually, under some circumstances quantum physics shows that the **ElectroMagnetic potentials** themselves have a physical significance (**Aharonov-Bohm effect** [1]) affecting the dynamics, in regions of space where Electric|Magnetic fields are absent [2].

The **ElectroMagnetic potentials** are discussed in the relativistic context in section § 61.04.

36.12.01.01 Lorenz Gauge

This § is referenced at pages:
[Never referenced.]

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|§ 10.1.3||

©|J.D.Jackson|From Lorenz to Coulomb and other explicit gauge transformations|*Am.J.Phys*, , ..., ..., ...*Ed.*, ... *70, 917* ...

©|J.A.Heras|How the potentials in different gauges yield the same retarded electric and magnetic fields|*Am.J.Phys*, , ..., ..., ...

A most used gauge choice in relativistic physics is the Lorenz gauge [3], which **has the virtue of providing a description with space and time treated on the same footing** (a relativistically covariant description):

$$\frac{1}{c^2}\partial_t \Phi + \mathbf{div}\,\mathbf{A} = 0 \quad . \tag{36.12.04}$$

→ 1731 2220

Given any set of **ElectroMagnetic potentials** one can determine a set of **ElectroMagnetic potentials** satisfying the **Lorenz Gauge** by replacing the gauge transformations (36.12.02), (36.12.03) into (36.12.04) and imposing the Lorenz condition on the new **ElectroMagnetic potentials** to find an equation for Λ:

$$\frac{1}{c^2}\partial_t \Phi' + \mathbf{div}\,\mathbf{A}' = 0 \implies \nabla^2\Lambda - \frac{1}{c^2}\frac{\partial^2 \Lambda}{\partial t^2} = -\left(\frac{1}{c^2}\partial_t \Phi + \mathbf{div}\,\mathbf{A}\right) \quad .$$

Note that the condition does not specify uniquely the potentials. In fact any other set of **ElectroMagnetic potentials** derived from a set of **ElectroMagnetic potentials** satisfying the **Lorenz Gauge** , via a function Λ such that

$$\nabla^2\Lambda - \frac{1}{c^2}\frac{\partial^2 \Lambda}{\partial t^2} \quad , \tag{36.12.05}$$

still satisfies the **Lorenz Gauge** condition (36.12.04). All these potentials are are said to belong to the **Lorenz Gauge** .

The **Lorenz Gauge** is particularly suitable for providing a relativistically covariant condition. Actually it is the only one possibility linear in the EM potentials.

The **Lorenz Gauge has the virtue of allowing the separation of the scalar electric potential and vector magnetic potential in the wave equations** derived by **Maxwell Equations** (see section § 49.01).

[1] R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ... 2.15.4 and 2.15.5
[2] The discussion about **Aharonov-Bohm effect** is still a lively argument among physicists, with an infinite scientific literature.
[3] It was proposed by the Danish physicist L.V.Lorenz, although it is often erroneously attributed to the Dutch physicist H.A.Lorentz.

DRAFT IN PROGRESS

36.12.01.02 Coulomb Gauge

This § is referenced at pages:
[Never referenced.]

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|§ 10.1.3||
©|J.D.Jackson|From Lorenz to Coulomb and other explicit gauge transformations|*Am.J.Phys*, , ..., ..., ...*Ed.*, ... *70, 917* ...
©|J.A.Heras|How the potentials in different gauges yield the same retarded electric and magnetic fields|*Am.J.Phys*, , ..., ..., ...

In the static case the choice which is most often used is the so-called Coulomb gauge, which gives rise to **Poisson equation** for the potentials:

$$\boxed{\mathbf{div}\,\mathbf{A} = 0} \quad . \tag{36.12.06}$$

Note that the **Lorenz Gauge** is equivalent to the Coulomb gauge in stationary conditions.

From any given gauge one can deduce:

$$\mathbf{div}\,\mathbf{A}' = \mathbf{div}\,\mathbf{A} + \nabla^2\Lambda \quad ,$$

so that the Λ that solves the equation

$$\nabla^2\Lambda = -\mathbf{div}\,\mathbf{A} \quad ,$$

gives **ElectroMagnetic potentials** in the Coulomb gauge from any potential $\mathbf{A}$.

36.12.01.03 Temporal Gauge

This § is referenced at pages:
[Never referenced.]

©|J.D.Jackson|From Lorenz to Coulomb and other explicit gauge transformations|*Am.J.Phys*, , ..., ..., ...*Ed.*, ... *70, 917* ...
©|J.A.Heras|How the potentials in different gauges yield the same retarded electric and magnetic fields|*Am.J.Phys*, , ..., ..., ...

The temporal gauge:

$$\boxed{\Phi = 0} \quad , \tag{36.12.07}$$

is often used when describing the radiation of ElectroMagnetic waves. It has the virtue of describing both the $\mathbf{E}$ and $\mathbf{B}$ field by means of the **vector magnetic potential** $\mathbf{A}$ only. However, it might be rather impractical in static cases, as the **vector magnetic potential** for a static field would be time-dependent.

To keep the temporal gauge, for any gauge transformation:

$$\partial_t\Lambda = 0 \quad .$$

36.12.01.04 Kirchhoff Gauge

36.12.02
Scalar Potential of the ElectroMagnetic Fields

©|R.H. Romer - Am.J.Phys, , ..., ..., ...Ed., ... 50, 1089 (1982)|||

©|F.Reif - Am.J.Phys, , ..., ..., ...Ed., ... 50, 1048 (1982)|||

The **scalar electric potential** , Φ, allows to express the line-integral (along any open curve) of the irrotational field $\mathbf{E} + \partial_t \mathbf{A}$, that is the circulation, in terms of the potential at the boundary of the curve:

$$\Phi[B] - \Phi[A] = -\int_A^B \mathbf{E} \cdot \mathbb{d}\mathbf{L} - \int_A^B \partial_t \mathbf{A} \cdot \mathbb{d}\mathbf{L} \quad , \tag{36.12.08}$$

thanks to the **gradient theorem** .

The difference of potential is the same for all curves having the same extremes.

It must be emphasized that, in non static cases, the potential difference is not the line-integral of the electric field.

Therefore, in the general case, one must be very careful not to confuse between:

- difference of potential: $\Phi[B] - \Phi[A]$, for the conservative field Φ;
- the line integral for the electric field: $\int_A^B \mathbf{E} \cdot \mathbb{d}\mathbf{L}$.

Obviously: $\Phi[P] - \Phi[P] = 0$.

Note that, as for the static case, even if the **scalar electric potential** is not uniquely determined, the difference of potential calculated by means of the difference of its values is always well-defined.

36.12.03
Vector Potential of the ElectroMagnetic Fields

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|2.15||

The **vector magnetic potential** , $\mathbf{A}$, allows to express the surface-integral (across any open surface) of the solenoidal field $\mathbf{B}$, that is the flux, in terms of the line-integral the boundary of the surface:

$$\Phi_\Sigma \equiv \iint_\Sigma \mathbf{B} \cdot \mathbb{d}\mathbf{S} = \oint_{\partial\Sigma} \mathbf{A} \cdot \mathbb{d}\mathbf{L} \quad .$$

thanks to the **rotor theorem** .

The flux of the magnetic field is the same for all surfaces having the same boundary.

Note that, as for the static case, even if the **vector magnetic potential** is not uniquely determined, its circulation around any given closed curve is the same for all possible equivalent **vector magnetic potentials** .

DRAFT - LAY-PROGRESS

36.12.04
Other (Less Useful) Potentials

Vector Electric Potential

In certain cases it is possible to introduce a vector electric potential. A necessary and sufficient condition is that the scalar charge density $\rho[\mathbf{r}]$ is zero inside the 2-connected space region considered. An alternative necessary and sufficient condition is that the flux of the electric field is zero for all possible closed surfaces in the region.

This is the analogous of the magnetic vector potential. However, it has little interest in practice, because the use of the scalar potential is normally easier. It might be somewhat useful to solve ElectroStatics problems by analogy with known solutions of MagnetoStatics problems, read § 41.03.07.

Scalar Magnetic Potential

©|J.Franklin, *Classical ElectroMagnetism*, 2017, 2ndEd, ...Ed., WEB - URL.|§ 7.10|*Different expressions and discussions.*|

In certain cases it is possible to introduce a scalar magnetic potential. A necessary and sufficient condition is that the vector current density $\mathbf{j}[\mathbf{r}]$ is zero inside the 1-connected space region considered. An alternative necessary and sufficient condition is that the circulation of the magnetic field is zero for all possible closed loops in the region.

This is the analogous of the **scalar electric potential** It has a wide interest for calculations in presence of matter and permanent magnets only, read § 39. It might be also useful to solve MagnetoStatics problems by analogy with known solutions of ElectroStatics problems, read § 41.03.07.

36.12.05
Introducing the ElectroMagnetic Potentials Into Maxwell Equations

The second and 3rd **Maxwell Equations** have been used to introduce the **ElectroMagnetic potentials** . One still need to exploit the first and 4th **Maxwell Equations** , those containing the generators of the ElectroMagnetic fields. The introduction of the **ElectroMagnetic potentials** into the first and fourth of **Maxwell Equations** gives:

$$\boxed{\nabla^2\Phi + \partial_t \mathbf{div}\,\mathbf{A} = -\rho/\varepsilon_0} \tag{36.12.09}$$

→ 1734 1735 2220

$$\boxed{\boldsymbol{\nabla}^2\mathbf{A} - \varepsilon_0\mu_0\frac{\partial^2\mathbf{A}}{\partial t^2} - \mathbf{grad}(\mathbf{div}\,\mathbf{A} + \varepsilon_0\mu_0\partial_t\Phi) = -\mu_0\mathbf{j}} \; . \tag{36.12.10}$$

→ 1734 1735

The two equations (36.12.09), (36.12.10) are not decoupled. However, the gauge invariance freedom (read § 36.12.01) can be used to simplify the equations and decouple them, giving equations (49.01.01) and (49.01.02).

Note that **Maxwell Equations** contain two kind of generators of ElectroMagnetic fields: charges and currents. However, they are related by the charge continuity equation and, therefore, they are not truly independent. This explains why it is often possible to solve problems by only considering either charge only or current only as the generators of ElectroMagnetic fields. Actually, also points where $\partial_t\mathbf{E} \neq 0$ or $\partial_t\mathbf{B} \neq 0$ are vortexes, so they generate a rotor.

DRAFT - IN PROGRESS

36.12.06
ElectroMagnetic Potentials for Static ElectroMagnetic Fields

This § is referenced at pages:
[Never referenced.]

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||
©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|||

The use of the **ElectroMagnetic potentials** definitions (equations (36.12.01), (36.12), as well as equations (36.12.02), (36.12.03)) in **Maxwell Equations** gives, in the static case and either the Coulomb or Lorenz gauges, identical in this case, the **Poisson equations** (read § 49.01 and the two equations (36.12.09), (36.12.10)):

$$\boxed{\nabla^2\Phi = -\rho/\varepsilon_0} \quad , \tag{36.12.11}$$

→ 1736 1743

$$\boxed{\boldsymbol{\nabla}^2\mathbf{A} = -\mu_0\mathbf{j}} \quad . \tag{36.12.12}$$

→ 1736 1743

In absence of charges the **Poisson equations** reduce to **Laplace equations** :

$$\boxed{\nabla^2\Phi = 0} \quad , \tag{36.12.13}$$

$$\boxed{\boldsymbol{\nabla}^2\mathbf{A} = 0} \quad . \tag{36.12.14}$$

Scalar/vector field satisfying **Laplace equation** are said to be harmonic functions.

Note that **Poisson equations** were derived from the first and fourth Maxwell equations, those involving the Charge|Current producing the ElectroMagnetic fields. In fact the second and third equations do not contain Charge|Current, and the information from those two equations were used to introduce the concept of **ElectroMagnetic potentials** .

Note also that the **Poisson equations** have accomplished the decoupling of the Electric|Magnetic parts of **Maxwell Equations** which can be treated in an independent way.

The equation for the **vector magnetic potential** has the additional difficulty that, due to the **Coulomb/Lorenz Gauge** condition, the three components of the **vector magnetic potential** are not independent.

$$\boxed{\frac{\mathrm{d}(\mathcal{K} + q\Phi)}{\mathrm{d}t} = \frac{\partial(q\Phi - q\,\mathbf{v}\cdot\mathbf{A})}{\partial t}}$$

$$\boxed{\frac{\mathrm{d}(\mathbf{p} + q\mathbf{A})}{\mathrm{d}t} = -\mathbf{grad}(q\Phi - q\,\mathbf{v}\cdot\mathbf{A}) \qquad \text{the derivative does not act on } \mathbf{v}} \quad .$$

PREFLIGHT-PROGRESS

36.13 Static Solution for Limited Distribution of the Sources|Sinks

In the static case, Electric|Magnetic fields and charge|current are decoupled in equations (36.08.06), (36.08.07), (36.08.08), (36.08.02).

Assume there are **limited distribution of the Sources|Sinks**:

- different from zero only in a limited region of space (functions with compact support);
- the module of the functions are limited functions (no infinity).

In the **Coulomb/Lorenz Gauge** the solutions to **Poisson equations** , equations (36.12.11), (36.12.12), subject to the boundary conditions of zero at infinity,

$$\lim_{|\mathbf{x}|\longrightarrow\infty} \Phi[\mathbf{x}] = 0 \qquad \lim_{|\mathbf{x}|\longrightarrow\infty} |\mathbf{A}[\mathbf{x}]| = 0 \quad , \tag{36.13.01}$$

→ 1736

in the case when ρ or $\mathbf{j}$ are **limited distribution of the Sources|Sinks**, are:

$$\Phi[\mathbf{x}] = \frac{1}{4\pi\varepsilon_0}\iiint \frac{\rho[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}} \quad , \tag{36.13.02}$$

→ 1736 1743 2224

$$\mathbf{A}[\mathbf{x}] = \frac{\mu_0}{4\pi}\iiint \frac{\mathbf{j}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}} \quad . \tag{36.13.03}$$

→ 1736 1743 1776 1780 2224

The **scalar electric potential** and **vector magnetic potential** , even in the **Coulomb/Lorenz Gauge** , are defined to within a constant term as the gradient, divergence and rotor of a constant are null. This arbitrariness is removed by the condition (36.13.01) of zero at infinity.

The **scalar electric potential** and **vector magnetic potential** , from equations (36.13.02) and (36.13.03), are clearly continuous for any well-behaved charge/current density.

The above expression (36.13.03) for the **vector magnetic potential** must have zero divergence (Lorenz/Coulomb gauge in steady conditions), as it can be shown by direct calculation of the divergence and use of formula (16.12.01) for a steady current distribution, which is divergence-less.

It is worth noting that the expression for the **vector magnetic potential** implies that any infinitesimal current element gives a contribution to the **vector magnetic potential** parallel to the current element itself.

In case the Charge|Current densities can be modeled as surface or line distributions, in addition to volume distributions, the above relations, (36.13.02) and (36.13.03), can be written as follows.

From (z: depth, w width and ℓ: length):

$$\rho\,\mathrm{d}V \longrightarrow \rho\,\mathrm{d}z\,\mathrm{d}w\,\mathrm{d}L = (\rho\,\mathrm{d}z)\;\mathrm{d}w\,\mathrm{d}L = \rho_{\mathrm{S}}\,\mathrm{d}w\,\mathrm{d}L = (\rho_{\mathrm{S}}\,\mathrm{d}w)\;\mathrm{d}L = \rho_{\mathrm{S}}\,\mathrm{d}S = \rho_{\mathrm{L}}\,\mathrm{d}L \quad ,$$

one finds:

$$\Phi[\mathbf{x}] = \frac{1}{4\pi\varepsilon_0}\iiint \frac{\rho[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}} + \frac{1}{4\pi\varepsilon_0}\iint \frac{\rho_{\mathrm{S}}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}\mathbf{S}_y + \frac{1}{4\pi\varepsilon_0}\int \frac{\rho_{\mathrm{L}}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}L_y \quad . \tag{36.13.04}$$

→ 1743

From (z: depth, w width and ℓ: length):

$$\mathbf{j}\,\mathrm{d}V \longrightarrow \mathbf{j}\,\mathrm{d}z\,\mathrm{d}w\,\mathrm{d}L = (\mathbf{j}\,\mathrm{d}z)\;\mathrm{d}w\,\mathrm{d}L = \mathbf{j}_{\mathrm{S}}\,\mathrm{d}w\,\mathrm{d}L = (\mathbf{j}_{\mathrm{S}}\,\mathrm{d}w)\;\mathrm{d}L = \mathbf{j}_{\mathrm{S}}\,\mathrm{d}S = I\,\mathbf{dL} \equiv \mathbf{j}_{\mathrm{L}}\,\mathrm{d}L$$

$$\text{with} \qquad I\,\mathbf{dL} \equiv \mathbf{j}_{\mathrm{L}}\,\mathrm{d}L \quad , \tag{36.13.05}$$

one finds:

$$\mathbf{A}[\mathbf{x}] = \frac{\mu_0}{4\pi}\iiint \frac{\mathbf{j}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}V_{\mathbf{y}} + \frac{\mu_0}{4\pi}\iint \frac{\mathbf{j}_{\mathrm{S}}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}S_y + \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}_{\mathrm{L}}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\,\mathrm{d}L_y \quad . \tag{36.13.06}$$

→ 1743 1805

Note that in the above equations, the surfaces and curves may be open; clearly, charge conservation must be obeyed.

