Consider a uniformly charged plane thin circular ring of radius \(R\) carrying a total charge \(Q\). Let \(z\) be the axis of the ring, with origin at the center of the ring.
Calculate the potential and electric field on the axis by direct calculation.
Calculate, if possibile, the electric field from the potential.

\section*{SOLUTION}
\[
\Phi[z]=\frac{1}{4 \pi \varepsilon_{0}} \int \frac{\mathrm{~d} q}{d}=\frac{1}{4 \pi \varepsilon_{0}} \frac{Q}{\sqrt{R^{2}+z^{2}}} .
\]

Consider a uniformly charged plane thin circular disk of radius \(R\) carrying a total charge \(Q\). Let \(z\) be the axis of the disk, with origin at the center of the ring.
Calculate the potential and electric field on the axis by direct calculation and using the results of the previuos point, that is considering the disk made of infinitesimal rings carrying an infinitesiamal charge d \(q\).
Calculate, if possibile, the electric field from the potential.
Check the signs of potential and electric field and the validity of the discontinuity relations.

\section*{SOLUTION}
\[
\begin{gathered}
\Phi[z]=\frac{1}{4 \pi \varepsilon_{0}} \int_{r=0}^{R} \frac{2 \pi \rho_{\mathrm{S}} r \mathrm{~d} r}{\sqrt{r^{2}+z^{2}}}=\frac{\rho_{\mathrm{S}}}{2 \varepsilon_{0}}\left(\sqrt{R^{2}+z^{2}}-|z|\right) . \\
E_{z}[z]=-\frac{\partial \Phi}{\partial z}=\frac{\rho_{\mathrm{S}}}{2 \varepsilon_{0}}\left(\frac{z}{\sqrt{R^{2}+z^{2}}}-\frac{z}{|z|}\right) .
\end{gathered}
\]

Consider the two limiting cases of very large and very small distance with respect to the radius and check that the results reduce to what one expects from known results.

\section*{SOLUTION}
\[
\left\{\begin{aligned}
\lim _{z \rightarrow z^{+}} E_{z}[z]= & +\frac{\rho_{\mathrm{S}}}{2 \varepsilon_{0}}, \\
\lim _{z \rightarrow z^{-}} E_{z}[z]= & -\frac{\rho_{\mathrm{S}}}{2 \varepsilon_{0}}
\end{aligned} \quad\right. \text { as for an infinite plane }
\]

Calculate the potential at one point at the edge of the disk.

\section*{SOLUTION}

Use a Coordinate System in polar coordinate centered at the point on the edge.
\[
\Phi=\frac{1}{4 \pi \varepsilon_{0}} \int_{\theta=-\pi / 2}^{\theta=+\pi / 2} \int_{r=0}^{2 R \cos \theta} \frac{\rho_{\mathrm{S}} r \mathrm{~d} r \mathrm{~d} \theta}{r}=\frac{\rho_{\mathrm{S}} R}{\pi \varepsilon_{0}}
\]

Calculate the potential on the axis by direct integration in two dimensions.
Consider a uniformly charged sphere of radius \(R\) carrying a total charge \(Q\). Let \(z\) be the axis of the sphere, with origin at the center of the ring.

Calculate the potential and electric field on the axis by direct calculation and using the results of the previuos point, that is considering the sphere made of infinitesimal dikss carrying an infinitesiamal charge \(\mathrm{d} q\).

\section*{33-015 \(\checkmark\) A Spherical Shell}

Consider a uniformly charged thin spherical shell of radius \(R\) carrying a total charge \(Q\). Let \(z\) be the axis, with origin at the center of the sphere.

Calculate the potential at any point, internal and external to the shell, by direct integration.
Compare the results with the known result deriving from Gauss law.
Use the above result to calculate the potential of a sphere with uniform charge density.

\section*{33-016 \(\checkmark\) Electric Potential on the Axis of a Thin Circular Right Cylinder}
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
Calculate the electric potential on the axis of a thin circular right cylinder of radius \(R\) and length \(L\) with uniform charge density and total charge \(Q\).

\section*{33-017 \(\checkmark\) Electric Potential on the Axis of a Thick Circular Right Cylinder}

Calculate the electric potential on the axis of a thick circular right cylinder of internal radius \(R_{1}\), external radius \(R_{2}\) and thickness \(D\) with a uniform charge density and total charge \(Q\).

\section*{33-018 \(\checkmark\) ElectroMagnetic Potentials}

This § is referenced at pages:

©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P16.3||
Si consideri il campo elettromagnetico descritto dal potenziale:
\[
\Phi_{1}=0 \quad \mathbf{A}_{1}=\left(x B_{0}-t E_{0}\right) \hat{\mathbf{e}}_{2} .
\]
1. Calcolare i campi elettrico e magnetico.
\begin{tabular}{|lll|}
\hline SOLUTION \\
\hline \(\mathbf{E}=E_{0} \hat{\mathbf{e}}_{2}\) & \(\mathbf{B}=B_{0} \hat{\mathbf{e}}_{3}\) & \\
\hline
\end{tabular}
2. Calcolare la circuitazione del campo elettrico attorno ad una qualunque linea chiusa.
3. Calcolare l'integrale di linea del campo elettrico tra i due punti generici \(O=\left\{x_{0}, y_{0}, z_{0}\right\}\) e \(P=\left\{x_{1}, y_{1}, z_{1}\right\}\).

\section*{SOLUTION}

Il campo elettrico in questo problema è conservativo.
\[
\int_{O}^{P} \mathbf{E} \cdot \mathrm{~d} \mathbf{r}=E_{0}\left(y_{1}-y_{0}\right)
\]
4. Si consideri il potenziale:
\[
\Phi_{2}=-E_{0} y \quad \mathbf{A}_{2}=\frac{1}{2} \mathbf{B} \times \mathbf{r} \quad \text { con } \mathbf{B}=B_{0} \hat{\mathbf{e}}_{3}
\]

Dimostrare che descrive lo stesso campo elettromagnetico del potenziale (1). Determinare la funzione che descrive la trasformazione di gauge che fa passare dal primo four-potenziale al secondo.

\section*{SOLUTION}
\[
\Lambda[\mathbf{x}, t]=-B_{0} \frac{x y}{2}+E_{0} y t+\mathrm{constant}
\]

\section*{33-019 \(\checkmark\) A Rotating Metal Disk}
©||.E.Irodov, Problems In General Physics, 1988, MIR publishers Moscow, ...Ed., ....|3.290||
A metal disc of radius \(a=25 \mathrm{~cm}\) rotates with a constant angular velocity \(\omega=130 \mathrm{rad} / \mathrm{s}\) about its axis. Find the potential difference between the center and the rim of the disc if: the external magnetic field is absent; the external uniform magnetic field is \(B=5.0 \mathrm{mT}\) is directed perpendicular to the disc.

\section*{33-020 \(\checkmark\) A Sheet of Charge}

A plane sheet of charge, with thickness \(d\) much smaller than its dimensions, carries a uniform charge density per unit volume, \(\rho\). Let \(z\) be the axis perpendicular to the plane, with origin at the center of the sheet of charge, so that the charge density is uniform for \(|z| \leq d / 2\) and zero otherwise.
Determine the scalar potential produced by the sheet of charge as a function of \(z\) taking zero potential at \(z=0\).

\section*{SOLUTION}

Solve Poisson equation and apply the continuity of the scalar potential and its derivative. Fix the arbitrary constant remaining

\section*{33-021 \(\checkmark\) Static Fields in the Temporal Gauge}

Consider two constant and homogeneous fields, \(\mathbf{E}\) and \(\mathbf{B}\), and determine the ElectroMagnetic potentials that, in the temporal gauge ( \(\Phi=0\) ), give rise to them.

\section*{33-022 \(\checkmark\) Potential of a Uniformly Charged Spherical Shell}

This § is referenced at pages:
[Never referenced.]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Example 2.7||
Find the potential at every point in space of a uniformly charged spherical shell by direct integration.

\section*{SOLUTION}

Use a system of spherical coordinates centered at the center of the sphere and with its \(z\) axis passing by the point \(P\) where the potential must be calculated. Then integrate in rings perpendicular to \(z\) axis, so that all the points of the ring have the same distance from the point \(P\).

33-023 \(\checkmark\) Forza Tra Le Armature Di Un Condensatore Piano
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|31.40||
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
Si determini la forza di attrazione tra le due armature di un condensatore piano con due armature di area \(A\) a distanza \(x\), cariche con carica \(Q\).
Do the calculation by considering:
1. the electric field and surface charges;
2. the method of virtual works, that is use the change of the energy of the system for an infinitesimal change of the distance between the armatures, \(x\), at constant charge;
3. the method of virtual works, that is use the change of the energy of the system for an infinitesimal change of the distance between the armatures, \(x\), at constant voltage;
4. the concept of ElectroStatic pressure.

\section*{33-024 \(\checkmark\) A Superconducting Loop}

Show that the magnetic flux through a perfectly conducting loop is constant.

\section*{SOLUTION}

Apply Faraday-Neumann-Lenz (integral form) to the loop: as \(\mathbf{E}\) is always zero the magnetic flux must be constant.
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 5.21||
Is Ampere law consistent with the general rule that the divergence of a rotor is always zero? Show that Ampere law cannot be valid, in general, outside magnetostatics. Is there any such defect in the other three Maxwell equations?

\section*{33-025 Explicit Construction of the Vector Potential}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 5.31||

\section*{33-026 \(\checkmark\) Helmholtz Coils}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|35.10 35.26 35.27||
Helmholtz coils are a practical tool to obtain a uniform magnetic field.
Consider two identical plane circular loops, of radius \(R\), located coaxially and separated by a variable distance \(D\) and carrying a constant current \(I\). Let the \(z\) axis be the axis of the two loops and let the origin be located at the middle point.
Determine the magnetic field at the middle point \(\left(\mathbf{B}_{0}\right)\) as a function of \(D\) and compare it with the magnetic fields \(\left(\mathbf{B}_{1}\right)\) at the center of the two loops.
Study the family of functions \(B_{z}[z, D]\) for different values of the parameter \(D\).
Determine the distance \(D\) such that the relative difference between \(B_{1}\) and \(B_{0}\) is minimal and show that, placing the two loops at the distance \(D\), the magnetic field near the middle point is uniform up to third-order in the distance from the middle point along the axis of the two loops.

\section*{SOLUTION}
\[
B_{z}=\frac{\mu_{0} I R^{2}}{2}\left(\frac{1}{\left(R^{2}+(z+D / 2)^{2}\right)^{3 / 2}}+\frac{1}{\left(R^{2}+(z-D / 2)^{2}\right)^{3 / 2}}\right)
\]

\section*{33-027 \(\checkmark\) A Rotating Uniformly Charged Ring of Charge}

This § is referenced at pages:
[1776, 1776]
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.9||
Consider a thin ring of radius \(R\) with a uniformly distributed charge \(Q\) on it. The ring rotates around its axis with constant angular velocity \(\omega\).
1. Show that the Magnetic Dipole moment is:
\[
\mathrm{m}=\frac{Q R^{2}}{2} \boldsymbol{\omega}
\]
2. Find the relation of the Magnetic Dipole moment to the angular moment.

\section*{33-028 \(\checkmark\) A Rotating Uniformly Charged Circular Disk}

This § is referenced at pages:
[1776, 1776]
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|35.32||
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P 11.10||
A thin circular disk of radius \(R\) carries a uniformly distributed charge \(Q\). The disk rotates with a constant angular velocity \(\omega\) around its axis.

Calculate the magnetic field at the center of the disk.
Calculate the Magnetic Dipole moment.

\section*{SOLUTION}
\[
\begin{aligned}
\mathbf{B} & =\frac{\mu_{0} \omega Q}{2 \pi R} \frac{\boldsymbol{\omega}}{\omega} \\
\mathrm{~m} & =\frac{Q R^{2}}{4} \boldsymbol{\omega}
\end{aligned}
\]

\section*{33-029 \(\checkmark\) A Rotating Uniformly Charged Spherical Shell}

\section*{This § is referenced at pages:}
[1776, 1776, 1777, 1777, 1878, 1878]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Example 5.11|Explicit calculation ©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P 11.9||

A spherical shell of radius \(R\) carries a uniformly distributed charge \(Q\). The sphere rotates with a constant angular velocity \(\omega\) around one of its diameters.

Calculate the vector potential at any point in space.
Calculate the Magnetic Dipole moment.
Calculate the magnetic field at any point in space.

\section*{SOLUTION}

The integration is not trivial but it can be carried on. A suitable choice of the Coordinate System make the integration a lot easier.
Choose an Coordinate System centered at the center of the sphere with its \(z\) axis passing by the point \(P\) where the vector potential is going to be calculated and let \(\boldsymbol{\omega}\) lie in the \(z x\) plane and making an angle \(\psi\) with the \(z\) axis. Use spherical coordinates, with the vector position \(\mathbf{x}\) defining the integration variable on the spherical shell. This Coordinate System is useful because it allows to integrate on one variable at constant distance from the infinitesimal element and the point \(P\), making the integration in one of the variables trivial.

Therefore, using equations (33.12.06) in the surface current expression, one finds:
\[
\begin{gathered}
\boldsymbol{\omega}=\omega\left(\sin \psi \hat{\mathbf{e}}_{1}+\cos \psi \hat{\mathbf{e}}_{3}\right) \\
\mathbf{x}=R\left(\sin \theta \cos \phi \hat{\mathbf{e}}_{1}+\sin \theta \sin \phi \hat{\mathbf{e}}_{2}+\cos \theta \hat{\mathbf{e}}_{3}\right) \\
\mathbf{j}_{\mathrm{S}}=\rho_{\mathrm{S}}(\boldsymbol{\omega} \times \mathbf{x}) \\
\mathbf{A}=\frac{\mu_{0}}{4 \pi} \iint \frac{\rho_{\mathrm{S}}(\boldsymbol{\omega} \times \mathbf{x}) R^{2} \sin \theta}{\sqrt{R^{2}+r^{2}-2 r R \cos \theta}} \mathrm{~d} \theta \mathrm{~d} \phi
\end{gathered}
\]
all terms in \(\boldsymbol{\omega} \times \mathbf{r}\) but \(-\hat{\mathbf{e}}_{2} \sin \psi \cos \theta\) are proportional to either \(\sin \phi\) or \(\cos \phi\), the integral in \(\mathrm{d} \phi\) is zero: ,
\(\mathbf{A}=2 \pi \frac{\mu_{0}}{4 \pi} \rho_{\mathrm{S}} \omega R^{3} \hat{\mathbf{e}}_{2} \sin \psi \int_{+1}^{-1} \frac{u \mathrm{~d} u}{\sqrt{R^{2}+r^{2}-2 r R u}}=\frac{\mu_{0} \rho_{\mathrm{S}} \omega R^{3} \sin \psi \hat{\mathbf{e}}_{2}}{2} \begin{cases}-\frac{2 r}{3 R^{2}} & \text { for } 0<r<R \\ -\frac{2 R}{3 r^{2}} & \text { for } 0<R<r\end{cases}\)
the above result can be written in vector form as ,
\[
\mathbf{A}[\mathbf{r}]=\left\{\begin{array}{lc}
\frac{\mu_{0} \rho_{\mathrm{S}} R^{4}}{3} \frac{\boldsymbol{\omega} \times \mathbf{r}}{r^{3}} & \text { for } 0<R<r \\
\frac{\mu_{0} \rho_{\mathrm{S}} R}{3} \boldsymbol{\omega} \times \mathbf{r} & \text { for } 0<r<R
\end{array}\right.
\]

As the result has been written in vector form and it is correct for the special choice of the Coordinate System it is always valid.
The Magnetic Dipole moment, integrating the infinitesimal rings perpendicular to the \(z\) axis, is:
- using the concept of total current:
\[
\mathrm{d} m_{z}=\mathrm{d} I A=\nu \rho_{\mathrm{S}}(2 \pi R \sin \theta) R \mathrm{~d} \theta\left(\pi R^{2} \sin ^{2} \theta\right)
\]
using the concept of surface current:
\[
\mathrm{d} m_{z}=\left|\mathbf{j}_{\mathrm{S}}\right| R \mathrm{~d} \theta A=\rho_{\mathrm{S}} \omega R \sin \theta R \mathrm{~d} \theta\left(\pi R^{2} \sin ^{2} \theta\right)
\]

Integration gives:
\[
\mathrm{m}=\frac{Q R^{2}}{3} \boldsymbol{\omega}
\]

The magnetic field inside the sphere is uniform:
\[
\mathbf{B}=\frac{2}{3} \mu_{0} \rho_{\mathrm{S}} R \omega \quad r<R, \text { uniform inside the sphere }
\]

The magnetic field outside the sphere is a pure Magnetic Dipole moment field.

\section*{33-030 \(\checkmark\) A Comparison of Rotating Uniformly Charged Objects}

Compare the Magnetic Dipole momenta of problems § 33-027 - Basic Laws of ElectroMagnetism, § 33-028 - Basic Laws of ElectroMagnetism and §33-029 - Basic Laws of ElectroMagnetism and explain why the numerical factors of one with respect to the other are as they are for the same total charge.

\section*{SOLUTION}

As far as the production of magnetic moment is concerned:
- Ring: it is the most efficient: the total charge is all at the maximum distance;
- Disk: it is less efficient than the ring;
- Spherical shell: it is less efficient than the ring but more efficient than the disk as the projection of the charge on the equatorial plane is not uniform but more densely packed near the edge.

\section*{33-031 \(\checkmark\) A Rotating Uniformly Charged Sphere}

This § is referenced at pages:
[Never referenced.]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Problem 5.58|Explicit calculation|
A uniformly charged solid sphere of radius \(R\) carries a total charge \(Q\). It is rotating with angular velocity \(\omega\) about one diameter, the \(z\) axis.
1. What is the Magnetic Dipole moment of the sphere?
2. Find the average magnetic field within the sphere (use the results in section § 33.18.02-Basic Laws of ElectroMagnetism).
3. Find the approximate vector potential at a point at distance \(r \gg R\) from the center of the sphere.
4. Find the exact potential at a point at a point at distance \(r \gg R\) from the center of the sphere, outside the sphere and check that it is consistent with the previuos question.
5. Find the magnetic field at a point inside the sphere, and check that it is consistent with § 33.18.02 - Basic Laws of ElectroMagnetism.

\section*{SOLUTION}

Use the result of problem §33-029 - Basic Laws of ElectroMagnetism: \(m=\frac{Q R^{2}}{3} \omega\) and let \(\rho_{\mathrm{S}} \rightarrow \rho \mathrm{d} r:\)
\[
\begin{gathered}
\mathrm{m}=\frac{Q R^{2}}{5} \boldsymbol{\omega} . \\
\mathbf{B}_{\mathrm{ave}}=\frac{\mu_{0}}{4 \pi} \frac{2 \mathrm{~m}}{R^{3}}
\end{gathered}
\]

The field is a point Dipole field outside the sphere.

\section*{33-032 \(\checkmark\) Generation of the Earth Magnetic Field}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.27 37.28||
The Earth magnetic field can be described as a Magnetic Dipole field generated by a Dipole moment \(m=8.0 \cdot 10^{22} \mathrm{~J} / \mathrm{T}\) located - approximately - at the center of the Earth and aligned - approximately - with the Earth rotation axis.
1. What current, flowing inside a hypothetical current loop running all around the equator, would be able to produce, at large distances, such a field?
2. Could one use such an apparatus to cancel the magnetic field at large distances?
3. Could one use such an apparatus to cancel the magnetic field at the Earth surface?
4. If the field would be produced by a iron sphere uniformly Magnetized, at saturation, what radius would be necessary for such a sphere? The Magnetic Dipole moment of a iron atom is \(m=2.1 \cdot 10^{-23} \mathrm{~J} / \mathrm{T}\).

\section*{33-033 \(\checkmark\) Earth Magnetic Field}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.29||
The Earth magnetic field can be described as a Magnetic Dipole field generated by a Dipole moment \(m=8.0 \cdot 10^{22} \mathrm{~J} / \mathrm{T}\) located - approximately - at the center of the Earth and aligned - approximately - with the Earth rotation axis. The real axis is not exactly aligned with the Earth rotation axis, however. The latitude as measured from the equator of the equatorial plane of the magnetic field is called the magnetic latitude, \(L_{m}\).
1. Show that the intensity of the field is given by:
\[
B=\frac{\mu_{0}}{4 \pi} \frac{m}{r^{3}} \sqrt{1+3\left(\sin L_{m}\right)^{2}} .
\]
2. Show that the inclination, \(\phi\), of the field related to the magnetic latitude by:
\[
\tan \phi=2 \tan L_{m}
\]

\section*{33-034 Magnetic Dipole Moment of a Rotating Bar}

A long and thin bar, made of an insulating material, is uniformly charged. Its length is \(L\), its mass is \(M\), and the total charge is \(Q\), uniformly distributed along its length. The bar rotates with angular velocity \(\omega\) around an axis orthogonal to the bar and passing by its center.

Calculate the Magnetic Dipole moment of the bar and the gyromagnetic ratio.
\begin{tabular}{|ll|}
\hline SOLUTION \\
\hline \(\mathrm{m}=\frac{Q L^{2}}{24} \boldsymbol{\omega} \quad g=1 \quad\). \\
\hline
\end{tabular}

\section*{33-035 \(\checkmark\) Three Wires}
©|Lim Yung-Kuo, Problems And Solutions On Electromagnetism, 1993, World Scientific, ...Ed., ....|2006||
Consider three straight long parallel wires lying on the same plane and equally spaced by a distance \(a\). Let the radius of the wires be much smaller than the distance between wires. Each wire carries the same current \(I\) in the same direction.
1. Calculate the points were the magnetic field is zero.
2. Suppose that the two external wires are kept fixed while the middle wire is moved rigidly by a small amount, \(x \ll a\), in the same plane of the other two wires and keeping it parallel to the other two wires. Determine the subsequent motion of the middle wire after it is left.
3. Suppose that the two external wires are kept fixed while the middle wire is moved rigidly by a small amount, \(y \ll a\), in the direction perpendicular to the plane of the other two wires and keeping it parallel to the other two wires. Determine the subsequent motion of the middle wire after it is left.

\section*{SOLUTION}
1. \(x= \pm a / \sqrt{3}\).
2. Both harmonic motion with \(\omega_{0}^{2}=\frac{\mu_{0} I^{2}}{m \pi a^{2}}\), with \(m\) mass of the wire.

\section*{33-036 A Rotating Cylindrical Shell}
©|Lim Yung-Kuo, Problems And Solutions On Electromagnetism, 1993, World Scientific, ...Ed., ....|2019||
A cylindrical shell of electric charge has length \(L\) and radius \(R\), with \(L \gg R\). The surface charge density is \(\rho_{\mathrm{S}}\) and the cylinder rotates with an angular velocity \(\omega\), which increases with time as \(\omega=k t\) with \(k\) a positive constant.
1. Determine the magnetic field inside the cylinder.
2. Determine the electric field inside the cylinder.
3. Determine the total electric field energy and the total magnetic field energy inside the cylinder.

\section*{33-037 \(\checkmark\) A Magnetic Sextupole Lens}
©|Lim Yung-Kuo, Problems And Solutions On Electromagnetism, 1993, World Scientific, ...Ed., ....|2093||
A Magnetic Dipole, \(m\), is placed in a magnetic field given by:
\[
\mathbf{B}=\alpha\left(x^{2}-y^{2}\right) \hat{\mathbf{e}}_{1}-2 \alpha x y \hat{\mathbf{e}}_{2}
\]
where \(\alpha\) is a constant.
Determine the Force|Torque on the Dipole as a function of the position.
Determine the force on a point particle with velocity \(\mathbf{v}=v_{z} \hat{\mathbf{e}}_{3}\) as a function of its \(x y\) coordinates.

\section*{33-038 A Discharging Capacitor}
©|I.E.Irodov, Problems In General Physics, 1988, MIR publishers Moscow, ...Ed., ....|3.348||
A plane capacitor is made of two circular flat disks and a homogeneous weakly conducting medium inside them. The capacitor is charged and the battery is removed afterwards. Show that, as long as edge effects can be neglected, the magnetic field inside the capacitor is zero.

\section*{33-039 \(\checkmark\) A Simple Quadrupole Charge Distribution}

Consider two identical real Electric Dipoles made of point charges \(\pm q\) at a distance \(d\). The four charges are all located along the \(z\) axis, with the two negative charges at the origin and the two positive charges at \(z= \pm d\).
Calculate the electric field at large distances along the \(z\) axis, and show that is goes like \(z^{-4}\).

\section*{SOLUTION}
\[
E_{z}=\frac{3 q d^{2}}{2 \pi \varepsilon_{0} z^{4}}
\]

\section*{33-040 \(\checkmark\) A Plane Square Loop}

Consider a square plane loop of current of side \(L\) carrying a constant current \(I\). Calculate the magnetic field along its axis.

33-041 \(\checkmark\) A Plane Polygonal Loop
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P 11.3||
Consider a plane loop of current carrying a constant current \(I\) and having the shape of a regular polygon with \(n\) sides inscribed in a circle of radius \(R\).
Calculate the magnetic field at the center.
Calculate the magnetic field along its axis.
Find, for both previus questions, the limiting case for \(n \rightarrow \infty\) at fixed \(R\).

\section*{33-042 \(\checkmark\) Ampère Law and Plane Loops}

Consider a circular plane loop of current of radius \(R\) carrying a constant current \(I\). Calculate the circulation of the magnetic field along a circuit going along the axis of the loop closing the integration path with a semi-circle of infinite radius. Be careful to evaluate the value of the circulation along the semi-circle of infinite radius. Verify that Ampère law is satisfied.
Consider a square plane loop of current of side \(L\) carrying a constant current \(I\). Calculate the circulation of the magnetic field along a circuit going along the axis of the loop closing the integration path with a semi-circle of infinite radius. Be careful to evaluate the value of the circulation along the semi-circle of infinite radius. Verify that Ampère law is satisfied.

\section*{33-043 \(\checkmark\) A Non-Plane Current Loop}

A circular loop of wire carrying a steady current \(I=1\) A has radius \(r=1 \mathrm{~cm}\) lies in the \(x y\) plane with its center at the origin. It is then bent so that half loop lies in the \(y z\) plane and the other half-loop lies in the \(x y\) plane.
1. What is the Magnetic Dipole moment?
2. What is the magnetic field at \(r_{1}=\{D, 0,0\}, r_{2}=\{0, D, 0\}\) and \(r_{3}=\{0,0, D\}\), with \(D=15 \mathrm{~m}\) ?

\section*{33-044 \(\checkmark\) Rotational Equilibrium of Two Dipoles}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.3||
Consider two identical Magnetic Dipoles, away from any other external magnetic field. The first Dipole is kept fixed at the origin of a orthonormal Cartesian Coordinates Coordinate System with its Dipole moment directed along the \(z\) axis. The second Dipole is kept at some distance \(r\) from the first Dipole, free to rotate.
1. Determine the equilibrium position, with respect to rotation, when the second Dipole is located on the \(z\) axis. Is the equilibrium stable or unstable?
2. Determine the equilibrium position, with respect to rotation, when the second Dipole is located on the \(x-y\) plane. Is the equilibrium stable or unstable?
3. Write the expression of the potential energy of interaction of the two Dipoles.

\section*{33-045 Freno Elettromagnetico E Correnti Di Focault}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|36.39||
©|J.P.Pérez et al., 5 Vol., , ..., ..., ...Ed., WEB - URL.|||
Un freno elettromagnetico a correnti di Focault è formato da un disco circolare di raggio \(R\) di materiale conduttore spesso \(s\) e con conducibilità \(\sigma\) che ruota attorno al suo asse con velocità angolare \(\omega\). Un campo magnetico esterno costante ed omogeneo \(B\) perpendicolare al piano del disco è applicato su una piccola porzione del disco di dimensioni sia radiale che trasversale pari ad \(a \ll R\) che dista \(r \ll R\) dal centro del disco.
Determinare l'espressione approssimata del momento frenante sul disco e della potenza dissipata per effetto Joule.