Moreover, the Charge|Current densities may be not given in advance, but can depend on the Electric|Magnetic field present in the neighborhood, which in turn, depend on the Charge|Current densities themselves.

See the analogous discussion for the gravitational **Multipole** development in section § 29.05. Read also section, § 36.14, § 36.14, § 36.14.06, § 36.14.07, § 29.05.04.

The following general results can be derived for static ElectroMagnetic fields when the stationary charges and steady currents are different from zero in a spatially-limited region of space only.

Assume that all the stationary charges and steady currents are inside a sphere of radius R, centered on the origin of a suitable Coordinate System, and observe the **ElectroMagnetic potentials** /fields from a point $\mathbf{r}$ at a very large distance with respect to R: $|\mathbf{r}| \gg R$.

Note that the non-static and/or higher than second order development includes in general other multipole types, namely the so-called polar/axial toroidal moments [1]

Read § 29.05.01 for the analogous development of the gravitational potential, which is identical to the one of the ElectroStatic potential and very similar, apart from the vector current density instead of a scalar function.

See [2], for more details.

36.14.01
Cartesian Multipoles

The following notation will be used: $r \equiv |\mathbf{r}|$ and $x \equiv |\mathbf{x}|$.

Let denote generically with $\underline{s}[\mathbf{x}]$, either the mass volume density (scalar), the charge volume density (scalar) or the current volume density (vector); let $\underline{\Phi}[\mathbf{r}]$ be the correspondent scalar or component of the vector potential.

$$\underline{s}[\mathbf{x}] = 0 \qquad |\mathbf{x}| \geq r_0 \quad ,$$
$$\lim_{r \longrightarrow \infty} \Phi[\mathbf{r}] = 0 \quad , \tag{36.14.01}$$

$$(1+w)^{-1/2} = 1 - \frac{1}{2}w + \frac{3}{8}w^2 + \mathcal{O}\left(w\right)^3 \qquad \text{convergent for } w < 1 \quad , \tag{36.14.02}$$

$$\Phi[\mathbf{r}] = K \iiint \frac{\underline{s}[\mathbf{x}]}{|\mathbf{r}-\mathbf{x}|}\, \mathrm{d}V_{\mathbf{x}} = K \iiint \frac{\underline{s}[\mathbf{x}]}{\sqrt{r^2 + x^2 - 2\,\mathbf{r}\cdot\mathbf{x}}}\, \mathrm{d}V_{\mathbf{x}} = \quad ,$$

$$K \iiint \frac{\underline{s}[\mathbf{x}]}{r} \left(1 - 2\frac{\mathbf{r}\cdot\mathbf{x}}{r^2} + \frac{x^2}{r^2}\right)^{-1/2} \mathrm{d}\mathbf{x} = \quad ,$$

$$K \iiint \frac{\underline{s}[\mathbf{x}]}{r} \left(1 + \frac{\mathbf{r}\cdot\mathbf{x}}{r^2} + \frac{3}{2}\left(\frac{\mathbf{r}\cdot\mathbf{x}}{r^2}\right)^2 - \frac{x^2}{2r^2} + \mathcal{O}\left(\frac{x}{r}\right)^3\right) \mathrm{d}V_{\mathbf{x}} \quad ,$$

$$\Phi[\mathbf{r}] = \Phi_0[\mathbf{r}] + \Phi_1[\mathbf{r}] + \Phi_2[\mathbf{r}] + \mathcal{O}\left(\frac{r_0}{r}\right)^3 \quad . \tag{36.14.03}$$

The problem of the convergence of the series expansion is not discussed here.

36.14.02
Monopole Terms

Electric monopole term:

$$\boxed{\Phi[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\frac{q}{r} + \mathcal{O}\left(\frac{1}{r}\right)^2 \qquad \lim_{|\mathbf{r}|\to\infty} |\Phi|[\mathbf{r}] = 0} \quad . \tag{36.14.04}$$

Magnetic Monopole term:

$$\boxed{\mathbf{A}[\mathbf{r}] = \mathbf{0} + \mathcal{O}\left(\frac{1}{r}\right)^2 \qquad \lim_{|\mathbf{r}|\to\infty} |\mathbf{A}|[\mathbf{r}] = 0} \quad . \tag{36.14.05}$$

In the magnetic case the monopole terms is always zero, as there is no magnetic monopole. Mathematically, the volume integral of a space-limited stationary current distribution is zero, read § 36.20.48.

DRAFT-IN-PROGRESS

36.14.03
Electric|Magnetic Dipole terms

Read § 36.14.04, § 36.14.05 for discussion on quadruple moments.

36.14.03.01 Electric Dipole term

The dipole term is straightforward from equation 36.14.01 for the electric case.

Define the **Electric Dipole** moment:

$$\boxed{\mathbf{p} \equiv \iiint \rho \mathbf{x} \, \mathrm{d}V \longrightarrow \quad \text{for point charges} \quad = \sum_k q_k \mathbf{r}_k} \quad . \tag{36.14.06}$$

→ 1087 1781 1842

Read § 36.20.52: the **Electric Dipole** moment is independent of the origin of the Coordinate System as long as the total charge is zero.

The development, to first-order in $|\mathbf{r}|/R$, of the **scalar electric potential** at large distance, $|\mathbf{r}| \gg R$, for the spatially-limited stationary charge density gives:

$$\boxed{\Phi[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{p}\cdot\mathbf{r}}{r^3} + \mathcal{O}\left(\frac{1}{r}\right)^3 \qquad \lim_{|\mathbf{r}|\to\infty} |\Phi|[\mathbf{r}] = 0} \quad . \tag{36.14.07}$$

This development has the monopole and **Dipole** terms, the higher-order terms have been omitted.

Read § 36-018 for an example of electric field at large distance.

An **order-of-magnitude estimate** for the **Electric Dipole** moment is: $|\mathbf{p}| \approx QD$.

36.14.03.02 Scalar Potential of Two Equal Opposite Point Charges at Large Distances

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|||

Consider two equal and opposite charges, $\pm|q|$, located at $Q_\pm = \{0, 0, \pm d/2\}$ in a orthonormal Cartesian Coordinates Coordinate System. Consider a point $P = \{x, y, z\}$ located at distance r for the origin with a polar angle θ with respect to the z axis ($\cos[\theta] = z/r$). Let $r_\pm$ the distances between P and the two charges. At large distances with respect to the distance between the two charges one can find:

$$r_\pm \gg d \implies \Phi = \frac{1}{4\pi\varepsilon_0}|q|\left(\frac{1}{r_+} - \frac{1}{r_-}\right) \simeq \frac{1}{4\pi\varepsilon_0}|q|\frac{d\cos[\theta]}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{p}\cdot\mathbf{r}}{r^3} \qquad \text{with } \mathbf{p} = q\,(\mathbf{r}_+ - \mathbf{r}_-) = q\mathbf{d} \quad .$$

36.14.03.03 Magnetic Dipole term

The magnetic dipole term from equation 36.14.01 requires some rewriting.

$$\begin{aligned}
&\underline{s}[\mathbf{x}] \longrightarrow \mathbf{j}[\mathbf{x}] \quad , \\
&\frac{K}{r^3}\iiint \mathbf{j}[\mathbf{x}]\,(\mathbf{r}\cdot\mathbf{x})\;\mathrm{d}V_\mathbf{x} = \quad , \\
\longrightarrow (1) \qquad &\text{line circuit} \qquad = \frac{IK}{r^3}\oint (\mathbf{r}\cdot\mathbf{x})\;\mathrm{d}\mathbf{L} = \frac{K}{r^3}\mathbf{r}\wedge I\iint \mathrm{d}\mathbf{S} \quad , \\
\longrightarrow (2) \qquad &= \text{volume} \qquad \frac{K}{r^3}\mathbf{r}\wedge\iiint\left(\frac{\mathbf{x}\wedge\mathbf{j}}{2}\right)\mathrm{d}V_\mathbf{x} \quad ,
\end{aligned} \tag{36.14.08}$$

where the passage (1) comes from equation (16.07.08) and (16.13.06) the passage (2) comes from the properties of a stationary current [1].

Read § 36.14.03.04 a different derivation for a plane loop.

Define the **Magnetic Dipole** moment:

$$\boxed{\mathbf{m} \equiv \frac{1}{2}\iiint (\mathbf{x}\wedge\mathbf{j})\;\mathrm{d}V \longrightarrow \quad \text{for wire current loops} \quad = \sum_k I_k \mathbf{S}_k} \quad . \tag{36.14.09}$$

→ 1087 1780 1781 1884

[1] See J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...

UNDER IN PROGRESS

Read § 36.20.52: the **Magnetic Dipole** moment is independent of the origin of the Coordinate System as long as the current distribution has zero integral which is always the case for limited and steady current distribution, read § 16.12.07 and equation (16.12.03).

The development, to first-order in $|\mathbf{r}|/R$, of the **vector magnetic potential** at large distance, $|\mathbf{r}| \gg R$, for spatially-limited steady current density:

$$\mathbf{A}[\mathbf{r}] = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\wedge\mathbf{r}}{r^3} + \mathcal{O}\left(\frac{1}{r}\right)^3 \qquad \lim_{|\mathbf{r}|\to\infty} |\mathbf{A}|[\mathbf{r}] = 0 \quad . \tag{36.14.10}$$

The higher-order terms have been omitted.

Read § 36-025 for an example of magnetic field at large distance.

An **order-of-magnitude estimate** for the **Magnetic Dipole** moment is: $|\mathbf{m}| \approx IA$.

36.14.03.04 Vector Potential of a Plane Stationary Current Loop at Large Distances

This § is referenced at pages:
[1739]

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...||*The ...*

Consider a plane current loop, made of a thin wire, described by the area vector $\mathbf{S}$ and diameter of the order of $d \approx \sqrt{S}$. At large distances with respect to the linear dimensions of the plane circuit it is possible to show that:

$$r \gg d \implies \mathbf{A} = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\wedge\mathbf{r}}{r^3} \qquad \text{with } \mathbf{m} = I\mathbf{S} \quad .$$

Consider the plane loop in the xy plane, with origin inside the loop (for simplicity of the geometry only, read § 36.20.52) and look for the potential at $P = \{0, y > 0, z > 0\}$, at a **distance large with respect to the linear dimensions of the plane circuit**. The constant current is $I > 0$ running counterclockwise, positive according to the usual conventions.

Note that, ***large distance*, implies that all directions from any current loop element to the observation point are treated as parallel, in the three dimensions.**

The line integral of the current can be split in its x and y components. As there is no z component in the integral, we know that $\hat{\mathbf{e}}_3 \cdot \mathbf{A} = 0$.

The x component is equal to the integral along the full range in x of the pairs of elements at $\{x, y_+\}$ and $\{x, y_-\}$, bringing to the result two contributions of opposite sign whose difference is

$$\propto \Delta r/r^2 \simeq \sin\theta\,(|y_+| + |y_-|)\,/r^2 \quad , \tag{36.14.11}$$

because in this approximation the two distances are measured from parallel lines in a plane at the fixed x, $\sin\theta$ is fixed and r is the distance of P from the loop. Finally, the resulting integral is:

$$\frac{\sin\theta}{r^2}\int_{x_{min}}^{x_{max}} (|y_+| + |y_-|)\ \mathrm{d}x = \frac{\sin\theta}{r^2}[\text{loop surface area}] \equiv \frac{A\sin\theta}{r^2} \tag{36.14.12}$$

and negative.

The y component is the integral along the full range in y of the pairs of elements at $\{x_+, y\}$ and $\{x_-, y\}$, which have opposite sign and same distance because in this approximation the two distances are measured from parallel lines in the plane containing $\{x_+, y\}$, $\{x_-, y\}$ and P.

Therefore:

$$\mathbf{A}[0, y, z] = \frac{\mu_0}{4\pi}\left\{-\frac{IA\sin\theta}{r^2}, 0, 0\right\} = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\wedge\mathbf{r}}{r^3} \qquad \text{in the chosen Coordinate System} \quad .$$

As the vector equation is valid in a specific Coordinate System, we know it is a valid equation in general, thanks to the **Principle of Covariance** , read § 20.03.06:

$$\mathbf{A}[0, y, z] = \frac{\mu_0}{4\pi}\left\{-\frac{IA\sin\theta}{r^2}, 0, 0\right\} \longrightarrow \mathbf{A}[\mathbf{r}] = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\wedge\mathbf{r}}{r^3} \quad .$$

DRAFT - IN-PROGRESS

36.15 Summary of ElectroStatics and MagnetoStatics

- Stationary charges give constant electric fields: ElectroStatics.
- Steady currents give constant magnetic fields: MagnetoStatics.

The relations (36.13.04), (36.13.06) allows to calculate the electric and magnetic fields from equations (36.12.01), (36.12) taken in static conditions:

$$\boxed{\mathbf{div}\mathbf{B}=0 \implies \mathbf{B}=+\mathbf{rot}\mathbf{A}} \quad , \qquad \boxed{\mathbf{rot}\mathbf{E}=0 \implies \mathbf{E}=-\mathbf{grad}\Phi} \quad . \tag{36.15.01}$$

Gauge invariance is obviously effective.

36.16 Discontinuities at a surface

This § is referenced at pages:
[1723, 1735]

©|V.Namias|Am.J.Phys, , ..., ..., ...Ed., ... 56, 898 (1988) - doi: 10.1119/1.15406|*Definitive!*|

The discontinuities for the **ElectroMagnetic potentials** ($c = 1$) read:

$$\boxed{\hat{\mathbf{n}} \wedge \Delta \mathbf{A} = \mathbf{0} \qquad \hat{\mathbf{n}} \Delta \Phi - (\mathbf{v} \cdot \hat{\mathbf{n}}) \, \Delta \mathbf{A} = \mathbf{0}} \quad . \tag{36.16.01}$$

→ 1744

In the **Lorenz Gauge** one finds:

$$\boxed{\hat{\mathbf{n}} \wedge \Delta \mathbf{A} - (\mathbf{v} \cdot \hat{\mathbf{n}}) \, \Delta \Phi = 0} \quad . \tag{36.16.02}$$

→ 1744

The condition deriving from the **Lorenz Gauge** (36.16.02) when combined with the general condition for the potentials (36.16.01) gives:

$$\boxed{\Delta \Phi = 0 \qquad \hat{\mathbf{n}} \wedge \Delta \mathbf{A} = \mathbf{0}} \quad . \tag{36.16.03}$$

Read § 36.16.03.

Discontinuities of the Fields and Potentials at Moving Surfaces

This § is referenced at pages:
[2233]

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|Introduction||

©|M.Born & E.Wolf, *Principles Of Optics*, 1986, CUP, 6thEd., ...|Appendix 6|*Moving surfaces.*|

©|V.Namias|Am.J.Phys, , ..., ..., ...Ed., ... 56, 898 (1988) - doi: 10.1119/1.15406|*Definitive!*|

The equation for discontinuities deriving from the divergence equations apply equally to moving surface, while the ones from the rotor equations needs to be modified, as it is clear from the fact that the latter equations involve time derivatives.

Read § 36.16.03.

36.16.02.01 Normal Components

The equations for the discontinuity of the normal components, equations (36.09.01), (36.09.02), are valid for surfaces in motion too, provided the surface charge density for the electric case is the one seen in the laboratory system.

36.16.02.02 Tangential Components

The equations for the discontinuity of the tangential components, must be modified, in the case of moving surfaces, and assume a more complex form depending on the velocity, $\mathbf{v}$, of the moving surface.

The discontinuity for the tangential component of the electric fields becomes:

$$\boxed{\hat{\mathbf{n}}\wedge\Delta\mathbf{E} - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\mathbf{B} = \mathbf{0}} \quad . \tag{36.16.04}$$

The discontinuity for the tangential component of the magnetic fields becomes:

$$\boxed{\hat{\mathbf{n}}\wedge\Delta\mathbf{B} + \varepsilon_0\mu_0\,(\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\mathbf{E} = \mu_0\mathbf{j}_S} \quad . \tag{36.16.05}$$

These two equations imply the necessary condition:

$$\boxed{\hat{\mathbf{n}}\cdot\mathbf{j}_S - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\rho_S = 0} \quad . \tag{36.16.06}$$

36.16.03
Summary of EM discontinuities

This § is referenced at pages:
[1719, 1735, 1744, 1745]

$$c = 1 \quad , \tag{36.16.06}$$

$$\hat{\mathbf{n}}\wedge\Delta\mathbf{E} - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\mathbf{B} = 0 \quad , \tag{36.16.07}$$

$$\hat{\mathbf{n}}\wedge\Delta\mathbf{H} - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\mathbf{D} = \mathbf{j}_S \quad , \tag{36.16.08}$$

$$(\mathbf{v}\cdot\mathbf{j}_S) - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\rho_S = 0 \quad , \tag{36.16.09}$$

$$\hat{\mathbf{n}}\Delta\Phi - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\mathbf{A} = 0 \quad \Leftrightarrow \quad \Delta\Phi - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\hat{\mathbf{n}}\cdot\Delta\mathbf{A} = 0 \quad , \tag{36.16.10}$$

$$\hat{\mathbf{n}}\cdot\Delta\mathbf{A} - (\mathbf{v}\cdot\hat{\mathbf{n}})\,\Delta\Phi = 0 \quad \text{from the Lorenz gauge condition} \quad , \tag{36.16.11}$$

$$\Delta\Phi = 0 \quad \hat{\mathbf{n}}\cdot\Delta\mathbf{A} = 0 \quad \text{from the last two equations} \quad . \tag{36.16.12}$$

In the Lorentz gauge both **ElectroMagnetic potentials** are continuous also for moving surfaces.

For charge/current discontinuities at moving boundaries see the references.

(*a*) The order of symbols for base units in this Table is different from that in the 8th edition following a decision by the CCU at its 21st meeting (2013) to return to the original order in Resolution 12 of the 11th CGPM (1960) in which newton was written kg m s^{-2}, the joule as kg m^2 s^{-2} and J s as kg m^{-2} s^{-1}. The intention was to reflect the underlying physics of the corresponding quantity equations although for some more complex derived units this may not be possible.

(*b*) The radian is the coherent unit for plane angle. One radian is the angle subtended at the center of a circle by an arc that is equal in length to the radius. It is also the unit for phase angle. For periodic phenomena, the phase angle increases by 2π rad in one period. The radian was formerly an SI supplementary unit, but this category was abolished in 1995.

(*c*) The steradian is the coherent unit for solid angle. One steradian is the solid angle subtended at the center of a sphere by an area of the surface that is equal to the squared radius. Like the radian, the steradian was formerly an SI supplementary unit.

(*d*) The hertz shall only be used for periodic phenomena and the becquerel shall only be used for stochastic processes in activity referred to a radionuclide.

(*e*) Electric potential difference is also called “voltage” in the United States and in many countries, as well as “electric tension” or simply “tension” in some countries.

(*f*) The degree Celsius is used to express Celsius temperatures. The numerical value of a temperature difference or temperature interval is the same when expressed in either degrees Celsius or in kelvin.

(*g*) In photometry the name steradian and the symbol sr are usually retained in expressions for units

(*h*) Activity referred to a radionuclide is sometimes incorrectly called radioactivity.

(*i*) See CIPM Recommendation 2 on the use of the sievert (PV, 2002, **70**, 205).

The seven base units and 22 units with special names and symbols may be used in combination to express the units of other derived quantities. Since the number of quantities is without limit, it is not possible to provide a complete list of derived quantities and derived units. Table 5 lists some examples of derived quantities and the corresponding coherent derived units expressed in terms of base units. In addition, Table 6 lists examples of coherent derived units whose names and symbols also include derived units. The complete set of SI units includes both the coherent set and the multiples and sub-multiples formed by using the SI prefixes.

This publication is available free of charge from: https://doi.org/10.6028/NIST.SP.330-2019

36.20.02
Hypothetical Magnetic Charges and Currents

Consider an hypothetical world where Magnetic Charges and Currents exist.

This introduction will remove the asymmetry in **Maxwell Equations** : Electric Charges generate the **E** field while Electric Currents generate the **B** field; Magnetic Charges generate the **B** field while Magnetic Currents generate the **E** field.

1. Rewrite **Maxwell Equations** to account for Magnetic Charges and Currents by exploiting the parallel between Electric Charges, Currents and Electric Fields versus Magnetic Charges, Currents and Magnetic Fields.

36.20.03
Average EM Fields

36.20.03.01 Average Electric Fields

This § is referenced at pages:
[1714]

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|4.1||

It can be shown that, given a stationary charge distribution, the average value of the electric field over a spherical volume of radius R, centered at $\mathbf{r}_0$, is:

$$\iiint_{r\le R} \mathbf{E}[\mathbf{x}]\, \mathrm{d}V_{\mathbf{x}} = -\frac{1}{3\varepsilon_0}\mathbf{p}$$ if the sphere encloses all the charges ,

$$\iiint_{r\le R} \mathbf{E}[\mathbf{x}]\, \mathrm{d}V_{\mathbf{x}} = \frac{4\pi R^3}{3}\mathbf{E}[\mathbf{r}_0]$$ if the sphere is external to all the charges .

36.20.03.02 Average Magnetic Fields

It can be shown that, given a steady current distribution, the average value of the magnetic field over a spherical volume of radius R, centered at $\mathbf{r}_0$, is:

$$\iiint_{r\le R} \mathbf{B}[\mathbf{x}]\, \mathrm{d}V_{\mathbf{x}} = \frac{2\mu_0}{3}\mathbf{m}$$ if the sphere encloses all the currents ,

$$\iiint_{r\le R} \mathbf{B}[\mathbf{x}]\, \mathrm{d}V_{\mathbf{x}} = \frac{4\pi R^3}{3}\mathbf{B}[\mathbf{r}_0]$$ if the sphere is external to all the currents .

PREFINAL-PROGETTI

36.20.04
Static Charge Density at the Surface of a Conductor

©|J.D.Jackson, *Classical Electrodynamics*, 1999, J.Wiley & Sons, 3rdEd., ...|problem 1.11||

Use Gauss law to prove that at the surface of a curved charged conductor, the normal derivative of the electric field, under static conditions, is given by:

$$\frac{1}{E}\frac{\partial E}{\partial n} = -\left(\frac{1}{R_1}+\frac{1}{R_2}\right) \quad .$$

where R_1 and R_2 are the principal radii of curvature of the surface.

36.20.05
☒ Infinite Uniformly Charged Plane

This § is referenced at pages:
[1787]

Let ρ_S be the uniform surface charge density and $\hat{\mathbf{n}}$ the unit vector normal to the plane, with an arbitrary orientation, from semi-space (1) to semi-space (2). It can be shown that electric fields on the two sides are given by:

$$\mathbf{E}_2 = +\frac{\rho_S}{2\varepsilon_0}\hat{\mathbf{n}} \qquad \mathbf{E}_1 = -\frac{\rho_S}{2\varepsilon_0}\hat{\mathbf{n}} \quad .$$

The law for the discontinuity of the normal components of $\mathbf{E}$ apply.

By symmetry and charges location the electric field is normal to the plane. The orientation of the electric field must be opposite on the two sides; in fact when rotating the plane by π around any axis in the plane the orientation of the electric field after rotation must be the same as before, as the charge density is unchanged.

The direction of the field can be also determined by the Coulomb law (36.06).

Gauss law immediately implies that the field does not depend on the distance from the plane.

Do the calculation by direct integration from Coulomb law and **superposition principle** .

36.20.06
☒ Infinite Uniform Current Plane

This § is referenced at pages:
[1787, 2253, 2253]

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|E5.8||

Let $\mathbf{j}_S$ be the uniform surface current density and $\hat{\mathbf{n}}$ the unit vector normal to the plane, with an arbitrary orientation, from semi-space (1) to semi-space (2). It can be shown that magnetic fields on the two sides are given by:

$$\mathbf{B}_2 = +\frac{\mu_0}{2}\mathbf{j}_S \wedge \hat{\mathbf{n}} \qquad \mathbf{B}_1 = -\frac{\mu_0}{2}\mathbf{j}_S \wedge \hat{\mathbf{n}} \quad .$$

The law for the discontinuity of the tangential components of $\mathbf{B}$ apply.

The field cannot be perpendicular to the plane. In fact, a perpendicular field with the same orientation on the two sides is ruled out by the argument that when rotating the plane by π around any axis in the plane parallel to $\mathbf{j}_S$ the orientation of the magnetic field after rotation must be the same as before, as the current density is unchanged. Moreover, a perpendicular field with opposite orientations on the two sides is ruled out by the argument that it violates Gauss law for magnetism for any surface crossing the plane.

It can be shown that, by symmetry and currents location, the magnetic field is parallel to the plane and perpendicular to $\mathbf{j}_S$, with opposite orientation on the two sides of the plane.

DRAFT IN PROGRESS

The direction of the field can be also determined by the Biot-Savart law (36.06). In fact every strip of current of infinite length and infinitesimal width parallel to $\mathbf{j}_S$ gives rise to a magnetic field perpendicular to $\mathbf{j}_S$. Moreover, for every point there are infinite pairs of strips at the same distance and opposite sides whose contributions perpendicular to the plane cancel.

Ampère law immediately implies that the field does not depend on the distance from the plane.

Do the calculation by direct integration from Biot-Savart law and **superposition principle** .

36.20.07

☒ Plane double layer of opposite charges

Consider two parallel planes, charged with uniform surface charges of opposite sign, $\pm|\rho_S|$, and separated by a distance d.

1. Determine the scalar electric potential as a function of the distance from the middle of the two planes.

36.20.08

☒ ElectroStatic Pressure

©|W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...|||

An application of the **superposition principle** .

Free charges at equilibrium locate at the surface of a conductor. Therefore an ElectroStatic pressure acts on free charges at the surface. As the macroscopic field external to the conductor is normally much smaller that the microscopic fields preventing the escape of the free charges this ElectroStatic pressure is actually transmitted to the material medium which is the support of the free charges.

It can be calculated by application of the **superposition principle** , by considering the force on an infinitesimal piece of surface.

Consider the plane surface with a surface charge density ρ_S and let the unit vector from side 1 to side 2 be $\hat{\mathbf{n}}$ and the electric fields on the two sides be $\mathbf{E}_1$ and $\mathbf{E}_2$. Assume $(\mathbf{E}_1 \parallel \mathbf{E}_2) \parallel \hat{\mathbf{n}}$. In fact in order to calculate the pressure, that is the force normal to the surface, only the components of $\mathbf{E}$ perpendicular to the surface contribute, thanks to the functional form of the Lorentz force.

In the most general case, when the direction of the fields are arbitrary, it is necessary to use the **Maxwell stress tensor** to determine all the forces [1].

Consider a small piece of surface and the field felt by its charges. Take a piece of surface of size D, much smaller that the absolute values of the two radii of curvature of the surface at the point:

$$D \ll |\rho_1| \qquad \text{and} \qquad D \ll |\rho_2| \quad ,$$

so that it can be considered plane.

The field felt by the small piece of surface $\mathrm{d}\mathbf{S}$ is given by the field generated by all other charges and it is given by:

$$\mathbf{E} = \frac{\mathbf{E}_1 + \mathbf{E}_2}{2} \parallel \hat{\mathbf{n}} \quad ,$$

as it is ready shown by using the **superposition principle** .

First note that $\mathbf{E}$ is continuous inside the hole left when ideally removing $\mathrm{d}\mathbf{S}$.

[1] W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...

DRAFT - IN PROGRESS

$$\mathbf{E}_{\text{hole}} + \mathbf{E}_{\text{by } \mathbb{d}\mathbf{S}\text{into2}} = \mathbf{E}_{\text{hole}} + \frac{\rho_S}{2\varepsilon_0} = \mathbf{E}_2 \quad ,$$

$$\mathbf{E}_{\text{hole}} + \mathbf{E}_{\text{by } \mathbb{d}\mathbf{S}\text{into1}} = \mathbf{E}_{\text{hole}} - \frac{\rho_S}{2\varepsilon_0} = \mathbf{E}_1 \quad ,$$

$$\Longrightarrow \mathbf{E}_{\text{hole}} = \frac{\mathbf{E}_2 + \mathbf{E}_1}{2} \quad ,$$

$$\Longrightarrow \mathbf{E}_{\text{by } \mathbb{d}\mathbf{S}\text{into2}} - \mathbf{E}_{\text{by } \mathbb{d}\mathbf{S}\text{into1}} = \mathbf{E}_2 - \mathbf{E}_1 \quad .$$

The force acting on the small piece of surface $\mathbb{d}S$ is thus:

$$\mathbb{d}\mathbf{f} = \rho_S \frac{\mathbf{E}_1 + \mathbf{E}_2}{2} \mathbb{d}S = \varepsilon_0 \left(E_2 - E_1\right) \frac{E_1 + E_2}{2} \hat{\mathbf{n}} \, \mathbb{d}S = \varepsilon_0 \frac{\left(E_2^2 - E_1^2\right)}{2} \hat{\mathbf{n}} \, \mathbb{d}S \quad .$$

The ElectroStatic pressure is thus:

$$\boxed{p_E = \varepsilon_0 \frac{\left(E_2^2 - E_1^2\right)}{2} \qquad \text{force directed from side 1 to side 2}} \quad . \tag{36.20.01}$$

→ 1759

It is thus given by the difference of the energy densities on the two sides.

Note the inverted sign with respect to equation (36.20.02). Note also that the force is directed along the normal to the surface, as in equation equation (36.20.02), which is parallel to the electric field, at variance with respect to equation (36.20.02).

It is important to stress that, in order to calculate the force acting on a small piece of surface charge, the ElectroStatic field produced by all the other charges must be used, excluding the contribution to the field by the small piece of surface charge itself.

36.20.09

☒ MagnetoStatic Pressure

©|W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...|||

An application of the **superposition principle** .

It can be calculated by application of the **superposition principle** , by considering the force acting on a strip of current of infinite length and infinitesimal width parallel to $\mathbf{j}_S$.

Consider a plane surface with a surface current density $\mathbf{j}_S$ and let the unit vector from side 1 to side 2 be $\hat{\mathbf{n}}$ and the magnetic fields on the two sides be $\mathbf{B}_1$ and $\mathbf{B}_2$.

Take a piece of surface of size D, much smaller that the absolute values of the two radii of curvature of the surface at the point:

$$D \ll |\rho_1| \qquad \text{and} \qquad D \ll |\rho_2| \quad ,$$

so that it can be considered plane.

Assume $(\mathbf{B}_1 \parallel \mathbf{B}_2) \perp \hat{\mathbf{n}}$ and $(\mathbf{B}_1 \parallel \mathbf{B}_2) \perp \mathbf{j}_S$.

In fact in order to calculate the pressure, that is the force normal to the surface, only the components of $\mathbf{B}$ perpendicular to $\mathbf{j}_S$ give a non-zero contribution and only the components parallel to the surface contribute to the pressure, thanks to the functional form of the Lorentz force.

In the most general case, when the direction of the fields are arbitrary, it is necessary to use the **Maxwell stress tensor** to determine all the forces [1].