\section*{SOLUTION}

Si consideri l'areola alla stregua di un conduttore in moto in un campo magnetico esterno disposta radialmente al disco. Il conduttore è lungo \(a\) (misurato radialmente) e ha sezione \(a s\), nel piano trasverasale.
Il campo magnetico mette in moto le cariche libere e la corrente che ne risulta fa si che il conduttore venga frenato. La forza elettromotrice indotta vale allora:
\[
|\varepsilon| \simeq v B a
\]
e può essere considerata localizzata nella areola dove c'è il campo magnetico. La corrente indotta assume un valore che dipende dalla resistenza del circuito. La corrente indotta si chiuderà nel disco in qualche modo. Di certo però la resistenza complessiva offerta dal circuito sarà poco superiore a quella della sola areola, in quanto il resto del conduttore è molto più grande. Allora, essendo,
\[
R \simeq \frac{a}{\sigma a s}
\]
valore approssimato per difetto, si ha:
\[
I \simeq \frac{v B a}{R}=\frac{v B a}{\frac{a}{\sigma a s}}=\sigma v B a s
\]

La forza frenante sulla areola vale:
\[
F \simeq \sigma v B^{2} a^{2} s
\]
e il momento che ne risulta vale:
\[
\Gamma \simeq \sigma \omega r^{2} B^{2} a^{2} s
\]

Notare che la schematizzazione adottata per \(\mathbf{B}\) è molto cruda in quanto il campo magnetico non può annularsi bruscamente al di fuori della areola entro cui è supposto essere costante.
La potenza dissipata per effetto Joule vale allora:
\[
P_{J} \simeq R I^{2}=\sigma \omega^{2} r^{2} B^{2} a^{2} s .
\]

Discussione della legge di induzione nella forma completa...

\section*{33-046 \(\checkmark\) Force on a Current Carrying Conductor of Arbitrary Shape}

Consider a piece of current wire of arbitrary shape, with starting point (S) and end point (E), carrying a steady current \(I\).
1. Write the expression of the total force on it when it is immersed in a constant and uniform magnetic field.
2. What is the result for a closed loop?
3. Every piece of the wire is immersed in the magnetic field produced by the other pieces of the wire and therefore also feels a force due to the other pieces of wire. What is the effect of these forces?

\section*{SOLUTION}

Let \(\mathbf{L}\) be the vector from the starting point ( S ) to the end point ( E ) of the wire
\[
\mathbf{F}=I \mathbf{L} \times \mathbf{B}
\]

33-047 \(\checkmark\) Energy Balance of a Bar Moving in a Magnetic Field
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|§ 36-4||
Consider the situation described in § 33.18.21 - Basic Laws of ElectroMagnetism and write the energy balance, that is who does work and where the work done ends-up.

\section*{33-048 Earth Magnetic Field MagnetoStatic Pressure}

Determine the magnetic pressure due to the Earth magnetic field at the magnetic poles. Compare the value with the Earth atmospheric pressure Assume that the Magnetic Dipole moment is proportional to the angular velocity of the Earth: how much faster would the angular velocity need to be for the magnetic pressure to be comparable to the atmospheric pressure?

\section*{33-049 \(\checkmark\) Force on a fixed dipole in terms of the shear tensor of the field}

This § is referenced at pages:

\section*{Introduction}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|6.0||
Everyday macroscopic world is dominated by the ElectroMagnetic interactions. In fact, gravitational interactions are so weak that, apart from weight, have little effect on everyday phenomena. On the other hand, weak and strong interactions are only relevant at microscopic level, because they are short-range interactions, with ranges of the order of 1 fm or less.
Matter is almost everywhere: therefore it is important to understand how ElectroMagnetic fields behave in presence of matter and the other way round.

The interaction between ElectroMagnetic fields (including ElectroMagnetic waves) and matter explains many common phenomena, such as:
- Electric phenomena:
- the attraction of small pieces of paper by an electrised object;
- the attraction of a Polarizable material inside a charged capacitor;
- the increase of the capacity of a capacitor when inserting a material medium between its faces;
- the electric screening effect of a Polarizable material.
- Magnetic phenomena:
- the strong attraction of iron materials from a magnet;
- the weak attraction of some materials (such a aluminum) from a magnet;
- the weak repulsion of some materials (such as copper and silver) from a magnet;
- the increase of the inductance of a solenoid when a iron material is inserted inside it;
- the magnetic screening effect of certain materials.
- EM waves phenomena:
- why the sky is blue and the Sun is red at sunset;
- why gold is yellowish;
- how Polaroid glasses work;
- why X-rays are refracted in a opposite way with respect to light rays;
- why at a certain point of the reenter maneuver of a spaceship the radio communication is not working;
- why silver coatings give good mirrors.

The ElectroMagnetic fields interacts with the constituents of matter, including atomic nuclei, electrons, atoms and molecules, as well as elementary particles. The correct and full explanation of these interactions must use quantum-relativistic physics but most phenomena can be approximately and easily described by means of classical physics on the macroscopic scale.
The interaction of charged (point) particles with matter is classically described by the Lorentz force:
\[
\mathbf{F}=q(\mathbf{E}+\mathbf{v} \times \mathbf{B}) .
\]

Particles, atoms and molecules might also possess an Electric|Magnetic permanent Dipole moment and also higher order Electric|Magnetic multipole moments. In the former case the interaction must include the effect of the interaction of the Dipole moment with the field (Read § 35 - Electric Properties of Matter, § 36 - Magnetic Properties of Matter), the interaction energy being:
\[
\begin{array}{|lll}
\hline U_{e}=-\mathrm{p} \cdot \mathbf{E} & U_{m}=-\mathrm{m} \cdot \mathbf{B} & \text { ifoif } \mathrm{p} / \mathrm{m} \text { are permanent/fixed/rigid Dipoles } \\
\hline
\end{array}
\]
in the case the Electric|Magnetic Dipole moment are considered to be permanent (that is fixed) and not dependent of the external (applied) fields. Read § 38.02.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for linear Polarizable|Magnetizable Dipoles. The involved interaction energies turn out to be small in most cases.

Even if no permanent Dipole moment is present, in absence of external fields, the presence of external fields may induce one; the system is Polarizable|Magnetizable. Note that this may be also the case for
subatomic particles. Matter made of constituents having permanent dipoles is normally called (di)polar matter, for both the electric and the magnetic case.
The interactions with matter of electric with respect to magnetic fields play very different roles. The reason is simple and fundamental. Atoms and molecules are made of electrically charged particles which move with velocities generally small compared with the speed of light. A magnetic field exerts no force at all on a stationary electric charge while the force on a moving charged particle is proportional to the particle speed and therefore small for non-relativistic velocities. For instance, modules of electric and magnetic fields of ElectroMagnetic waves are linked by the relation \(E=c B\), so that the ratio of electric to magnetic forces is of the order of \(v / c\) (see section § 42 - ElectroMagnetic Waves). Electric forces overwhelmingly dominate the atomic scene, not magnetic forces. Magnetism appears, in our world at least, to be a relativistic effect. The story would be different if matter were made of magnetically charged particles.
Two different extreme models are usually considered to simplify the modeling of phenomena, in the so-called classical theory of ElectroMagnetism in matter:
- the case of a perfectly insulating material, where all the electrons are bound near a certain region (atom, molecule, ...) and kept there by an attractive force; generally speaking in a perfectly insulating material there are no charges free to move at all; a perfectly insulating material is called a dielectric material or simply a dielectric;
- the case of a perfectly conducting material, where there exist either electrons or ions (and|or any other charged particles) totally free to move; generally speaking in a perfectly conducting material there are a number of charges completely free to move, such as in a plasma; a perfectly conducting material is often just called a conducting material or simply a conductor.
Obviously the distinction between perfect insulators/conductors is not a sharp one and most material cannot be considered neither perfect insulators nor perfect conductors.
Two approaches are possible.
- In the microscopic approach the interaction is described at a microscopic level.
- In the macroscopic approach one does not attempt to describe every single particle, but the bulk properties of matter are considered on a large scale, expressing the properties of the medium in presence of the ElectroMagnetic fields; electric susceptibility, magnetic susceptibility and conductivity are the three basic properties. The advantage of the latter approach is that the properties used to describe the interaction between ElectroMagnetic fields and matter can be easily measured and can be incorporated in the basic laws of ElectroMagnetism. Note that those macroscopic properties, by their definition, are meaningful in every context, also beyond classical physics.
A decent microscopic discussion requires the use of modern quantum-relativistic physics as well as statistical physics.

\subsection*{34.01.01 Inadequacy of Classical Physics to a Microscopic Description}

Classical physics in unable to give a full and coherent description of microscopic ElectroMagnetic phenomena, even if in most cases it gives models and predictions very close to the reality.
- One first example is the picture of a neutral atom as one positive point charge (the nucleus) with the electrons orbiting around the nucleus which would give rise, classically, to a time-changing Electric Dipole which would radiate energy thus making the atom unstable.
- One second example is that classical physics does not give any magnetic phenomenon in matter, that is to say if classical physics is followed coherently until the end it can be shown that no magnetic phenomenon exists \({ }^{a}\).
\({ }^{\text {a }}\) R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....
© - QUOTE
R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., .... ...it is not possible to understand the magnetic effects of materials in any honest way from the point of view of classical physics. Such magnetic effects are a completely quantum-mechanical phenomenon. It is, however, possible to make some phony classical arguments and to get some idea of what is going on.
34.01.02 Nomenclature and Conventions
- The term dielectric material will be used to identify a perfectly insulating material.
- The effects of external electric fields on matter are called (induced) Polarization.
- The effects of external magnetic fields on matter are called (induced) Magnetization.
- The term Polarizable material will be used to identify a material which Polarizes, that is it acquires a Electric Dipole moment, if and only if it is under the effect of external electric fields.
- The term Magnetizable material will be used to identify a material which Magnetizes, that is it acquires a Magnetic Dipole moment, if and only if it is under the effect of external magnetic fields.

\title{
Macroscopic Description of ElectroMagnetic Fields in Presence of Matter
}

\section*{This § is referenced at pages:}
[1810, 1810, 1820, 1820, 1853, 1853, 1863, 1863]
Read also sections § 35.04 - Electric Properties of Matter, § 36.04 - Magnetic Properties of Matter.
All the properties of matter in presence of ElectroMagnetic fields can be described, to a first approximation, from a macroscopic point of view, via an Electric Dipole and|or a Magnetic Dipole moment acquired by the material medium.
In presence of ElectroMagnetic fields we can think that any volume element, macroscopically small but large on a microscopic scale, acquires an induced electric Dipole moment and|or a induced Magnetic Dipole moment. It will be then described by a Dipole moment per unit volume. The medium has thus become Polarized/Magnetized.
We will assume that this is sufficient to describe the macroscopic properties of matter in presence of ElectroMagnetic fields. Note that this kind of model is not always sufficient and a more complex description might be required, which takes into account additional higher-order ElectroMagnetic Multipoles, read § ?? - ?? and references therein..
Under certain circumstances, some materials may have a Polarization/Magnetization even in absence of external fields. In this case, the induced moments add, not necessarily linearly, to the pre-existing permanent moments.

It is usually assumed that the material medium has no free charge and no free currents. If this is not the case, the principle of superposition can be applied.
In any case:
\[
\begin{aligned}
& \mathrm{p}_{0} \rightarrow \mathrm{p}_{0}+\Delta \mathrm{p} \\
& \mathrm{~m}_{0} \rightarrow \mathrm{~m}_{0}+\Delta \mathrm{m}
\end{aligned}
\]

We limit to a macroscopic description only. In fact any serious microscopic description must be based on Relativistic Quantum Physics and on Statistical Physics.

\subsection*{34.02.01 Average Fields}

This § is referenced at pages:
[2289, 2289]
© ||Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....||
When ElectroMagnetic fields are considered in presence of matter one should consider that the ElectroMagnetic fields are rapidly changing at the atomic-molecular scale and that macroscopic pieces of matter contain a number of elementary unit of the order of the Avogadro number. A detailed knowledge is clearly not possible. In most cases it is not even necessary nor useful. One should consider the average value of the ElectroMagnetic fields on a scale that is large, microscopically, but macroscopically small. The macroscopic, space averaged ElectroMagnetic fields \((\mathbf{F} \equiv\{\mathbf{E}, \mathbf{B}\})\) are thus defined as the space average of the microscopic ElectroMagnetic fields, as long as the average is taken on a volume which is small on a macroscopic scale but large on the microscopic scale:
\[
\langle\mathbf{F}\rangle[\mathbf{x}] \equiv \lim _{\tau \rightarrow 0} \frac{1}{\tau} \iiint_{\tau} \mathbf{F}[\mathbf{x}+\mathbf{y}] \mathrm{d} \mathbf{y} \quad \tau:=|\mathbf{y}| \leq R \quad R \text { microscopically large and macroscopically small }
\]

The volume \(\tau\) is a suitable volume around the point \(\mathbf{x}\) (that is around \(\mathbf{y}=\mathbf{0}\) ) and the limiting process must be intended in the above-mentioned macroscopic sense: the volume \(\tau\) must be large on a microscopic scale but small on the macroscopic scale, the scale of change of macroscopic properties.

In fact the volume must be small enough to be able to describe wave phenomena of wavelength \(\lambda\), in case of changing ElectroMagnetic fields. Therefore if the atomic scale size is \(\approx a_{0}\), the size of the averaging region, \(R\), must be such that:
\[
a_{0} \ll R \ll \lambda
\]
clearly depending on the wavelength.
Clearly these assumptions prevent from dealing with very short wavelength waves, depending on the inter-molecular distances.
In a more more sophisticated approach, one can introduce a kernel smoothing function, \(K[\mathbf{y}]\), to define the average field:
\[
\langle\mathbf{F}\rangle[\mathbf{x}] \equiv \lim _{\tau \longrightarrow 0} \frac{1}{\tau} \iiint_{\tau} \mathbf{F}[\mathbf{x}+\mathbf{y}] K[\mathbf{y}] \mathrm{d} \mathbf{y} \quad \tau:=|\mathbf{y}| \leq R \quad R \text { microscopically/macroscopically large/small }
\]

Once the definition and ubiquitous use of macroscopic (averaged) ElectroMagnetic fields inside matter is clear the averaging symbol \(\rangle\) is normally omitted.

The averaging to define average fields inside matter is exactly the same procedure with exactly the same motivations as the averaging when defining the concept of density of a piece of real matter.

See figure 34.2 for the equivalence between microscopic and averaged (macroscopic) ElectroMagnetic fields.

Read § 38.03.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for more discussion.

\subsection*{34.02.02 Charges and Currents as Producers of ElectroMagnetic Fields}

This § is referenced at pages:
[1923, 1923]
©|F.Wegner, Classical Electrodynamics, 2003, ..., ...Ed., WEB - URL.|14||
©|L.D.Landau et al., Electrodynamics of continuous media, ..., ..., ...Ed., ....|§ 6, 29||
The density of the charges and currents can be separated into different contributions:
\(\rho=\rho^{\mathrm{F}}+\rho^{\mathrm{P}}\)
\(\mathbf{j}=\mathbf{j}^{\mathrm{F}}+\mathbf{j}^{\mathrm{P}}+\mathbf{j}^{\mathrm{M}}\),

The distinction is between freely accessible Charge|Current, those which can be to some extent controlled by the experimenter, and bound/inaccessible Charge|Current, over which, typically, the experimenter has no access.
The free charge and current densities, \(\rho^{\mathrm{F}}\) and \(\mathbf{j}^{\mathrm{F}}\), are the freely moving contributions which can be controlled is some way, in principle. As their study is not fundamentally different from the case of absence of matter and the superposition principle applies, they will be normally assumed to be zero.

The Polarization charge and current densities, \(\rho^{\mathrm{P}}\) and \(\mathbf{j}^{\mathrm{P}}\), are the Polarization contributions coming from bound charges which can only move/deform/orient to a limited extent nearby some point inside the medium. They are charges within regions that are inaccessible to observation but which might give rise to net boundary or volume charge densities, due to imperfect charge cancellation on an atomic scale. These charges might include the equivalent charges from elementary Electric Dipole moments of particles/Atoms|Molecules.

The Magnetization current density, \(\mathbf{j}^{\mathrm{M}}\), comes from the currents at the atomic/molecular level which can only move/deform/orient to a limited extent nearby some point inside the medium. They are steady currents that flow within regions that are inaccessible to observation but which might give rise to net boundary or volume currents, due to imperfect orbit cancellation on an atomic scale. These currents include the equivalent currents from elementary Magnetic Dipole moments of particles/Atoms|Molecules.
(a) As a source of external electric field \(\mathbf{E}\)

because a bit of polarized matter, volume \(d a \cdot d z\), has dipole moment equal to that of:

[More generally, for nonuniform polarization, polarized matter is equivalent to a charge distribution \(\rho=-\operatorname{div} \mathbf{P}\).]
(b) As a source of external magnetic field B

because a bit of magnetized matter, volume \(d a \cdot d z\), has dipole moment equal to that of:Current

[More generally, for nonuniform magnetization, magnetized matter is equivalent to a current distribution \(\mathbf{J}=c \operatorname{curl} \mathbf{M}\) ]

PROOF THAT THE EQUIVALENCE EXTENDS TO THE SPATIAL AVERAGE OF THE INTERNAL FIELDS

Consider a wide, thin, uniformly polarized slab and its equivalent sheets of surface charge. Near the middle the

external field is slight and \(\mathbf{E}^{\prime}\) is uniform. If \(\nabla \times \mathbf{E}=0\) for the internal field, then \(\oint_{C} \mathbf{E} \cdot d \boldsymbol{l}=0\). But \(\mathbf{E}=\mathbf{E}^{\prime}\) on the external path. Hence \(\int_{1}^{2} \mathbf{E} \cdot d \boldsymbol{l}=\int_{1^{\prime}}^{2^{\prime}} \mathbf{E}^{\prime} \cdot d \boldsymbol{l}^{\prime}\) for all internal paths.

CONCLUSION: \(\langle\mathbf{E}\rangle=\mathbf{E}^{\prime}\); the spatial average of the internal electric field is equal to the field \(\mathbf{E}^{\prime}\) that would be produced at that point in empty space by the equivalent charge distribution described above (together with any external sources).

Consider a long uniformly magnetized column and its

for the internal field, then \(\int_{S} \mathbf{B} \cdot \boldsymbol{d} \mathbf{a}=0\). But \(\mathbf{B}=\mathbf{P}^{\prime}\) on the surface external to the column. Hence \(\int_{S_{1}} \mathbf{B} \cdot d \mathbf{a}=\int_{S_{1}} \mathbf{B}^{\prime} \cdot d \mathbf{a}^{\prime}\) over any interior portion of surface like \(S_{1}, S_{2}\), etc.

CONCLUSION: \(\langle\mathbf{B}\rangle=\mathbf{B}^{\prime}\); the spatial average of the internal magnetic field is equal to the field \(\mathbf{B}^{\prime}\) that would be produced at that point in empty space by the equivalent current distribution described above ('together with any external sources).

Figure 34.1: Average ElectroMagnetic fields (from E.Purcell)
(a) As a source of external electric field \(\mathbf{E}\)

(More generally, for nonuniform polarization, polarized matter is equivalent to a charge distribution \(\rho=-\operatorname{div} \mathbf{P}\).)
(b) As a source of external magnetic field \(\mathbf{B}\)

is equivalent to:

because a bit of magnetized matter,
volume \(d a \cdot d z\), has dipole moment equal to that of: \(\rightarrow \quad \begin{gathered}\text { Current }\end{gathered}\)

A uniformly magnetized block can be divided into such layers. Hence the block has the same external field as the wide ribbon of surface current with \(\mathcal{J}=M\).
(More generally, for nonuniform magnetization magnetized matter is equivalent to a current distribution \(\mathbf{J}=\operatorname{curl} \mathbf{M}\).)

PROOF THAT THE EQUIVALENCE EXTENDS TO
THE SPATIAL AVERAGE OF THE INTERNAL FIELDS

Consider a wide, thin, uniformly polarized slab and its equivalent sheets of surface charge.

Near the middle the external field is slight and \(\mathbf{E}^{\prime}\) is uniform. If \(\nabla \times \mathbf{E}=0\) for the internal field, then \(\oint_{C} \mathbf{E} \cdot d \boldsymbol{l}=0\). But \(\mathbf{E}=\mathbf{E}^{\prime}\) on the external path. Hence \(\int_{1}^{2} \mathbf{E} \cdot d \boldsymbol{l}=\int_{1^{\prime}}^{2^{\prime}} \mathbf{E}^{\prime} \cdot d \boldsymbol{l}^{\prime}\) for all internal paths.

Conclusion: \(\langle\mathbf{E}\rangle=\mathbf{E}^{\prime}\); the spatial average of the internal electric field is equal to the field \(\mathbf{E}^{\prime}\) that would be produced at that point in empty space by the equivalent charge distribution described above (together with any external sources).

for the internal field, then \(\int_{S} \mathbf{B} \cdot d \mathbf{a}=0\). But \(\mathbf{B}=\mathbf{B}^{\prime}\) on the surface external to the column. Hence \(\int_{S_{1}} \mathbf{B} \cdot d \mathbf{a}=\int_{S_{1}^{\prime}} \mathbf{B}^{\prime} \cdot d \mathbf{a}^{\prime}\) over any interior portion of surface, like \(S_{1}, S_{2}\), etc.

Conclusion: \(\langle\mathbf{B}\rangle=\mathbf{B}^{\prime}\); the spatial average of the internal magnetic field is equal to the field \(\mathbf{B}^{\prime}\) that would be produced at that point in empty space by the equivalent charge distribution described above (together with any external sources).

Figure 11.19.

Figure 34.2: Average ElectroMagnetic fields (from E.Purcell)

Note, however, that the distinction has some degree of arbitrariness, and it is partly conventional, see section § 38.03.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology. The most important issue, however, is not how Charge|Current are separated into free and bound/inaccessible parts, but to make sure that all Charge|Current are counted once and only once.
No real Magnetization charge density exist, coherently with the fact that magnetic charges do not exist. However, under certain circumstances, it might be useful to introduce a formal Magnetization charge density, \(\rho^{M}\), to solve some problems, read \(\S 36\) - Magnetic Properties of Matter.
The common characteristic of Polarization charges and Polarization|Magnetization current densities is that they cannot basically be controlled by external as they are strongly bound, but they are the consequence of the reaction of matter to external ElectroMagnetic fields.
The following fundamental assumption is done: it is assumed that the different contributions can always be identified and that they never mix each other. Therefore for these charge and current densities one has:
\[
\begin{array}{r}
0=\partial_{t} \rho^{\mathrm{F}}+\operatorname{divj}^{\mathrm{F}} \\
0=\partial_{t} \rho^{\mathrm{P}}+\operatorname{divj}^{\mathrm{P}} \\
0=\operatorname{div}^{\mathrm{M}} \quad \text { because } \rho^{\mathrm{M}}=0
\end{array}
\]

The components of the microscopic world necessary to describe ElectroMagnetism in matter are: molecules; atoms (and their constituents: protons, electrons and neutrons); EM radiation (photons); ionized Atoms|Molecules, producing positively or negatively charged atomic/molecular ions and free electrons.
The behavior of such components may be substantially different from that of ordinary macroscopic objects and must be described by Quantum Relativistic Physics. However many phenomena can be usefully described, at least from a qualitative point of view, by semi-classical models.
It is useful to introduce, without any attempt of derivation nor completeness, some ultra-elementary concepts about the quantum-relativistic treatment of the particle-like and wave-like properties of elementary particles, even if this goes beyond the realm of Classical Physics.
In what follows it will be always assumed that one deals with the microscopic ElectroMagnetic fields and their microscopic description, that is no macroscopic description of matter is included. In other words ElectroMagnetic fields and particles are considered in vacuum.

\subsection*{34.03.01 Dynamical Quantities: Mass Energy Linear|Angular Momentum in Relativistic Physics}

Relativistic Physics links space and time and is relevant only for speeds close to the speed of light.

\section*{Energy and Linear Momentum}

Energy and linear momentum are given by:
\[
\epsilon=m \gamma c^{2} \quad \mathbf{p}=m \gamma \mathbf{v} \quad \text { with } \quad \gamma=\frac{1}{\sqrt{1-v^{2} / c^{2}}}
\]

The relation between energy and linear momentum is given by:
\[
\epsilon=\sqrt{p^{2} c^{2}+m^{2} c^{4}}
\]

Moreover, the speed is given by:
\[
\mathbf{v}=c^{2} \frac{\mathbf{p}}{\epsilon}
\]

\section*{Angular Momentum}

\subsection*{34.03.02 Dynamical Quantities: Mass Energy Linear|Angular Momentum in Quantum Physics}

Quantum Physics introduces a wave-like character for any particle as well as a particle-like character for any wave.

\section*{Energy and Linear Momentum}

The link between energy and frequency of the particle/wave is:
\(\epsilon=h \nu=\hbar \omega \quad\) with the Planck constant, a fundamental constant of Nature, \(\quad \hbar \equiv \frac{h}{2 \pi}=1.055 \cdot 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\)

Physical observables of a system may be quantised, in Quantum Physics, that is they cannot assume any value but they can only assume a well-defined set of discrete values related to the Planck constant, the fundamental constant of Quantum Physics.
The energy and linear momentum may be quantised.

\section*{Angular Momentum}

The angular momentum is always quantised, in Quantum Physics, that is it cannot assume any value but it can only assume a well-defined set of discrete values related to the Planck constant, the fundamental constant of Quantum Physics.
The full description of angular momentum requires Quantum Physics.
Let us only consider a generic angular momentum, \(\mathbf{j}\), and its projection along any arbitrary but fixed axis (let us say the \(z\) axis).
Any angular momentum, \(\mathbf{j}\), in Quantum Physics can assume a squared module value given by:
\[
|\mathbf{j}|^{2}=j(j+1) \hbar^{2} \quad \text { with } j \text { any non-negative integer or positive half-odd value }
\]

For an angular momentum \(j\) the projection of the angular momentum along any fixed axis (assume the \(z\) axis) can assume the \(2 j+1\) values:
\[
j_{z}=(-j,-j+1, \ldots,+j-1,+j) \hbar .
\]

\section*{Orbital Angular Momentum}

As for classical physics one deals with orbital angular momentum:
\[
\ell \equiv \mathbf{r} \times \mathbf{p}
\]

Any orbital angular momentum, \(\ell\), in Quantum Physics can assume a squared module value given by:
\[
|\ell|^{2}=\ell(\ell+1) \hbar^{2} \quad \text { with } \ell \text { any non negative integer } .
\]

The component along any axis (assume the \(z\) axis) can only assume integer values (in units of \(\hbar\) ):
\[
\ell_{z}=k \hbar \quad \text { with } k \text { any integer number with }|k| \leq \ell
\]

\section*{Spin Angular Momentum}

Elementary particles also have an intrinsic angular momentum, the spin angular momentum, s, not connected to any kind of rotation of the particle around itself, but acting under all respects as an intrinsic angular momentum, that is an angular momentum with respect to the location of the particle (for point particles) or with respect to the Center-Of-Mass of the system (for extended, non point systems).
Most common elementary particles have either spin \(1 / 2\) (matter particles) or spin 1 (mediators of interactions).
Most common particles, including protons, neutrons and electrons, have spin \(1 / 2\), that is the component of the spin angular momentum along any axis (assume the \(z\) axis) can only assume the values:
\[
s_{z}= \pm \frac{\hbar}{2} .
\]

Other particles, the most common being the photons, have spin 1, that is the component of the spin angular momentum along any axis (assume the \(z\) axis) can only assume the values:
\[
s_{z}=-\hbar, 0,+\hbar .
\]

The photon is special as a spin 1 particle, because its mass is zero. In fact, the \(s_{z}=0\) value does not exist and therefore the component of the spin angular momentum along any axis can only assume the two values: \(s_{z}= \pm \hbar\).

\section*{Total Angular Momentum}

The total angular momentum of any system of particles is given by the sum of the orbital angular momenta, \(\ell\), plus the spin angular momenta, s :
\[
\mathbf{J}=\sum_{k}\left(\ell_{k}+\mathbf{s}_{k}\right)
\]

\subsection*{34.03.03 Mole and Avogadro Number}

The concept of mole and Avogadro number provide the link between the microscopic world and the macroscopic one.
The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of Carbon 12 (at rest and in their ground state); the symbol is mol. When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles, or specified groups of such particles (or possibly any kind of objects).
A mole of objects contains a number of Avogadro objects.
The molar mass of any substance is the mass of a number of Avogadro objects (measured in \(\mathrm{kg} / \mathrm{mol}\) in the SI).
\[
N_{A}=6.022 \cdot 10^{23} \mathrm{~mol}^{-1}
\] TOC

\subsection*{34.03.04 Matter - Atoms Molecules and Common Elementary Particles}

All common matter is made of atoms.
Atoms may bond each other via chemical bonds. A chemical bond is a purely quantum-mechanical phenomenon.
Atoms may group in small molecules (a few atoms), in large molecules (more than hundreds atoms), or in crystalline solids, which are large regular structures made of, a priori, an infinite number of atoms or molecules. The terms amorphous solid, non-crystalline solid, disordered solid, glass or liquid have no precise structural meaning beyond the description that the structure is not crystalline on any significant scale. The separation of nearest neighbor atoms or molecules is approximately constant. Disordered crystalline alloys are such that different atoms randomly occupy the sites of a regular crystal lattice.
Atoms group by sharing some of their electrons.
Atoms and molecules may appear in either the gaseous or liquid state.
Quite often Atoms|Molecules may be ionized, by loosing or capturing electrons and therefore ordinary matter may be also composed of positive ions and negative free electrons. A plasma is a gas made of positive ions and negative free electrons.
Every atom is made of a nucleus, made of protons and neutrons, plus electrons orbiting around the nucleus. The orbiting electrons are more appropriately thought as an negative charge diffuse electron cloud.
The number of protons in an atom is called the atomic number, \(Z\). It is equal to the number of electrons, for a neutral atom. The total number of protons plus neutrons in a nucleus (collectively called nucleons) is called the mass number of the nucleus, \(A\). It is \(A \geq Z\). Chemical properties are only determined by the atomic number \(Z\) and there exist, for many elements, different isotopes, that is atoms with the same atomic number but different mass number.
Atoms of different elements form a logic structure described by D. I. Mendeleev, explained by the shell structure of the electron orbitals which, in turn, is explained by Quantum Relativistic Physics.