Consider a small strip of surface, along the surface current, and the field felt by its currents. The field felt by the small strip of surface is given by the field generated by all other currents and it is given by:

$$\mathbf{B} = \frac{\mathbf{B}_1 + \mathbf{B}_2}{2} \perp \hat{\mathbf{n}} \quad ,$$

as it is readily shown by using the **superposition principle** .

[1] W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...

DRAFT-NOT-IN-PROGRESS

Similarly to the case of ElectroStatic pressure one can determine the MagnetoStatic pressure:

$$p_B = \frac{(B_1^2 - B_2^2)}{2\mu_0} \qquad \text{force directed from side 1 to side 2} \quad . \tag{36.20.02}$$

→ 1758

It is thus given by the difference of the energy densities on the two sides.

Note the inverted sign with respect to equation (36.20.01). Note also that the force is directed along the normal to the surface, as in equation equation (36.20.01), which is perpendicular to the magnetic field, at variance with respect to equation (36.20.01).

It is important to stress that, in order to calculate the force acting on a small piece of surface current, the MagnetoStatics field produced by all the other currents must be used, excluding the contribution to the field by the small piece of surface current itself.

36.20.10

☒ Dipole Interactions: Internal Forces Between a Pair of Rigid Dipoles

This § is referenced at pages:
[1309, 1309, 1760, 1761]

Consider two ideal **Electric Dipoles** , $\mathbf{p}$ and $\mathbf{p}_0$, and find the internal forces of the system.

WORKED SOLUTION

The following properties of **Dipole** fields and interactions are exemplified for electric fields and Dipoles but are obviously equally valid for magnetic fields and **Dipoles** .

The electric potential produced at $\mathbf{r}$ by an **Electric Dipole** $\mathbf{p}_0$ located at the origin is, from equation (16.12.05):

$$\Phi[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(\frac{\mathbf{p}_0\cdot\mathbf{r}}{r^3}\right) \quad .$$

From this expression the electric field can be easily obtained by differentiation:

$$\mathbf{E}[\mathbf{r}] = -\mathbf{grad}\Phi[\mathbf{r}] \implies E_k[\mathbf{r}] = -\frac{\partial}{\partial x^k}\Phi[\mathbf{r}] = -\frac{1}{4\pi\varepsilon_0}\frac{\partial}{\partial x^k}\left(\frac{p_j x_j}{r^3}\right) \quad .$$

The result is (equation (36.07.01)):

$$\mathbf{E}[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(3\frac{(\mathbf{p}_0\cdot\mathbf{r})}{r^5}\mathbf{r} - \frac{\mathbf{p}_0}{r^3}\right) \quad . \tag{36.20.03}$$

Locate a second **Dipole** $\mathbf{p}$ at $\mathbf{r}$.

The electric field generated by the second **Dipole** at the origin (the location of the first **Dipole**) can be obtained by changing $\mathbf{r} \longrightarrow \mathbf{r}' = -\mathbf{r}$, (which does not make any change) and using the **Dipole** $\mathbf{p}$ as a Sources | Sinks:

$$\mathbf{E}_0[\mathbf{r}] = \frac{1}{4\pi\varepsilon_0}\left(3\frac{(\mathbf{p}\cdot\mathbf{r})}{r^5}\mathbf{r} - \frac{\mathbf{p}}{r^3}\right) \quad . \tag{36.20.04}$$

The interaction energy can be calculated from equation (41.05.04) as:

$$\Phi = \Phi[r,\theta] = -\,\mathbf{p}\cdot\mathbf{E} \quad . \tag{36.20.05}$$

→ 1760

The force on the second **Dipole** due to the field of the first **Dipole** is given by:

$$\mathbf{f} = -\mathbf{grad}\Phi = \mathbf{grad}[\,\mathbf{p}\cdot\mathbf{E}] \implies f_k = \frac{\partial}{\partial x^k}(p_j E_j) \quad .$$

One finds:

$$\mathbf{f}[\mathbf{r}] = 3\frac{1}{4\pi\varepsilon_0}\left(\frac{\mathbf{p}_0\,(\mathbf{p}\cdot\mathbf{r}) + \mathbf{p}\,(\mathbf{p}_0\cdot\mathbf{r})}{r^5} - 5\frac{\mathbf{r}\,(\mathbf{p}\cdot\mathbf{r})\,(\mathbf{p}_0\cdot\mathbf{r})}{r^7} + \frac{\mathbf{r}\,(\mathbf{p}\cdot\mathbf{p}_0)}{r^5}\right) \tag{36.20.06}$$

CC BY NC ND

This force is clearly non-central. The two last terms are purely radial, while the first one has, in general, both a radial and a transverse part.
The force is symmetrical over the two **Dipoles** .
The force on the first **Dipole** due to the field of the second **Dipole** can be obtained by changing $\mathbf{r} \longrightarrow \mathbf{r}' = -\mathbf{r}$, causing the change of sign of the force (because $\mathbf{r}$ appears an odd number of times at the numerator):

$$\mathbf{f}_0[\mathbf{r}'] = -\mathbf{f}[\mathbf{r}] \quad .$$

36.20.11
☒ Dipole Interactions: Internal Torques Between a Pair of Rigid Dipoles

This § is referenced at pages:
[1309, 1309, 1761]

Consider two ideal **Electric Dipoles** , $\mathbf{p}$ and $\mathbf{p}_0$, and find the internal forces of the system.
Show that the force between the **Dipoles** is not radial, that is it is not necessarily directed along the line joining the centers of the two **Dipoles** . How does this compare with the expression of Newton third law?
Show that the internal torques sum to zero and that this is valid for any choice of the pole.

WORKED SOLUTION

Refer to problem § 36.20.10 for notations ad setup.
The torque acting on the second **Dipole** with respect to the pole $\mathbf{r}$ can be readily obtained from equation (36.20.05) as follows.
The interaction energy at a fixed point only depends on the angle between the **Dipole** moment and the electric field at the point, θ. In terms of θ one can write:

$$\delta\Phi \ = +Ep\sin[\theta]\ \delta\theta \quad ,$$

showing that the module of the torque is:

$$|\boldsymbol{\gamma}| = Ep\sin[\theta] \quad .$$

The direction is determined by noting that in order to have a torque tending to align the **Dipole** with the field, is it is required by minimizing the potential energy, the torque must be perpendicular to both $\mathbf{p}$ and $\mathbf{E}$, as it is required for a torque tending to align by rotation $\mathbf{p}$ towards $\mathbf{E}$. The orientation of the torque is determined by checking the right-hand rule to find that the correct sign is given by the expression:

$$\boldsymbol{\gamma} = \mathbf{p}\wedge\mathbf{E} \quad .$$

In an equivalent formal way the torque acting on the second **Dipole** with respect to the pole $\mathbf{r}$ can be readily obtained from equation (36.20.05) by varying $\mathbf{p}$ while keeping fixed both $\mathbf{r}$ and $\mathbf{p}_0$:

$$\delta\Phi \ = -\mathbf{E}\cdot\delta\mathbf{p} \ = -\mathbf{E}\cdot(\ \delta\boldsymbol{\theta}\wedge\mathbf{p}) = -\ \delta\boldsymbol{\theta}\cdot(\mathbf{p}\wedge\mathbf{E}) \Longrightarrow \boldsymbol{\gamma} = \mathbf{p}\wedge\mathbf{E} \quad .$$

The torque acting on the first **Dipole** with respect to the origin as a pole $\mathbf{r}$ can be readily obtained from the potential energy of the first **Dipole** in the field of the second Dipole by varying $\mathbf{p}_0$ while keeping fixed both $\mathbf{r}$ and $\mathbf{p}$:

$$\delta\Phi_0 \ = -\ \delta\boldsymbol{\theta}\cdot(\mathbf{p}_0\wedge\mathbf{E}_0) \Longrightarrow \boldsymbol{\gamma}_0 = \mathbf{p}_0\wedge\mathbf{E}_0 \quad .$$

The torque acting on the second **Dipole** with respect to the pole at the origin due to the force $\mathbf{f}$ can be readily obtained from:

$$\boldsymbol{\gamma}_L = \mathbf{r}\wedge\mathbf{f} = \frac{1}{4\pi\varepsilon_0}\left(\frac{3\,\mathbf{r}\wedge(\mathbf{p}\,(\mathbf{p}_0\cdot\mathbf{r}) + \mathbf{p}_0\,(\mathbf{p}\cdot\mathbf{r}))}{r^5}\right) \quad ,$$

showing that the force is not central.
However, the internal torques with respect to the origin sum to zero:

$$\boldsymbol{\gamma}_L + \boldsymbol{\gamma}_0 + \boldsymbol{\gamma} = 0 \quad .$$

Magnetic Scalar potential for a Point Magnetic Dipole

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|problem 5.51||

In static conditions, in absence of current densities, Maxwell equations show that the magnetic file is irrotational. Under these conditions one can introduce a scalar magnetic potential, in parallel to what is done in electrostatics.

1. Construct a scalar magnetic potential for a Point Magnetic Dipole.
2. Construct a scalar magnetic potential for a spinning spherical shell uniformly charged.
3. Construct a scalar magnetic potential for the interior of a solid spinning sphere uniformly charged.

36.20.14
Which Expression of the Force on a Point Magnetic Dipole

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|E6.5||

A uniform current density, $\mathbf{j} = j\widehat{\mathbf{e}}_3$ fills a slab in the yz plane, from $x = -a$ to $x = +a$, perpendicular to the x axis.

- A **Magnetic Dipole** $\mathbf{m} = \mathbf{m}_0\widehat{\mathbf{e}}_1$ is situated at the origin. Find the force on the **Dipole** .
- A **Magnetic Dipole** $\mathbf{m} = \mathbf{m}_0\widehat{\mathbf{e}}_2$ is situated at the origin. Find the force on the **Dipole** .

In the ElectroStatic case the expressions (36.05.02), (36.05.04) are always equivalent.
However, this is not always the case for the magnetic analogs (36.05.06), (36.05.07) as this example shows.

1. Explain why equations (36.05.06), (36.05.07) are not equivalent in this example.

DRAFT - IN PROGRESS

36.20.15
Equilibrium Position of Two Dipoles

This § is referenced at pages:
[Never referenced.]

©|W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...|P 1.11||

Consider two **Dipoles** , $\mathbf{p}_1$ and $\mathbf{p}_2$, located at $\mathbf{r}_1$ and $\mathbf{r}_2$ such that the two positions can change but the distance cannot change. Let θ_1 and θ_2 be the angles made by the two **Dipoles** with the vector joining the position of the two **Dipoles** : $\mathbf{R} \equiv \mathbf{r}_2 - \mathbf{r}_1$.

1. Show that, if the distance $|\mathbf{R}|$ is kept constant, and the angle θ_1 is kept fixed as well then the equilibrium position is given by: $\tan[\theta_2] = -2\tan[\theta_1]$.

36.20.16
Dipolo in Campo Elettrico Uniforme

This § is referenced at pages:
[1763]

Dimostrare che ponendo un dipolo elettrico in un campo elettrico uniforme $\mathbf{E}_0$, con il momento di dipolo parallelo al campo:

1. esiste una superficie equipotenziale centrata sul dipolo che è una sfera;
2. determinarne il raggio.

WORKED SOLUTION

Il potenziale è la somma del potenziale prodotto dal dipolo più il potenziale prodotto dal campo elettrico uniforme ($\mathbf{E}_0 = E_0\widehat{\mathbf{e}}_z$). Introduciamo un asse z parallelo al campo elettrico $\mathbf{E}_0$ ed al momento di diplo elettrico. Allora:

$$\Phi[\mathbf{r}] = \Phi_0 - E_0 z + \frac{1}{4\pi\varepsilon_0}\frac{p\cos[\theta]}{r^2} = \Phi_0 - E_0 r\cos[\theta] + \frac{1}{4\pi\varepsilon_0}\frac{p\cos[\theta]}{r^2} = \Phi_0 - \cos[\theta]\left(E_0 r - \frac{1}{4\pi\varepsilon_0}\frac{p}{r^2}\right) \quad .$$

Affinché ci sia una superficie equipotenziale che sia una sfera deve essere:

$$E_0 r - \frac{1}{4\pi\varepsilon_0}\frac{p}{r^2} = 0 \qquad \Longrightarrow \qquad r = \left(\frac{1}{4\pi\varepsilon_0}\frac{p}{E_0}\right)^{1/3} \quad . \tag{36.20.08}$$

→ 1762

Tale sfera è a potenziale uniforme di valore uguale al valore del potenziale del campo $\mathbf{E}_0$ nel punto in cui si pone il dipolo.
Alla superficie della sfera il campo elettrico è radiale, essendo una superficie equipotenziale. Usando l'espressione del campo elettrico del dipolo si ha:

$$\mathbf{E} = \left(\frac{1}{4\pi\varepsilon_0}\frac{2p\cos[\theta]}{r^3} + E_0\cos[\theta]\right)\frac{\mathbf{r}}{r} = 3E_0\cos[\theta]\frac{\mathbf{r}}{r} \quad .$$

Tale risultato è utilizzabile per calcolare il campo elettrico di una sfera conduttrice in un campo elettrico uniforme. Si introduce al centro della sfera un dipolo immagine di valore dato dalla relazione (36.20.08):

$$p = 4\pi\varepsilon_0 r^3 E_0 \quad .$$

è importante notare che il campo elettrico indotto è proporzionale al campo elettrico esterno (inducente).
Il campo elettrico esterno alla sfera può essere determinato come sovrapposzione del campo elettrico $\mathbf{E}_0$ e del campo elettrico prodotto dal dipolo immagine. Il potenziale assunto dalla sfera è pari al

potenziale del campo elettrico $\mathbf{E}_0$ nel punto in cui viene posto il centro della sfera e la densità di carica superficiale indotta, che perturba il campo elettrico $\mathbf{E}_0$, vale:

$$\sigma = 3\varepsilon_0 E_0 \cos[\theta] \quad .$$

Poichè il campo elettrico entro la sfera conduttrice deve essere nullo tale densità di carica superficiale deve produrre all'interno della sfera un campo elettrico uguale ed opposto al campo esterno $\mathbf{E}_0$. Si può dimostrare che il momento di dipolo elettrico della distribuzione di carica superficiale vale esattamente $p\widehat{\mathbf{e}}_z$:

$$\mathbf{p} = \int \rho_S \mathbf{r}\, \mathrm{d}\mathbf{S} = -3\varepsilon_0 E_0 r^3 \int \cos^2[\theta]\ \mathrm{d}V\ \mathrm{d}\cos[\theta] = 4\pi\varepsilon_0 r^3 E_0 \quad .$$

36.20.17

☒ Forza Su Una Sfera Conduttrice Nel Campo Di Una Carica Puntiforme

Una piccola sfera conduttrice di raggio R è immersa nel campo elettrico prodotto da una carica puntiforme q, posta a distanza $r \gg R$. Determinare la forza che agisce sulla sfera.

WORKED SOLUTION

Il campo elettrico prodotto dalla carica puntiforme non è uniforme però, data al condizione $r \gg R$ lo si può considerare, in prima approssimazione, uniforme nella regione occupata dalla sfera.
Il momento di dipolo indotto sulla sfera conduttrice, si veda il problema § 36.20.16, vale:

$$p_i = 4\pi\varepsilon_0 R^3 E_0 \quad .$$

Considerando un Coordinate System sferiche centrato sulla carica puntiforme tale momento di dipolo indotto si scrive:

$$\mathbf{p}_i = 4\pi\varepsilon_0 R^3 \left(\frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}\right)\widehat{\mathbf{e}}_r = \frac{pR^3}{r^2}\widehat{\mathbf{e}}_r \quad .$$

La forza che ne risulta è allora data dalla (36.05.02).
La forza è sempre attrattiva.
Notare che, se il campo elettrico fosse esattamente uniforme, la forza risultante sarebbe esattamente nulla.

36.20.18

☒ Magnitude of the Time-Varying Contributions in Maxwell Equations

This § is referenced at pages:
[1717]

The circulation of $\mathbf{E}$ is only given by the changes in the magnetic field with time, at variance with the circulation of $\mathbf{B}$, which depends not only on the changes in the electric field with time but also on the conduction current.

36.20.18.01 Estimate of the Displacement Current Density Term

Consider typical everyday values and a Sinusoidal|Cosinusoidal time-dependence of all the relevant quantities.