The atomic radius as a function of the atomic number for the elements is shown in figure 34.3, showing the behavior dictated by the electronic shell structure.
The molar volume as a function of the atomic number for the elements is shown in figure 34.4, showing the behavior dictated by the electronic shell structure.
All the interaction between atoms and on scales larger that the atomic scale up to the everyday world are dominated by ElectroMagnetic interactions.

\subsection*{34.03.04.01 Mass Charge Size and Lifetime}

It is: \(m_{p} \simeq m_{n} \simeq 1836 \cdot m_{e}\) and \(m_{e}=9.11 \cdot 10^{-31} \mathrm{~kg}\).
Given the above values of the masses it turns out that, to a first approximation, every atom has a mass roughly equal to \(M \simeq A \mathrm{u}\), with u the atomic mass unit. It is defined as one twelfth of the rest mass of an unbound atom of Carbon-12 in its nuclear and electronic ground state: \(\mathrm{u}=1.66 \cdot 10^{-27} \mathrm{~kg}\).
It is: \(-q_{e}=q_{p}=1.6 \cdot 10^{-19} \mathrm{C}\) and \(q_{n}=0\).
The typical size of an atomic nucleus is given by: \(r=r_{0} A^{1 / 3}\), with \(r_{0}=1.25 \cdot 10^{-15} \mathrm{~m}\).
All the neutral isolated atoms have a radius of the order of \(R \approx(0.3 \div 3.0) \cdot 10^{-10} \mathrm{~m}\).
Electrons, as far as one knows, are elementary structure-less point particles. Protons and neutrons have a non zero size of about \(10^{-15} \mathrm{~m}\) and are made of quarks.
Electrons and protons, as far as one knows, are stable particles. Neutrons are stable when bound inside an atomic nucleus but they have a lifetime of about 15 min when they are free.

Figure 34.3: Atomic radius as a function of the atomic number for the elements.

Figure 34.4: Molar volume as a function of the atomic number for the elements.

\subsection*{34.03.05 Atoms and Aggregates of Atoms}

Atoms: perfectly well defined.
Atoms can aggregate in many ways into molecules via a chemical bond, a purely quantum-mechanical effect:
- single-atom molecules: noble gases;
- a-few-atoms molecules: water, carbon dioxide, etc.;
- many-atoms molecules: organic molecules, sugar, etc.;
- macro-molecules: millions of AMU (e.g. DNA);
- crystalline solids: lattice of positive and negative ions, atom identity lost;
- metallic solid: valence electrons shared by the positive ions of the lattice, atom identity lost.

In general, any recognizable aggregation among atoms will be called in short molecule.
34.03.06 Data

\subsection*{34.03.07 Other Properties}
34.03.07.01 Intrinsic Electric Dipole Moments of Common Elementary Particles

As far as one knows today the intrinsic Electric Dipole moments of common elementary particles are compatible with zero.

\subsection*{34.03.07.02 Magnetic Dipole Moments}

\section*{Orbital Magnetic Dipole Moment}

In general a orbital Magnetic Dipole moment is produced by orbital angular momentum.
The associated orbital Magnetic Dipole (read § 36.10.02-Magnetic Properties of Matter) moment is:
\[
\boldsymbol{\mu}_{\ell}=g_{\ell} \frac{q}{2 m} \ell=\frac{q}{2 m} \ell \quad q \text { with algebraic sign; } g_{\ell}=+1 .
\]

\section*{Intrinsic Magnetic Dipole Moments of Common Elementary Particles}

Associated to the intrinsic angular momentum (spin) elementary particles may have an intrinsic magnetic Dipole moment, typically expressed as:
\[
\boldsymbol{\mu}_{s}=g_{s} \frac{|q|}{2 m} \mathbf{s}
\]
in terms of the absolute value of the electron charge, a mass (typically the mass of the particle or a strictly related mass) and the gyromagnetic ratio \(g_{s}\), a specific property of any particle (a pure number).

\section*{Total Magnetic Dipole Moments}

Associated to both the spin angular momentum and orbital angular momentum there is a total Magnetic Dipole moment, connected to the total angular momentum, \(\mathbf{j}\), of the particle:
\[
\boldsymbol{\mu}_{j}=g_{j} \frac{|q|}{2 m} \mathbf{j}
\]

The factor \(g_{j}\) is called the gyromagnetic ratio: it is the ratio of the Magnetic Dipole moment to the total angular momentum of a system.
In general one defines the gyromagnetic ratio of a system in terms of its mass mass \(M\) and the absolute value of the elementary charge of electron/proton \((e \equiv e>0)\) as:
\[
\begin{equation*}
\boldsymbol{\mu}_{j} \equiv g_{j} \frac{e \hbar}{2 M}(\mathbf{j} / \hbar) \tag{34.03.01}
\end{equation*}
\]

Note that there is sometimes confusion in the literature as the name gyromagnetic ratio is sometimes used as in the above equation (34.03.01), for \(g\), while it is sometimes used as in equation (36.10.01), for \(\gamma\).
The quantities for the electron are usually defined in terms of the Bohr-magneton. It is defined, in terms of the mass of the electron, as:
\[
\begin{equation*}
\mu_{\mathrm{B}}=\frac{e \hbar}{2 m_{e}}=0.9274 \cdot 10^{-23} \mathrm{~A} \cdot \mathrm{~m}^{2}=0.9274 \cdot 10^{-23} \mathrm{~J} / \mathrm{T} \tag{34.03.02}
\end{equation*}
\]

The quantities for protons and neutrons (collectively called nucleons) are usually defined in terms of the nuclear-magneton. It is defined, in terms of the mass of the nucleon, as:
\[
\begin{equation*}
\mu_{\mathrm{N}}=\frac{e \hbar}{2 m_{N}}=0.5051 \cdot 10^{-26} \mathrm{~A} \cdot \mathrm{~m}^{2}=0.5051 \cdot 10^{-26} \mathrm{~J} / \mathrm{T} \tag{34.03.03}
\end{equation*}
\]
where the nucleon mass is defined as the average value of the proton and neutron mass:
\[
m_{N} \equiv \frac{m_{p}+m_{n}}{2}
\]

Common values are:
\[
\begin{array}{ll}
g_{s}=+5.586 & \text { proton }, \\
g_{s}=-3.826 & \text { neutron }, \\
g_{s}=-2.002 & \text { electron }, \\
g_{\ell}=1 & \text { orbital angular momentum, exact } .
\end{array}
\]

\section*{Magnetic Dipole Moments of Atoms and Molecules}

Some atoms and molecules have electron orbitals such that there is net un-balance of the negative electron currents which gives rise to an overall Magnetic Dipole moment.
The order of magnitude of these Magnetic Dipole moments is the Bohr-magneton (34.03.02).
34.03.07.03 Intrinsic Polarizability|Magnetizability of Common Elementary Particles

As far as one knows today the electron is a point particle, that is it has not been possible, yet, to measure any size of it with the current experimental instruments.
On the other hand one knows that protons and neutrons have a finite size of the order of \(10^{-15} \mathrm{~m}\). Therefore, in principle, they have an intrinsic Polarizability and and intrinsic Magnetizability, and both of them have been, in fact, measured.

\subsection*{34.03.08 Radiation: Particle-Like Properties of ElectroMagnetic Radiation (Photons)}

In quantum-relativistic physics ElectroMagnetic radiation is described as particles called photons \((\gamma)\) with zero mass, zero electric charge, zero Electric|Magnetic Dipole moment, and intrinsic spin angular momentum equal to one in \(\hbar\) units:
\[
m_{\gamma}=0 \quad\left(s_{\gamma}\right)_{z}= \pm \hbar
\]

Photons, as far as one knows, are stable elementary structure-less point particles.

\section*{Examples and Physical Applications}

\subsection*{34.04.01 \(\checkmark\) Inter-atomic/Inter-Molecular Distances}

Show that the relation giving the average distance between Atoms|Molecules is:
\[
d=\left(\frac{\mathcal{M}_{0}}{\eta_{\mathrm{M}} \mathcal{N}_{\mathrm{A}}}\right)^{1 / 3}
\]
in terms of the molar mass, \(\mathcal{M}_{0}\), and the mass density, \(\eta_{\mathrm{M}}\), of the substance. Find the value of \(d\) for solid iron and liquid water.
The ratio between molar mass and mass density is called molar volume (volume per mole), \(v_{m}\), show that:
\[
\frac{\Delta V}{N}=\frac{\mathcal{M}_{0}}{\eta_{M} \mathcal{N}_{\mathrm{A}}} \Longrightarrow v_{m} \equiv \frac{\Delta V}{N} \mathcal{N}_{\mathrm{A}}=\frac{\mathcal{M}_{0}}{\eta_{\mathrm{M}} \mathcal{N}_{\mathrm{A}}} .
\]

\subsection*{34.04.02 \(\checkmark\) Molar Volume}

This § is referenced at pages:
[1808, 1808, 1851, 1851]
How many iron atoms per unit volume are in a piece of solid iron?
How many molecules per unit volume are in a ideal gas at a temperature of zero degrees Celsius and one atmosphere pressure?

\section*{SOLUTION}

Molar volume of solid iron: \(7.11 \mathrm{~cm}^{3} /\) mole. Therefore the number of iron atoms per cubic meters is: \(8.5 \cdot 10^{28}\) atoms \(/ \mathrm{m}^{3}\).
Molar volume of ideal gas: \(R T / p\). At \(T=273.15 \mathrm{~K}\) and \(p=101.325 \mathrm{kPa}\) :
\[
v_{m}=22.414 \mathrm{l} / \mathrm{mol} \Longrightarrow 44.6 \mathrm{~mol} / \mathrm{m}^{3} \Longrightarrow 2.7 \cdot 10^{25} \text { molecules } / \mathrm{m}^{3}
\]

\subsection*{34.04.03 \(\checkmark\) Drift Velocity in Copper}

Copper has: \(Z=29, \eta_{\mathrm{M}}=8.96 \mathrm{~kg} / \mathrm{dm}^{3}\) and \(\mathcal{M}_{0}=63.6 \mathrm{~g} / \mathrm{mol}\).
Calculate the molar volume of Copper:
\[
v_{m}=\frac{\mathcal{M}_{0}}{\eta_{\mathrm{M}}}=6 \mathrm{~cm}^{3} / \mathrm{mol} .
\]

Assume a simple model of copper such that one electron per atom is free to move and contributes to the current, that is the valence is \(\mathcal{V}=1\).
Take a current \(I=10\) A flowing in a copper wire of section \(S=1 \mathrm{~mm}^{2}: j \approx 10^{7} \mathrm{~A} / \mathrm{m}^{2}\).
\[
\eta_{\mathrm{N}}=\frac{N}{\Delta V}=\frac{m}{\mathcal{M}_{0}} \frac{\mathcal{N}_{\mathrm{A}}}{V} \mathcal{V}=\eta_{\mathrm{M}} \frac{\mathcal{N}_{\mathrm{A}}}{\mathcal{M}_{0}} \mathcal{V}=8.4 \cdot 10^{28} \mathrm{~m}^{-3}
\]

The resulting drift velocity is:
\[
v \equiv \frac{j}{e \eta_{\mathrm{N}}}=1 \mathrm{~mm} / \mathrm{s} .
\]

Note that the drift velocity is very small but when, for instance, one closes/opens a switch in a circuit with a lamp the lamp switches on/off very quickly: why?

\subsection*{34.04.04 \(\checkmark\) Semi-Classical ElectroMagnetic Properties of an Hydrogen Atom}

This § is referenced at pages:
[Never referenced.]
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.7||
Consider the simple classical model of an hydrogen atom as a heavy point charge, the proton, plus an electron orbiting around the proton in a circular orbit of radius \(a_{0}=0.5 \cdot 10^{-10} \mathrm{~m}\) (the so-called Bohr radius determined by quantum physics).
Calculate the electric field produced by the proton at the position of the electron.
\[
E=\frac{1}{4 \pi \varepsilon_{0}} \frac{q_{e}}{a_{0}^{2}}=6 \cdot 10^{11} \mathrm{~V} / \mathrm{m}
\]

This is a very large field, with respect to everyday electric fields.
Calculate the current associated to the electron orbit.
\[
\frac{1}{4 \pi \varepsilon_{0}} \frac{q_{e}^{2}}{a_{0}^{2}}=m_{e} \omega^{2} a_{0} \Longrightarrow \nu=\frac{q_{e}}{2 \pi a_{0}} \sqrt{\frac{1}{4 \pi \varepsilon_{0}} \frac{1}{m_{e} a_{0}}}=7 \cdot 10^{15} \mathrm{~Hz} \Longrightarrow I=q_{e} \nu=1 \mathrm{~mA} .
\]

Note that the electron revolution frequency is in the range of the order of magnitude of the frequency of visible light.
The velocity of the electron is:
\[
v=2 \pi a_{0} \nu=2 \cdot 10^{6} \mathrm{~m} / \mathrm{s}=0.007 c
\]

The non relativistic approximation is thus justified.
Calculate the magnetic field produced by the electron at the center of its orbit (that is where the proton is).
\[
B_{0}=\frac{\mu_{0} I}{2 a_{0}}=12 \mathrm{~T}
\]

This is a very large field, with respect to everyday magnetic fields.
Calculate the Magnetic Dipole moment due to the motion of the electron around its orbit.
\[
\mu_{L}=I \pi a_{0}^{2}=8 \cdot 10^{-24} \mathrm{~A} \cdot \mathrm{~m}^{2} \approx \frac{q_{e} \hbar}{2 m_{e}} \equiv \text { the Bohr-magneton } \equiv \mu_{\mathrm{B}} .
\]

In fact all the magnetic orbital moments of atoms have the same order of magnitude of the Bohr-magneton.
Calculate the interaction energy between the Magnetic Dipole moment of the proton and the magnetic field produced by the electron \(\left(\mu_{p}=\left(m_{e} / m_{N}\right) \mu_{B}=0.5 \cdot 10^{-26} \mathrm{~A} \cdot \mathrm{~m}^{2}\right)\) :
\[
|U| \simeq \mu_{p} B_{0}=6 \cdot 10^{-26} \mathrm{~J} .
\]

Calculate the interaction energy between the Magnetic Dipole moment of one electron and an external magnetic field \(B_{0}=1.0 \mathrm{~T}\) :
\[
|U| \simeq \mu_{B} B_{0}=0.9 \cdot 10^{-23} \mathrm{~J} .
\]

The above energies must be compared with the much larger energies:
- the typical thermal energies at room temperature of \(\approx k T \simeq 0.025 \mathrm{eV} \simeq 4 \cdot 10^{-21} \mathrm{~J}\), that is the order of magnitude of the kinetic energies of the atom and its constituents;
- the typical electric interaction energies, for instance the one between the electron and the proton of the hydrogen atom: \(4.6 \cdot 10^{-18} \mathrm{~J}\).
34.04.05 \(\checkmark\) Equivalent Current Due to Magnetization

Consider a sphere of iron ( \(\left.\eta_{\mathrm{M}}=7.86 \cdot 10^{3} \mathrm{~kg} / \mathrm{m}^{3}, \mathcal{M}_{0}=56 \mathrm{~g} / \mathrm{mol}\right)\) with \(R=10 \mathrm{~cm}\) and assume that every atom contributes with one orbital electron to the Magnetic Dipole moment for one Bohr-magneton. Imagine all Bohr-magnetons in the sphere are aligned.
Find the current in a loop of radius \(R\) giving the same Magnetic Dipole moment.

\section*{SOLUTION}

Experimentally one can study the effects of matter on electric fields (and vice-versa) by inserting a material inside a an empty capacitor. When any material is inserted inside an empty capacitor the capacity always increases.
Similarly any piece of material is attracted inside an empty capacitor.
Under the influence of an external electric field the atoms and|or molecules of the medium react collectively: the medium becomes Polarized.
In fact, we know that matter is made of electrons, ions, atoms, molecules etc.. These are in turn composed of other particles, possibly composed particles. Instead of describing the material as a volume of structure-less but non-vacuum jelly, it is described as a collection of electrons|ions|atoms|molecules etc. inhabiting a vacuum.

This § is referenced at pages:
[1851, 1851]
The effects of external electric fields on matter can be described, to a first approximation, by means of a suitable distribution of Electric Dipoles. This hypothesis is normally assumed when studying the response of matter to electric fields. Note, however, that under certain circumstances the inclusion of higher-order multipoles fields might become necessary.

Matter generally reacts to an external electric field by Polarization. On the microscopic point of view this can be understood by either of two mechanisms:
- deformation of the microscopic charge distributions: Polarization by deformation of non-dipolar matter; it is oriented with the external field.
- orientation of pre-existing microscopic Electric Dipoles: Polarization by orientation of dipolar matter; in these cases a Polarization by deformation exists as well, but it is normally negligible with respect to the Polarization by orientation; it is oriented with the external field.
Induced Polarization is always directed with the external field, so it is often called para-electricity (paraelectric matter), similar to para-magnetism, as opposed to dia-magnetism; see section § 36.02 - Magnetic Properties of Matter.

Note that, while the entity of the deformation and|or orientation of the single atom/molecule may be very small, the large number of Atoms \(\mid\) Molecules in macroscopic matter can make the effect a very large one (read § 34.04.02 - Electric|Magnetic Properties of Matter). In fact the number of atoms per cubic meter for ordinary matter has values in the range \(\left(10^{25} \div 10^{29}\right)\) atoms \(/ \mathrm{m}^{3}\).

Polarization by deformation and orientation can be understood, from a qualitative point of view, without invoking quantum-relativistic physics, which is however necessary for a quantitative understanding.
Note that materials exists having a built-in Polarization even in absence of external applied electric fields: they are generically called here ferro-electric materials.
Because, to a first approximation, the effect of external fields on matter may be described either as induction of Dipoles and|or orientation of existing Dipoles, the electrical field produced by the Polarized material can be thus replaced by the electrical field produced by a continuous Dipole distribution.

\subsection*{35.02.01.01 Polarisability of an Isotropic Molecule}
© (Raimond|excellent||
The polarisability of an isotropic atom/molecule (or any other microscopic system) is defined as the average Electric Dipole moment, p, induced by an external electric field \(\mathbf{E}_{0}\) :
\[
\left.\alpha_{\mathrm{e}} \equiv \frac{1}{\varepsilon_{0}} \frac{\partial \mathrm{p}}{\partial E_{0}}\right|_{E_{0}=0} \quad \text { for the case } \mathrm{p} \| \mathbf{E}_{0} \text { (isotropic atom/molecule) },
\]
for a permanent Electric Dipole moment: \(\mathrm{p}_{0}\).
The Polarizability is the second derivative of the interaction energy with respect to external electric field calculated at zero field:
\[
\alpha_{\mathbf{e}} \equiv-\left.\varepsilon_{0}^{-1} \frac{\partial^{2} u_{e}}{\partial E_{0}^{2}}\right|_{E_{0}=0}
\]
with no factor \(1 / 2\), because it is a Polarizable systems with factor \(1 / 2\) in the interaction energy.
The above discussion applies to a single atom/molecule: a permanent Dipole may be present, even in absence of an external field, and an induced moment is generally always present.
Whenever a large number of Atoms|Molecules is present, one should introduce the macroscopic averaging, in terms of the Polarization density, section \(\S 35.02 .01-35.02 .01\); in fact, \(\mathbf{E}_{0}\) is actually the local field:
\[
\mathbf{E}_{0} \longrightarrow \mathbf{E}_{\text {LOC }}
\]

Even if each atom/molecule possesses a permanent Dipole, a random arrangement may result in a zero total Dipole in absence of an external field.

The induced Polarization includes the effect of alignment of the permanent Dipoles, which is generally opposed by temperature. See section § 38.04.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.
The polarisability is always a positive number:
\[
\alpha_{\mathrm{e}} \geq 0
\]

One should assume that a linear relation apply as long as the external electric field is not too big. Note that for large external fields the relation may become non-linear, so that the polarisability may loose some of its meaning and become field-dependent.
Note that in general whenever a permanent Electric Dipole moment, \(\mathrm{p}_{0}\), is present, this is normally much larger than the induced Electric Dipole moment, at least for external fields not too large.
By definition the physical dimensions of the polarisability is a volume. Note, however, that in the literature slightly different definitions may be found.

\subsection*{35.02.01.02 Polarisability of a Non-Isotropic Axially-Symmetric Molecule}

If a molecule is not isotropic, but axially-symmetric, it is rather obvious that the polarisability might depend of the direction of the applied field. Consider for instance a bi-atomic molecule: one expects that the induced Dipole moment is different for an external electric field applied along the axis of the molecule with respect to an external electric field applied perpendicularly to it. Therefore one can write for this kind of molecule (having one axis of symmetry):
\[
\mathrm{p} \simeq \varepsilon_{0}\left(\alpha_{\mathrm{e} \|}\left[E_{0}\right] \mathbf{E}_{\|}+\alpha_{\mathrm{e} \perp}\left[E_{0}\right] \mathbf{E}_{\perp}\right) \quad \text { superposition principle } .
\]

\subsection*{35.02.01.03 Polarisability of a General Non-Isotropic Molecule}

The general case is discussed in \(\S 35.06 .03\) - Electric Properties of Matter in the completely analogous case of the Polarization vector.

\subsection*{35.02.01.04 All Materials Undergo Polarization by Deformation}

This § is referenced at pages:
[1853, 1853]
Consider an atom/molecule: all charge densities associated with electrons and ions will be deformed by the application of an external field giving an induced Electric Dipole moment.

Assume that two charge distributions, with equal and opposite charges, are superimposed, and have the same centers of charge, like the electron and proton clouds in a neutral atom. The electric dipole moment is zero.

In presence of an external electric field, both charge distributions are affected and move their centers of charge in opposite directions. An electric dipole moment is induced, parallel to the external field.
Let us then assume a simple semi-classical model such that, in absence of external fields, the two opposite center of charges coincide and cancel, while in presence of external fields, the two center of charges do not coincide anymore anymore so that there is an induced electric dipole moment, parallel to the external field.

This will be modeled as two equal and opposite charges, separated by the relative positions of the two centers of charge.

Read \(\S\) 36.02.01.04 - Magnetic Properties of Matter, for similarities and differences.

\subsection*{35.02.02 Definition of the Polarization}

Remembering that the definition of electric dipole is, by definition, additive, see (33.13.03), the macroscopic Polarization field is defined as:
\[
\begin{equation*}
\mathbf{P} \equiv \lim _{\Delta V \rightarrow 0} \frac{\Delta \mathrm{p}}{\Delta V} \equiv \lim _{\Delta V \rightarrow 0} \frac{\sum_{k} \mathrm{p}_{k}(\text { inside } \Delta V)}{\Delta V} \equiv \eta_{\mathrm{N}}\langle\mathrm{p}\rangle \tag{35.02.01}
\end{equation*}
\]

The limiting process in equation (35.02.01) must be interpreted in the sense of taking macroscopic volumes, containing a large enough number of microscopic systems, as discussed in §34.02-Electric|Magnetic Properties of Matter.

The Polarization \(\mathbf{P}\) turns out to be the electric dipole moment per unit volume.

\subsection*{35.02.02.01 A Polarized Medium: Some Simple Cases}
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||

Note that it is difficult to imagine the electric field produced by a large number (of the order of Avogadro number) of Electric Dipoles.
However it will be shown that the electric field is the one given by an equivalent charge distribution.

\section*{A Large plane slab Uniformly Polarized perpendicular to is faces}

\section*{This § is referenced at pages:}
[1812, 1812]
From the elementary interpretation of Polarization as aligned Electric Dipoles one easily finds the following results.
Zero volume charge density at internal points.
Zero surface charge density on the lateral surface.
Surface charge density at the two bases: \(\pm \mathbf{P} \cdot \mathbf{n}\).
Consider, in fact, a surface of area \(A\) at one of the two bases and calculate the charge per unit area:
\[
\Delta Q=q \eta_{\mathrm{N}} A d=\left(q d \eta_{\mathrm{N}}\right) A=P A \Longrightarrow\left|\rho_{\mathrm{S}}\right|=P \equiv|\mathbf{P}| .
\]

Regardless the details of the Electric Dipole distribution the electric field produced is the same as the one produced by a surface charge on the bases.

\section*{A long circular cylinder Uniformly Polarized Perpendicular along its axis}

\section*{A Cylinder Uniformly Polarized Along Its Axis}

\section*{A Sphere Uniformly Polarized}

\section*{A Spherical Shell With Radial Polarization}

Assume a uniform radial distribution of the all elementary identical electric Dipoles in a sphere:
\[
\left\{\begin{array}{l}
\mathbf{P}=p \eta_{\mathbb{N}} \hat{\mathbf{e}}_{r} \equiv P_{r} \hat{\mathbf{e}}_{r} \quad R_{1}<r<R_{2}, \\
\mathbf{P}=0 \quad \text { otherwise }
\end{array}\right.
\]

From equations (35.02.03), (35.02.04) one finds: \(\rho^{\mathrm{P}}=-2 P_{r} / r\) as well as \(\rho^{\mathrm{P}}\left[R_{1}\right]=-P_{r}\) and \(\rho^{\mathrm{P}}\left[R_{2}\right]=+P_{r}\).
Total charge inside any spherical shell with radii \(R_{1} \leq r_{1}<r_{2} \leq R_{2}: Q=-4 \pi P_{r}\left(r_{2}^{2}-r_{1}^{2}\right)\).
Total surface charges: \(Q\left[R_{2}\right]=4 \pi P_{r} R_{2}^{2}\) and \(Q\left[R_{1}\right]=-4 \pi P_{r} R_{1}^{2}\).
Total Polarization charge is zero.
Note that every spherical shell has more electric charge, when increasing the distance from the center.

\section*{A Plane Capacitor}

This § is referenced at pages:
[Never referenced.]
A capacitor completely filled with a material medium always increases its capacity by a factor \(\epsilon\), with respect to its vacuum capacity, where \(\epsilon\), the relative Electric-Permittivity under static conditions, is a property of the material and its state (for instance temperature).
Note that the definition of capacity does not make any reference to the material medium between the conductors.
Consider in fact an isolated large plane capacitor filled with a material medium. Electric Dipoles either align with the electric field, if they already exist, or are created, aligned with the electric field on average. The matter close to the positive armature is then negatively charged and the matter close to the negative armature is positively charged. The charge on the armatures has not changed while the electric field between the armatures has decreased, so the difference of potential. The definition of capacity then shows that capacity increased.

In case the capacitor is connected to a battery the electric field between the armatures must not change and, due to the Polarization charges of opposite sign near the armatures, the free charge has to increase to keep the same field. The definition of capacity then shows that capacity increased, as well.
Electric Dipoles align with the electric field and the electric field is decreased. This is opposite with respect to the magnetic case due to the basic difference between Electric|Magnetic Dipoles (read § 38.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology).

\subsection*{35.02.03.01 A Non-Polarized Medium}

Consider a non Polarized insulating medium. The electric field effects due to positive and negative charges in atoms and|or molecules cancel each other:
- either because, for non-dipolar molecules, (that is molecules without a net Electric Dipole moment), the positive and negative charges of each molecule have the same center-of-charge (and any other higher-order Electric Dipole moment vanishes);
- or because, for dipolar-molecules, the random orientation of the Dipoles produces a net zero Dipole moment (which is contrasted by thermal motion, featuring kinetic energies of the order of \(\approx k T\) ).

\subsection*{35.02.03.02 A Polarized Medium With No Free Charges (A Simple Heuristic Model)}

This § is referenced at pages:
[Never referenced.]
A simple heuristic model is developed in this section. A better and more general, but still heuristic model, is developed in \(\S\) 35.02.03.03 - Electric Properties of Matter An exact, but purely formal, derivation is carried on in § 35.03 - Electric Properties of Matter.
From the simple examples one might guess that, in general, that the Polarization surface charge density is (read \(\S 35.02 .02 .01\) - Electric Properties of Matter):
\[
\rho_{\mathrm{S}}=\mathbf{P} \cdot \mathbf{n}
\]

Consider a piece of matter divided into small parallelepiped blocks, with sides parallel to the axes, \(\Delta x\), \(\Delta y\) and \(\Delta z\) long. Consider, for instance, \(P_{z}\) changing along \(z\) and two neighboring blocks centered at the same \(x\) and \(y\) and at \(z\) and \(z+\Delta z\). The total charge at the common face is:
\[
\Delta x \Delta y\left(P_{z}[z]-P_{z}[z+\Delta z]\right) \simeq \Delta x \Delta y \Delta z\left(-\frac{\partial P_{z}}{\partial z}\right)
\]

Considering, similarly, the contributions of \(P_{x}\) changing along \(x\) and \(P_{y}\) changing along \(y\) one finds the total charge per unit volume:
\[
\rho^{\mathrm{P}}=-\operatorname{div} \mathbf{P} .
\]
35.02.03.03 A Polarized Medium With No Free Charges (A Simple Heuristic Model) a More General Case

This § is referenced at pages:
[1812, 1812]
Consider any fixed volume \(\Omega\), inside a Polarized medium, and a small (infinitesimal) part of its boundary, the closed surface \(\partial \Omega\); the infinitesimal part of the closed surface is defined by the vector dS.

Assume that there are no free charges in the medium and the medium is not Polarized in absence of the external (applied) field. In case there are free charges the superposition principle may be applied.

Assume a very simplified model where Polarization is built from a number of all identical real Electric Dipoles of value \(\mathrm{p}=|q| \mathbf{d}\), all with the same charges, \(\pm|q|\), and where \(\mathbf{d}\) is the vector from the negative charge to the positive one; both of them, a priori, may depend on the position.

The Polarization may be due to any effect (deformation and|or orientation); for simplicity, the demonstration only considers deformation.

The Electric Dipole moments, a priori, might depend on the location: \(\mathrm{p}=\mathrm{p}[\mathrm{x}]\).
The charge exiting outside the element of surface \(\mathrm{d} \mathbf{S}\) in \(\partial \Omega\), is calculated by counting the number of Dipoles cut by the surface element dS. Note that this might have both a contribution from Dipoles near the surface, internal to it, whose charge exits the volume when Polarized and from Dipoles near the surface, external to it, whose charge enters the volume when Polarized. In any case one can write (by implicitly considering space-averaged values):
\[
\mathbf{P} \| \mathrm{p} \quad \delta Q_{\mathrm{P}}[\mathbf{x}]=|q| \eta_{\mathrm{N}}[\mathbf{x}] d \mathrm{~d} S \cos \theta=\mathbf{P}[\mathbf{x}] \cdot \mathrm{d} \mathbf{S}
\]

Note: the above is meaningful for a closed surface only. In general: the total charge crossing the surface as a consequence of Polarization is thus given by the contribution of all Dipoles which are cut by the piece of surface. Rule: look for real Electric Dipoles cut by the closed surface.

Therefore the total charge exiting any closed surface inside the medium is the flux of the Polarization vector:
\[
\begin{equation*}
Q_{\mathrm{P}}=\oiint_{\partial \Omega} \mathbf{P} \cdot \mathrm{d} \mathbf{S} \tag{35.02.02}
\end{equation*}
\]
\(\rightarrow\) 1813
As equation (35.02.02) is valid for any arbitrary surface inside the medium we always have that the charge exiting any closed surface is given by the flux of the Polarization vector \(\mathbf{P}\). Therefore inside the surface there is an equal and opposite charge left:
\[
-Q_{\mathrm{P}}=-\oiint_{\partial \Omega} \mathbf{P} \cdot \mathrm{d} \mathbf{S}=-\iiint_{\Omega} \boldsymbol{\operatorname { d i v }} \mathbf{P} \mathrm{d} V \equiv \iiint_{\Omega} \rho^{\mathrm{P}} \mathrm{~d} V
\]
and, as the surface is arbitrary, one can conclude, by applying the divergence theorem, (Read also equation (35.03.03)):
\[
\rho^{\mathrm{P}} \equiv-\operatorname{div} \mathbf{P}[\mathbf{x}]
\]

Applying the result to the surface \(\partial \Omega\) one finds the surface Polarization charge density (Read also equation (35.03.03)):
\[
\rho_{\mathrm{S}}^{\mathrm{P}} \equiv+\hat{\mathbf{n}} \cdot \mathbf{P}[\mathbf{x}]
\]

All in all it was found, for a very special model of Polarization and setup that Polarization charge density is expressed by the relations:
\[
\begin{gather*}
\rho^{\mathrm{P}} \equiv-\operatorname{div} \mathbf{P}[\mathbf{x}]  \tag{35.02.03}\\
\rho_{\mathrm{S}}^{\mathrm{P}} \equiv+\hat{\mathbf{n}} \cdot \mathbf{P}[\mathbf{x}] \tag{35.02.04}
\end{gather*}
\]

Equations (35.02.03), (35.02.04), derived in a static situation and in absence of free charges, are assumed
\(\rightarrow\)
18111813 to be valid in all cases.

Another derivation, a formal one, under the same hypothesis is summarised in section § 35.03 .01 Electric Properties of Matter.
It can be shown, in a more formal way, that the above results are indeed valid under any circumstance, with a mathematical derivation giving less room to physical intuition.
Note that, in the derivation above, the Polarization can in fact change along the surface, without spoiling the validity of the derivation. However when using the divergence theorem to derive equation (35.02.03) one must think of choosing a smaller and smaller (infinitesimal) surface in order to pick-up a point property inside the medium.

\subsection*{35.02.03.04 Equivalence of a Polarized Material to Coulombian Charge Densities}

This § is referenced at pages:
[Never referenced.]
In general, a piece of material with a given Polarization produces the same electric fields as the volume charge density (35.02.03) plus the surface charge density (35.02.04).
See Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ...., for the equivalence of the equivalent field with the average field in matter.

\subsection*{35.02.04 Polarization Current Density}

This § is referenced at pages:
[1814, 1814, 1923, 1923]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
In non-static situations a changing Polarization produces a current:
\[
\begin{equation*}
\mathbf{j}^{\mathrm{p}}=\partial_{t} \mathbf{P} \text {. } \tag{35.02.05}
\end{equation*}
\]

Assume a very simplified model where Polarization (by deformation) is built from a number of Electric Dipoles of value \(\mathrm{p}=|q| \mathbf{d}\), all with the same charges, \(\pm|q|\), and where \(\mathbf{d}\) is the vector from the negative charge to the positive one, a priori depending on the position. The number density, \(\eta_{\mathrm{N}}[\mathbf{x}]\), is assumed to be independent of time but, possibly, dependent of the position. In terms of the definition of current density, \(\mathbf{j}^{\mathrm{P}}[\mathbf{x}, t] \equiv|q| \eta_{\mathrm{N}}[\mathbf{x}] \mathbf{v}[\mathbf{x}, t]\), one then has:
\[
\begin{gathered}
\mathbf{P}[\mathbf{x}, t]=|q| \eta_{\mathrm{N}}[\mathbf{x}] \mathbf{d}[\mathbf{x}, t]=\eta_{\mathrm{N}}[\mathbf{x}] \mathrm{p}[\mathbf{x}, t], \\
\mathbf{j}^{\mathrm{P}}[\mathbf{x}, t] \equiv|q| \eta_{\mathrm{N}}[\mathbf{x}] \mathbf{v}[\mathbf{x}, t]=\partial_{\mathrm{t}} \mathbf{P}[\mathbf{x}, t] .
\end{gathered}
\]

It can also be shown that the term \(\mathbf{j}^{\mathrm{P}}\) is necessary in the Maxwell Equation in presence of matter in order to warrant the charge conservation. Read § 35.02.04 - Electric Properties of Matter.
More formally, based on conservation of the Polarization charge, and taking the time derivative of the Polarization charge density, the conservation equation provides immediately equation (35.02.05).
Read also § 38.03 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

\subsection*{35.03}

\section*{Calculation of the Electric Field Produced by a Given Polarization}

This § is referenced at pages:
[1812, 1812, 1858, 1858]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
Note that when dealing with systems with pre-assigned Polarization (ferro-electric materials, for instance), as opposed to the case of linear systems, for which the Polarization is related to the electric field, there is no a priori relation between electric field and Polarization. In particular, as opposed to isotropic materials, electric field and Polarization need not to be parallel.

\subsection*{35.03.01 Fields Produced by Polarized Matter: A Formal Treatment}

This § is referenced at pages:
[1813, 1813]
The expressions for the volume and surface Polarization charge densities, equations (35.02.03), (35.02.04), can be also deduced, in a purely formal way, from the ElectroStatic field of a distribution of Electric Dipoles as follows.
The electric field produced by a given (pre-assigned) Polarization \(\mathbf{P}[\mathbf{x}]\) can be calculated from the definition itself of the Polarization as a volume density of electrical Dipoles.
The ElectroStatic potential, using equations (14.14.05), (14.14.01), (14.07.03), is given by:
\[
\begin{gather*}
\Phi[\mathbf{x}]=\frac{1}{4 \pi \varepsilon_{0}} \iiint_{\tau} \frac{\mathbf{P}[\mathbf{y}] \cdot(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y} \tag{35.03.01}
\end{gather*}=,
\]
\[
\begin{equation*}
\frac{1}{4 \pi \varepsilon_{0}} \oiint_{\partial \tau} \frac{\hat{\mathbf{n}} \cdot \mathbf{P}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} S[\mathbf{y}]+\frac{1}{4 \pi \varepsilon_{0}} \iiint_{\tau}\left(\frac{-\operatorname{div} \mathbf{P}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\right) \mathrm{d} \mathbf{y} \tag{35.03.02}
\end{equation*}
\]
where the integral is extended to the region of space, \(\tau\), where the Polarizable material is present, that is where the Polarization is non zero.

Equation (35.03.01) shows that the electric field produced by any Polarization can be expressed in terms of an equivalent volume charge density, \(\rho^{\mathrm{P}}\), and an equivalent surface charge density, \(\rho_{\mathrm{S}}^{\mathrm{P}}\), such that:
\[
\begin{equation*}
\rho^{\mathrm{P}} \equiv-\operatorname{div} \mathbf{P}[\mathbf{y}] \quad \rho_{\mathrm{S}}^{\mathrm{P}} \equiv+\hat{\mathbf{n}} \cdot \mathbf{P}[\mathbf{y}] \tag{35.03.03}
\end{equation*}
\]

Note that the relations (35.03.03) imply that the material medium is globally neutral, as it follows from the divergence theorem.

Read also § 36.03 - Magnetic Properties of Matter.

\section*{CHAPTER II}

\section*{ELECTROSTATICS OF DIELECTRICS}

\section*{§6. The electric field in dielectrics}

Weshall now go on to consider a static electric field in another class of substances, namely dielectrics. The fundamental property of dielectrics is that a steady current cannot flow in them. Hence the static electric field need not be zero, as in conductors, and we have to derive the equations which describe this field. One equation is obtained by averaging equation (1.3), and is again
\[
\begin{equation*}
\operatorname{curl} \mathbf{E}=0 \tag{6.1}
\end{equation*}
\]

A second equation is obtained by averaging the equation \(\operatorname{div} \mathbf{e}=4 \pi \rho\) :
\[
\begin{equation*}
\operatorname{div} \mathbf{E}=4 \pi \bar{\rho} \tag{6.2}
\end{equation*}
\]

Let us suppose that no charges are brought into the dielectric from outside, which is the most usual and important case. Then the total charge in the volume of the dielectric is zero; even if it is placed in an electric field we have \(\int \bar{\rho} \mathrm{d} V=0\). This integral equation, which must be valid for a body of any shape, means that the average charge density can be written as the divergence of a certain vector, which is usually denoted by \(-\mathbf{P}\) :
\[
\begin{equation*}
\bar{\rho}=-\operatorname{div} \mathbf{P}, \tag{6.3}
\end{equation*}
\]
while outside the body \(\mathbf{P}=0\). For, on integrating over the volume bounded by a surface which encloses the body but nowhere enters it, we find \(\int \bar{\rho} \mathrm{d} V=-\int \operatorname{div} \mathbf{P} \mathrm{d} V=-\oint \mathbf{P} \cdot \mathrm{df}\) \(=0 . \mathbf{P}\) is called the dielectric polarization, or simply the polarization, of the body. A dielectric in which \(\mathbf{P}\) differs from zero is said to be polarized. The vector \(\mathbf{P}\) determines not only the volume charge density (6.3), but also the density \(\sigma\) of the charges on the surface of the polarized dielectric. If we integrate formula (6.3) over an element of volume lying between two neighbouring unit areas, one on each side of the dielectric surface, we have, since \(\mathbf{P}=0\) on the outer area (cf. the derivation of formula (1.9)),
\[
\begin{equation*}
\sigma=P_{n}, \tag{6.4}
\end{equation*}
\]
where \(P_{n}\) is the component of the vector \(\mathbf{P}\) along the outward normal to the surface.
To see the physical significance of the quantity \(\mathbf{P}\) itself, let us consider the total dipole moment of all the charges within the dielectric; unlike the total charge, the total dipole moment need not be zero. By definition, it is the integral \(\int \mathrm{r} \bar{\rho} \mathrm{d} V\). Substituting \(\bar{\rho}\) from (6.3) and again integrating over a volume which includes the whole body we have
\[
\int \mathbf{r} \bar{\rho} \mathrm{d} V=-\int \mathbf{r} \operatorname{div} \mathbf{P} \mathrm{d} V=-\oint \mathbf{r}(\mathrm{d} \mathbf{f} \cdot \mathbf{P})+\int(\mathbf{P} \cdot \operatorname{grad}) \mathbf{r} \mathrm{d} V
\]

The integral over the surface is zero, and in the second term we have \((\mathbf{P} \cdot \mathrm{grad}) \mathbf{r}=\mathbf{P}\), so that
\[
\begin{equation*}
\int \mathbf{r} \bar{\rho} \mathrm{d} V=\int \mathbf{P} \mathrm{d} V \tag{6.5}
\end{equation*}
\]

Thus the polarization vector is the dipole moment (or electric moment) per unit volume of the dielectric. \(\dagger\)
Substituting (6.3) in (6.2), we obtain the second equation of the electrostatic field in the form
\[
\begin{equation*}
\operatorname{div} \mathbf{D}=0 \tag{6.6}
\end{equation*}
\]
where we have introduced a quantity \(\mathbf{D}\) defined by
\[
\begin{equation*}
\mathbf{D}=\mathbf{E}+4 \pi \mathbf{P} \tag{6.7}
\end{equation*}
\]
called the electric induction. The equation (6.6) has been derived by averaging the density of charges in the dielectric. If, however, charges not belonging to the dielectric are brought in from outside (we shall call these extraneous charges), then their density must be added to the right-hand side of equation (6.6):
\[
\begin{equation*}
\operatorname{div} \mathbf{D}=4 \pi \rho_{\mathrm{ex}} . \tag{6.8}
\end{equation*}
\]

On the surface of separation between two different dielectrics, certain boundary conditions must be satisfied. One of these follows from the equation curl \(\mathbf{E}=0\). If the surface of separation is uniform as regards physical properties, \(\ddagger\) this condition requires the continuity of the tangential component of the field:
\[
\begin{equation*}
\mathbf{E}_{t 1}=\mathbf{E}_{t 2} \tag{6.9}
\end{equation*}
\]
cf. the derivation of the condition (1.7). The second condition follows from the equation \(\operatorname{div} \mathbf{D}=0\), and requires the continuity of the normal component of the induction:
\[
\begin{equation*}
D_{n 1}=D_{n 2} . \tag{6.10}
\end{equation*}
\]

For a discontinuity in the normal component \(D_{n}=D_{z}\) would involve an infinity of the derivative \(\partial D_{z} / \partial z\), and therefore of div \(\mathbf{D}\).

At a boundary between a dielectric and a conductor, \(\mathbf{E}_{t}=0\), and the condition on the normal component is obtained from (6.8):
\[
\begin{equation*}
\mathbf{E}_{t}=0, \quad D_{n}=4 \pi \sigma_{\mathrm{ex}} \tag{6.11}
\end{equation*}
\]
where \(\sigma_{\mathrm{ex}}\) is the charge density on the surface of the conductor; cf. (1.8), (1.9).

\section*{§7. The permittivity}

In order that equations (6.1) and (6.6) should form a complete set of equations determining the electrostatic field, they must be supplemented by a relation between the induction \(\mathbf{D}\) and the field \(\mathbf{E}\). In the great majority of cases this relation may be supposed linear. It corresponds to the first terms in an expansion of \(\mathbf{D}\) in powers of \(\mathbf{E}\), and. its correctness is due to the smallness of the external electric fields in comparison with the internal molecular fields.

The linear relation between \(\mathbf{D}\) and \(\mathbf{E}\) is especially simple in the most important case, that

\footnotetext{
\(\dagger\) It should be noticed that the relation (6.3) inside the dielectric and the condition \(\mathbf{P}=0\) outside do not in themselves determine \(\mathbf{P}\) uniquely; inside the dielectric we could add to \(\mathbf{P}\) any vector of the form curl \(f\). The exact form of \(\mathbf{P}\) can be completely determined only by establishing its connection with the dipole moment.
\(\ddagger\) That is, as regards composition of the adjoining media. temperature, etc. If the dielectric is a crystal, the surface must be a crystallographic plane.
}

\subsection*{35.03.01.01 An Important Warning}

It should be stressed that, rigorously, the previous derivation only applies to the case of ideal Dipoles, so that the point where the field is calculated can be considered far enough that the field of a ideal (point) Dipole can be used. The problem of the previous derivation is the fact that the starting point of (36.03.01) is only valid for distant points, not certainly inside the Dipole distribution itself.
The analysis showing that the above results is, nevertheless, exact can be found in the literature \({ }^{2}\).

\section*{© - QUOTE}

All in all it is the result the same as integrating for ideal Dipoles. All revolves around the fact that the average field over any sphere due to the charge inside is the same as the field at the center of a uniformly Polarized sphere with the same total Dipole moment. That is no matter how the actual microscopic charge configuration is, one can always replace it by a smooth distribution of perfect Dipoles, if one wants the macroscopic (average) field.
35.03.02 Fields Produced by Polarized Matter: A Physical Approach

The result of equation (35.03.02) is what one obtains straightforwardly considering that a Polarized material has a volume and surface Polarization charge density, given by equations (35.03.03), which must be considered as normal charges. The result of equation (35.03.02) is then the expression of the potential from the given charge densities.

\footnotetext{
\({ }^{2}\) See, for instance, D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ...., § 4.2.3 and 6.2.3
}

This § is referenced at pages:
[1788, 1788, 1863, 1863]
Read § 34.02 - Electric|Magnetic Properties of Matter, § 36.04-Magnetic Properties of Matter.
The electric field inside matter is rapidly changing in time as well as on distances of the order of the inter-atomic distances. For instance the electric field near the surface of an hydrogen nucleus is about \(10 \cdot 10^{21} \mathrm{~V} / \mathrm{m}\); the electric field in the inter-atomic region is basically zero, due to the neutrality of the atoms.
The macroscopic electric field is defined as the spatial average of the microscopic electric field, as long as the average is taken on a volume which is small on a macroscopic scale and large on the microscopic scale:
\[
\langle\mathbf{E}\rangle[\mathbf{x}] \equiv \lim _{\tau \longrightarrow 0} \frac{1}{\tau} \iiint_{\tau} \mathbf{E}[\mathbf{x}+\mathbf{y}] \mathrm{d} \mathbf{y} \quad \tau:=|\mathbf{y}| \leq R, R \text { macroscopically small and microscopically large }
\]
where the limiting process must be intended in the above-mentioned macroscopic sense.
The macroscopic electric field can be calculated from the Polarization.

\subsection*{35.05.01 Maxwell Equations in Matter: Electric Fields}

Let us rewrite Maxwell Equations in terms of Polarization and Magnetization as well as Electric|Magnetic fields.
The total charge density is given by the sum of the density of free charges, \(\rho^{\mathrm{F}}\), plus the bound, Polarization charges, \(\rho^{\mathrm{P}}\). It follows, for the divergence equation:
\[
\begin{gather*}
\varepsilon_{0} \operatorname{div} \mathbf{E}=\left(\rho^{\mathrm{F}}+\rho^{\mathrm{P}}\right)  \tag{35.05.01}\\
\operatorname{div} \mathbf{D} \equiv \rho^{\mathrm{F}} \\
\mathbf{D} \equiv \varepsilon_{0} \mathbf{E}+\mathbf{P} \\
\hline
\end{gather*}
\]
\[
\begin{equation*}
\boldsymbol{\operatorname { r o t }} \mathbf{D}=+\boldsymbol{\operatorname { r o t }} \mathbf{P}-\varepsilon_{0} \partial_{t} \mathbf{B} \tag{35.05.03}
\end{equation*}
\]

Only the non-homogeneous equations change.
Note that, in general, the producers of vector \(\mathbf{D}\) are not only the free charges, as it follows from equation (35.05.02), but also the Polarization, as it follows from equation (35.05.01). In fact according to Helmholtz theorem (section § 14.07.05 - Elements of Vector Calculus) a vector field can be uniquely reconstructed from the knowledge of both its divergence and its rotor.
In fact the analogous of Coulomb law for \(\mathbf{D}\) and free charges does not exist!
Note however that in special configurations endowed with some symmetry it might be possible to determine the \(\mathbf{D}\) vector by using only one of the equations (35.05.02), (35.05.01). In particular the vector \(\mathbf{D}\) is not conservative, even in stationary conditions, while \(\mathbf{E}\) is. The utility of the \(\mathbf{D}\) vector lies in the fact that, usually, the free charges are known while the Polarization charges are not.

\section*{Constitutive Relations for Electric Response}

\subsection*{35.06.01 Homogeneity Isotropy and Time-(Non)Invariance in Electric Response}

Read § 19.02 - Some Miscellaneous Topics and § 19.03-Some Miscellaneous Topics.

\subsection*{35.06.02 Constitutive Relation - Rigid (Frozen-In) Polarization}

In case the material is such that, for instance,
\[
\mathbf{P}[\mathbf{E}=0] \equiv \mathbf{P}_{\mathrm{R}} \equiv \quad \text { fixed } \quad \neq 0
\]
the material has a Polarization even in absence of external (applied) field (a rigid|frozen-in Polarization).
The case of so-called rigid|frozen-in Polarization concerns materials having a fixed Polarization, in particular a Polarization independent of any external electric field or, better, a non zero Polarization when the external (applied) field is zero.
Note, in particular, that the concept of susceptibility has no meaning when dealing with a rigid|frozen-in Polarization.
rigid|frozen-in Polarization implies anisotropy. However, the lack of isotropy, that is failure to obey rotational symmetry in space, is in this case just hidden (spontaneously broken symmetry), by the need to choose one specific direction in space, among infinite equivalent directions. Normally every substance, above its Curie temperature, loses its rigid|frozen-in Polarization to become manifestly isotropic.

\subsection*{35.06.03 Equation of State (Constitutive Relation) of Linear Electric Response}

This § is referenced at pages:
[1810, 1810]
The introduction of the vector field \(\mathbf{D}(\) or \(\mathbf{P})\) amounts to introducing a new variable. It is thus necessary to introduce one more equation to solve the problem. The equation to add is not a law of Nature but it is a constitutive equation characterizing the properties of the piece of matter involved, that is an equation of state:
\[
\begin{equation*}
\mathbf{P}=\mathbf{P}[\mathbf{E}, \mathbf{B}] \quad \text { or } \quad \mathbf{D}=\mathbf{D}[\mathbf{E}, \mathbf{B}] \tag{35.06.01}
\end{equation*}
\]

A linear material is defined by a linear equation in terms of the symmetrical electric susceptibility tensor, \(\left\{\boldsymbol{\chi}_{\mathbf{E}}\right\}_{{ }_{k j}}[\mathbf{x}]:\)
\[
P_{k}[\mathbf{x}]=\varepsilon_{0}\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{k j} E_{j}[\mathbf{x}] \Longrightarrow\left(\begin{array}{c}
P_{x} \\
P_{y} \\
P_{z}
\end{array}\right)=\varepsilon_{0}\left(\begin{array}{lll}
\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{x x} & \left\{\chi_{\mathrm{E}}\right\}_{x y} & \left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{x z} \cdot \\
\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{y y}^{\bullet} & \left\{\chi_{\mathrm{E}}\right\}_{y y} & \left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{y z}^{\bullet} \\
\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{z x} & \left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{z y} & \left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}_{z z}
\end{array}\right) \cdot\left(\begin{array}{c}
E_{x} \\
E_{y} \\
E_{z}
\end{array}\right) \quad \text { with }\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}=\left\{\boldsymbol{\chi}_{\mathrm{E}}\right\}[\mathbf{x}]
\]

A linear and homogeneous material is such that the susceptibility does not depend on the position:
\[
P_{k}[\mathbf{x}]=\varepsilon_{0}\left\{\chi_{\mathrm{E}}\right\}_{k j} E_{j}[\mathbf{x}]
\]

An linear and isotropic material is such that the susceptibility does not depend on the direction, that is the electric susceptibility tensor is multiple of the identity:
\[
P_{k}[\mathbf{x}]=\varepsilon_{0} \chi_{\mathrm{E}}[\mathbf{x}] \delta_{k j}^{\prime} E_{j}[\mathbf{x}]=\varepsilon_{0} \chi_{\mathrm{E}}[\mathbf{x}] E_{k}[\mathbf{x}] .
\]

In all the above cases one introduces the Electric-Permittivity, linking \(\mathbf{D}\) and \(\mathbf{E}\) :
\[
\mathbf{D} \equiv \epsilon_{\mathrm{R}} \varepsilon_{0} \mathbf{E} \quad \epsilon_{\mathrm{R}} \equiv 1+\chi_{\mathrm{E}} \quad \text { in static conditions }
\]

In the isotropic case one can show that the Electric-Permittivity satisfies:
\[
\epsilon_{\mathrm{R}} \equiv 1+\chi_{\mathrm{E}} \geq 1
\]

Note that linearity is not a property of the medium itself but a property of the medium and the applied external (applied) fields: for small enough fields the response is linear, that is the linear approximation of the development in series of Taylor is applied, while for large enough fields the response will certainly cease to be linear.

\subsection*{35.06.03.01 Refraction of Electric Field Lines in LHI Electric Media (No Free Charges)}

This § is referenced at pages:
[1867, 1867]
Read also § 36.06.03.01 - Magnetic Properties of Matter.
Consider two electric LHI media, such that:
\[
\mathbf{D}=\epsilon_{\mathrm{R}} \varepsilon_{0} \mathbf{E}
\]

Consider a smooth surface, separating the two different media with different physical properties, a point
P at the surface where the normal is \(\hat{\mathbf{n}}\), oriented from medium (1) towards medium (2), and define \(\Delta \mathbf{A} \equiv \mathbf{A}_{2}-\mathbf{A}_{1}\).
Assume there is no free surface charge density at the surface in such a way that both the normal component of \(\mathbf{D}\) and the tangential component of \(\mathbf{E}\) are continuous.
Note that the two tangential components and the normal vector to the surface are co-planar vectors, thanks to the continuity of the tangential component of the \(\mathbf{E}\) field.
The incident|refraction angle, \(\alpha_{e}\), (read § 13.06.05 - Elements of Vector Algebra), is defined as the arc-tangent of the ratio of the modules of the tangential, \(V_{t}\), and normal, \(V_{n}\), components of the vector field:
\[
\tan \alpha_{e}=\frac{\left|V_{t}\right|}{\left|V_{n}\right|} \quad 0 \leq \alpha_{e} \leq \pi / 2 .
\]

As the angle is always \(0 \leq \alpha_{e} \leq \pi / 2\) and the therefore the modules of the components must be used.
The following relations apply:
\[
\begin{array}{|c}
\hline E_{t 2}=E_{t 1} \\
\epsilon_{\mathrm{R} 2} E_{n 2}=\epsilon_{\mathrm{R} 1} E_{n 1} \\
\hline D_{n 2}=D_{n 1} \quad \frac{D_{t 2}}{\epsilon_{\mathrm{R} 2}}=\frac{D_{t 1}}{\epsilon_{\mathrm{R} 1}} \\
\hline
\end{array}
\]

If one defines the refraction angle, \(\alpha\), of the field lines, as the angle between the vector and the normal to the surface, one can write the above relations as:
\[
\frac{\tan \alpha_{1}}{\epsilon_{\mathrm{R} 1}}=\frac{\tan \alpha_{2}}{\epsilon_{\mathrm{R} 2}} \Longrightarrow \frac{\tan \alpha}{\epsilon_{\mathrm{R}}}=\mathrm{constant}
\]
valid for both \(\mathbf{E}\) and \(\mathbf{D}\) field lines.
Remember that Field lines are, by definition, continuous: in fact, they are solutions of a differential equation.