Note that in case the harmonic frequency is much larger than the values assumed below ($\nu \approx 10^2$ Hz), the conclusions may change drastically.

First Method

- Electric field:
  1. $E \approx 1.2{\cdot}10^2$ V/m (typical electric field at the Earth surface, directed downward);
  2. $E \approx 5.4{\cdot}10^{-3}$ V/m (electric field inside a copper wire with 1 mm radius carrying a current of 1 A);
- $\nu \approx 10^2$ Hz (frequency of household electric power);
- $I \approx 14$ A (typical maximum current of household electric power, from the difference of potential, $\Delta\Phi = 230$ V, and typical maximum available power, $P = 3.3$ kW);
- $j \approx I/S \approx 7{\cdot}10^6$ A/m^2 (for a typical wire cross-sectional area $S \approx 2$ mm^2);
- $L \approx 10$ m (order of magnitude of typical physical household lengths).

The displacement current term is thus $\varepsilon_0\mu_0\partial_t E \approx 1.3{\cdot}10^{-13}$ (SI units), for the larger value of the electric field above.

The conduction current term is thus $\mu_0 j \approx 9$ (SI units).

The order of magnitude of **B** resulting from the displacement current is: $B \approx L\varepsilon_0\mu_0\partial_t E \approx 1.3{\cdot}10^{-12}$ T, quite smaller than typical everyday values.

Therefore the rotor of **B** is typically affected much more by the conduction current than by the displacement current. The latter is often negligible with respect to the former.

The displacement current is obviously important whenever the conduction current is zero and|or the frequency is large.

Second Method

Assume a Ohmic conductor. In this case both the conduction current and the displacement current are proportional to the electric field (the displacement current to the frequency of the electric field also).

$$\left(\mu_0\sigma + \frac{\omega}{c^2}\right) E \approx \left(10^{-6}\sigma + 10^{-17}\omega\right) E \quad .$$

Also for a good insulator, such as pure water with $\sigma \approx 4{\cdot}10^{-6}$ (SI units), the conduction current is much larger than the displacement current for frequencies up to the kHz.

36.20.18.02 Estimate of the Faraday-Neuman-Lenz Term

Consider typical everyday values and a Sinusoidal|Cosinusoidal time-dependence of all the relevant quantities.

- Magnetic field:
  1. $B[t] \approx 0.5{\cdot}10^{-4}$ T (the magnetic field at the Earth surface);
  2. $B[t] \approx 2{\cdot}10^{-5}$ T (the magnetic field near a typical wire of current carrying a current of 1 A at a distance of 1 cm);
- $\nu \approx 10^2$ Hz (frequency of household electric power).
- $L \approx 10$ m (order of magnitude of typical physical lengths).

One finds, for the value of the time variation of the magnetic field near a wire $\nu B \approx 2{\cdot}10^{-3}$ (SI units), for the smaller value of the magnetic field above.

One finds then, for the induced electric field: $E \sim L\nu B \approx 2{\cdot}10^{-2}$ V/m.

The order of magnitude of the resulting E is thus: $\approx 10^{-2}$ V/m, not far from typical everyday values and close to the electric field inside a typical wire of current.

Note that in case the harmonic frequency is much larger than the assumed $\nu \approx 10^2$ Hz, the conclusions may change drastically.

DRAFT-IN-PROGRESS

36.20.19
Some Conductibilities

Unit of measure of the resistance: Ohm (Ω).
Unit of measure of conductance: Siemens (S).
Relation: $\Omega = \mathrm{S}^{-1}$.
See tables in appendix: 7.13, 7.14, 7.15, 7.17, 9.16 and 9.17.

36.20.20
☒ A Junction Between Two Different Conductors

Consider two cylindrical conductors with the same section shape and dimension of area S, length L_1 and L_2, made of different materials with **conductivity** σ_1 and σ_2. The two conductors are coupled, on their bases, to made a conducting junction. A potential difference $\Delta\Phi \equiv \Phi_1 - \Phi_2 > 0$ is applied at the two extremes. The current then flows from the conductor 1 towards the conductor 2.

1. Determine the current at the discontinuity in steady conditions and no leakage currents at the surface.
2. Determine the electric fields at the discontinuity in steady conditions and no leakage currents at the surface.
3. Determine the charges at the discontinuity in steady conditions and no leakage currents at the surface.

WORKED SOLUTION

The normal component of $\mathbf{j}$ must be continuous, in steady conditions, as charges cannot escape from the interface between the two conductors. Therefore the normal component of the electric field must be discontinuous and a surface charge accumulates at the interface.

$$R \equiv R_1 + R_2 = \frac{1}{S}\left(\frac{L_1}{\sigma_1} + \frac{L_2}{\sigma_2}\right) \quad ,$$

$$I = \frac{\Delta\Phi}{R} \Longrightarrow |\mathbf{j}| = \frac{\Delta\Phi}{\left(\frac{L_1}{\sigma_1} + \frac{L_2}{\sigma_2}\right)} = \frac{\Delta\Phi\sigma_1\sigma_2}{\sigma_1 L_2 + \sigma_2 L_1} = |\mathbf{j}_1| = |\mathbf{j}_2| \quad ,$$

$$\mathbf{j} = \sigma\mathbf{E} \Longrightarrow \quad ,$$

$$E_1 = \frac{\Delta\Phi\sigma_2}{\sigma_1 L_2 + \sigma_2 L_1} \quad ,$$

$$E_2 = \frac{\Delta\Phi\sigma_1}{\sigma_1 L_2 + \sigma_2 L_1} \quad ,$$

$$\rho_S = \varepsilon_0 (E_2 - E_1) = \frac{\Delta\Phi\varepsilon_0 (\sigma_1 - \sigma_2)}{\sigma_1 L_2 + \sigma_2 L_1} = \varepsilon_0 \left(\frac{1}{\sigma_2} - \frac{1}{\sigma_1}\right) |\mathbf{j}| \quad .$$

Note that the expression $\rho_S = \varepsilon_0 (E_2 - E_1)$, with our conventions, gives the correct sign of the charge. If $E_1 > E_2$ the flux across a small close surface crossing the interface is negative and the surface charge density is therefore negative. If $E_1 < E_2$ the flux across a small close surface crossing the interface is positive and the surface charge density is therefore positive.

Numerical Example

Copper and Silver, with $L_1 = L_2 = 0.1$ m and $\Delta\Phi = 100$ V.
One finds: $\rho_S = 10^{-8}$ C/m^2 $\simeq 7{\cdot}10^{11}$ electrons/m^2.

36.20.21
☒ Relaxation Time Inside a Ohmic Homogeneous and Isotropic Conductor

This § is referenced at pages:
[1978, 2338]

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|17.1.2||
©|W.K.H.Panoffsky & M.Phillips, *Classical Electricity And Magnetism*, 1962, Addison-Wesley, 2ndEd., ...|7.4||

Read also § 41-010.
Within a region of non-vanishing **conductivity** there can be no permanent distribution of free charges.

1. It is known that charge density is zero at interior points of conductors in equilibrium. How is this situation reached when there is a charge at some interior point ?
2. Suppose that at a certain time a free charge density ρ_0 exists inside a small region of a homogeneous and isotropic medium having **conductivity** σ. Determine the time development of the free charge density.

WORKED SOLUTION

Inside a homogeneous, isotropic and linear medium having **conductivity** σ one has: $\mathbf{j} = \sigma\mathbf{E}$, whenever only the effects of electric fields are relevant. From the charge continuity equation and from Maxwell first equation one finds:

$$\rho[\mathbf{x}, t] = \rho_0[\mathbf{x}] \exp\left[-\frac{\sigma}{\varepsilon_0} t\right] \quad ,$$

implying a time constant, τ, (relaxation time):

$$\boxed{\tau = \frac{\varepsilon_0}{\sigma}} \quad .$$

Therefore any initial free charge distribution inside a conductor decays exponentially with time at any point in a manner wholly independent of the applied field. If the charge is initially zero it remains zero forever.
This shows that within any region of non zero **conductivity** there can be no permanent distribution of free charge. If free charges are initially concentrated inside some small region their density starts to diminish exponentially but the charge cannot reappear at any other point within the conductor. Outside the region the charge density must vanish identically, as it was zero at the beginning. Therefore, outside the initial region, the flow is divergence-less. The flow will be arrested at the surface and this surface charge will start to appear at the exact instant that the interior charge begins to fade away, for the total charge is constant.
In all but the poorest conductors the relaxation time is exceedingly short:

- Copper: $\sigma^{-1} = 1.7{\cdot}10^{-8}\ \Omega \cdot \mathrm{m}$; it follows: $\tau \approx 1{\cdot}10^{-20}$ s.
- Quartz: $\sigma^{-1} = 1{\cdot}10^{16}\ \Omega \cdot \mathrm{m}$; it follows: $\tau \approx 1{\cdot}10^{5}$ s.

This fact justifies the use of the quasi-static approximation (zero charge and zero electric field inside any conductor) in many cases, not only is striclty static situations.

36.20.22
Surface Current in Ohmic Conductors

This § is referenced at pages:
[1728]

Ohmic conductors might carry surface currents if and only if they are perfect conductors.
It is an essential assumption that it is a Ohmic conductor.
In fact, consider a thin surface layer where the current flows, of thickness h:

$$\mathbf{j}_S = \mathbf{j}h = h\sigma\mathbf{E} \quad .$$

The above relations shows that in order to have a finite surface current, $0 < |\mathbf{j}_S| < \infty$, in the limit $h \to 0$, with a non infinite electric field the **conductivity** must tend to infinity.

Also note that in a perfect conductor $\mathbf{E}$ is zero inside, therefore the tangential component, which is continuous and the electric field is tangential in stationary conditions, is zero just outside, as well as inside. The fact that $\mathbf{E}$ is zero in a perfect conductor makes still stronger the previous conclusion that **conductivity** must tend to infinity.

36.20.23
☒ A Moving Bar in a Constant and Uniform Magnetic Field (1)

This § is referenced at pages:
[1769, 1769, 2394, 2395]

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|36.7||

Compare with § 36.20.24.
Consider a constant and uniform magnetic field, directed along the direction of the z axis.
A closed rectangular circuit is located in the xy plane. It is made of a U-shaped fixed part, having the short side with length a along the y direction and the two long sides along the x direction, plus a bar oriented along the y direction which can move along the x direction while still keeping the circuit electrically closed.
The bar moves in the positive x direction with speed $\mathbf{V}$ thanks to the intervention of a suitable external force. Let us determine the induced emf and describe the situation both from the point of view of the fixed observer and the observer moving with the bar.

Description of the Observer Seeing the Moving Bar

The observer at rest with the U-shaped part of the circuit is called, in short, the stationary observer.
The Lorentz force on the single free charge, with drift velocity $\mathbf{v}_D$, inside the circuit is:

$$\mathbf{F} = q\,(\mathbf{V} + \mathbf{v}_D) \wedge \mathbf{B} \quad ,$$

with

$$\mathbf{F}_{\parallel} = q\,\mathbf{V} \wedge \mathbf{B} \parallel (-\mathbf{e}_2) \qquad \mathbf{F}_{\perp} = q\,\mathbf{v}_D \wedge \mathbf{B} \parallel (-\widehat{\mathbf{e}}_1) \parallel (-\mathbf{V}) \quad .$$

The Lorentz force catalyzes the process putting in motion the free charges. Once the free charges are moving along $(-\mathbf{e}_2)$ they become subject to a component of the Lorentz force directed along $(-\mathbf{V})$.
In a steady situation, when charges move at constant speed, that is the current is uniform after any transient has disappeared, the two forces $\mathbf{F}_{\parallel}$ and $\mathbf{F}_{\perp}$ are counterbalanced by two equal and opposite forces, as in this situation the total force on any charge must be zero:

$$\mathbf{F}_{\parallel} + \mathbf{f} = q\,\mathbf{V} \wedge \mathbf{B} + \mathbf{f} = 0 \qquad \mathbf{f}\text{: friction encountered by the free moving charge} \quad ,$$

$$\mathbf{F}_{\perp} + \mathbf{N} = q\,\mathbf{v}_D \wedge \mathbf{B} + \mathbf{N} = 0 \qquad \mathbf{N}\text{: force exerted by the wire on the free charge} \quad .$$

Note that both forces $\mathbf{f}$ and $\mathbf{N}$ are forces provided by the wire and acting on the free charges and that $\mathbf{N}$ can arise from the internal electric field generated by the unbalance of charges due to force $\mathbf{F}_{\perp} \parallel (-\mathbf{V})$ (Hall effect). The force $\mathbf{N}$ prevents the free charges from exiting the wire. In the usual case of a crystalline

DRAFT - IN PROGRESS

wire the external agent move the wire structure while the free electrons are moved backwards and the unbalance creates the Hall field which in turn keeps the electrons from leaving the wire.

Note that the Lorentz force never does any work. The positive work on the free charges is done by force $\mathbf{N}$ ($\pi[\mathbf{N}] > 0$), in fact, while the negative work on the free charges is done by force $\mathbf{f}$ ($\pi[\mathbf{f}] < 0$). The total power on the (point) free charges is zero in steady conditions (no change of kinetic energy):

$$\pi[\mathbf{f}] \equiv \mathbf{f}\cdot(\mathbf{V}+\mathbf{v}_{\text{D}}) = \mathbf{f}\cdot\mathbf{v}_{\text{D}} < 0 \quad ,$$
$$\pi[\mathbf{N}] \equiv \mathbf{N}\cdot(\mathbf{V}+\mathbf{v}_{\text{D}}) = \mathbf{N}\cdot\mathbf{V} > 0 \quad ,$$
$$\pi = (\mathbf{f}+\mathbf{N})\cdot(\mathbf{V}+\mathbf{v}_{\text{D}}) = \mathbf{f}\cdot\mathbf{v}_{\text{D}} + \mathbf{N}\cdot\mathbf{V} = \pi[\mathbf{f}] + \pi[\mathbf{N}] = -q\,\mathbf{v}_{\text{D}}\wedge(\mathbf{V}\wedge\mathbf{B}) - q\,\mathbf{V}\wedge(\mathbf{v}_{\text{D}}\wedge\mathbf{B}) = 0 \quad ,$$
$$\pi[\mathbf{F}] = 0 \quad .$$

Note that the force $\mathbf{N}$ is, **from the mechanical point of view, a constraint force which can do work because the constraint is moving**.

The energy dissipated (by Joule effect or other means) by the circuit, in the end, comes from the work done on the moving bar by the external agent which keeps the bar moving at constant speed. **The role of the Lorentz force is essential in converting this work into kinetic energy of the free charges which is finally dissipated by the circuit**. This is similar to the role of static friction in a rolling cylinder.

Description of the Observer Moving With the Moving Bar

At startup, the observer moving with the moving bar (in short: the moving observer) does not see any force along $\mathbf{e}_2$ in the bar, as the charge is not moving, and thus she cannot explain the start of the current in the conductor via the magnetic part of the Lorentz force. After the current has started, she only sees a straight standard Hall effect, but she cannot explain the startup of the current when the bar is set into motion. In steady conditions, she needs to invoke and electric field to explain the charge moving at constant speed along the wire against the friction and producing the work which is dissipated by Joule effect. Moreover, she needs to invoke an electric field to startup and maintain the current in the circuit, as the relativity principle impose that the source of the emf must be located in the bar, the same as for the stationary observer.

So one might think that the observer moving with the bar also sees an electric field, as he is moving with respect to a pure magnetic field. Now, there is a big trouble, because she knows that any electric field must be produced either by charges or by a time changing magnetic field, and she sees none of them.

Moreover, she seems to have another problem, because if we assume a constant and uniform electric field, as it sounds reasonable given that we started from a constant and uniform magnetic field, this gives rise to an opposite effect on the far side of the U-shaped part of the circuit, if that is immersed into the same magnetic field too. In fact, one needs to remember that, when considering currents, one must always consider the full, closed circuit, that is the return path of currents.

The problem on the other side, however, is not there when one realizes that the far side of the U-shaped part of the circuit is in motion, with respect to the moving observer, with velocity $(-\mathbf{V})$, in a magnetic field. In fact, if we assume that the magnetic field seen by the moving observer is the same as the one seen by the stationary observer, an approximation which turns out to be correct only for non relativistic velocities $\mathbf{V}$, we can conclude that in the far side of the U-shaped part of the circuit the force due to the electric field exactly balances the part of force due to the magnetic field of the Lorentz force, that is the total Lorentz force on any charge is zero.