\section*{A High Electric-Permittivity Medium}

Suppose that \(\epsilon_{\mathrm{R} 2} \gg \epsilon_{\mathrm{R} 1}\) : it follows that \(\alpha_{2} \gg \alpha_{1}\) so that the field lines are, in medium 1 , almost perpendicular to the surface.
In fact in case medium (2) has a very high Electric-Permittivity, \(\epsilon_{\mathrm{R} 2} \gg \epsilon_{\mathrm{R} 1}\), the field lines inside the high-Electric-Permittivity medium tend to run almost parallel to the surface, while outside the high-Electric-Permittivity medium the field lines tend to exit the medium almost perpendicularly to the surface.
As an example: medium 2 is a conductor, which means \(\chi_{\mathrm{E}} \rightarrow \infty\)

\subsection*{35.06.04 Non-Linear Materials}

This § is referenced at pages:
[Never referenced.]
In case the constitutive relation between the Polarization and electric field is not linear the concept of electric susceptibility is generalized as a differential concept, because one is interested in the description of the Polarization for small changes of the electric field near a prescribed value of the electric field.
Actually, in general, the relation is a non linear-one, except for very small external fields, and therefore one considers the expansion in Taylor series truncated to first-order.
Considering for simplicity isotropic materials, such that \(\mathbf{P} \| \mathbf{E}\), the definition of susceptibility is thus generalized to:
\(\chi_{\mathrm{E}} \equiv \frac{1}{\varepsilon_{0}} \frac{\partial P}{\partial E} \quad\) or better, in case other parameters \(X\) may affect the polarization: \(\left.\quad \chi_{\mathrm{E}} \equiv \frac{1}{\varepsilon_{0}} \frac{\partial P}{\partial E}\right|_{X}\),
(35.06.02)
as a function of the components of the Polarization and electric field along their common direction and keeping constant any other possibly relevant parameter, \(X\) (such as temperature).
Note that the linear response in normally limited to small fields, while for large enough fields the response shows non-linear terms; see, for a relevant and important example, § 38.04.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology. In other words linearity is not a property of the material alone but a property of the material in a certain field.
The general response, equation (35.06.01), can be developed in Taylor series such that linear materials are described by the linear term of the development.
The linearity/non-linearity is in fact a property of the material plus the intensity of the field, not a property of the material alone as the linearity of the response depends on the intensity of the field.

Read § 38.02 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology, § 38.05 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

We want to find the relation between the microscopic polarisability and the macroscopic susceptibility. In fact there is in general a difference between the average field in matter and the local field acting on a certain molecule, at least for dense media. The average field in fact also includes the effect of the field produced by the molecule itself and its neighboring molecules.

The desired relation is Clausius-Mossotti equation, giving the relation between the susceptibility and Polarizability|Magnetizability based on the relation between the local field (acting on the single molecule) and the average macroscopic fields. It applies to substances which are linear and isotropic on the macroscopic scale. Therefore, even if it is not totally general, it is very good to understand the relation between Polarizability|Magnetizability, the local field and the (macroscopic) fields.

Consider a linear isotropic non-dipolar dense medium. The local field can be calculated via a spherical cavity, as it looks reasonable for a isotropic material. The medium outside the sphere is treated as a continuous medium; the medium inside the sphere is treated as a set of Polarized molecules. Read § 35.10.07.02 - Electric Properties of Matter and § 35.10.08 - Electric Properties of Matter for the calculation of relevant quantities. Imagine a iper-simplified model such that the space allotted to each molecule is a sphere of radius \(R\).

It is a good choice for gases and liquids. Actually for gases there is no significant difference between the local fields and the average field.

Under these assumptions one finds, for the local field on the test molecule, \(\mathbf{E}_{\mathrm{L}}\), in term of the macroscopic \(\mathbf{E}\) and \(\mathbf{P}\) :
\[
\begin{gathered}
\mathbf{E}_{\mathrm{L}}=\mathbf{E}+\frac{\mathbf{P}}{3 \varepsilon_{0}} \\
\mathbf{P}=\eta_{e} \alpha_{\mathrm{e}} \varepsilon_{0} \mathbf{E}_{\mathrm{L}}, \\
\mathbf{P}=\frac{\eta_{e} \alpha_{\mathrm{e}} \varepsilon_{0}}{1-\eta_{e} \alpha_{\mathrm{e}} / 3} \mathbf{E} .
\end{gathered}
\]

Finally the Clausius-Mossotti equation is found:
\[
\begin{equation*}
\chi_{\mathrm{E}}=\frac{3 \eta_{e} \alpha_{\mathrm{e}}}{3-\eta_{e} \alpha_{\mathrm{e}}} \quad \frac{\eta_{e} \alpha_{\mathrm{e}}}{3}=\frac{\chi_{\mathrm{E}}}{3+\chi_{\mathrm{E}}}=\frac{\epsilon_{\mathrm{R}}-1}{\epsilon_{\mathrm{R}}+2} \tag{35.09.01}
\end{equation*}
\]

The polarisability \(\alpha_{\mathrm{e}}\) has dimensions of a volume: \(\left[\alpha_{\mathrm{e}}\right]=L^{3}\).
Note that the above relations are somewhat different from equation 35.10.01: there the polarizability is linked to the polarization of the sphere itself; here, the polarizability is linked to the polarization of the embedding material.
The corrective factor at denominator increases the susceptibility. When \(\eta_{e} \alpha_{\mathrm{e}} \ll 1\) (for instance at very low density) one finds \(\chi_{\mathrm{E}} \simeq \eta_{e} \alpha_{\mathrm{e}}\).
If \(\alpha_{\mathrm{e}}\) increases then the electric susceptibility increases and \(\mathbf{P}\) increases and \(\mathbf{E}_{\mathrm{L}}\) increases and this makes \(\mathbf{P}\) increase: it is positive feedback.

One cannot extrapolate too much because the linearity is then lost. However if \(\eta_{e} \alpha_{\mathrm{e}}\) is too big the system can lock in a Polarized state, even in absence of external electrical field, just due to fluctuations.
Consider, as an example, \(\mathrm{BaTiO}_{3}\). Below \(T=118{ }^{\circ} \mathrm{C}\) it is a ferro-electric material. Going above \(T=118{ }^{\circ} \mathrm{C}\) it becomes a normal electric material because the density decreases due to the increase of the temperature. It remains a normal electric material with large \(\epsilon_{\mathrm{R}}\), due to the polar character of its structure. If the temperature is decreased below \(T=118^{\circ} \mathrm{C}\) the density increases and the internal Electric Dipoles locks in a Polarized state.
In general, compare with \(\S 36.09\) - Magnetic Properties of Matter: \(\eta_{m} \neq \eta_{e}\).
If the molecules are dipolar-molecules the above derivation is not correct. The correct model was worked out in this case by Onsager.
Read also § 36.09 - Magnetic Properties of Matter.

35.10.02 Electric Dipole Moment and Interactions of a HCI Molecule

This § is referenced at pages:
[1831, 1831]
© |Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|9.4||
Consider a molecule of HCl . The distance between the two atoms is \(d=126 \mathrm{pm}\). Assumes that it is a purely ionic molecule, that is the electron from the H atom is totally transferred to the Cl atom, as in a pure ionic bond. In this hypothesis one estimates its Electric Dipole moment as: \(\widetilde{p}=e d=2.01 \cdot 10^{-29} \mathrm{C} \cdot \mathrm{m}\). However the real measured Electric Dipole moment is smaller than that, \(p=3.43 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m}\), so that \(p=0.17 \widetilde{p}\).
Permanent Electric Dipole moments have values of the order of one debye \(\equiv 1 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m}\).
Consider then the following model: a positive H ion plus a neutral Cl atom with one electron at some distance \(d^{\prime}\) from the H positive ion and determine \(d^{\prime}\).
Also consider the following alternative model: a positive H ion plus a positive Cl ion with one pair of electrons at some distance \(d^{\prime \prime}\) from the H positive ion and determine \(d^{\prime \prime}\).
Calculate the interaction energy with a typical inter-atomic electric field of \(E \approx 1.4 \cdot 10^{11} \mathrm{~V} / \mathrm{m}\) produced by a charge \(e\) at a distance of one A.

\section*{SOLUTION}

First model: the average distance between the electron and the H nucleus is \(d^{\prime}=0.17 d\). In fact (the neutral Cl atom gives no contribution):
\[
p=e d^{\prime}=0.17 e d \Longrightarrow d^{\prime}=0.17 d
\]

In fact: \(d^{\prime}=0 \Longrightarrow p=0\) and \(d^{\prime}=d \Longrightarrow p=e d=\widetilde{p}\).
Interaction energy: \(\left|U_{e}\right|=p E=5 \cdot 10^{-19} \mathrm{~J}\). It is large, comparable to interaction energies between point charges and much larger than magnetic interactions. However \(E \approx 10^{12} \mathrm{~V} / \mathrm{m}\) requires distances of about \(10^{-10} \mathrm{~m}\), but this is the size of the HCl molecule. Moreover, the interaction gives rise to a strong attractive force between the point charge (nucleus or electron) leading to some kind of collapse of the system.

\subsection*{35.10.03 Polarization of a Hydrogen Atom According to J. J. Thomson Model}

This § is referenced at pages:
[1832, 1832, 1948, 1948]
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
Consider a Hydrogen atom.
Model a neutral atom as a point positive charge (the nucleus) surrounded by a uniform cloud of negative charge with radius \(a \approx 0.5 \cdot 10^{-10} \mathrm{~m}\). This is J.J.Thomson model.
First consider the stability of the equilibrium of the system, under small perturbations.
Assume that the negative electron cloud does not suffer any deformation, which is certainly a good approximation for small perturbations. Imagine the proton is shifted with respect to the center of the negative electron cloud. The negative electron cloud applies a restoring force on the proton, which pushes it back to the center, so that the equilibrium is a stable one.

Secondly, consider the effects of an external static and uniform electric field.
Assume that the cloud is shifted by an amount \(b\), without any deformation, when an external electric field, \(\mathbf{E}_{0}\), is applied; assume the external field \(\mathbf{E}_{0}\) is along \(z\). The hypothesis of non deformation of the spherical shape of the electron cloud is justified by the result we are going to find, showing that the displacement is a tiny one.
One might expect that the relative shift is proportional to the ratio between the external electric field and the typical electric fields inside the atom. It can be roughly estimated as follows:
\[
\frac{\Delta z}{a} \approx \frac{E_{0}}{E} \Longrightarrow \Delta z \approx \frac{4 \pi \varepsilon_{0} a^{3}}{e} E_{0} \quad E \approx \frac{1}{4 \pi \varepsilon_{0}} \frac{e}{a^{2}} \approx 1.4 \cdot 10^{11} \mathrm{~V} / \mathrm{m}
\]

Note the huge value of the electric field inside the atom.
The result can be made more quantitative as follows. Let the external electric field be along the \(z\) axis and only consider modules along the \(z\) direction. According to this simple model the equilibrium condition for the nucleus implies that force acting on the nucleus by the cloud of negative charge, \(E_{-}\), must be equal and opposite to the force on the nucleus by the external (applied) field, \(E_{0}\) :
\[
q E_{0}=q E[b]=q \frac{\rho b}{3 \varepsilon_{0}}=\frac{q^{2} b}{4 \pi \varepsilon_{0} a^{3}} \quad E[b]=E_{0} \text { at equilibrium }
\]
and the induced Dipole moment
\[
p=b q=4 \pi \varepsilon_{0} a^{3} E_{0}
\]

The polarisability, \(\alpha_{\mathrm{e}}\), is defined, in terms of the external (applied) field, in equation (35.02.01.01). Assume \(a=0.5 \cdot 10^{-10} \mathrm{~m}\) and \(E_{0}=10^{5} \mathrm{~V} / \mathrm{m}\). The electric polarisability is: \(\alpha_{\mathrm{e}}=1.6 \cdot 10^{-30} \mathrm{~m}^{3}\).
Note that the electric polarisability has dimension of a volume and that the result is the correct order of magnitude of the volume of the hydrogen atom.

One finds: \(b=9 \cdot 10^{-18} \mathrm{~m}\) that is much less than the dimensions of the nucleus. Therefore the atom is very rigid with respect to typical external electric fields. This approximation of non-distorted electron cloud is justified by the result: \(b \ll a_{0}\).

The resulting induced Electric Dipole moment is: \(p \simeq 1.4 \cdot 10^{-36} \mathrm{C} \cdot \mathrm{m}\); this is much less that a typical permanent Dipole moment (see the HCl molecule \(\S 35.10 .02\) - Electric Properties of Matter, for which \(\left.p \simeq 3.4 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m}\right)\).

For the sake of comparison the measured polarisability is: \(\alpha_{\mathrm{e}}=0.7 \cdot 10^{-30} \mathrm{~m}^{3}\).
The value of \(3 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m}\) is quite typical for Electric Dipole moments of molecules. sometimes the unit of measure called debye, is used: \(3.3356 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m}\).

As the restoring electric field is of the order of \(E \approx 10^{11} \mathrm{~V} / \mathrm{m}\) one may expect a linear response up to external electric fields \(E_{0} \ll 10^{11} \mathrm{~V} / \mathrm{m}\).

\subsection*{35.10.04 Polarization of a Hydrogen Atom With Exponential Electron Charge Density}

This § is referenced at pages:
[Never referenced.]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 4.2||
According to quantum physics, the electron in a hydrogen atom, in the fundamental state, has a charge density:
\[
\rho[r]=\frac{e}{\pi a_{0}^{3}} \exp \left[-2 r / a_{0}\right]
\]
where \(q\) is the charge of the electron and \(a_{0}\) is the Bohr radius.
Find the atomic polarisability of such an atom assuming that the electron charge distribution is not distorted by the external electric field and that the nucleus moves by an amount \(b \ll a_{0}\). This approximation is justified by the results of the problem with uniform charge density as well as, afterwards, by the result found with this approximation.

\section*{SOLUTION}
\[
\begin{gathered}
4 \pi r^{2} E[r]=\frac{1}{\varepsilon_{0}} \int_{s=0}^{r} \rho[s] 4 \pi s^{2} \mathrm{~d} s=\frac{4 \pi}{\varepsilon_{0}} \frac{e}{\pi a_{0}^{3}} \int_{s=0}^{r} s^{2} \exp \left[-2 s / a_{0}\right] \mathrm{d} s \quad \text { Gauss law for a sphere of radius } r \\
\int_{s=0}^{r} s^{2} \exp \left[-2 s / a_{0}\right] \mathrm{d} s=\frac{1}{4} a_{0}\left(a_{0}^{2}-\exp -\frac{2 r}{a_{0}}\left(2 a_{0} r+a_{0}^{2}+2 r^{2}\right)\right) \simeq \frac{r^{3}}{3}-\frac{r^{4}}{2 a_{0}}+\frac{2 r^{5}}{5 a_{0}^{2}}+O\left(r^{6}\right) \\
E[r]=\frac{e r}{3 \varepsilon_{0} \pi a_{0}^{3}} \\
\alpha_{\mathrm{e}}=3 \pi a_{0}^{3}
\end{gathered}
\]

Not so different from the model with uniform charge distribution.
35.10.05 Polarization of a Hydrogen Atom With Electron Charge Density Proportional to the Distance

This § is referenced at pages:
[Never referenced.]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
Let us study a simple case of Non-Linear response.
The induced Electric Dipole moment of an atom/molecule is proportional to the external (applied) electric field. This is a first-order approximation, not a fundamental law of nature, and it is easy to invent exceptions examples.
Suppose, for example, that the charge density of the electron cloud is proportional to the distance from the center, up to a distance \(R\) and all the other hypotheses of example §35.10.03 - Electric Properties of Matter:
\[
\begin{cases}\rho[r]=\beta r & \text { for } r<R \\ \rho[r]=0 & \text { for } r>R\end{cases}
\]
- How much is \(\beta\) for a total charge \(q\) ?
- To what power of \(E\) is the induced Electric Dipole moment proportional in this case?
- Under what conditions the first-order approximation holds?

\section*{SOLUTION}
\[
\left\{\begin{array}{l}
E[r]=\frac{\beta r^{2}}{4 \varepsilon_{0}} \quad \text { for } r<R \\
E[r]=\frac{Q}{4 \pi \varepsilon_{0} r^{2}} \quad \text { for } r>R
\end{array}\right.
\]

One finds: \(p \propto \sqrt{E_{0}}\)

\subsection*{35.10.06 Van Der Waals Forces}

The name Van Der Waals forces refers to inter-molecular forces between point charges, permanent or induced Dipoles and|or higher-order ElectroMagnetic Multipoles. It is also sometimes used loosely as a synonym for the totality of intermolecular forces.
Van Der Waals forces are relatively weak compared to normal chemical bonds.
They typically have a repulsive core, preventing the two systems to collapse.
They fall into three different categories.
- Keesom forces (orientation): forces between permanent charges, Dipoles and|or higher-order Multipoles.
- Debye forces (induction): forces between permanent charges, Dipoles and|or higher-order Multipoles and an induced Dipole and|or higher-order Multipole.
- London forces (dispersion): transient induced Dipole-Dipole or higher-order Multipoles interactions. These are sometimes called Van Der Waals forces themselves. The instantaneous fluctuations of Electric Dipole momenta of neutral molecules/atoms give rise to an Electric Dipole field which polarises nearby molecules/atoms in such a way that an attractive force with an interaction energy
going as the inverse sixth-power of the distance. The interaction is a quantum effect, in the sense that it disappears if the Planck constant is let to go to zero. The zero point energy of the system is lowered by the Dipole-Dipole coupling. The interaction does not depend for its existence on any overlap of the charge densities of the two atoms.
Point charge with Dipole interactions: attractive force with an interaction energy going as the inverse third-power of the distance.
Dipole with Dipole interactions: attractive force with an interaction energy going as inverse sixth-power of the distance.

In case of induced Multipoles the force is always attractive, as explained in section § 38.02.02-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

\subsection*{35.10.07 Rigid (Frozen-In) Polarization}

Note that for a uniform Polarization one simply has:
\[
\mathrm{p} \equiv \iiint \mathbf{P} \mathrm{~d} \mathbf{y}=\mathbf{P} \Delta V \quad \text { for uniform } \mathbf{P}
\]

\subsection*{35.10.07.01 A Uniformly Polarized Cylinder}

By taking into account the Polarization charges it is clear that the electric field, \(\mathbf{E}\), produced by such a cylinder is exactly the same as the one produced by a circular capacitor with the same surface charge density. As the Polarization is known a priori the \(\mathbf{D}\) field can be calculated from its definition.

The electric field obviously resembles the field of a Dipole, at large distances, as always. Near the cylinder one can think of the field as produced by an array of real Electric Dipoles (pairs of equal and opposite sign charges) put side by side.

\subsection*{35.10.07.02 A Uniformly Polarized Sphere}

\section*{This § is referenced at pages:}
[1827, 1827, 1835, 1835, 1877, 1877, 1878, 1878]
Compare with \(\S\) 36.10.04.02 - Magnetic Properties of Matter
The field inside a Polarized sphere is uniform, while the external field is exactly a Dipole field.
The \(\mathbf{E}\) field has sources at the surface of the sphere, therefore the density of field lines changes crossing the surface.

The \(\mathbf{D}\) field has no sources at the surface of the sphere and its flux is conserved, so the density of flux lines is.

\section*{Direct Calculation}
©|S.Bobbio \& E.Gatti, Elettromagnetismo E Ottica, 1991, Bollati-Boringhieri, ...Ed., ....|5.3||

From the microscopic interpretation of the Polarization, if one assumes that matter is made of all identical systems, one can imagine that the uniformly Polarized sphere comes from the uniform displacement of a grid of positive/negative charges, such that relative position of the positive charges with respect to negative charges is \(\boldsymbol{\delta}\).

The scalar potential is thus the potential of two uniformly charged spheres whose centers are displaced by a small amount \(\boldsymbol{\delta}\), with \(\delta \ll R\). Let \(|q|\) be the absolute value of the charge of our model and \(\eta_{\mathrm{N}}\) the number of charges per unit volume.

Direct calculation: external field.

The potential external to the sphere is the potential of an Electric Dipole, as the two uniformly charged spheres behave like point charges outside their radius:
\[
\mathrm{p}=q \eta_{\mathrm{N}}\left(\frac{4}{3} \pi R^{3}\right) \boldsymbol{\delta} \equiv \mathbf{P}\left(\frac{4}{3} \pi R^{3}\right) \quad \text { with } \quad \mathbf{P}=q \eta_{\mathrm{N}} \boldsymbol{\delta} \equiv \eta_{\mathrm{N}} \mathrm{p}
\]
giving a potential, outside the sphere,
\[
\Phi[\mathbf{x}]=\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathbf{r} \cdot \mathrm{p}}{r^{3}} \quad \text { for }|\mathbf{x}|>R \quad \text { with: } \quad \mathrm{p}=\mathbf{P}\left(\frac{4}{3} \pi R^{3}\right)
\]
for a uniformly Polarized sphere of radius \(R\) and Polarization \(\mathbf{P}\). Note that this is exactly the potential of an Electric Dipole at any point externally to the sphere, not only at large distances.

Direct calculation: internal field.
The potential internal to the sphere is the potential of two superimposed uniformly charged spheres, with charges of different sign, and with the center of the positive charge displaced with respect to the center of the negative charge by an amount \(\boldsymbol{\delta}\). Let \(\mathbf{r}_{+}\)and \(\mathbf{r}_{-}\)be, respectively, the position of the centers of the two charge distributions and \(\mathbf{r}\) the position of the point, internal to the sphere, where we want to calculate the electric field. Therefore we have:
\[
-\boldsymbol{\delta} \equiv\left(\mathbf{r}_{+}-\mathbf{r}_{-}\right)
\]
giving an electric field:
\[
\mathbf{E}_{\mathrm{I}}=\frac{|q| \eta_{\mathrm{N}}}{3 \varepsilon_{0}}\left(\mathbf{r}_{+}-\mathbf{r}_{-}\right)=-\frac{|q| \eta_{\mathrm{N}}}{3 \varepsilon_{0}} \boldsymbol{\delta}=-\frac{\mathbf{P}}{3 \varepsilon_{0}} \quad \mathbf{D}_{\mathrm{I}} \equiv\left(\varepsilon_{0} \mathbf{E}_{\mathrm{I}}+\mathbf{P}\right)=+\frac{2}{3} \mathbf{P}
\]

Therefore:
\[
\mathbf{E}_{\mathrm{I}}=-\frac{\mathbf{P}}{3 \varepsilon_{0}} \quad \mathbf{D}_{\mathrm{I}} \equiv\left(\varepsilon_{0} \mathbf{E}_{\mathrm{I}}+\mathbf{P}\right)=+\frac{2}{3} \mathbf{P}
\]

Therefore the potential internal to the sphere (according to the results in §33.18.61-Basic Laws of ElectroMagnetism) is:
\[
\Phi[\mathbf{r}]=\frac{\mathbf{P} \cdot \mathbf{r}}{3 \varepsilon_{0}} \quad \text { for }|\mathbf{r}|<R
\]

Note that the internal electric field is such that:
\[
\mathbf{E}_{\mathrm{I}} \cdot \mathbf{P} \leq 0
\]
and compare with the analogous magnetic situation in § 36.10.04.02 - Magnetic Properties of Matter. The difference of the two cases is a reflection of the fundamental difference, at small distances, between the fields produced by a real Electric Dipole and a real Magnetic Dipole (read § 38.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology).

\section*{A Purely Formal Calculation}

Start from equation (35.03.01), with \(\mathbf{P}\) uniform,
\[
\Phi[\mathbf{x}]=\frac{1}{4 \pi \varepsilon_{0}} \iiint_{\tau} \frac{\mathbf{P}[\mathbf{y}] \cdot(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\frac{1}{4 \pi \varepsilon_{0}} \mathbf{P} \cdot \iiint_{\tau} \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\frac{1}{4 \pi \varepsilon_{0}} \mathbf{P} \cdot \mathbf{I}[\mathbf{x}]
\]

Read § 38-014 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for the calculation of \(\mathbf{I}[\mathbf{x}]\).

It follows:
\[
\Phi[\mathbf{x}]=\frac{1}{4 \pi \varepsilon_{0}} \mathbf{P} \cdot \mathbf{I}[\mathbf{x}]=\left\{\begin{array}{lr}
\frac{1}{3 \varepsilon_{0}} \mathbf{P} \cdot \mathbf{x} & \text { for }|\mathbf{x}| \leq R \\
\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathbf{P} \cdot \mathbf{x}}{x^{3}} \tau & \text { for }|\mathbf{x}|>R
\end{array}\right.
\]
\[
\text { with } \tau=\frac{4}{3} \pi R^{3}
\]

The scalar potential \(\Phi\) is the same as a Electric Dipole, outside the sphere. It is the scalar potential of a uniform field, inside the sphere. The equipotential surfaces of \(\Phi\) inside the sphere are planes perpendicular the axis of the sphere (the diameter of the sphere parallel to \(\mathbf{P}\) ). Remember that the scalar potential, in static conditions, is defined to within an arbitrary constant.

\subsection*{35.10.08 A Sphere of LHI Material in a Uniform and Constant External Electric Field}

This § is referenced at pages:
[1827, 1827, 1841, 1841, 1843, 1843, 1843, 1843, 1879, 1879, 1880, 1880, 1920, 1920]
©|J.P.Pérez et al., 5 Vol.
..Ed., WEB - URL.|21.V.4||

Compare with \(\S 36.10 .05\) - Magnetic Properties of Matter.
It can be shown that, for any LHI sphere or ellipsoid, the induced Polarization is uniform in an external uniform field.

For a sphere of LHI material with electric susceptibility \(\chi_{\mathrm{E}}\) in an external electric field \(\mathbf{E}_{0}\) the following relations apply.

Be careful to distinguish between the external applied field \(\mathbf{E}_{0}\) and the average field inside the sphere E.

One first need to calculate the Polarization, so that the Electric Dipole moment is known and the results of \(\S 35.10 .07 .02\) - Electric Properties of Matter can be used.

The internal field can be calculated as follows.
\[
\begin{gathered}
\begin{array}{|}
\mathbf{P} \equiv \chi_{\mathrm{E}} \varepsilon_{0} \mathbf{E} \\
\mathbf{E}=\mathbf{E}_{0}-\frac{\mathbf{P}}{3 \varepsilon_{0}} \\
\mathbf{P}=\left(\frac{3 \chi_{\mathrm{E}}}{3+\chi_{\mathrm{E}}}\right) \varepsilon_{0} \mathbf{E}_{0} & \\
\mathbf{E}=\frac{3}{3+\chi_{\mathrm{E}}} \mathbf{E}_{0} \Longrightarrow|\mathbf{E}| \leq\left|\mathbf{E}_{0}\right| \quad \mathbf{E} \cdot \mathbf{E}_{0} \geq 0 \\
\mathbf{D}=\frac{3\left(1+\chi_{\mathrm{E}}\right)}{3+\chi_{\mathrm{E}}} \mathbf{D}_{0} \Longrightarrow|\mathbf{D}| \geq\left|\mathbf{D}_{0}\right| \quad \mathbf{D} \cdot \mathbf{D}_{0} \geq 0
\end{array} \\
\end{gathered}
\]

The meaning of dePolarizing field \(\mathbf{E}\) is clear when noting that the internal \(\mathbf{E}\) field is always smaller that the external (applied) field.

Note that in any case \(\mathbf{E}\) is parallel to \(\mathbf{E}_{0}\) and \(\mathbf{D}\) is parallel to \(\mathbf{D}_{0}\) (the coefficients are always positive). The case of a strictly non Polarizable object (or vacuum) is found for \(\chi_{\mathrm{E}}=0\).
The case of a perfect conductor can be recovered as \(\chi_{\mathrm{E}} \rightarrow \infty: \mathbf{E}=0, \mathbf{D}=3 \mathbf{D}_{0}\).
The Polarization is always parallel to the external (applied) field, as \(\chi_{\mathrm{E}}>0\).
The polarisability of the sphere is:
\[
\begin{equation*}
\alpha_{\mathrm{e}}=\frac{3 \chi_{\mathrm{E}}}{3+\chi_{\mathrm{E}}} \Delta V=\frac{3\left(\epsilon_{\mathrm{R}}-1\right)}{2+\epsilon_{\mathrm{R}}} \Delta V, \tag{35.10.01}
\end{equation*}
\]
and it is not strictly proportional to the electric susceptibility \(\chi_{\mathrm{E}}\).
The formal analogy, \(\mathbf{E} \Leftrightarrow \mathbf{H}\), with the case of the sphere in an external magnetic field (section § 36.10.05 - Magnetic Properties of Matter) is obvious, the only basic difference being that the electrical susceptibility is non negative while the magnetic susceptibility, \(\chi_{M}^{*}\), is constrained to be \(\chi_{M}^{*} \geq-1\).