In fact the relativistic transformations of the ElectroMagnetic fields, equations (61.03.01), (61.03.02), (61.03.03), (61.03.04), give, in the non-relativistic limit with $\gamma \simeq 1$:

$$\boxed{\mathbf{E}'_{\parallel} = \mathbf{E}_{\parallel} = 0} \quad ,$$
$$\boxed{\mathbf{B}'_{\parallel} = \mathbf{B}_{\parallel} = 0} \quad ,$$
$$\boxed{\mathbf{E}'_{\perp} = \gamma\left(\mathbf{E} + c^{+1}\,\boldsymbol{\beta}\wedge\mathbf{B}\right)_{\perp}} = \gamma\left(c^{+1}\,\boldsymbol{\beta}\wedge\mathbf{B}\right)_{\perp} = \gamma c\,\boldsymbol{\beta}\wedge\mathbf{B} \simeq \mathbf{V}\wedge\mathbf{B} \quad ,$$
$$\boxed{\mathbf{B}'_{\perp} = \gamma\left(\mathbf{B} - c^{-1}\,\boldsymbol{\beta}\wedge\mathbf{E}\right)_{\perp}} = \gamma\mathbf{B} \simeq \mathbf{B} \quad .$$

DRAFT - FOR PROOFREADING

CC BY NC ND

For this observer the forces on the far side of the circuit, taking into account relativistic effects, read:

$$q\gamma\,\mathbf{v}\wedge\mathbf{B} + q\,(-\mathbf{v})\wedge(\gamma\mathbf{B}) = 0 \quad .$$

Note that the **Galilei Transformation** , equations (58.04.01) provide the same result.

36.20.24
☒ A Moving Bar in a Constant and Uniform Magnetic Field (2)

This § is referenced at pages:
[1767, 1808, 2394, 2395]

Compare with § 36.20.23.

An even simpler case than section § 36.20.23 is when the rectangular circuit is a rigid one and it has only one of the short sides inside a magnetic field. The circuit is removed with constant speed. In this case all happens in the short side of the circuit, as it is inside the magnetic field: one observer only sees the magnetic force while the other one only sees the electric force.

Note that the **Galilei Transformation** , equations (58.04.01) provide the same result.

ElectroMagnetic Induction Law: Some Critical Cases

©|R.P.Feynman *et al.*, *The Feynman's Lectures On Physics*, 1964, Addison-Wesley, ...Ed., ...|||

In order to respect the mathematical derivation of the equivalence between the integral and differential formulations one needs to identify a line circuit, actually traveled by the real charges, corresponding to the mathematical circuit, so that $\mathbf{v}$ can be replaced by $\mathbf{u}$ in the integral of the emf.

Sliding Contact on a Solenoid

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|14.5.2||

A simple example shows how much care should be used when applying the Faraday-Neumann-Lenz to real circuits which are not simple line-circuits of invariable constitution.

A solenoid, made out of an helical winding, where a constant current I passes has two contacts: the first one is fixed at one the two extremes, while the second one can slide along the helical windings. The magnetic field flux is changing but it is clear that there cannot be any induced EM-motive force because there is no change of magnetic field anywhere nor any wire moving inside a magnetic field. Note also that the magnetic field flux is changing as a step function.

Homopolar Generator or Unipolar Generator or Disk Dynamo or Faraday Disc

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|14.5.2||

What is the circuit? You cannot define a line such that current passes there, as the circuit is not a line circuit. The usual contours used to use the cut-flux concept makes no sense: there is no current flow along the circumference which is winding into itself.

If one defines a circuit with a fixed line joining the center and the edge of the Faraday disk there is no change of flux inside, while one knows that there is an indiced emf!

The correct treatment can be found by using equation (36.10.06).

36.20.29
Ideal Plane Capacitor

This § is referenced at pages:
[1783, 1785]

An ideal plane capacitor is made of two identical parallel plane conducting plates of infinite extension charged with charges of equal magnitude and opposite sign ($Q_+ \equiv +|Q|$ and $Q_- \equiv -|Q|$). Let the z axis be perpendicular to the plates.

1. Show that the electric field is along z and uniform inside the capacitor.

Read also § 36.20.63.

WORKED SOLUTION

The system is invariant by translation along the x and y axes. Introduce a orthonormal Cartesian Coordinates Coordinate System. The electric field must be along z and it cannot depend on neither x nor y:

$$\mathbf{E}[\mathbf{r}] = \widehat{\mathbf{e}}_3 E_z[z] \quad .$$

In between the armatures the electric field is divergence-less, and therefore, from the expression of the divergence in orthonormal orthonormal Cartesian Coordinates Coordinate System:

$$\frac{\partial E_z}{\partial z} = 0 \quad ,$$

that is the electric field is uniform inside the capacitor.

36.20.30
Capacitance Coefficients via the Scalar Electric Potential

This § is referenced at pages:
[1746]

©|I.Smolić and B.Klajn|Capacitance Matrix Revisited|*WEB - URL*|

The **superposition principle** of ElectroMagnetic fields in linear systems is assumed to hold, as it is appropriate for linear systems.

Note that in presence of non-linear effects, for instance of materials with non-linear response, the proportionality between potential difference and charge is lost as the **superposition principle** does not apply.

Assume zero potential at infinity.

Consider a set of conductors with a common reference potential (typically zero at infinity).

36.20.30.01 Self-Capacitance

The self-capacitance of a conductor is defined in terms of the potential of the electric field as:

$$Q \equiv C\Phi \propto \Phi \quad .$$

The charge is proportional to the potential, as it can be shown from **Poisson equation** .

36.20.30.02 Mutual-Capacitance

Consider two conductors.

Let us use the notation $\{\}_{xy}$ to denote that x is the source of an effect seen by y: $(\{\}_{xy} \equiv \{\}_{x\to y})$.

Their mutual-capacitance is defined in terms of the charge induced on one conductor for a given potential of the other:

$$Q_{21} \equiv C_{21}\Phi_2 \qquad Q_{12} \equiv C_{12}\Phi_1 \quad .$$

In the case of an arbitrary number of conductors it can be shown in general that the **capacitance** and mutual-capacitance coefficients are subject to the following relations:

$$\boxed{C_{kk} > 0 \qquad C_{kj}^{\cdot\cdot} = C_{jk}^{\cdot\cdot} < 0 \qquad C_{kk} > -\sum_{j\neq k} C_{jk}^{\cdot\cdot}} \quad .$$

36.20.31 Capacitance of a Pair of Conductors

This § is referenced at pages:
[1746]

Consider two conductors, 1 and 2. The charge on one conductor is given by the sum of the charge produced by the potential of the conductor itself plus the charge produced by the potential of the other conductor:

$$Q_1 = Q_{11} + Q_{21} = C_1\Phi_1 + C_{21}\Phi_2 \quad ,$$
$$Q_2 = Q_{12} + Q_{22} = C_{12}\Phi_1 + C_2\Phi_2 \quad .$$

The above relation is justified by the **superposition principle** of ElectroMagnetic fields in linear systems.

The matrix thus defined is called the capacitance matrix; the concept can be easily extended to an arbitrary number of conductors.

The **capacitance** coefficients only depends on the geometry of the system and on the properties of the (linear) media present.

Note, in particular, that, in linear systems:

$$\boxed{Q_{11} \propto \Phi_1 \qquad \text{for } \Phi_2 = 0 \qquad Q_{21} \propto \Phi_2 \qquad \text{for } \Phi_1 = 0} \quad ,$$
$$\boxed{Q_{12} \propto \Phi_1 \qquad \text{for } \Phi_2 = 0 \qquad Q_{22} \propto \Phi_2 \qquad \text{for } \Phi_1 = 0} \quad .$$

It can be shown that:

$$\boxed{C_{11} \geq 0 \qquad C_{22} \geq 0 \qquad C \equiv C_{21} = C_{12} \leq 0} \quad .$$

36.20.31.01 Complete Charge Induction and the Capacitor

A capacitor is a system of two conductors having complete charge induction: $Q_1 + Q_2 = 0$

The **capacitance** of a capacitor can be calculated in terms of C_1, C_2 and $C \equiv C_{12} = C_{21}$, for $Q_1 = +Q > 0$ and $Q_2 = -Q < 0$ as:

$$\boxed{Q = \left(\frac{C^2 - C_1C_2}{C_1 + C_2 + 2C}\right)(\Phi_2 - \Phi_1)} \quad .$$

In fact inversion of the capacitance matrix leads to:

$$V_1 = \frac{CQ_2 - Q_1C_2}{C^2 - C_1C_2} \quad ,$$
$$V_2 = \frac{CQ_1 - Q_2C_1}{C^2 - C_1C_2} \quad .$$

Capacitance and Energy Balance With Self/Mutual Capacitance

This § is referenced at pages:
[1746]

36.20.33
Inductance Coefficients via the Magnetic Vector Potential

This § is referenced at pages:
[1746]

The **superposition principle** of ElectroMagnetic fields in linear systems is assumed to hold, as it is appropriate for linear systems.

Note that in presence of non-linear effects, for instance of materials with non-linear response, the proportionality between concatenated flux and current is lost as the **superposition principle** dose not apply.

Consider a set of thin closed current loops.

36.20.33.01 Self-Inductance

The self-inductance of a thin closed current loop is defined in terms of the concatenated flux of the magnetic field as:

$$\Phi \equiv LI = \oint_{\partial\Sigma} \mathbf{A} \cdot \mathrm{d}\mathbf{L} \propto I \quad .$$

The above relation clearly shows that the self-inductance does not depend on the current as the **vector magnetic potential** produced by a thin current wire is proportional to the current as it is clear from equation (**??**).

36.20.33.02 Mutual-Inductance

Consider two thin closed circuit loops carrying constant currents.

Let us use the notation $\{\}_{xy}$ to denote that x is the source of an effect seen by y: ($\{\}_{xy} \equiv \{\}_{x\to y}$).

Their mutual-inductance is defined in terms of the flux of the magnetic field of one circuit concatenated to the other one:

$$\Phi_{21} \equiv M_{21} I_2 \qquad \Phi_{12} \equiv M_{12} I_1 \quad .$$

The above relation clearly shows that the mutual-inductance does not depend on the current as the **vector magnetic potential** produced by a thin current wire is proportional to the current as it is clear from equation (**??**).

36.20.34
Inductance of a Pair of Circuits

This § is referenced at pages:
[1746]

Consider two thin closed circuit loops, 1 and 2. The flux of the magnetic field concatenated to one circuit is given by the sum of the flux given by the magnetic field produced by circuit itself plus the flux given by the magnetic field produced by the other circuit:

$$\Phi_1 = \Phi_{11} + \Phi_{21} = L_1 I_1 + M_{21} I_2 \quad ,$$
$$\Phi_2 = \Phi_{12} + \Phi_{22} = M_{12} I_1 + L_2 I_2 \quad .$$

The above relation is justified by the **superposition principle** of ElectroMagnetic fields in linear systems.

DRAFT - IN PROGRESS

The matrix thus defined is called the inductance matrix; the concept can be easily extended to an arbitrary number of circuits.

The inductance coefficients only depends on the geometry of the system and on the properties of the (linear) media present.

Note, in particular, that, for linear systems:

$$\boxed{\Phi_{11} \propto I_1 \quad \text{for } I_2 = 0 \qquad \Phi_{21} \propto I_2 \quad \text{for } I_1 = 0} \quad ,$$

$$\boxed{\Phi_{12} \propto I_1 \quad \text{for } I_2 = 0 \qquad \Phi_{22} \propto I_2 \quad \text{for } I_1 = 0} \quad .$$

36.20.35
Inductance and Energy Balance With Self/Mutual Inductance

This § is referenced at pages:
[1746]

Consider two closed fixed current circuits, with self-inductances L_1 and L_2 and mutual inductance M.

We want to determine the energy stored in the circuit by the generators when the currents I_1 and I_2 are switched on.

The result will show that the mutual inductance satisfies the relation:

$$\boxed{|M| \leq \sqrt{L_1 L_2}} \quad .$$

Let W be the work done by the two constant voltage generators (which are assumed to be ideal voltage generators).

Let us consider the energy balance between time $t = 0$, when $I_1 = I_2 = 0$, and the generic time $\bar{t}$.

Choose the conventional positive flow of the current as the one the voltage generators will push the current.

$$\mathcal{E}_1 - L_1 \frac{\mathrm{d}I_1}{\mathrm{d}t} - M \frac{\mathrm{d}I_2}{\mathrm{d}t} - R_1 I_1 = 0 \quad ,$$

$$\mathcal{E}_2 - L_2 \frac{\mathrm{d}I_2}{\mathrm{d}t} - M \frac{\mathrm{d}I_1}{\mathrm{d}t} - R_2 I_2 = 0 \quad ,$$

$$\mathrm{d}W = (\mathcal{E}_1 I_1 + \mathcal{E}_2 I_2)\ \mathrm{d}t \quad ,$$

$$W = \int_0^{\bar{t}} \mathrm{d}W = M I_1 I_2 + \frac{L_1 I_1^2}{2} + \frac{L_2 I_2^2}{2} + \int_0^{\bar{t}} \left(R_1 I_1^2 + R_2 I_2^2\right)\ \mathrm{d}t \quad ,$$

[Work done by the generators] = [Energy stored in the magnetic field] + [Energy dissipated by Joule effect] .

As the generators will do positive work in order to let the current flow and build the magnetic fields the energy stored in the magnetic field must be positive:

$$M I_1 I_2 + \frac{L_1 I_1^2}{2} + \frac{L_2 I_2^2}{2} \geq 0 \implies M^2 < L_1 L_2 \quad .$$

36.20.36
Mutual Inductance Coefficient of Two Circuits

This § is referenced at pages:
[1746, 1784]

Consider two thin closed circuit loops, Γ_1 and Γ_2, carrying currents I_1 and I_2. The mutual inductance coefficient of circuit Γ_1 to circuit Γ_2 is defined in terms of the flux of the magnetic field produced by the circuit Γ_1 and concatenated to circuit Γ_2, Φ_{12}, as:

$$\boxed{M_{12} \equiv \frac{\Phi_{12}}{I_1} = \frac{1}{I_1} \oint_{\Gamma_2} \mathbf{A}_1[\mathbf{y}_2] \cdot \mathrm{d}\mathbf{L}_2[\mathbf{y}_2] = \frac{\mu_0}{4\pi} \oint_{\Gamma_1} \oint_{\Gamma_2} \frac{\mathrm{d}\mathbf{L}_1[\mathbf{y}_1] \cdot \mathrm{d}\mathbf{L}_2[\mathbf{y}_2]}{|\mathbf{y}_1 - \mathbf{y}_2|}} \qquad (36.20.09)$$

→ 1775

DRAFT - EN PROGRESS

Equation (36.20.09), called **Neumann formula** , clearly show the symmetry of the mutual inductance coefficient:

$$\boxed{M_{21} = M_{12}} \quad .$$

The mutual inductance only depends on the flux lines concatenated with both circuits.

36.20.39
☒ Scalar Potential on the Axis of a Circular Charged Ring

This § is referenced at pages:
[1779]

Calculate the **scalar electric potential** on the axis of a thin plane circular ring of radius R carrying a uniform linear charge density λ.

From the knowledge of the **scalar electric potential** on the axis what can one say about the electric field?

WORKED SOLUTION

The electric field on the axis is directed along the axis by symmetry.

$$\mathrm{d}\Phi[0,0,z] = \frac{1}{4\pi\varepsilon_0}\frac{\lambda\,\mathrm{d}L}{\sqrt{R^2+z^2}} \quad ,$$

$$\Phi[0,0,z] = \frac{1}{4\pi\varepsilon_0}\frac{Q}{\sqrt{R^2+z^2}} \simeq \frac{1}{4\pi\varepsilon_0}\frac{Q}{R}\left(1 - \frac{z^2}{2R^2} + \frac{3z^4}{8R^4} + \mathcal{O}\left(\frac{1}{R}\right)^6\right) \quad ,$$

$$\Longrightarrow E_z = -\frac{\partial\Phi}{\partial z} = \frac{1}{4\pi\varepsilon_0}\frac{Qz}{(R^2+z^2)^{3/2}} \qquad \text{the change of sign at } z=0 \text{ is correct;} \quad ,$$

$$|z| \gg R \Longrightarrow E_z \simeq \frac{1}{4\pi\varepsilon_0}\frac{Qz}{|z|^3} \quad .$$

It is very important to note that it is not possible, in general, to derive the electric field from the knowledge of the potential in some part of space only, as one must be to take the gradient, for which the knowledge of potential at one point only is not enough. However, in this problem we know the **scalar electric potential** at all the points of the z axis, so that the directional derivative along the z axis, that is the electric field component along the z axis, can be calculated. Moreover, thanks to symmetry considerations, we know that, in this problem, the electric field is directed along the z axis, at any point of the z axis.