35.10.10 A Point Charge and Two Polarizable LHI Materials
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|4.4||
Assume that space is full with two Polarizable LHI materials separated by the plane \(z=0\). A point charge, \(q\), is placed at \(\mathbf{r}_{0}=\{0,0, d\}\). The material at \(z>0\) has Electric-Permittivity \(\epsilon_{\mathrm{R} 1}\). The material at \(z<0\) has Electric-Permittivity \(\epsilon_{\mathrm{R} 2}\).
The charge polarises both media and in particular a Polarization surface charge appears at the surface at \(z=0\). The point charge and the Polarization surface charge at the boundary exert a force one on the other. There is no Polarization volume charge density as there is no free charges in the material.

\section*{SOLUTION}

One exploits the uniqueness of the solution: we use one good solution so that it must be the unique one.
Everywhere at \(z \neq 0: \operatorname{rot} \mathbf{E}=0\). We can therefore define a potential, continuous at \(z=0\).
Assume the following potential, with image charges \(q^{\prime}\) at \(-\mathbf{r}_{0}\) and \(\left.q^{\prime \prime}\right)\) at \(\mathbf{r}_{0}\) :
\[
\begin{gathered}
z>0 \quad \Phi_{1}[\mathbf{r}]=\frac{1}{4 \pi \varepsilon_{0}} \frac{1}{\epsilon_{\mathrm{R} 1}}\left(\frac{q}{\left|\mathbf{r}_{0}-\mathbf{r}\right|}+\frac{q^{\prime}}{\left|\mathbf{r}_{0}+\mathbf{r}\right|}\right), \\
z<0 \quad \Phi_{2}[\mathbf{r}]=\frac{1}{4 \pi \varepsilon_{0}} \frac{1}{\epsilon_{\mathrm{R} 2}}\left(\frac{q^{\prime \prime}}{\left|\mathbf{r}_{0}-\mathbf{r}\right|}\right) .
\end{gathered}
\]

The potential at \(z>0\) is the potential of a Dipole with, a priori, different charges ( \(q^{\prime}\) not yet known). The potential at \(z<0\) is the potential of a point charge ( \(q^{\prime \prime}\) not yet known). A priori the sign of the two image charges \(q^{\prime}\) at \(-\mathbf{r}_{0}\) and \(q^{\prime \prime}\) at \(\mathbf{r}_{0}\), is not determined at all.
We have:
\[
r_{1}=\sqrt{x^{2}+y^{2}+(z-d)^{2}} \quad r_{2}=\sqrt{x^{2}+y^{2}+(z+d)^{2}} .
\]

Continuity of the potential at \(z=0\) implies:
\[
\Phi_{1}[\{x, y, 0\}]=\Phi_{2}[\{x, y, 0\}] \Longrightarrow \frac{q}{\epsilon_{\mathrm{R} 1}}+\frac{q^{\prime}}{\epsilon_{\mathrm{R} 1}}=\frac{q^{\prime \prime}}{\epsilon_{\mathrm{R} 2}} .
\]

Continuity of the normal components of \(\mathbf{D}\) at \(z=0\) implies (no free charges):
\[
\begin{aligned}
D_{n 1}[\{x, y, 0\}] & =D_{n 2}[\{x, y, 0\}] \\
\epsilon_{\mathrm{R} 1} E_{n 1}[\{x, y, 0\}] & =\epsilon_{\mathrm{R} 2} E_{n 2}[\{x, y, 0\}] \\
\left.\epsilon_{\mathrm{R} 1} \frac{\partial \Phi_{1}}{\partial z}\right|_{z=0} & =\left.\epsilon_{\mathrm{R} 2} \frac{\partial \Phi_{2}}{\partial z}\right|_{z=0}, \\
q & =q^{\prime}+q^{\prime \prime}
\end{aligned}
\]

Continuity of the tangential components of \(\mathbf{E}\) at \(z=0\) implies:
\[
E_{t 1}[\{x, y, 0\}]=E_{t 2}[\{x, y, 0\}],
\]
but this condition is not used to solve the problem.

The results are:
\[
q^{\prime}=q\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right) \quad q^{\prime \prime}=q\left(\frac{2 \epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right)
\]

The above results imply that the image charge \(q^{\prime \prime}\) has the same sign as the real charge. The surface at \(z=0\) is Polarized with Polarization surface charge:
\[
\rho_{\mathrm{S}}^{\mathrm{P}}=\hat{\mathbf{n}}_{12} \cdot\left(\mathbf{P}_{1}-\mathbf{P}_{2}\right) \equiv \hat{\mathbf{n}}_{1 \rightarrow 2} \cdot\left(\mathbf{P}_{1}-\mathbf{P}_{2}\right)=P_{z 2}-P_{z 1},
\]
where one should be careful with \(\hat{\mathbf{n}}_{12}=\{0,0,-1\}\) to avoid making errors with the sign of the surface Polarization charge.
As the free charge density is zero one can calculate the Polarization charge density as the total charge density:
\(\rho_{\mathrm{S}}^{\mathrm{P}}=\varepsilon_{0}\left(E_{z 2}-E_{z 1}\right)=\frac{1}{4 \pi \varepsilon_{0}} \frac{2 \varepsilon_{0} q d}{r^{3}} \frac{1}{\epsilon_{\mathrm{R} 1}}\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right)=\frac{q}{2 \pi} \frac{d}{\left(d^{2}+\rho^{2}\right)^{3 / 2}} \frac{1}{\epsilon_{\mathrm{R} 1}}\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right) \equiv \frac{\alpha q d}{\left(d^{2}+\rho^{2}\right)^{3 / 2}}\)
with \(\rho \equiv \sqrt{x^{2}+y^{2}}\).
The total Polarization charge can be calculated by integration:
\[
Q_{P}=\int_{\rho=0}^{+\infty} \rho_{\mathrm{S}}^{\mathrm{P}} 2 \pi \rho \mathrm{~d} \rho=\frac{q}{\epsilon_{\mathrm{R} 1}}\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right) .
\]

The force between the real charges (the component perpendicular to the interface) is calculated from Coulomb law (in vacuum!). The \(z\) component of force on the point charge (with the correct sign) is given by:
\[
\begin{gathered}
\mathrm{d} F_{\perp}=\frac{1}{4 \pi \varepsilon_{0}} \frac{q \mathrm{~d} q_{P}}{r^{2}} \frac{d}{r}=\frac{1}{4 \pi \varepsilon_{0}} \frac{2 \pi q d \rho \rho_{\mathrm{S}}^{\mathrm{P}} \mathrm{~d} \rho}{r^{3}}=\frac{\alpha q^{2} d^{2} \rho \mathrm{~d} \rho}{2 \varepsilon_{0}\left(d^{2}+\rho^{2}\right)^{3}} \\
\Longrightarrow F_{\perp}=\frac{\alpha q^{2}}{8 \varepsilon_{0} d^{2}}=\frac{q^{2}}{16 \pi \varepsilon_{0} d^{2}} \frac{1}{\epsilon_{\mathrm{R} 1}}\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right)=\frac{q^{2}}{4 \pi \varepsilon_{0}(2 d)^{2}} \frac{1}{\epsilon_{\mathrm{R} 1}}\left(\frac{\epsilon_{\mathrm{R} 1}-\epsilon_{\mathrm{R} 2}}{\epsilon_{\mathrm{R} 1}+\epsilon_{\mathrm{R} 2}}\right) .
\end{gathered}
\]

Limiting case: \(\epsilon_{\mathrm{R} 2}=\epsilon_{\mathrm{R} 1} \Longrightarrow \rho_{\mathrm{S}}^{\mathrm{p}}=0\); ok as there is not interface in this case.
Limiting case: \(\epsilon_{\mathrm{R} 2} \gg \epsilon_{\mathrm{R} 1}\); medium (2) becomes much more Polarized than medium (1) and therefore the induced density of Dipoles is much bigger in medium (2) than in medium (1) and therefore at the interface the density of Dipoles from medium (2) (a negative one if \(q>0\) ) is bigger than the density of Dipoles from medium (1) (a positive one if \(q>0\) ). Therefore \(\rho_{\mathrm{S}}^{\mathrm{P}}<0\) if \(q>0\).
Limiting case: \(\epsilon_{\mathrm{R} 2}<\epsilon_{\mathrm{R} 1}\); medium (1) becomes more Polarized than medium (2) and therefore the induced density of Dipoles is bigger in medium (1) than in medium (1) and therefore at the interface the density of Dipoles has the same sign as the charge \(q\). Therefore \(\rho_{\mathrm{S}}^{\mathrm{P}}>0\) if \(q>0\).
Limiting case: \(\epsilon_{\mathrm{R} 1}=1\) and \(\epsilon_{\mathrm{R} 2} \rightarrow \infty\); it is in fact a charge in vacuum in front of a conductor, with electric field lines perpendicular to the interface. In this case:
\[
\rho_{\mathrm{S}}^{\mathrm{P}}=-\frac{q}{2 \pi} \frac{d}{\left(d^{2}+\rho^{2}\right)^{3 / 2}} \quad Q_{P}=-q \quad F_{\perp}=-\frac{q^{2}}{4 \pi \varepsilon_{0}(2 d)^{2}} .
\]

Limiting case: \(d=0\); there is no charge density at the interface because the Polarization is everywhere perpendicular to the interface.
The Polarization charge volume density inside the medium is given by the divergence of \(\mathbf{P}\) that is proportional to the divergence of \(\mathbf{E}\), that is zero away from the position of the real point charge. It is very important to note that when one calculates the force one must use all and only the real charges: the free point charge and the induced Polarization charges. One must use the normal Coulomb law in vacuum and not the Coulomb law with \(\epsilon_{\mathrm{R}}\) ! The latter, in fact, only applies when one uses the free charges because then the \(\epsilon_{\mathrm{R}}\) factor keeps memory of the screening of the Polarization charges.

Figure 35.1: The \(\mathbf{D}\) field has never sources, but it may have vortexes. The \(\mathbf{E}\) field has sources at the surface of the sphere, therefore the density of field lines changes crossing the surface.

Figure 35.2: The \(\mathbf{E}\) field has sources at the surface of the sphere, therefore the density of field lines changes crossing the surface (the flux is not conserved while crossing the Polarization surface charges).

Figure 35.3: Field lines of \(\mathbf{D}\) for a point charge embedded in a Polarizable material (with \(\epsilon_{\mathrm{R}}=\epsilon_{\mathrm{R} 1}\) ) near a semi-infinite slab of Polarizable material (with \(\epsilon_{\mathrm{R}}=\epsilon_{\mathrm{R} 2}\) ).

\section*{35-003 A Cubic Polarizable Material With rigid|frozen-in Polarization}

A cube of Polarizable material of side \(d\), with one vertex at the origin and sides parallel to the Cartesian planes, carries a rigid|frozen-in Polarization \(\mathbf{P}=k \mathbf{r}\) where \(k\) is a constant.
1. Determine the dimensions of \(k\).
2. Find all the Polarization charges.
3. Write the expression of the electric field at large distances.

\section*{35-004 A Spherical Shell With rigid|frozen-in Polarization}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Problem 4.15||
A spherical shell, with internal radius \(r_{1}\) and external radius \(r_{2}\), has a rigid|frozen-in Polarization \(\mathbf{P}[\mathbf{r}]=k \hat{\mathbf{e}}_{r} / r\) where \(k\) is a suitable constant. There is no free charge anywhere. Determine the electric field everywhere
- either calculating directly the electric field from the Polarization charges;
- or calculating \(\mathbf{D}\) first and \(\mathbf{E}\) after.

Note that the medium is not a LHI medium.

\section*{35-005 A Polarizable LHI Sphere in an Applied Uniform and Constant Electric Field (1)}

Read also § 35.10.08 - Electric Properties of Matter.
A Polarizable LHI sphere of radius \(R\) in put into an external applied uniform and constant electric field, \(\mathrm{E}_{0}\).
Assume that the electric field produced by the Polarization charges of the sphere is \(\mathbf{E}^{\prime} \| \mathbf{E}_{0}\), uniform ad parallel to the applied electric field internally to the sphere, and a Dipole field, externally to the sphere.
Show that this defines a solution at all points in space satisfying the required conditions at the boundaries, including infinity (so this is the solution for the uniqueness of the solution).
Determine the value of the electric field produced by the Polarization charges by imposing the appropriate boundary conditions.

\section*{SOLUTION}

Let \(\mathbf{E}\) be the total electric field, superposition of the applied field and the field produced by the Polarization charges of the sphere.
The relation between Electric Dipole moment and Polarization is:
\[
\mathrm{p}=\mathbf{P} \frac{4 \pi R^{3}}{3}
\]

Use spherical coordinates with the \(z\) axis along the direction of the applied electric field \(\mathbf{E}_{0}\). The external, \(r \geq R\), potential is:
\[
\Phi=\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathrm{p} \cdot \mathbf{r}}{r^{3}}-z E_{0} .
\]

The external, \(r \geq R\), field is:
\[
\begin{gathered}
\mathbf{E}[\mathbf{r}]=\frac{1}{4 \pi \varepsilon_{0}}\left(\frac{3(\mathrm{p} \cdot \mathbf{r}) \mathbf{r}}{r^{5}}-\frac{\mathrm{p}}{r^{3}}\right)+E_{0} \hat{\mathbf{e}}_{3} \\
\left\{\begin{array}{l}
E_{r}=\frac{1}{4 \pi \varepsilon_{0}} \frac{2 \mathrm{p} \cos \theta}{r^{3}}+E_{0} \cos \theta \quad \text { in fact: } \hat{\mathbf{e}}_{3} \cdot \hat{\mathbf{e}}_{r}=\cos \theta \\
E_{\theta}=\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathrm{p} \sin \theta}{r^{3}}-E_{0} \sin \theta \quad \text { in fact: } \cos \theta+\pi / 2=-\sin \theta
\end{array}\right.
\end{gathered}
\]

Take, conventionally, the fields \(\mathbf{P}\) and \(\mathbf{E}^{\prime}\) oriented as the \(z\) axis; if their components turns out to be negative its real orientation would be opposite.
The internal, \(r \leq R\), potential is:
\[
\Phi=-z E^{\prime}
\]

The internal, \(r \leq R\), field is:
\[
\begin{gathered}
\mathbf{E}[\mathbf{r}]=E^{\prime} \hat{\mathbf{e}}_{3}, \\
\left\{\begin{array}{l}
E_{r}=E^{\prime} \cos \theta \\
E_{\theta}=-E^{\prime} \sin \theta
\end{array}\right.
\end{gathered}
\]

The above electric fields are solutions to the Maxwell Equations both externally and internally to the sphere; in fact they are both divergence-less and rotor-less.
The unknown internal field \(\mathbf{E}^{\prime}\) can be determined imposing the boundary conditions.
The boundary conditions for the tangential component of \(\mathbf{E}\) at \(r=R\) (continuity) and the definition of electric susceptibility form a system of two equations with two unknowns, \(\mathbf{E}^{\prime}\) and \(\mathbf{P}\) which can be solved:
\[
\begin{aligned}
\sin \theta\left(\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathrm{p}}{R^{3}}-E_{0}\right) & =-E^{\prime} \sin \theta \Longrightarrow E^{\prime}=E_{0}-\frac{P}{3 \varepsilon_{0}} \\
\mathbf{P} & =\chi_{\mathrm{E}} \varepsilon_{0} \mathbf{E}^{\prime}
\end{aligned}
\]

Note that \(P, E^{\prime}\) and \(E_{0}\) are the components along the \(\hat{\mathbf{e}}_{3}\) direction, not modules. The results shows that the internal field is the sum of the uniform applied field and the field produced by the Polarization charges. Solving the above system for the two unknowns, \(\mathbf{E}^{\prime}\) and \(\mathbf{P}\) one finds:
\[
\begin{aligned}
& \mathbf{P}=\frac{3 \chi_{\mathrm{E}}}{3+\chi_{\mathrm{E}}} \varepsilon_{0} \mathbf{E}_{0} \\
& \mathbf{E}^{\prime}=\frac{3}{3+\chi_{\mathrm{E}}} \mathbf{E}_{0}
\end{aligned}
\]

The discontinuity of the radial component gives the Polarization surface charge density equal, in this problem, to the total surface charge density as there is no free charge.
\[
\begin{gathered}
\Delta E_{r}=\left(\frac{1}{4 \pi \varepsilon_{0}} \frac{2 \mathrm{p}}{R^{3}}+E_{0}-E^{\prime}\right) \cos \theta=\Delta E_{r}=\frac{P}{\varepsilon_{0}} \cos \theta \\
\Longrightarrow \rho_{\mathrm{S}}^{\mathrm{P}}=P \cos \theta
\end{gathered}
\]

The external field gives, for the refraction of the field lines:
\[
\begin{gathered}
\tan \alpha_{\text {ext }} \equiv\left|\frac{E_{\theta}}{E_{r}}\right| \Longrightarrow, \\
\tan \alpha_{\text {ext }}=\left\lvert\, \frac{\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathrm{p}}{\frac{1}{R^{3}}-E_{0}} \frac{2 \mathrm{p}}{4 \pi \varepsilon_{0}} \frac{E_{0}}{R^{3}}\left|\tan \theta=\left|\frac{\frac{P}{3 \varepsilon_{0}}-E_{0}}{\frac{2 P}{3 \varepsilon_{0}}+E_{0}}\right| \tan \theta=\frac{1}{\epsilon_{\mathrm{R}}} \tan \theta>0\right.}{} .\right.
\end{gathered}
\]

The internal field gives, for the refraction of the field lines:
\[
\begin{gathered}
\tan \alpha_{\text {int }} \equiv\left|\frac{E_{\theta}}{E_{r}}\right| \Longrightarrow, ~ \\
\tan \theta>0
\end{gathered}
\]

The result is consistent with the general law for refraction of the filed lines, as the ElectricPermittivity outside is one.

\section*{35-006 A Polarizable LHI Sphere in an Applied Uniform and Constant Electric Field (2)}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Problem 4.22||
Read § 35.10.08 - Electric Properties of Matter.
Calculate the internal field by successive approximations as follows. Start assuming the internal electric field is the applied field \(\mathbf{E}_{0}\) and find the Polarization as in a LHI medium. Calculate the resulting internal electric field \(\mathbf{E}_{1}\) and find the Polarization as in a LHI medium. Go on and sum the series of the resulting electric fields.

\section*{35-007 A Polarizable LHI Sphere in an Applied Uniform and Constant Electric Field (3)}

Carry one the same problem as in § 35.10.08 - Electric Properties of Matter with a LHI medium having Electric-Permittivity different from the one of the LHI sphere. Show that the fields internal to the sphere are, in this case:
\[
\mathbf{E}=\frac{3 \epsilon_{\mathrm{R}}^{E}}{2 \epsilon_{\mathrm{R}}^{E}+\epsilon_{\mathrm{R}}^{I}} \mathbf{E}_{0} \quad \mathbf{P}=\left(\frac{3 \epsilon_{\mathrm{R}}^{E}\left(\epsilon_{\mathrm{R}}^{I}-1\right)}{2 \epsilon_{\mathrm{R}}^{E}+\epsilon_{\mathrm{R}}^{I}}\right) \varepsilon_{0} \mathbf{E}_{0} .
\]

Show, in particular, that the electric field internal to the sphere is increased/decreased according to the relative values of the Electric-Permittivity: \(\epsilon_{\mathrm{R}}{ }^{E} \gtreqless \epsilon_{\mathrm{R}}{ }^{I}\).
Study the qualitative behavior of the field lines in the two cases of Electric-Permittivity of the external medium larger or smaller than the one of the sphere.

\section*{SOLUTION}

If the Electric-Permittivity of the external medium is larger than the one of the sphere the field lines tend to be repelled by the sphere, like for a diamagnetic sphere in an external magnetic field.

\section*{35-008 Capacitor With a Polarizable Material or a Conductor Inside}

Take a plane ideal capacitor of area \(A\) and distance between the armatures equal to \(D\). Insert a slab of Polarizable material with relative Electric-Permittivity \(\epsilon\), thickness \(d \leq D\) parallel to the armatures, without touching the armatures. Find the capacity.

\section*{SOLUTION}

Capacitor with the Polarizable material slab inserted:
\[
\begin{gathered}
\Delta V=\frac{\sigma}{\varepsilon_{0}}\left(\frac{d}{\epsilon}+(D-d)\right), \\
C[\epsilon]=\frac{\varepsilon_{0} A}{D+d\left(\frac{1}{\epsilon}-1\right)}, \\
\lim _{\epsilon \longrightarrow \infty} C[\epsilon]=\frac{\varepsilon_{0} A}{D-d}
\end{gathered}
\]

Capacitor with the conducting slab inserted. It can be calculated as the series of two capacitors; only the sum of the two gaps, \(D-d\), matters.

\section*{35-009 A Spherical Capacitor}

A spherical capacitor is made of two surfaces of radii \(R_{1}\) and \(R_{2}\). It is filled with a LHI material with Electric-Permittivity \(\epsilon_{\mathrm{R}}=A\left(\frac{R_{1}}{r}\right)^{2}\).
1. Find the capacitance \(C\) of the capacitor.
2. If the charge on the capacitor is \(Q\) find the total energy stored in the capacitor.

\section*{35-010 An Ideal Plane Capacitor Filled With a Non Uniform Electric Material}

This § is referenced at pages:
[1845, 1845]
Determine the capacity of an ideal plane capacitor, with the armatures having area \(A\) and distance \(d\), filled with an isotropic and non uniform electric material with relative Electric-Permittivity depending on the distance from the armatures only. Let \(z\) be the axis perpendicular to the armatures, with origin at the negatively charged armature and directed towards the positively charged one. The relative ElectricPermittivity is the function \(\epsilon_{\mathrm{R}}[z]\) for \(0 \leq z \leq d\).
Calculate the Polarization charge (both volume and surface charges).

\section*{SOLUTION}
\[
\begin{gathered}
D=\rho_{\mathrm{S}}^{\mathrm{F}} \\
C \equiv \frac{|Q|}{|\Delta V|}=\varepsilon_{0} A\left(\int_{z=0}^{z=D} \epsilon_{\mathrm{R}}^{-1}[z] \mathrm{d} z\right)^{-1}
\end{gathered}
\]

Order of magnitude: for \(A=, d=\) one has \(C=\).
Alternative method: consider the Polarizable material medium as an infinite series of slices acting as capacitors in series.

\section*{35-011 An Ideal Plane Capacitor Filled With Two Uniform Electric Materials}

Solve problem § 35-010 - Electric Properties of Matter with two electric materials with different ElectricPermittivity whose interface is parallel to the armatures.
Calculate the Polarization charges.

\section*{35-012 A Spherical Insulating LHI Shell Surrounding a Point Charge}
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P-21.12||
A point charge \(Q\) is at the center, \(O\), of a insulating spherical shell of radii \(R_{1}\) and \(R_{2}\), previously uncharged and made of a LHI material with electric susceptibility \(\chi_{\mathrm{E}}\).
1. Calculate the electric and Polarization fields in all space.
2. Determine the total charge inside a sphere centered in \(O\), as a function of the radius \(r\).
3. Study the case when the electric susceptibility \(\chi_{\mathrm{E}}\) is very big, in the limit \(\chi_{\mathrm{E}} \longrightarrow \infty\).

\section*{SOLUTION}
in the polarizable material shell: \(\quad \rho^{\mathrm{F}}=\rho_{\mathrm{S}}^{\mathrm{F}}=0\),
\[
D[r]=\frac{1}{4 \pi} \frac{Q}{r^{2}} \quad \text { everywhere }
\]

\[
P[r]=\left\{\begin{array}{l}
\frac{1}{4 \pi} \frac{\chi_{\mathrm{E}}}{1+\chi_{\mathrm{E}}} \frac{Q}{r^{2}} \\
0 \quad \text { otherwise }
\end{array} \quad \text { for } R_{1}<r<R_{2}\right.
\]
\[
\rho^{\mathrm{P}}=-\operatorname{div} \mathbf{P}=0 \quad \text { as the polarization is an inverse-square field }
\]
\(Q_{1}=-Q \frac{\chi_{\mathrm{E}}}{1+\chi_{\mathrm{E}}} \quad Q_{2}=+Q \frac{\chi_{\mathrm{E}}}{1+\chi_{\mathrm{E}}}=-Q_{1} \quad\) as it should be, because the material medium is globally neutral,
if \(R_{2} \rightarrow \infty\) (observer immersed in the polarizable material) the effective charge seen is: \(\quad Q+Q_{1}=\frac{Q}{1+\chi_{\mathrm{E}}}\)
\[
\text { if } \chi_{E} \rightarrow \infty \text { one finds the results for a conductor: }
\]
\[
\chi_{\mathrm{E}} \rightarrow \infty \Longrightarrow Q_{2}=-Q_{1}=Q
\]

The Polarizable material screening effect is obtained when \(R_{2} \rightarrow \infty\), that is the observer is immersed in the Polarizable material and the effective charge seen is reduced with respect to the free point charge.

\section*{35-013 A Model for the Electric Polarization}

This § is referenced at pages:
[1942, 1942]
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P-21.10||
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
Consider the following model for a Polarizable medium. The medium is made of small conducting spheres of radius \(r\) much smaller than the average distance between the spheres.

Calculate the electric susceptibility of the medium as a function of the radius \(r\) and the number density, \(\eta_{\mathrm{N}}\), of the spheres. Assume that the medium is sufficiently dilute such that each sphere reacts to the external (applied) field only and it is not sensitive to the field produced by the other spheres.

\section*{35-014 Cavities Inside a Polarizable Material}

A uniform ElectroStatic field \(E_{0}=2 \cdot 10^{3} \mathrm{~V} / \mathrm{m}\) is present inside a linear, homogeneous isotropic material of Electric-Permittivity \(\epsilon_{\mathrm{R}}=3\). A long and thin cavity inside the material makes an angle \(\alpha=30^{\circ}\) with the direction of the electric field.
Calculate the value of the electric field inside the cavity.

\section*{SOLUTION}

Module: \(E=3.46 \cdot 10^{3} \mathrm{~V} / \mathrm{m}\). Direction: at an angle \(\beta=60^{\circ}\) with the direction of \(\mathbf{E}_{0}\).

\section*{35-015 A Conducting Sphere Surrounded by a Polarizable Material}
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P-21.9||
A conducting sphere has a radius \(R_{1}=1 \mathrm{~cm}\) and a charge \(Q=6 \cdot 10^{-8} \mathrm{C}\). It is surrounded by a non homogeneous Polarizable material sphere with internal radius \(R_{1}=1\) and external radius \(R_{2}=3 \mathrm{~cm}\). The Electric-Permittivity of the medium changes with the radial distance as \(\epsilon_{\mathrm{R}}=b / r^{2}\), with \(b=9 \cdot 10^{-4} \mathrm{~m}^{2}\).
1. Calculate, in all the space, the electric field, the Polarization field, the Polarization charge volume density and the Polarization charge surface density.
2. Study the case \(\epsilon_{\mathrm{R}} \longrightarrow \infty\).

\section*{35-016 A Polarized Cylinder}
©|Lim Yung-Kuo, Problems And Solutions On Electromagnetism, 1993, World Scientific, ...Ed., ....|2020, 2021||
A long solid cylinder of radius \(a\) is made of a material with a fixed Polarization, so that the Polarization is everywhere directed radially outward with a magnitude proportional to the distance from the axis: \(\mathbf{P}=P_{0} r \hat{\mathbf{e}}_{r}\). The cylinder rotates with constant angular velocity \(\omega\) around its axis, without any change in P.
1. Determine the charge density inside the cylinder.
2. Determine the magnetic field on the axis, far away from the edges of the cylinder.
3. Determine the electric field at any distance \(r\) for the axis, far away from the edges of the cylinder.
4. Determine the magnetic field at any distance \(r\) for the axis, far away from the edges of the cylinder.
5. Determine the total ElectroMagnetic energy stored per unit length of the cylinder both before the cylinder starts spinning and while it is spinning. Where does the extra energy come from?

\section*{35-017 Another Polarized Cylinder}

A very long cylinder, of radius \(R\), has \(\mathbf{P}\) Polarization uniform and perpendicular to the axis. For example, let the axis of the cylinder be along \(z\), and the Polarization is \(\mathbf{P}=\{0, P, 0\}\).
1. Find the electric field inside the cylinder.
2. Show that on the outside we have:
\[
\mathbf{E}(\mathbf{r})=\frac{R^{2}}{2 \epsilon_{0} r^{2}}(2(\mathbf{P} \cdot \hat{r}) \hat{\mathbf{r}}-\mathbf{P})
\]

Here, \(r\) and \(\hat{\mathbf{r}}\) are meant in cylindrical coordinates.

\section*{35-018 A Electric Dipole Inside an LHI Sphere}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|4.34||

A electric point Dipole is embedded at the center of a sphere of LHI material. Find the electric field inside and outside the sphere.

Experimentally one can study the effects of matter on magnetic fields (and vice-versa) by inserting a material inside a an empty inductor. When any material is inserted inside an empty inductor the inductance may change either slightly (either increasing or decreasing) or it may largely increase, depending on the material.

Similarly, some kind of materials are weakly attracted by a magnet, some kind of materials are strongly attracted by a magnet and some kind of materials are weakly repelled by a magnet.

Under the influence of an external magnetic field the atoms and|or molecules of the medium react collectively: the medium becomes Magnetized.

In fact, we know that matter is made of electrons, ions, atoms, molecules etc.. These are in turn composed of other particles, possibly composed particles. Instead of describing the material as a volume of structure-less but non-vacuum jelly, it is described as a collection of electrons|ions|atoms|molecules etc. inhabiting a vacuum.

\section*{Magnetization of Matter}

This § is referenced at pages:
[1808, 1808]
The effects of external magnetic fields on matter can be described, to a first approximation, by means of a suitable distribution of Magnetic Dipoles. This hypothesis is normally assumed when studying the response of matter to magnetic fields. Note, however, that under certain circumstances the inclusion of higher-order multipoles fields might become necessary.
Matter generally reacts to an external magnetic field by Magnetization. On the microscopic point of view this can be understood by either of two mechanisms:
- deformation of the microscopic currents distributions: Magnetization by deformation of nonmagnetic matter, dia-magnetism; it is opposite to the external field.
- orientation of pre-existing microscopic Magnetic Dipoles: Magnetization by orientation of magnetic matter; in these cases a Magnetization by deformation exists as well, but it is normally negligible with respect to the Magnetization by orientation; it is often called para-magnetism (para-magnetic matter); it is oriented with the external field.
Induced Magnetization can be either parallel (para-magnetism) or anti-parallel (dia-magnetism) to the external field, at variance with para-electricity; see section § 35.02 - Electric Properties of Matter.
Note that, while the entity of the deformation and|or orientation of the single atom/molecule may be very small, the large number of Atoms|Molecules in macroscopic matter can make the effect a large one (read § 34.04.02-Electric|Magnetic Properties of Matter). In fact the number of atoms per cubic meter for ordinary matter has values in the range \(\left(10^{25} \div 10^{29}\right)\) atoms \(/ \mathrm{m}^{3}\).

Magnetization by deformation (diamagnetism) and orientation (paramagnetism) can be understood, from a qualitative point of view, without invoking quantum-relativistic physics, which is however necessary for a quantitative understanding. On the other hand ferro-magnetism cannot be explained without quantum physics.
Note that materials exists having a built-in Magnetization even in absence of external applied magnetic fields: they are generically called here ferro-magnetic materials.
Because, to a first approximation, the effect of external fields on matter may be described either as induction of Dipoles and|or orientation of existing Dipoles, the magnetic field produced by the Magnetized material can be thus replaced by the magnetic field produced by a continuous Dipole distribution.
Note that an extremely important role is played in the Magnetization by orientation of magnetic matter by the fact that physical systems, down in scale to elementary particles, may have an intrinsic Magnetic Dipole moment.
36.02.01 Atomic/Molecular Magnetizability - Microscopic
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
36.02.01.01 Magnetizability of an Isotropic Molecule
©|Raimond|excellent||

The magnetisability of an isotropic atom/molecule (or any other microscopic system) is defined as the average Magnetic Dipole moment, \(m\), induced by an external magnetic field \(\mathbf{B}_{0}\) :
\[
\begin{gathered}
\left.\square \alpha_{\mathrm{m}} \equiv \mu_{0} \frac{\partial \mathrm{~m}}{\partial B_{0}}\right|_{B_{0}=0} \quad \text { for the case } \mathrm{m} \| \mathbf{B}_{0} \text { (isotropic atom/molecule) }, \\
\Longrightarrow \mathrm{m} \simeq \mathrm{~m}_{0}+\frac{1}{\mu_{0}} \alpha_{\mathrm{m}} \mathbf{B}_{0}+\mathcal{O}\left[\left(B_{0}\right)^{2}\right] \quad \text { for a permanent Magnetic Dipole moment: } \mathrm{m}_{0}
\end{gathered}
\]

The magnetisability is the second derivative of the interaction energy with respect to external magnetic field calculated at zero field:
\[
\alpha_{\mathrm{m}} \equiv-\left.\mu_{0} \frac{\partial^{2} \mathcal{U}_{m}}{\partial B_{0}^{2}}\right|_{B_{0}=0}
\]
with no factor \(1 / 2\), because it is a Magnetizable systems with factor \(1 / 2\) in the interaction energy.
The above discussion applies to a single atom/molecule: a permanent Dipole may be present, even in absence of an external field, and an induced moment is generally always present.

Whenever a large number of Atoms \(\mid\) Molecules is present, one should introduce the macroscopic averaging, in terms of the Magnetization density, section \(\S 36.02 .01-36.02 .01\); in fact, \(\mathbf{B}_{0}\) is actually the local field:
\[
\mathbf{B}_{0} \longrightarrow \mathbf{B}_{\mathrm{LOC}}
\]

Even if each atom/molecule possesses a permanent Dipole, a random arrangement may result in a zero total Dipole in absence of an external field.

The induced Magnetization includes the effect of alignment of the permanent Dipoles, which is generally opposed by temperature. See section § 38.04.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

The magnetisability can be both either positive or negative:
\[
\alpha_{\mathrm{m}} \gtreqless 0
\]

One should assume that a linear relation apply as long as the external magnetic field is not too big. One should assume that a linear relation apply as long as the external electric field is not too big. Note that for large external fields the relation may become non-linear, so that the magnetisability may loose some of its meaning and become field-dependent.

Note that in general whenever a permanent Magnetic Dipole moment, \(m_{0}\), is present, this is normally much larger than the induced Magnetic Dipole moment, at least for external fields not too large.

By definition the physical dimensions of the magnetisability is a volume. Note, however, that in the literature slightly different definitions may be found.

\subsection*{36.02.01.02 Magnetisability of a Non-Isotropic Axially-Symmetric Molecule}

If a molecule is not isotropic, but axially-symmetric, it is rather obvious that the magnetisability might depend of the direction of the applied field. Consider for instance a bi-atomic molecule: one expects that the induced Dipole moment is different for an external magnetic field applied along the axis of the molecule with respect to an external magnetic field applied perpendicularly to it.
Therefore one can write for this kind of molecule (having one axis of symmetry):
\[
\mathrm{m} \simeq \frac{1}{\mu_{0}}\left(\alpha_{\mathrm{m} \|}\left[B_{0}\right] \mathbf{B}_{\|}+\alpha_{\mathrm{m} \perp}\left[B_{0}\right] \mathbf{B}_{\perp}\right) \quad \text { superposition principle }
\]

\subsection*{36.02.01.03 Magnetisability of a General Non-Isotropic Molecule}

The general case is discussed in § 36.06.03-Magnetic Properties of Matter in the completely analogous case of the Magnetization vector.

\subsection*{36.02.01.04 All Materials Undergo Magnetization by Deformation (Dia-Magnetism)}

This § is referenced at pages:
[1810, 1810]
Consider an atom/molecule and assume that the overall Magnetic Dipole moment of the is zero.
If an external magnetic field is introduced the current densities will change in such a way to oppose to the change put in force by the external magnetic field. Therefore the current densities will change all generating a magnetic field opposing the change. Therefore the induced fields of the current densities will sum up each other. This is, qualitatively, diamagnetism, which is present in every atom/molecule.
Assume that two identical current distributions, with equal and opposite currents, are superimposed, like two electrons in an atom doing the same orbit with equal and opposite angular momenta. The magnetic dipole moment is zero.
In presence of an external magnetic field, both current distributions induce a magnetic field opposing the external one. A magnetic dipole moment is induced, opposite to the external field.
Let us then assume a simple semi-classical model such that, in absence of external fields, the opposite and identical currents cancel, while in presence of external fields the currents do not cancel anymore so that there is an induced magnetic dipole moment, anti-parallel to the external field.
This will be modeled as two non-equal and opposite total currents, on the same original space distributions.
Read § 35.02.01.04 - Electric Properties of Matter, for similarities and differences.

\subsection*{36.02.02 Definition of the Magnetization}

Remembering that the definition of magnetic dipole is, by definition, additive, see (33.13.04), the macroscopic Magnetization field is defined as:
\[
\begin{equation*}
\mathbf{M} \equiv \lim _{\Delta V \rightarrow 0} \frac{\Delta \mathrm{~m}}{\Delta V} \equiv \lim _{\Delta V \rightarrow 0} \frac{\sum_{k} \mathrm{~m}_{k}(\text { inside } \Delta V)}{\Delta V} \equiv \eta_{\mathrm{N}}\langle\mathrm{~m}\rangle \tag{36.02.01}
\end{equation*}
\]

The limiting process in equation (36.02.01) must be interpreted in the sense of taking macroscopic volumes, containing a large enough number of microscopic systems, as discussed in § 34.02-Electric|Magnetic Properties of Matter.
The Magnetization M turns out to be the magnetic dipole moment per unit volume.
36.02.02.01 A Magnetized Medium: Some Simple Cases
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
Note that it is difficult to imagine the magnetic field produced by a large number (of the order of Avogadro number) of Magnetic Dipoles.
However it will be shown that the magnetic field is the one given by an equivalent current distribution.

\section*{A Long Circular Cylinder Uniformly Magnetized Along Its Axis}

From the elementary interpretation of Magnetization as aligned Magnetic Dipoles one easily finds the following results.
Zero volume current density at internal points.
Zero surface current density at the two bases.
Surface current density on the lateral surface: \(\mathbf{M} \times \mathbf{n}\).
Consider, in fact, a line of length \(L\) on the lateral surface of the cylinder, parallel to its axis and calculate current concatenated per unit length:
\[
\Delta I=I \eta_{\mathrm{N}} A L=\left(I A \eta_{\mathrm{N}}\right) L=M L \Longrightarrow\left|\mathbf{j}_{\mathrm{S}}\right|=M \equiv|\mathbf{M}| .
\]

Regardless the details of the Magnetic Dipole distribution the magnetic field produced is the same as the one produced by a surface current on the lateral surface.

A Large Thin Slab Uniformly Magnetized Perpendicular to Its Faces
A Cylinder Uniformly Magnetized Along Its Axis

\section*{A Sphere Uniformly Magnetized}

\section*{A Spherical Shell With Radial Magnetization}

Assume a uniform radial distribution of the all elementary identical magnetic Dipoles in a sphere:
\[
\left\{\begin{array}{l}
\mathbf{M}=m \eta_{\mathbf{N}} \hat{\mathbf{e}}_{r} \equiv M_{r} \hat{\mathbf{e}}_{r} \\
\mathbf{M}=0 \quad R_{1}<r<R_{2} \\
\text { otherwise }
\end{array}\right.
\]

One finds \(\mathbf{j}^{\mathrm{M}}=0\) and \(\mathbf{j}_{\mathrm{S}}^{\mathrm{M}}=0\), from equations (36.02.03), (36.02.04).

\section*{A Circular Cylindrical Solenoid}

Consider a long circular cylindrical solenoid kept at constant current. When the solenoid is filled with a material the elementary Magnetic Dipoles may either align or anti-align with the magnetic field.
In the first case the Magnetization currents on the lateral face of the cylinder conspire with the free currents of the coil to increase the magnetic field inside the solenoid and thus the concatenated flux, that is the inductance. In the second case the reverse happens.
Magnetic Dipoles align with the magnetic field and the magnetic field is increased. This is opposite with respect to the electric case due to the basic difference between Electric|Magnetic Dipoles (read § 38.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology).

\subsection*{36.02.03.01 A Non-Magnetized Medium}

Consider a non Magnetized insulating medium. The magnetic field effects due the currents at the atomic and|or molecular level as well as the microscopic magnetic fields due to intrinsic Dipole moments of the particles cancel each other:
- either because, for non magnetic molecules, (that is molecules without a net Magnetic Dipole moment), the magnetic Dipole moment of the currents at the atomic and|or molecular level as well as the microscopic Magnetic Dipole moments of the particles sum to zero (and any other higher-order Magnetic Dipole moment vanishes);
- or because, for magnetic molecules, the random orientation of the Dipoles produces a net zero Dipole moment (which is contrasted by thermal motion, featuring kinetic energies of the order of \(\approx k T\) ).

\subsection*{36.02.03.02 A Magnetized Medium With No Free Currents (A Simple Heuristic Model)}

\section*{This § is referenced at pages:}
[Never referenced.]
A simple heuristic model is developed in this section. A better and more general, but still heuristic model, is developed in § 36.02.03.03 - Magnetic Properties of Matter An exact, but purely formal, derivation is carried on in § 36.03-Magnetic Properties of Matter.
From the simple examples one might guess that, in general, the Magnetization surface current density is:
\[
\mathbf{j}_{\mathrm{s}}=\mathbf{M} \times \mathbf{n}
\]

Consider the piece of matter divided into small parallelepiped blocks, with sides parallel to the axes, \(\Delta x\), \(\Delta y\) and \(\Delta z\) long.

See D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., .....

\subsection*{36.02.03.03 A Magnetized Medium With No Free Currents (A Simple Heuristic Model) a More General Case}

This § is referenced at pages:
[1855, 1855]
Consider any fixed open surface \(\Sigma\), inside a Magnetized medium, and a small (infinitesimal) part of its boundary, the closed line \(\partial \Sigma\); the infinitesimal part of the closed line is defined by the vector \(\mathrm{d} \mathbf{L}\).

Assume that there are no free currents in the medium and the medium is not Magnetized in absence of the external (applied) field. In case there are free currents the superposition principle may be applied.

Assume a very simplified model where Magnetization is built from a number of all identical real Magnetic Dipoles of value \(m=I \mathbf{A}\), all with the same currents, \(I\), and where \(\mathbf{A}\) is the vector describing the area of the current loop; both of them, a priori, may depend on the position.

The Magnetization may be due to any effect (deformation and|or orientation); for simplicity, the demonstration only considers deformation.

The Magnetic Dipole moments, a priori, might depend on the location: \(m=m[\mathbf{x}]\).

Assume that the distribution of microscopic currents is steady, in such a way that it is divergence-less:
\[
\operatorname{div} \mathbf{j}^{\mathrm{M}}=0
\]

This means that the current concatenated to a surface only depends on the boundary of the surface.
The current concatenated with the surface \(\Sigma\) can be calculated from the elementary current loops which are crossed by the closed line \(\partial \Sigma\), as any other current loop will give a zero net contribution. Any elementary circular current loop, of radius \(R\), concatenates with the line if and only if its center is at a distance less than \(R \cos \theta\) from the line.
If \(\theta\) is the angle between the Magnetization vector, \(\mathbf{M}\), and the infinitesimal line element, \(\mathrm{d} \mathbf{L}\), it is, (by implicitly considering space-averaged values):
\[
\mathbf{M} \| \mathrm{m} \quad \delta I_{\mathrm{M}}[\mathbf{x}]=I \eta_{\mathrm{N}}[\mathbf{x}] A \mathrm{~d} L \cos \theta=\mathbf{M}[\mathbf{x}] \cdot \mathrm{d} \mathbf{L}
\]

Note: the above is meaningful for a closed curve only. In general: the total current crossing the surface as a consequence of Magnetization is thus given by the contribution of all Dipoles which are cut by the boundary of the surface. Rule: look for real magnetic Dipoles concatenated by the closed curve.
The current concatenated with the surface \(\Sigma\) is thus given by the line-integral over its boundary of the Magnetization:
\[
\begin{equation*}
I_{\mathrm{M}}=\oint_{\partial \Sigma} \mathbf{M} \cdot \mathrm{d} \mathbf{L} \tag{36.02.02}
\end{equation*}
\]
where the orientation of the surface is connected to the orientation of the line by the right-hand rule in such a way that a positive \(\mathbf{M} \cdot \mathrm{d} \mathbf{L}\) gives rise to a positive current.

As equation (36.02.02) is valid for any arbitrary surface inside the medium we always have that the current crossing any open surface is given by the circulation of the Magnetization vector \(\mathbf{M}\) along the boundary of the surface. One can replace the line-integral using the rotor theorem:
\[
I_{\mathrm{M}}=\oint_{\partial \Sigma} \mathbf{M} \cdot \mathrm{d} \mathbf{L}=\iint_{\Sigma} \operatorname{rot} \mathbf{M} \cdot \mathrm{d} \mathbf{S} \equiv \iint_{\Sigma} \mathrm{j}^{\mathrm{M}} \cdot \mathrm{~d} \mathbf{S}
\]
showing that the current can be expressed as the flux across the surface of the rotor of the Magnetization.
As the surface \(\Sigma\) is arbitrary the above result implies that the rotor of the Magnetization is equal to the volume current density:
\[
\mathrm{j}^{\mathrm{M}} \equiv+\operatorname{rot} \mathrm{M}[\mathrm{x}]
\]

Equation (36.02.03.03) can be used to derive the surface Magnetization current. Apply it to an open curve, \(\Gamma\), at the surface of the material. Let the normal vector to the surface be \(\hat{\mathbf{n}}\). Define the unit vector \(\hat{\mathbf{N}}\) on the surface and orthogonal to \(d \mathbf{L}\) such that
\[
\hat{\mathbf{N}} \equiv \frac{\mathrm{d} \mathbf{L} \times \hat{\mathbf{n}}}{\mathrm{d} \mathbf{L}} \quad \Leftrightarrow \quad \mathrm{~d} \mathbf{L}(\mathbf{n} \times \mathbf{N})=\mathrm{d} \mathbf{L}
\]

One can then write, with \(\Gamma\) being in general any open line on the surface:
\[
I_{\mathrm{M}}=\int_{C} \mathbf{M} \cdot \mathrm{~d} \mathbf{L}=\int_{C} \mathbf{M} \cdot(\mathbf{n} \times \mathbf{N}) \mathrm{d} \mathbf{L}=\int_{C} \mathbf{N} \cdot(\mathbf{M} \times \mathbf{n}) \mathrm{d} \mathbf{L}=\int_{C} \mathbf{j}_{\mathrm{S}}^{\mathrm{M}} \cdot \hat{\mathbf{N}} \mathrm{~d} \mathbf{L}
\]

As the curve \(\Gamma\) is arbitrary on the surface the above result implies that the surface current density is thus:
\[
\mathbf{j}_{\mathrm{S}}^{\mathrm{M}} \equiv-\hat{\mathbf{n}} \times \mathbf{M}[\mathbf{x}]
\]

It can be shown by direct inspection that the signs are correct.
All in all it was found, for a very special model of Magnetization and setup that Magnetization current density is expressed by the relations:
\[
\begin{equation*}
\mathrm{j}^{\mathrm{M}} \equiv+\operatorname{rot} \mathrm{M}[\mathrm{x}] \tag{36.02.03}
\end{equation*}
\]

Equations (36.02.03), (36.02.04), derived in a static situation and in absence of free currents, are assumed
\(\rightarrow\)
18541856
\(\xrightarrow{1857} 1858\) to be valid in all cases.

Another derivation, a formal one, under the same hypotesis is summarized in section § 36.03.01Magnetic Properties of Matter.
It can be shown, in a more formal way, that the above results are indeed valid under any circumstance, with a mathematical derivation giving less room to physical intuition.
Note that, in the derviation above, the Magnetization can in fact change along the curve, without spoiling the validity of the derivation. However when using thre rotor theorem to derive equation (36.02.03) one must think of choosing a smaller and smaller (infinitesimal) curve in order to pick-up a point property inside the medium.

\subsection*{36.02.03.04 Equivalence of Magnetized Material to Amperian Current Densities}

This § is referenced at pages:
[Never referenced.]
In general, a piece of material with a given Magnetization produces the same magnetic fields as the volume current density (36.02.03) plus the surface current density (36.02.04). In case a Polarization current exists, it must be included as well to calculate the total magnetic field.
See Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ...., for the equivalence of the equivalent field with the average field in matter.

©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||

Note that when dealing with systems with pre-assigned Magnetization (ferro-magnetic materials, for instance), as opposed to the case of linear systems, for which the Magnetization is related to the magnetic field, there is no a priori relation between magnetic field and Magnetization. In particular, as opposed to isotropic materials, magnetic field and Magnetization need not to be parallel.

\subsection*{36.03.01 Fields Produced by Magnetized Matter: A Formal Treatment}

This § is referenced at pages:
[1856, 1856]
The expressions for the volume and surface Magnetization current densities, equations (36.02.03), (36.02.04), can be also deduced, in a purely formal way, from the MagnetoStatic field of a distribution of Magnetic Dipoles as follows.

The magnetic field produced by a given (pre-assigned) Magnetization \(\mathbf{M}[\mathbf{x}]\) can be calculated from the definition itself of the Magnetization as a volume density of Magnetic Dipoles.

The MagnetoStatic potential, using equations (14.14.06), (14.14.01), (14.07.04), is given by:
\[
\begin{gather*}
\mathbf{A [ \mathbf { x } ] = \frac { \mu _ { 0 } } { 4 \pi } \int \int \int _ { \tau } \frac { \mathbf { M } [ \mathbf { y } ] \times ( \mathbf { x } - \mathbf { y } ) } { | \mathbf { x } - \mathbf { y } | ^ { 3 } } \mathrm { d } \mathbf { y }}=  \tag{36.03.01}\\
\frac{\mu_{0}}{4 \pi} \iiint_{\tau} \mathbf{M}[\mathbf{y}] \times \operatorname{grad}_{\mathbf{y}}\left(\frac{1}{|\mathbf{x}-\mathbf{y}|}\right) \mathrm{d} \mathbf{y}=\frac{\mu_{0}}{4 \pi} \iiint_{\tau} \operatorname{rot}\left(\frac{-\mathbf{M}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\right) \mathrm{d} \mathbf{y}+\frac{\mu_{0}}{4 \pi} \iiint_{\tau}\left(\frac{1}{|\mathbf{x}-\mathbf{y}|}\right) \operatorname{rot} \mathbf{M}[\mathbf{y}] \mathrm{d} \mathbf{y}= \\
\frac{\mu_{0}}{4 \pi} \oiint_{\partial \tau} \frac{-\hat{\mathbf{n}} \times \mathbf{M}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} S[\mathbf{y}]+\frac{\mu_{0}}{4 \pi} \iiint_{\tau}\left(\frac{\operatorname{rot} \mathbf{M}[\mathbf{y}]}{|\mathbf{x}-\mathbf{y}|}\right) \mathrm{d} \mathbf{y} \tag{36.03.02}
\end{gather*}
\]
where the integral is extended to the region of space, \(\tau\), where the magnet is present, that is where the Magnetization is non zero.

Equation (36.03.01) shows that the magnetic field produced by any Magnetization can be expressed in terms of an equivalent volume current density, \(\mathbf{j}^{\mathrm{M}}\), and an equivalent surface current density, \(\mathbf{j}_{\mathrm{S}}^{\mathrm{M}}\), such that:
\[
\begin{equation*}
\mathbf{j}^{\mathrm{M}} \equiv+\operatorname{rot} \mathbf{M}[\mathbf{y}] \quad \mathrm{j}_{\mathrm{S}}^{\mathrm{M}} \equiv-\hat{\mathbf{n}} \times \mathbf{M}[\mathbf{y}] \tag{36.03.03}
\end{equation*}
\]

Read also § 35.03 - Electric Properties of Matter.

\section*{CHAPTER IV}

\section*{STATIC MAGNETIC FIELD}

\section*{§29. Static magnetic field}

A sTATIC magnetic field in matter satisfies two of Maxwell's equations, obtained by averaging the microscopic equations
\[
\begin{equation*}
\operatorname{div} \mathbf{h}=0, \quad \operatorname{curl} \mathbf{h}=\frac{1}{c} \frac{\partial \mathbf{e}}{\partial t}+\frac{4 \pi}{c} \rho \mathbf{v} . \tag{29.1}
\end{equation*}
\]

The mean magnetic field is usually called the magnetic induction and denoted by \(\mathbf{B}\) :
\[
\begin{equation*}
\overline{\mathrm{h}}=\mathbf{B} . \tag{29.2}
\end{equation*}
\]

Hence the result of averaging the first equation (29.1) is
\[
\begin{equation*}
\operatorname{div} \mathbf{B}=0 . \tag{29.3}
\end{equation*}
\]

In the second equation, the time derivative gives zero on averaging, since the mean field is supposed constant, and so we have
\[
\begin{equation*}
\text { curl } \mathbf{B}=(4 \pi / c) \overline{\rho \mathbf{v}} . \tag{29.4}
\end{equation*}
\]

The mean value of the microscopic current density is in general not zero in either conductors or dielectrics. The only difference between these two classes is that in dielectrics we always have
\[
\begin{equation*}
\int \bar{\rho} \overline{\mathbf{v}} \cdot \mathrm{df}=0, \tag{29.5}
\end{equation*}
\]
where the integral is taken over the area of any cross-section of the body; in conductors, this integral need not be zero. Let us suppose to begin with that there is no net current in the body if it is a conductor, i.e. that (29.5) holds.
The vanishing of the integral in (29.5) for every cross-section of the body means that the vector \(\overline{\rho \mathbf{v}}\) can be written as the curl of another vector, usually denoted by \(c \mathbf{M}\) :
\[
\begin{equation*}
\overline{\rho \mathbf{v}}=c \operatorname{curl} \mathbf{M}, \tag{29.6}
\end{equation*}
\]
where \(\mathbf{M}\) is zero outside the body; compare the similar discussion in \(\S 6\). For, integrating over a surface bounded by a curve which encloses the body and nowhere enters it, we have \(\int \overline{\rho \mathbf{v}} \cdot \mathrm{df}=c \int \operatorname{curl} \mathbf{M} \cdot \mathrm{df}=c \oint \mathbf{M} \cdot \mathrm{~d} \mathbf{1}=0\). The vector \(\mathbf{M}\) is called the magnetization of the body. Substituting it in (29.4), we find
\[
\begin{equation*}
\operatorname{curl} \mathbf{H}=0, \tag{29.7}
\end{equation*}
\]

Where the vector \(\mathbf{H}\) and the magnetic induction \(\mathbf{B}\) are related by
\[
\begin{equation*}
\mathbf{B}=\mathbf{H}+4 \pi \mathbf{M} \tag{29.8}
\end{equation*}
\]
which is analogous to the relation between the electric field \(\mathbf{E}\) and induction \(\mathbf{D}\). Although \(\mathbf{H}\) is, by analogy with \(\mathbf{E}\), usually called the magnetic field, it must be remembered that the true mean field is really \(\mathbf{B}\) and not \(\mathbf{H}\).

To see the physical significance of the quantity \(\mathbf{M}\), let us consider the total magnetic moment due to all the charged particles moving in the body. By the definition of the magnetic moment (see Fields, §44), this is \(\dagger\)
\[
\int \mathrm{r} \times \overline{\rho \mathbf{v}} \mathrm{d} V / 2 c=\frac{1}{2} \int \mathrm{r} \times \text { curl } \mathbf{M} \mathrm{d} V .
\]

Since \(\rho \mathbf{v} \equiv 0\) outside the body, the integral can be taken over any volume which includes the body. We transform the integral as follows:
\[
\int \mathrm{r} \times \text { curl } \mathbf{M d} V=-\oint \mathbf{r} \times(\mathbf{M} \times \mathrm{df})-\int(\mathbf{M} \times \operatorname{grad}) \times \mathbf{r} \mathrm{d} V .
\]

The integral over the surface outside the body is zero. In the second term we have \((\mathbf{M} \times \operatorname{grad}) \times \mathbf{r}=-\mathbf{M} \operatorname{div} \mathbf{r}+\mathbf{M}=-2 \mathbf{M}\). Thus we obtain
\[
\begin{equation*}
\frac{1}{2 c} \int \mathrm{r} \times \overline{\rho \mathbf{v}} \mathrm{d} V=\int \mathbf{M} \mathrm{d} V \tag{29.9}
\end{equation*}
\]

We see that the magnetization vector is the magnetic moment per unit volume. \(\ddagger\)
The equations (29.3) and (29.7) must be supplemented by a relation between \(\mathbf{H}\) and \(\mathbf{B}\) in order to complete the system of equations. For example, in non-ferromagnetic bodies in fairly weak magnetic fields, B and \(\mathbf{H}\) are linearly related. In isotropic bodies, this linear relation becomes a simple proportionality:
\[
\begin{equation*}
\mathbf{B}=\mu \mathbf{H} \tag{29.10}
\end{equation*}
\]

The coefficient \(\mu\) is called the magnetic permeability. We also have \(\mathbf{M}=\chi \mathbf{H}\), where the coefficient
\[
\begin{equation*}
\chi=(\mu-1) / 4 \pi \tag{29.11}
\end{equation*}
\]
is called the magnetic susceptibility.
Unlike the permittivity \(\varepsilon\), which always exceeds unity, the magnetic permeability may be either greater or less than unity. (It is, however, always positive, as we shall prove in \(\S 31\). The reason for the differing behaviour of \(\mu\) and \(\varepsilon\) is discussed in §32.) The magnetic susceptibility \(\chi\) may correspondingly be either positive or negative.
Another, quantitative, difference is that the magnetic susceptibility of the great majority of bodies is very small in comparison with the dielectric susceptibility. This difference arises because the magnetization of a (non-ferromagnetic) body is a relativistic effect, of order \(v^{2} / c^{2}\), where \(v\) is the velocity of the electrons in the atoms.§
In anisotropic bodies (crystals), the simple proportionality (29.10) is replaced by the linear relations
\[
\begin{equation*}
B_{i}=\mu_{i k} H_{k} . \tag{29.12}
\end{equation*}
\]

\footnotetext{
\(\dagger\) For clarity, it should be emphasized that \(\mathbf{r}\) here is a variable coordinate of integration, not the position vector of a microscopic particle; it therefore does not come under the averaging sign.
\(\ddagger\) The quantity \(M\) is completely determined only when this relation is established. The relation (29.6) inside the body, and \(\mathbf{M}=0\) outside it, do not uniquely define \(\mathbf{M}\) : the gradient of any scalar could be added to \(\mathbf{M}\) inside the body without affecting (29.6) (cf. the similar remark in the first footnote to §6).
§ The ratio \(v / c\) appears with \(H\) in the Hamiltonian of the interaction of the body with the magnetic field, and again in the magnetic moments of the atoms or molecules.
}

\subsection*{36.03.01.01 An Important Warning}

It should be stressed that, rigorously, the previous derivation only applies to the case of ideal Dipoles, so that the point where the field is calculated can be considered far enough that the field of a ideal (point) Dipole can be used. The problem of the previous derivation is the fact that the starting point of (36.03.01) is only valid for distant points, not certainly inside the Dipole distribution itself.