Note that for motion along the z axis $z=0$ is a stable equilibrium position for point particles of opposite sign with respect to the charge of the ring. Our calculation is not enough to say anything about motions in the xy plane.

The development of the potential in series written above shows that at large distance the field

resembles the field of a point charge, that the **Dipole** term is missing and the **Quadrupole** term is not zero.
Study the limits: $|z| \ll R$ and $R \to +\infty$.

Calculate the **vector magnetic potential** produced by an infinite straight circular solenoid having radius R and carrying a constant current I with n turns per unit length.
Note that one cannot use equation (36.13.03) since the current itself extends to infinity.

36.20.42
☒ Vector Potential on the Axis of a Circular Current Ring

©|J.P.Pérez *et al.*, *Électromagnétisme*, ..., DUNOD, ...Ed., WEB - URL.|11.4.4||

Calculate the **vector magnetic potential** on the axis of a thin plane circular ring of radius R carrying a steady current I.
From the knowledge of the **vector magnetic potential** on the axis what can one say about the magnetic field?

WORKED SOLUTION

At any point the axis of a circular current ring the **vector magnetic potential** is proportional to $\oint \mathbf{dL}$ that is zero for a circular current ring:

$$\mathbf{A} = \frac{\mu_0}{4\pi} I \oint \frac{\mathbf{dL}}{r} \quad .$$

In fact, the distance factor is constant and can be taken out the integral.
Nothing can be said about the magnetic field from the knowledge of the vector potential on a line as the rotor cannot be calculated from the knowledge of the values on a line only.
In this problem one needs to know the partial derivatives with respect to the x and y axes. In fact one should calculate the infinitesimal circulation per unit area in a plane perpendicular to the z axis, but the **vector magnetic potential** is only known on the z axis.

☒ EM Fields at Large Distances From Capacitors and Inductors

This § is referenced at pages:
[1782, 1782]

The electric field at a large distance from any capacitor is an **Electric Dipole** field, as it is the case for the electric field at a large distance from any limited time-independent charge distribution.

The magnetic field at a large distance from any solenoid is a **Magnetic Dipole** field, as it is the case for the electric field at a large distance from any limited time-independent current distribution.

36.20.48
☒ Magnetic Monopole Term

This § is referenced at pages:
[1738]

In equation (36.13.03) the first term in the multipole development is:

$$\iiint \mathbf{j}[\mathbf{r}]\, \mathrm{d}V \quad . \tag{36.20.10}$$

Show that is it always zero.

36.20.49
☒ Magnetic Dipole Moment of a Thin Closed Plane Current Loop (1)

This § is referenced at pages:
[1781]

Read § 16-009.

Show that the definition (36.14.09) reduces to the usual definition of **Magnetic Dipole** moment for a plane thin current loop in terms of the current, I, and the vector $\mathbf{S}$ describing the loop:

$$\boxed{\mathbf{m} = I\mathbf{S} \qquad \text{for a plane thin current loop}} \quad .$$

In fact for a thin plane current loop:

$$\boxed{\mathbf{m} = \frac{1}{2}\iiint (\mathbf{x}\wedge\mathbf{j}[\mathbf{x}])\ \mathrm{d}V_{\mathbf{x}} = \frac{I}{2}\oint \mathbf{x}\wedge \mathrm{d}\mathbf{L}[\mathbf{x}]} \quad .$$

In fact the integral can be evaluated on the plane surface having the plane current loop as a boundary, exploiting the geometrical interpretation of the vector product of two vectors, by taking an origin in the plane of the circuit. The integrand is the area of the triangle defined by $\mathbf{x}$ and $\mathrm{d}\mathbf{L}$. The integration over the closed circuit gives its surface.

The formal and more general derivation can be found in section § 36.20.51.

Read also § 36.20.50.

If the origin of the Coordinate System is outside the plane of the loop the result does not change as it is obvious from the geometrical interpretation and fact that

$$\oint \mathrm{d}\mathbf{L} = \mathbf{0} \quad .$$

- The calculation of the **Magnetic Dipole** moment of a current loop leads to the integral
$$\oint \mathbf{r} \wedge \mathbb{d}\mathbf{r} \quad .$$
Show that the scalar magnitude of the integral equals twice the area of the enclosed surface.
Use one of the forms of equation (16.07.10) or directly equations (16.13.05) to apply the result
$$\frac{1}{2}\oint_{\partial\Sigma} \mathbf{r} \wedge \mathbb{d}\mathbf{r} = \iint_{\Sigma} \mathbb{d}\mathbf{S} \qquad \text{with } \partial\Sigma = \Gamma \quad ,$$
to the Magnetic Dipole moment of a thin plane current loop, where the right-hand integral is independent of the surface Σ.
- Evaluate
$$\oint_{C} \mathbf{r} \wedge \mathbb{d}\mathbf{r} \quad ,$$
on a plane curve using elementary geometrical methods.

36.20.51
☒ Magnetic Dipole Moment of a Thin Closed Arbitrary Non-Plane Current Loop

This § is referenced at pages:
[1780, 1781]

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|Example 5.13||

Read § 16-009.
Show, using theorem (16.07.09), that the definition (36.14.09) can be re-written, for an arbitrary thin current loop carrying a current I and described by the curve Γ, as:
$$\mathbf{m} = I \iint_{\Sigma} \mathbb{d}\mathbf{S} \qquad \text{with } \Sigma \text{ any surface such that } \partial\Sigma = \Gamma \quad .$$
In fact if the current loop is not plane the component of the **Magnetic Dipole** moment along any axis is proportional, via the current, to the projected area of the circuit on the plane perpendicular to the axis.
The above integral is obviously independent of the choice of the surface.

36.20.52
☒ Dipole Moments: Independence on the Origin

This § is referenced at pages:
[1739, 1739, 1740]

The definition of **Electric Dipole** | **Magnetic Dipole** moments, equation (36.14.06) and (36.14.09), do not give any prescription on the choice of the origin of the Coordinate System.
Show that the Dipole Moment is indeed independent of this choice:
1. for any ElectroStatic charge distribution with with compact support and zero total charge;
2. for any MagnetoStatic steady current distribution with compact support.

DRAFT - EM - IN PROGRESS

WORKED SOLUTION

Consider the most general change of Coordinate System (roto-translation, Poincarè group):

$$\mathbf{x} \longrightarrow \mathbf{x}' \equiv \mathbb{R}\mathbf{x} + \mathbf{a} \quad .$$

- $$\mathbf{p} \longrightarrow \mathbf{p}' = \mathbf{p}' + Q\mathbf{a} \quad . \tag{36.20.11}$$
- Calculate $\mathbf{m}$ using this new Coordinate System, first assuming that $\mathbb{R} = \mathbb{I}$ (that is no rotation, translation only):

  $$\mathbf{m}' = (1/2) \iiint \mathbf{x}' \wedge \mathbf{j}'[\mathbf{x}'] \, \mathrm{d}V'_{\mathbf{x}} = (1/2) \iiint (\mathbf{x} + \mathbf{a}) \wedge \mathbf{j}[\mathbf{x}] \, \mathrm{d}V_{\mathbf{x}} = (1/2) \iiint \mathbf{x} \wedge \mathbf{j}[\mathbf{x}] \, \mathrm{d}V_{\mathbf{x}} = \mathbf{m} \quad , \tag{36.20.12}$$

  where the last steps follows from the fact that the volume integral of a steady current (that is a current satisfying $\mathbf{div}\mathbf{j} = 0$) which has a compact support is always zero, see (16.12.02).

The effect of a rotation of the Coordinate System is not a problem, as the **Dipole** moments are defined by a vector equation and are therefore independent of any rotation of the Coordinate System.

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|Problema 5.50||

Using similar calculations as in section § 36.20.36 show that the forces between the two stationary thin current loops with stationary currents are equal and opposite:

$$-\mathbf{f}_{2\to 1} = \mathbf{f}_{1\to 2} = -\frac{\mu_0}{4\pi} I_1 I_2 \oint_{\Gamma_1}\oint_{\Gamma_2} \mathbb{d}\mathbf{L}_1[\mathbf{y}_1]\cdot \mathbb{d}\mathbf{L}_2[\mathbf{y}_2]\frac{\mathbf{y}_2-\mathbf{y}_1}{|\mathbf{y}_1-\mathbf{y}_2|^3} \quad . \tag{36.20.13}$$

The **Action-Reaction Principle** for the forces is thus obeyed.

36.20.61
☒ Force on a Small Circular Current Loop on the Axis of a Real Circular Solenoid

This § is referenced at pages:
[1711]

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|||

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|11.4||

Assume that both the circular solenoid and the circular current loop (radius R) are coaxial with the z axis, with the solenoid centered at the origin, the currents having the same orientations, such that the magnetic field produced by the solenoid is parallel to the z axis and the circular current loop at positive z.

The current in the circular current loop is kept constant in some way.

$$\mathbb{d}\mathbf{f} = \mathbf{j}\wedge\mathbf{B}\ \mathbb{d}V = I\ \mathbb{d}\mathbf{L}\wedge\mathbf{B} \quad .$$

The radial components of the force sum to zero (the circular current loop tends to explode).

CC BY NC ND

Relation between $B_r[r,z]$ and $B_z[r,z]$ from the second **Maxwell Equation** : apply to a small cylinder coaxial with the z axis, with radius R and height Δz:

$$\pi R^2 \left(B_z[r,z+\Delta z] - B_z[r,z]\right) + 2\pi R \Delta z B_r[r,z] = 0 \implies R\frac{\partial B_z}{\partial z}[r,z] = -2B_r[r,z] \quad .$$

The z component of the force is (as $B_r > 0$) is attractive:

$$F_z = -2\pi R I B_r = \pi R^2 I \frac{\partial B_z}{\partial z} = \mathbf{m}_z \frac{\partial B_z}{\partial z} \quad .$$

The orientation of the current in the circular current loop with respect to the current in the solenoid determines whether the force is attractive or repulsive; it actually depends on the sign of the product IB_r.

Compare with equation (36.05.07), with $\mathbf{m} = \mathbf{m}_z \widehat{\mathbf{e}}_3$:

$$\mathbf{f}_m = \left(\mathbf{m}_z \frac{\partial}{\partial z}\right)\mathbf{B} \qquad \text{at } r = 0 \quad . \tag{36.20.14}$$

The magnetic field components perpendicular to the z axis are zero, by symmetry, on the axis; therefore their derivative along z is zero and the force is along z.

Ideal circular Solenoid

This § is referenced at pages:
[1771, 1787]

©|J.P.Pérez *et al.*, 5 Vol., , ..., ..., ...Ed., WEB - URL.|11.6.2||

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|||

An ideal circular solenoid is made of an infinitely long circular conducting cylinder where a uniform current exist having no components along the axis of the solenoid. The axis of the solenoid is coincident with the z axis and a cylindrical coordinate system is used.

Assume that the thickness, t, of the sheet is negligible with respect to the radius, R, so that the current can be approximated with a surface current:

$$\mathbf{j}_S = \mathbf{j}_S = |\mathbf{j}_S|\widehat{\mathbf{e}}_\theta \qquad \text{for } r = R\text{; zero otherwise} \quad .$$

Show that the magnetic field is along z and uniform inside the solenoid.

WORKED SOLUTION

Introduce a cylindrical Coordinate System, with the z axis along the axis of the solenoid. The system is invariant by translations along the z axis and by rotations around the z axis. Therefore the components of the magnetic field cannot depend on z nor ϕ: any component of the field can only depend on r.
A radial component is forbidden. In fact if the current is reversed the magnetic field will reverse its direction. But reversing the current amount to rotate by π the solenoid around any axis perpendicular to the axis of the solenoid and and passing by it, which would not reverse the direction of the magnetic field. Note that a similar argument does not hold for a finite length solenoid, as its radial component is not, and must not be, independent of z.

DRAFT - EN - Ugo Pisa

Alternatively, if a radial component would exist, it would be independent of both z and ϕ, so that the flux across any closed circular cylinder coaxial with the z axis would be non-zero, this violating **Maxwell Equations** . Note that a divergence-less radial field with the given constraints, must be of the form: $B_r = \alpha/r$, which is singular on the z axis, so that it is not a valid field for this problem.
A tangential component is forbidden as well. In fact it would be independent of ϕ so that Ampère law would be violated around any circular path concentric with the solenoid axis and perpendicular to it.
Therefore the magnetic field must be along z and it cannot depend on neither z nor ϕ:

$$\mathbf{B}[\mathbf{r}] = \widehat{\mathbf{e}}_3 B_z[r] \quad .$$

Read also § 36.20.29.
Ampère law then implies that the magnetic field is uniform both inside and outside the solenoid. Moreover, the discontinuity law applies, and it provides the value of the uniform field.
Alternatively, in between the solenoid as well as outside it the magnetic field is rotor-less, and therefore, from the expression of the rotor in cylindrical coordinates:

$$\frac{\partial B_z}{\partial r} = 0 \quad ,$$

that is the magnetic field is uniform inside and outside the solenoid.

36.20.64
A Circular Infinite Solenoid With Helicoidal Windings

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|§ 35-6||

Read also § 36.20.65 and § 39-010.

Consider a cylindrical circular solenoid of radius R and length L, with $L \gg R$ and helicoidal windings spaced by a distance p, $p \ll R$, which is made by a thin wire with $n \equiv 1/p$ windings per unit length. Let the z axis be coincident with the axis of the solenoid and the origin at the center of the solenoid.

1. Determine the ratio between the internal purely longitudinal magnetic field, $\mathbf{B}_{\mathrm{I}}$, and the external purely azimuthal magnetic field, $\mathbf{B}_{\mathrm{E}}$.
2. Calculate the magnetic field at very large distances, $|\mathbf{r}| \gg L$.

Note that the external field can be reduced by adding a second layer of windings with a backward stepping with respect to the first one.

WORKED SOLUTION

$$B_{\mathrm{E}}[\mathbf{r}] = \frac{\mu_0 I}{2\pi\sqrt{x^2+y^2}} \qquad \text{for } \sqrt{x^2+y^2} > R \text{ and } |z| \ll L/2 \quad .$$

$$\frac{B_{\mathrm{E}}}{B_{\mathrm{I}}} = \frac{1}{2\pi n\sqrt{x^2+y^2}} \quad .$$

CC BY NC ND

36.20.65
☒ Field on the Axis of an Ideal Circular Finite Solenoid

This § is referenced at pages:
[1786, 1918]

An ideal circular solenoid is made of a circular cylindrical conducting plate of length L and radius R where a uniform surface current $\mathbf{j}_S$ exist having no components along the axis of the solenoid. Let the z axis be the axis of the solenoid.

1. Calculate the magnetic field along the z axis.
2. Show that the result reduces to the result of problem § 36.20.63 in the case of infinite length.

WORKED SOLUTION

Measuring the z coordinate with respect to the center of the solenoid and letting the angles ϕ_+ and ϕ_- be the angles with respect to the axis over which the edges of the solenoid are seen from the point where one wants to calculate the field one finds:

$$B_z[x=0,y=0,z]=\frac{\mu_0|\mathbf{j}_S|}{2}\left(\frac{L+2z}{\sqrt{(L+2z)^2+4R^2}}+\frac{L-2z}{\sqrt{(L-2z)^2+4R^2}}\right)=\frac{\mu_0|\mathbf{j}_S|}{2}(\cos[\phi_+]+\cos[\phi_-])\quad .$$

☒ EM Potentials for Uniform and Static ElectroMagnetic Fields

This § is referenced at pages:
[1865]

1. Show that the **scalar electric potential** describing a uniform and constant electric field, $\mathbf{E}$, is:

$$\Phi = -\mathbf{E}\cdot\mathbf{x} + k \qquad \text{with } k \text{ arbitrary constant} \quad .$$

2. The term $\mathbf{E}\cdot\mathbf{x}$ of the potential sets an origin of the coordinates at $\mathbf{x} = \mathbf{0}$, which might seem to be incompatible with the fact the electric field is uniform in all space with no privileged points. Show that the arbitrariness of the origin is kept by the presence of the term k in the potential.

WORKED SOLUTION

Coordinate translation:

$$\mathbf{y} = \mathbf{x} + \mathbf{a} \quad .$$

It follows:

$$\begin{aligned}\Phi &= -\mathbf{E}\cdot\mathbf{x} + k = -\mathbf{E}\cdot(\mathbf{x}+\mathbf{a}) + \mathbf{E}\cdot\mathbf{a} + k \quad , \\ &= -\mathbf{E}\cdot\mathbf{y} + \mathbf{E}\cdot\mathbf{a} + k = \Phi' + k' \quad .\end{aligned}$$

Show that the **vector magnetic potential** describing a uniform and constant magnetic field, $\mathbf{B}$, is:

$$\mathbf{A} = \frac{1}{2}\mathbf{B}\wedge\mathbf{x} + \mathbf{grad}\Lambda[\mathbf{x},t] \qquad \text{with } \Lambda[\mathbf{x},t] \text{ arbitrary function} \quad .$$

The term $\frac{1}{2}\mathbf{B}\wedge\mathbf{x}$ of the potential sets an origin of the coordinates at $\mathbf{x} = \mathbf{0}$, which might seem to be incompatible with the fact that the magnetic field is uniform in all space with no privileged points.

Show that the arbitrariness of the origin is kept by the presence of the term $\mathbf{grad}\Lambda[\mathbf{x},t]$ in the potential.

WORKED SOLUTION

Coordinate translation:

$$\mathbf{y} = \mathbf{x} + \mathbf{a} \quad .$$

It follows:

$$\begin{aligned}\mathbf{A} &= \frac{1}{2}\mathbf{B}\wedge\mathbf{x} + \mathbf{grad}\Lambda[\mathbf{x},t] = \frac{1}{2}\mathbf{B}\wedge(\mathbf{x}+\mathbf{a}) - \frac{1}{2}\mathbf{B}\wedge\mathbf{a} + \mathbf{grad}\Lambda[\mathbf{x},t] \quad , \\ &= \frac{1}{2}\mathbf{B}\wedge(\mathbf{x}+\mathbf{a}) - \frac{1}{2}\mathbf{grad}(\,\mathbf{x}\cdot(\,\mathbf{B}\wedge\mathbf{a})) + \mathbf{grad}\Lambda[\mathbf{x},t] = \mathbf{A}' + \mathbf{grad}\big(\Lambda'[\mathbf{x},t]\big) \quad .\end{aligned}$$

☒ Vector Potential for Uniform and Static Magnetic Field

1. Show that the **vector magnetic potential** of a homogeneous field, $\mathbf{B} = B_0\widehat{\mathbf{e}}_3$, in a rectangular system of coordinates, can be expressed as:
$$\mathbf{A} = -\widehat{\mathbf{e}}_1 C_1 B_0 y + +\widehat{\mathbf{e}}_2 C_2 B_0 x \qquad C_1 + C_2 = 1 \qquad C_1 \text{ and } C_2 \text{ constants} \quad .$$
2. Show that the **vector magnetic potential** of a homogeneous field, $\mathbf{B} = B_0\widehat{\mathbf{e}}_3$, in a cylindrical system of coordinates, can be expressed as:
$$\mathbf{A} = \frac{B_0 r}{2}\widehat{\mathbf{e}}_\theta \quad .$$
3. Show that the **vector magnetic potential** of a homogeneous field, $\mathbf{B} = B_0\widehat{\mathbf{e}}_3$, in a spherical system of coordinates, can be expressed as:
$$\mathbf{A} = \frac{B_0 r \sin\theta}{2}\widehat{\mathbf{e}}_\psi \quad .$$
4. In all cases, how is it possible that a uniform field (invariant under translations) is described by a potential whose module depends on the distance from a arbitrary origin of the Coordinate System?

☒ ElectroStatic Energy of a Thin Circular Ring

©|Berkeley Physics Course, Vol. 2, E.M.Purcell & D.J.Morin, *Electricity And Magnetism*, 2013, CUP, ...Ed., ...|||

Consider a thin circular ring of radius R with a total charge Q uniformly distributed along it. Model the system as a finite number, n, of point charges uniformly distributed on a circle of radius R and consider the appropriate limiting process.

1. Calculate the ElectroStatic energy.

Read § 36-017.

36.20.71

☒ Energia Elettrostatica Di Una Sfera Carica Con Densità Di Carica Omogenea

1. Determine the ElectroStatic potential energy of a spherical charge distribution of radius R and uniform charge density, with a total charge Q.

WORKED SOLUTION

$$\Phi = \frac{1}{4\pi\varepsilon_0}\frac{3Q^2}{5R}$$

36.20.72

☒ Energia Di Due Distribuzioni Di Carica

Si supponga di avere due distribuzioni di carica distinte, con densità di carica di volume: $\rho_1[\mathbf{x}]$ e $\rho_2[\mathbf{x}]$.

1. Determinare l'energia elettrostatica della configurazione, in funzione dei campi elettrici $\mathbf{E}_1$ e $\mathbf{E}_2$ prodotti dalle due singole distribuzioni di carica.

WORKED SOLUTION

Data una qualunque distribuzione di carica di volume, $\rho[\mathbf{x}]$, limitata si ha:
$$\Phi_e = \frac{1}{2}\iiint \rho[\mathbf{x}]\Phi[\mathbf{x}]\,\mathrm{d}V_{\mathbf{x}} = \Phi_e = \iiint u[\mathbf{x}]\,\mathrm{d}V_{\mathbf{x}} \qquad u[\mathbf{x}] = \frac{1}{2}\varepsilon_0|\mathbf{E}[\mathbf{x}]|^2 \quad .$$
Siano $\mathbf{E}_1[\mathbf{x}]$ e $\mathbf{E}_2[\mathbf{x}]$ i campi elettrici prodotti dalle due distribuzioni di carica $\rho_1[\mathbf{x}]$ e $\rho_2[\mathbf{x}]$ da sole.

DRAFT - IN - PROGRESS

Per il principio di sovrapposizione

$$\mathbf{E}[\mathbf{x}] = \mathbf{E}_1[\mathbf{x}] + \mathbf{E}_2[\mathbf{x}] \quad ,$$

ne allora

$$\Phi_e = \frac{1}{2}\varepsilon_0 \int \left(|\mathbf{E}_1|^2 + |\mathbf{E}_2|^2 + 2\,\mathbf{E}_1 \cdot \mathbf{E}_2 \right) \mathrm{d}\mathbf{x}$$

Se ne conclude che l'energia complessiva del sistema è data dalla somma delle due auto-energie più l'energia di interazione.
Come corollario si può dire che, tutte le volte che in un cambio di configurazione dei campi elettrici una certa distribuzione di carica non cambia il suo termine di auto-energia può essere trascurato perchè immutato.
This is true even if the self-energy turns out to be infinite, that is for point charges.

Consider a cylindrical circular solenoid of radius R and length L, with $L \gg R$ and treat it as an ideal solenoid. Assume the current is changing with time in some way, so that the flux of the magnetic field concatenated with the circuit is changing with time. Consider a plane circular closed circuit consisting of two resistors, R_1 and R_2, located in a plane perpendicular to the axis of the solenoid and concentric to it. Two voltmeters are connected to the two points, A and B, where the two resistors are connected. The closed circuit voltmeter-resistor do not encircle the solenoid at all.

Note that any real voltmeter always measures, between A and B: $\int_A^B E \cdot \mathrm{d}\mathbf{L}$. In fact a typical voltmeter is a high-resistance instrument which measures the current passing inside it. If the voltemter is connected to two points in such a away that the closed loop does not have any change of the magnetic filed flux inside it then the voltage betwen the two points is the same as the one measured by the voltmeter, neglecting the perturbation induced by the insertion of the voltmeter.

The voltmeter, assumed to be a Ohmic instrument, measures the line integral of the electric field. If it is crossed by a measured current I on a wire of sectional area A and its internal resistence is R one has:

$$\mathrm{d}\Phi = I\, \mathrm{d}R = I\frac{\mathrm{d}\mathbf{L}}{\sigma A} = \frac{j\, \mathrm{d}\mathbf{L}}{\sigma} = E\, \mathrm{d}\mathbf{L} \quad .$$

1. What do the two voltmeters measure?

Do not confuse differences between the **scalar electric potential** at different points with line integrals of the electric field, as these are two different concepts in non-static conditions.

Magnetic Field of the Earth

©|WEB - URL |||

The magnetic field of the Earth (read § 39.08.02) is modeled, near the earth surface, as a **Magnetic Dipole** field, as we are reasonably far away from the Charge|Current producing the ElectroMagnetic fields, which are typically located close the center of the Earth. The **Magnetic Dipole** field of the Earth is closely described by a **Magnetic Dipole** located close to the center of the Earth inclined with respect to the Earth rotation axis. Uranus has a magnetic field modeled by a **Magnetic Dipole** located far away from the center of Uranus and inclined by $59\ ^\circ$ with respect to the rotation axis.

36-004 ✓ Tangential components of discontinuities of the fields

Demonstrate the implications in equation (36.09.05) and (36.09.06).

36-005 ✓ Rotational Equilibrium of Two Dipoles

©|D.Halliday & R.Resnick & K.S.Krane, *Fisica*, 2003/2004, C.E.A., 5thEd., ...|37.3||

Consider two identical **Magnetic Dipoles** , away from any other external magnetic field. The first **Dipole** is kept fixed at the origin of a orthonormal Cartesian Coordinates Coordinate System with its **Dipole** moment directed along the z axis. The second **Dipole** is kept at some distance r from the first **Dipole** , free to rotate.

1. Determine the equilibrium position, with respect to rotation, when the second **Dipole** is located on the z axis. Is the equilibrium stable or unstable?
2. Determine the equilibrium position, with respect to rotation, when the second **Dipole** is located on the $x - y$ plane. Is the equilibrium stable or unstable?
3. Write the expression of the potential energy of interaction of the two **Dipoles** .

Read § 36.20.12.

36-006 Force on a fixed dipole in terms of the shear tensor of the field

This § is referenced at pages:
[1965, 1967]

Show that the force on a fixed dipole (equation (36.05.02) and equation (36.05.03)) can be written in terms of the symmetrical shear tensor of the external field, $\mathbb{S}$, outside charges/currents and in static conditions, as:

$$f_k = p_i \mathbb{S}[\mathbf{E}]_{ik} \qquad f_k = m_i \mathbb{S}[\mathbf{B}]_{ik} \quad . \tag{36.21.01}$$

DRAFT-IN-PROGRESS

36-007 ✓ Super-Conducting Magnet of the CMS Experiment at CERN

It is the world largest superconducting solenoid magnet, as of year 2006 [1] Main parameters of the CMS magnet: size: $13\ \mathrm{m} \times 5.9\ \mathrm{m}$ (length times diameter); current: $I = 19.5\ \mathrm{kA}$; magnetic field: $4\ \mathrm{T}$; stored energy: $E = 2.7\ \mathrm{GJ}$; mass: $M = 220\ \mathrm{ton}$.

The solenoid tends to explode due to the radial magnetostatic pressure.

1. Calculate the radial magnetostatic pressure.
2. Compare with a typical pressure of automotive tires, relative to atmospheric pressure, which is about two atm.

36-008 ✓ A Superconducting Loop

©|D.J.Griffiths, *Introduction To Electrodynamics*, 1999, Prentice Hall, 3rdEd., ...|problem 5.21||

Show that the magnetic flux through a perfectly conducting loop is constant.

WORKED SOLUTION

Apply Faraday-Neumann-Lenz (integral form) to the loop: as $\mathbf{E}$ is always zero the magnetic flux must be constant.

36-009 A Discharging Capacitor

©|I.E.Irodov, *Problems In General Physics*, 1988, MIR publishers Moscow, ...Ed., ...|3.348||

A plane capacitor is made of two circular flat disks and a homogeneous weakly conducting medium inside them. The capacitor is charged and the battery is removed afterwards.

1. Show that, as long as edge effects can be neglected, the magnetic field inside the capacitor is zero.

36-010 Resistance and Discharge Time on a Cylindrical Capacitor

1. Determine the time constant for the discharge of a real cylindrical capacitor as a function of the geometrical parameters and properties of the material between the armatures.

36-011 ✓ Force on a Current Carrying Conductor of Arbitrary Shape

Consider a piece of current wire of arbitrary shape, with starting point (S) and end point (E), carrying a steady current I.

1. Write the expression of the total force on it when it is immersed in a constant and uniform magnetic field.
2. What is the result for a closed loop?
3. Every piece of the wire is immersed in the magnetic field produced by the other pieces of the wire and therefore also feels a force due to the other pieces of wire. What is the effect of these forces?

WORKED SOLUTION

Let $\mathbf{L}$ be the vector from the starting point (S) to the end point (E) of the wire

$$\mathbf{F} = I\,\mathbf{L}\wedge\mathbf{B} \quad .$$

[1] See, for instance WEB - URL and WEB - URL

DRAFT - IN PROGRESS

36-012 ✓ ElectroStatic Quadrupole Field (1)

Consider the ElectroStatic field of § 16.12.04.06:

$$\mathbf{E}[\mathbf{r}] = k\,(y\widehat{\mathbf{e}}_1 + x\widehat{\mathbf{e}}_2) \quad .$$

1. Calculate the electric potential.
2. Calculate the field lines.
3. Rewrite the potential in cylindrical coordinates and show that it satisfies **Poisson equation** .

WORKED SOLUTION

As the field is both irrotational and solenoidal it can be an ElectroStatic field outside the charges producing the electric field.

1. The potential difference does not depend on the path and therefore one can choose a path that makes the integral easy. Let us calculate the potential at $P = \{x, y, 0\}$ using as a reference point the origin of the Coordinate System: O. Use the intermediate point $A = \{x, 0, 0\}$.

$$\Phi(P) - \Phi(O) = -\int_O^P \mathbf{E}\cdot \mathbb{d}\boldsymbol{\ell} = \quad ,$$

$$\Longrightarrow \quad ,$$

$$-\left(\int_O^A + \int_A^P\right) \mathbf{E}\cdot \mathbb{d}\boldsymbol{\ell} = -\int_O^A \mathbf{E}\cdot \mathbb{d}\boldsymbol{\ell} - \int_A^P \mathbf{E}\cdot \mathbb{d}\boldsymbol{\ell} = -\int_0^x ky\ \mathbb{d}x - \int_0^y kx\ \mathbb{d}y = 0 - \int_0^y kx\ \mathbb{d}y = -kxy \quad .$$

Equipotential surfaces are the equilateral hyperbolas:

$$xy = \text{constant} \quad .$$

A suitable set of electrodes held at the appropriate potential can be used to build such a field.

2.

$$\frac{\mathbb{d}\mathbf{r}}{\mathbb{d}s} = \mathbf{E} \qquad \text{with the field lines parameterised by } \mathbf{r} = \mathbf{r}[s] \quad ,$$

$$\begin{cases} \dfrac{\mathbb{d}x[s]}{\mathbb{d}s} = ky \\ \dfrac{\mathbb{d}y[s]}{\mathbb{d}s} = kx \end{cases} \quad , \qquad \Longrightarrow \frac{\mathbb{d}x}{y} = \frac{\mathbb{d}y}{x} \Longrightarrow x^2 - y^2 = \text{constant} \equiv c \quad .$$

The above solution of the system of differential equations gave the field lines in implicit form. The explicit parameterised form of the field lines can be found to be:

$$x[s] = A\exp[+ks] + B\exp[-ks] \quad ,$$
$$y[s] = A\exp[+ks] - B\exp[-ks] \quad ,$$

where the integration constants A and B are linked to the integration constant c of the implicit form by:

$$c = 4AB \quad .$$

3.

$$\Phi[r, \phi] = -kr^2 \sin[\phi]\cos[\phi] \quad .$$