The analysis showing that the above results is, nevertheless, exact can be found in the literature \({ }^{1}\).

\section*{© - QUOTE}

All in all it is the result the same as integrating for ideal Dipoles. All revolves around the fact that the average field over any sphere due to the current inside is the same as the field at the center of a uniformly Magnetized sphere with the same total Dipole moment. That is no matter how the actual microscopic current configuration is, one can always replace it by a smooth distribution of perfect Dipoles, if one wants the macroscopic (average) field.
36.03.02 Fields Produced by Magnetized Matter: A Physical Approach

The result of equation (36.03.02) is what one obtains straightforwardly considering that a Magnetized material has a volume and surface Magnetization current density, given by equations (36.03.03), which must be considered as normal currents. The result of equation (36.03.02) is then the expression of the potential from the given current densities.

\footnotetext{

[1788, 1788, 1820, 1820]
Read § 34.02 - Electric|Magnetic Properties of Matter, § 35.04 - Electric Properties of Matter.
The magnetic field inside matter is rapidly changing in time as well as on distances of the order of the inter-atomic distances.

The macroscopic magnetic field is defined as the spatial average of the microscopic magnetic field, as long as the average is taken on a volume which is small on a macroscopic scale and large on the microscopic scale:
\(\langle\mathbf{B}\rangle[\mathbf{x}] \equiv \lim _{\tau \longrightarrow 0} \frac{1}{\tau} \iiint_{\tau} \mathbf{B}[\mathbf{x}+\mathbf{y}] \mathrm{d} \mathbf{y} \quad \tau:=|\mathbf{y}| \leq R, R\) macroscopically small and microscopically large
(36.04.01)
where the limiting process must be intended in the above-mentioned macroscopic sense.
The macroscopic magnetic field can be calculated from the Magnetization.

\subsection*{36.05.01 Maxwell Equations in Matter: Magnetic Fields}

Let us rewrite Maxwell Equations in terms of Polarization and Magnetization as well as Electric|Magnetic fields \({ }^{2}\).
The total current density is given by the sum of the density of free currents, \(\mathbf{j}^{\mathrm{F}}\), plus the Polarization currents, \(\mathbf{j}^{\mathrm{P}}\), plus the bound, Magnetization currents, \(\mathbf{j}^{\mathrm{M}}\) :
\[
\mathbf{j}=\mathbf{j}^{\mathrm{F}}+\mathbf{j}^{\mathrm{P}}+\mathbf{j}^{\mathrm{M}}
\]

In case of macroscopic moving matter, also conventions currents should be added (for fluids), read § 19.01.03.03 - Some Miscellaneous Topics.

It follows, for the rotor equation:
\[
\begin{equation*}
\operatorname{rot} \mathbf{B}=\mu_{0}\left(\mathbf{j}^{\mathrm{F}}+\mathbf{j}^{\mathrm{P}}+\mathrm{j}^{\mathrm{M}}\right)+\varepsilon_{0} \mu_{0} \partial_{t} \mathbf{E} \tag{36.05.01}
\end{equation*}
\]
\(\boldsymbol{\operatorname { r o t }} \mathbf{H} \equiv \mathbf{j}^{\mathrm{F}}+\partial_{t} \mathbf{D}\)
\[
\begin{equation*}
\mathbf{H} \equiv \mathbf{B} / \mu_{0}-\mathbf{M} \tag{36.05.02}
\end{equation*}
\]

It follows, for the divergence equation:
\[
\begin{gather*}
\operatorname{div} \mathrm{B}=0  \tag{36.05.03}\\
\operatorname{div} \mathrm{H}=-\operatorname{div} \mathrm{M}
\end{gather*}
\]

Only the non-homogeneous equations change.
Note that, in general, the producers of vector \(\mathbf{H}\) are not only the free currents, as it follows from equation (36.05.02), but also the Magnetization, as it follows from equation (36.05.01). In fact according to Helmholtz theorem (section § 14.07.05 - Elements of Vector Calculus) a vector field can be uniquely reconstructed from the knowledge of both its divergence and its rotor.

In fact the analogous of Biot-Savart law for \(\mathbf{H}\) and free currents does not exist!
Note however that in special configurations endowed with some symmetry it might be possible to determine the \(\mathbf{H}\) vector by using only one of the equations (36.05.02), (36.05.01). In particular the vector \(\mathbf{H}\) is not solenoidal, even if \(\mathbf{B}\) is. The utility of the \(\mathbf{H}\) vector lies in the fact that, usually, the free currents are known while the Polarization and Magnetization currents are not.

\footnotetext{
\({ }^{2}\) Please note that most physicists call \(\mathbf{H}\) the magnetic field and \(\mathbf{B}\) the magnetic induction field. This nomenclature is an heritage of the old times when it was thought that \(\mathbf{H}\) was the basic magnetic field. Nowadays we know that \(\mathbf{B}\) is the basic magnetic field while \(\mathbf{H}\) is just an auxiliary field defined as a suitable combination of the field \(\mathbf{B}\) and the Magnetization field, \(\mathbf{M}\). In order to emphasize this facts we will use the nomenclature the magnetic field for \(\mathbf{B}\) and we will avoid a specific name for \(\mathbf{H}\) which will be just called the auxiliary magnetic field \(\mathbf{H}\). Read also § 35.05 - Electric Properties of Matter.
}
36.05.02 Discontinuity of the Magnetic Fields

This § is referenced at pages:
[1707, 1707]
The discontinuity equations derived in \(\S 33.08\) - Basic Laws of ElectroMagnetism translate, in presence of matter, into:
\[
\begin{array}{|c|}
\hline \hat{\mathbf{n}} \cdot \Delta \mathbf{B}_{\perp}=0 \\
\hat{\mathbf{n}} \times \Delta \mathbf{H}_{\|}=\mathrm{j}_{\mathrm{S}}^{\mathrm{F}}
\end{array}
\]

\subsection*{36.06.01 Homogeneity Isotropy and Time-(Non)Invariance in Magnetic Response}

Read § 19.02 - Some Miscellaneous Topics and § 19.03-Some Miscellaneous Topics.

\subsection*{36.06.02 Constitutive Relation - Rigid (Frozen-In) Magnetization}

In case the material is such that, for instance,
\[
\mathbf{M}[\mathbf{B}=0] \equiv \mathbf{M}_{\mathrm{R}} \equiv \quad \text { fixed } \quad \neq 0
\]
the material has a Magnetization even in absence of external (applied) field (a rigid|frozen-in Magnetization).
The case of so-called rigid|frozen-in Magnetization concerns materials having a fixed Magnetization, in particular a Magnetization independent of any external magnetic field or, better, a non zero Magnetization when the external (applied) field is zero.
Note, in particular, that the concept of susceptibility has no meaning when dealing with a rigid|frozen-in Magnetization.
rigid|frozen-in Magnetization implies anisotropy. However, the lack of isotropy, that is failure to obey rotational symmetry in space, is in this case just hidden (spontaneously broken symmetry), by the need to choose one specific direction in space, among infinite equivalent directions. Normally every substance, above its Curie temperature, loses its rigid|frozen-in Magnetization to become manifestly isotropic.

\subsection*{36.06.03 Equation of State (Constitutive Relation) of Linear Magnetic Response}

This § is referenced at pages:
[1853, 1853]
The introduction of the vector field \(\mathbf{H}\) (or \(\mathbf{M}\) ) amounts to introducing a new variable. It is thus necessary to introduce one more equation to solve the problem. The equation to add is not a law of Nature but it is a constitutive equation characterizing the properties of the piece of matter involved, that is an equation of state:
\[
\begin{equation*}
\mathbf{M}=\mathbf{M}[\mathbf{E}, \mathbf{B}] \quad \text { or } \quad \mathbf{H}=\mathbf{H}[\mathbf{E}, \mathbf{B}] \tag{36.06.01}
\end{equation*}
\]

A linear material is defined by a linear equation in terms of the symmetrical magnetic susceptibility tensor, \(\left.\left\{\chi_{\mathrm{E}}\right\}_{k j} \ddot{\mathrm{x}}\right]\) :
\[
M_{k}[\mathbf{x}]=\frac{1}{\mu_{0}}\left\{\boldsymbol{\chi}_{M}\right\}_{k j} B_{j}[\mathbf{x}] \Longrightarrow\left(\begin{array}{c}
M_{x} \\
M_{y} \\
M_{z}
\end{array}\right)=\frac{1}{\mu_{0}}\left(\begin{array}{cccc}
\left\{\chi_{M}\right\}_{x x} & \left\{\chi_{M}\right\}_{x y} & \left\{\chi_{M}\right\}_{x z} & , \\
\left\{\chi_{M}\right\}_{y x} & \left\{\chi_{M}\right\}_{y y} & \left\{\chi_{M}\right\}_{y z} & , \\
\left\{\chi_{M}\right\}_{z x} & \left\{\chi_{M}\right\}_{z y} & \left\{\chi_{M}\right\}_{z z}
\end{array}\right) \cdot\left(\begin{array}{c}
B_{x} \\
B_{z_{y}} \\
B_{z}
\end{array}\right) \quad \text { with }\left\{\chi_{M}\right\}=\left\{\chi_{M}\right\}[\mathbf{x}]
\]

A linear and homogeneous material is such that the susceptibility does not depend on the position:
\[
M_{k}[\mathbf{x}]=\frac{1}{\mu_{0}}\left\{\chi_{\mathrm{m}}\right\}_{k j} B_{j}[\mathbf{x}]
\]

An linear and isotropic material is such that the susceptibility does not depend on the direction, that is the magnetic susceptibility tensor is multiple of the identity:
\[
M_{k}[\mathbf{x}]=\frac{1}{\mu_{0}} \chi_{\mathrm{M}}[\mathbf{x}] \delta_{k j} B_{j}[\mathbf{x}]=\frac{1}{\mu_{0}} \chi_{\mathrm{M}}[\mathbf{x}] B_{k}[\mathbf{x}]
\]

In all the above cases one introduces the Magnetic-Permeability, linking \(\mathbf{H}\) and \(\mathbf{B}\) :
\[
\mathbf{B} \equiv \mu_{\mathrm{R}} \mu_{0} \mathbf{H} \quad \mu_{\mathrm{R}} \equiv 1+\chi_{\mathrm{M}}^{*} \equiv \frac{1}{1-\chi_{\mathrm{M}}}
\]

In the isotropic case one can show that the Magnetic-Permeability satisfies:
\[
\mu_{\mathrm{R}} \equiv 1+\chi_{\mathrm{M}}^{*} \equiv \frac{1}{1-\chi_{\mathrm{M}}} \geq 0 \quad \text { in static conditions }
\]

Note that linearity is not a property of the medium itself but a property of the medium and the applied external (applied) fields: for small enough fields the response is linear, that is the linear approximation of the development in series of Taylor is applied, while for large enough fields the response will certainly cease to be linear.

\subsection*{36.06.03.01 Refraction of Magnetic Field Lines in LHI Magnetic Media (No Free Currents)}

This § is referenced at pages:
[1823, 1823]
Read also § 35.06.03.01 - Electric Properties of Matter.
Consider two magnetic LHI media, such that:
\[
\mathbf{B}=\mu_{\mathrm{R}} \mu_{0} \mathbf{H}
\]

Consider a smooth surface, separating the two different media with different physical properties, a point P at the surface where the normal is \(\hat{\mathbf{n}}\), oriented from medium (1) towards medium (2), and define \(\Delta \mathbf{A} \equiv \mathbf{A}_{2}-\mathbf{A}_{1}\).
Assume there is no free surface current density at the surface in such a way that both the normal component of \(\mathbf{B}\) and the tangential component of \(\mathbf{H}\) are continuous.
Note, that in this case, the two tangential components and the normal vector to the surface are co-planar vectors, thanks to the absence of free surface currents density at the surface which implies the continuity of the tangential component of the \(\mathbf{H}\) field.
The incident|refraction angle, \(\alpha_{m}\), (read \(\S 13.06 .05\) - Elements of Vector Algebra), is defined as the arc-tangent of the ratio of the modules of the tangential, \(V_{t}\), and normal, \(V_{n}\), components of the vector field:
\[
\tan \alpha_{m}=\frac{\left|V_{t}\right|}{\left|V_{n}\right|} \quad 0 \leq \alpha_{m} \leq \pi / 2
\]

As the angle is always \(0 \leq \alpha_{m} \leq \pi / 2\) and the therefore the modules of the components must be used.
The following relations apply:
\[
\begin{gathered}
B_{n 2}=B_{n 1} \quad \frac{B_{t 2}}{\mu_{\mathrm{R} 2}}=\frac{B_{t 1}}{\mu_{\mathrm{R} 1}} \\
H_{t 2}=H_{t 1} \quad \mu_{\mathrm{R} 2} H_{n 2}=\mu_{\mathrm{R} 1} H_{n 1}
\end{gathered}
\]

If one defines the refraction angle, \(\alpha\), of the field lines, as the angle between the vector and the normal to the surface, one can write the above relations as:
\[
\frac{\tan \alpha_{1}}{\mu_{\mathrm{R} 1}}=\frac{\tan \alpha_{2}}{\mu_{\mathrm{R} 2}} \Longrightarrow \frac{\tan \alpha}{\mu_{\mathrm{R}}}=\text { constant }
\]
valid for both \(\mathbf{B}\) and \(\mathbf{H}\) field lines.
Remember that Field lines are, by definition, continuous: in fact, they are solutions of a differential equation.

\section*{A High Magnetic-Permeability Medium}

Suppose that \(\mu_{\mathrm{R} 2} \gg \mu_{\mathrm{R} 1}\) : it follows that \(\alpha_{2} \gg \alpha_{1}\) so that the field lines are, in medium 1, almost perpendicular to the surface.
In fact in case medium (2) has a very high Magnetic-Permeability, \(\mu_{\mathrm{R} 2} \gg \mu_{\mathrm{R} 1}\), the field lines inside the high-Magnetic-Permeability medium tend to run almost parallel to the surface, while outside the high-Magnetic-Permeability medium the field lines tend to exit the medium almost perpendicularly to the surface.
As an example: medium 2 is a LHI medium with very high Magnetic-Permeability.

\subsection*{36.06.03.02 Old Historical Definition of the Magnetic Suscpetibility}

For an isotropic material the following relations apply.
The correct definition of magnetic suscpetibility should be:
\[
\begin{equation*}
\chi_{\mathrm{M}} \equiv \mu_{0} \frac{M}{B} . \tag{36.06.02}
\end{equation*}
\]

However, hystorically, the following one has been adopted:
\[
\begin{equation*}
\chi_{\mathrm{M}}^{*} \equiv \frac{M}{H} \tag{36.06.03}
\end{equation*}
\]

The relation between the two susceptibilities is:
\[
\begin{equation*}
\chi_{\mathrm{M}}=\frac{\chi_{\mathrm{M}}^{*}}{1+\chi_{\mathrm{M}}^{*}} \quad \chi_{\mathrm{M}}^{*}=\frac{\chi_{\mathrm{M}}}{1-\chi_{\mathrm{M}}} \tag{36.06.04}
\end{equation*}
\]
\(\rightarrow\) 1926
The relation with the Magnetic-Permeability is:
\[
\begin{equation*}
\mu_{\mathrm{R}}=\frac{1}{1-\chi_{\mathrm{M}}}=1+\chi_{\mathrm{M}}^{*} . \tag{36.06.05}
\end{equation*}
\]

It is to be noted that, on practical grounds, the difference between \(\chi_{M}\) and \(\chi_{\mathrm{M}}^{*}\) is negligible. In fact for all linear media (diamagnetic and paramagnetic media) the magnetic susceptibility is so small that the two values of \(\chi_{M}\) and \(\chi_{M}^{*}\) are very close. In fact:
\[
\frac{\chi_{\mathrm{M}}}{\chi_{\mathrm{M}}^{*}}=\frac{1}{1+\chi_{\mathrm{M}}^{*}}=1-\chi_{\mathrm{M}}
\]

Note, in particular, that \(\chi_{M}^{*} \geq-1\) and \(\chi_{M} \leq+1\) always have the same sign (in their range of definition).
On the other hand for non-linear materials the definition of magnetic susceptibility itself must be generalized (read § 36.06.04-Magnetic Properties of Matter).

\subsection*{36.06.04 Non-Linear Materials}

This § is referenced at pages:
[1868, 1868]
In case the constitutive relation between the Magnetization and magnetic field is not linear the concept of magnetic susceptibility is generalized as a differential concept, because one is interested in the description of the Magnetization for small changes of the magnetic field near a prescribed value of the magnetic field.
Actually, in general, the relation is a non linear-one, except for very small external fields, and therefore one considers the expansion in Taylor series truncated to first-order.
Considering for simplicity isotropic materials, such that \(\mathbf{M} \| \mathbf{B}\), the definition of susceptibility is thus generalized to:
\(\chi_{\mathrm{M}} \equiv \mu_{0} \frac{\partial M}{\partial B} \quad\) or better, in case other parameters \(X\) may affect the magnetisazion: \(\left.\quad \chi_{\mathrm{M}} \equiv \mu_{0} \frac{\partial M}{\partial B}\right|_{X}\),
(36.06.06)
as a function of the components of the Magnetization and magnetic field along their common direction and keepting costant any other possibly relevant paramenter, \(X\) (such as temeprature).
Note that the linear response in normally limited to small fields, while for large enough fields the response shows non-linear terms; see, for a relevant and important example, § 38.04.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology. In other words linearity is not a property of the material alone but a property of the material in a certain field.
The general response, equation (36.06.01), can be developed in Taylor series such that linear materials are described by the linear term of the development.
The linearity/non-linearity is in fact a property of the material plus the intensity of the field, not a property of the material alone as the linearity of the response depends on the intensity of the field.
36.07

Forces and Torques on Matter in External (Applied) Magnetic Fields

\title{
Additional Topics in Magnetism
}

\subsection*{36.08.01 Einsten-deHaas Effect}
©|M.Bertin \& J.P.Faroux \& J.Renault, Milieux diélectriques et milieux aimantés, 1984, Dunod, ...Ed., WEB - URL|Pag. 148|Einstein-deHaas effe
Consider a cylindrical bar with circular section made of an LHI material with high MagneticPermeability (soft iron, for instance) suspended along its length, at the center of its basis, by means of wire with very small torsional constant.
Let us introduce a mechanical model which is capable to explicitly describe the contribution of the molecular angular momenta. The model is a rigid body with particles with spin uniformly distributed inside it.
In case the bar is rotating around its axis the angular momentum can be calculated, at the molecular level in a classical way, by means of the Koënig theorem, as the orbital angular momentum of the whole molecule plus the orbital angular momentum of the electrons orbiting around the nuclei, which we can consider the spin angular momentum of the molecule. The mass of the nuclei is assumed to be much larger than the mass of the electrons. The contributions of all the molecules must be summed.
If a magnetic field is switched on, parallel to the axis of the un-Magnetized cylinder, when the cylinder is standing still, the cylinder assumes a Magnetization parallel to the external (applied) field and therefore no torque is expected. Nevertheless the cylinder starts to rotate against the restoring torque by the wire.
As the initial angular momentum was zero, in fact, the alignment of the microscopic currents build an angular momentum which must be counter-balanced by the rotation of the cylinder. At the initial time, assuming an instantaneous switching on of the external magnetic field, when there is no effect from the torsion wire, the angular velocity is given by the total angular momentum balance:
\[
0=I \omega+M V / \gamma \quad \mathrm{m} \equiv \gamma \mathbf{j}=g \frac{e}{2 m} \mathbf{j}
\]
in terms of the moment of inertia, \(I\), of the bar with respect to it axis, its Magnetization M and its volume.
In practice, in the real experiment, the external magnetic field is quickly switched up and down so that the cylinder starts an oscillatory motion and one looks for the resonance.
The measurements give a gyromagnetic ratio whose order of magnitude is close to \(\gamma_{e}\) but in general it is often close to twice its value. Therefore, the experiment suggests that Magnetization must have additional contributions in addition to the orbital currents.
The inverse effect exists: the Barnett effect is the Magnetization of an uncharged body when spun around an axis.

\subsection*{36.08.02 Earth Magnetic Field}

This § is referenced at pages:
[1763, 1763]
The details of the formation of the magnetic fields of the Earth, planets and stars are not well understood. Anyway, at large enough distance, we know that any magnetic field can be approximated as a diple field, regardsless of the (uknown) details of the generating current distributions.
Therefore the Earth magnetic field is approximated by a Dipole field. The charts of the magnetic field at the Earth surface are shown in figure 36.1 (intensity), figure 36.2 (inclination) and figure 36.3 (declination), all from : WEB - URL.
Some planets have magnetic fields with a magnetic Quadrupole component of the same order of magnitude as the Dipole moment.

Figure 36.1: Earth Surface Magnetic Field Map (1)

Figure 36.2: Earth Surface Magnetic Field Map (2)
36.08.03 Magnetic Shielding
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|5.12|Calculation for a spherical shell|
There are many situations where a certain region of space must be shielded by external magnetic fields. This can be achieved by using a material with high magnetic susceptibility to surround the region. In fact a material with high magnetic susceptibility has the tendency to attract the magnetic field lines.
It can be shown that a spherical shell of material with high magnetic susceptibility when palced inside an external magnetic field has a residual internal magnetic field is inversely proportional to \(\chi_{\mathrm{M}}^{*}\).
The most effective magnetic shielding material is called mumetal. It is an alloy of Copper, Chromium, Nickel and Iron. The maximum magnetic susceptibility of mumetal is about \(\approx 10^{5}\) and, moreover, it has a low residual and coercitive field.

©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....| esercizio 4.38|SOLUZIONE rigorosa |
We want to find the relation between the microscopic magnetisability and the macroscopic susceptibility. In fact there is in general a difference between the average field in matter and the local field acting on a certain molecule, at least for dense media. The average field in fact also includes the effect of the field produced by the molecule itself and its neighboring molecules.
The desired relation is Clausius-Mossotti equation, giving the relation between the susceptibility and Polarizability|Magnetizability based on the relation between the local field (acting on the single molecule) and the average macroscopic fields. It applies to substances which are linear and isotropic on the macroscopic scale. Therefore, even if it is not totally general, it is very good to understand the relation between Polarizability|Magnetizability, the local field and the (macroscopic) fields.
Proceed as in §35.09 - Electric Properties of Matter. Consider a linear isotropic non-magnetic dense medium. The local field can be calculated via a spherical cavity, as it looks reasonable for a isotropic material. The medium outside the sphere is treated as a continuous medium; the medium inside the sphere is treated as a set of Magnetized molecules. Read § 36.10.04.02-Magnetic Properties of Matter and \(\S 36.10 .05\) - Magnetic Properties of Matter for the calculation of relevant quantities. Imagine a iper-simplified model such that the space allotted to each molecule is a sphere of radius \(R\).

It is a good choice for gases and liquids. Actually for gases there is no significant difference between the local fields and the average field. The case of linear magnetic response is always such that the susceptibility is very small with respect to one. Therefore the linear Magnetization effects are so small that there would be no real need, in practice, to carry on the developments of section § 35.09-Electric Properties of Matter.
One finds, as in § 35.09 - Electric Properties of Matter, the magnetic Clausius-Mossotti equation:
\[
\chi_{\mathrm{M}}=\frac{3 \eta_{m} \alpha_{\mathrm{m}}}{3+2 \eta_{m} \alpha_{\mathrm{m}}} \neq \chi_{\mathrm{M}}^{*} \quad \frac{\eta_{m} \alpha_{\mathrm{m}}}{3}=\frac{\chi_{\mathrm{M}}}{3-2 \chi_{\mathrm{M}}}=\frac{\mu_{\mathrm{R}}-1}{\mu_{\mathrm{R}}+2}
\]

The magnetisability \(\alpha_{\mathrm{m}}\) has dimensions of a volume: \(\left[\alpha_{\mathrm{m}}\right]=L^{3}\).
Note that the above relations are somewhat different from equation 36.10.02: there the magnetisability is linked to the magnetization of the sphere itself; here, the magnetisability is linked to the magnetization of the embedding material.
The corrective factor at denominator decreases the susceptibility, if \(\alpha_{\mathrm{m}}>0\) (paramagnetism) and increases the susceptibility, if \(\alpha_{\mathrm{m}}<0\). When \(\eta_{m} \alpha_{\mathrm{m}} \ll 1\) (for instance at very low density) one finds \(\chi_{\mathrm{M}} \simeq \eta_{m} \alpha_{\mathrm{m}}\).
In general, compare with \(\S 35.09\) - Electric Properties of Matter: \(\eta_{m} \neq \eta_{e}\).
If the molecules are magnetic molecules the above derivation is not correct.
The case of non-linear magnetic response requires a much more complex treatment.

\section*{Examples and Physical Applications}

\subsection*{36.10.01 Some Values of the Static Magnetic-Permeability}

\subsection*{36.10.02 Gyromagnetic Ratio and the Bohr-Magneton}

This § is referenced at pages:
[1798, 1798]
The Magnetic Dipole moment of a point charge orbiting around a point in a central force field, located at the origin of the Coordinate System and parameterized in terms of time, is given, by:
\[
\mathrm{m}=\frac{I}{2} \oint \mathbf{r} \times \mathrm{d} \mathbf{r}=\frac{I}{2} \int_{t=0}^{T} \mathbf{r}[t] \times \mathbf{v}[t] \mathrm{d} t=\frac{I}{2} \frac{\ell}{m} T=\frac{q}{2 m} \ell \equiv \gamma \ell
\]
in terms of the current \(I\), and the conserved orbital angular momentum; it is either parallel or anti-parallel to the angular momentum depending on the sign of the charge.
The value \(\gamma\), characteristic of each particle/system, is sometimes called the gyromagnetic ratio. It has the sign of the electric charge:
\[
\begin{equation*}
\mathrm{m} \equiv \gamma \ell \tag{36.10.01}
\end{equation*}
\]

Note that there is sometimes confusion in the literature as the name gyromagnetic ratio is sometimes \(g\).

Due to the additivity both of angular momenta and of Magnetic Dipole momenta, the relation can be generalized to a generic set of charges:
\[
\mathrm{m}=\sum_{k} \frac{q_{k}}{2 m_{k}} \boldsymbol{\ell}_{k} \equiv \sum_{k} \gamma_{k} \ell_{k}
\]
which can be further simplified in the case all the particles have the same gyromagnetic ratio, \(\gamma\) :
\[
\mathrm{m}=\gamma \mathbf{L}
\]

In the case of the electron the gyromagnetic ratio is:
\[
\gamma_{e} \equiv-\frac{e}{2 m_{e}} \equiv-\frac{\left|q_{e}\right|}{2 m_{e}}<0
\]

\subsection*{36.10.03 Effect of a Magnetic Field on Atomic Orbits}

\subsection*{36.10.04 Rigid (Frozen-In) Magnetization}

Note that for a uniform Magnetization one simply has:
\[
\mathrm{m} \equiv \iiint \mathbf{M} \mathrm{~d} \mathbf{y}=\mathbf{M} \Delta V \quad \text { for uniform } \mathbf{M}
\]

\subsection*{36.10.04.01 A Uniformly Magnetized Cylinder}

By taking into account the Magnetization currents it is clear that the magnetic field, B, produced by such a cylinder is exactly the same as the one produced by a circular solenoid with the same surface current density. As the Magnetization is known a priori the \(\mathbf{H}\) field can be calculated from its definition.
The magnetic field obviously resembles the field of a Dipole, at large distances, as always. Near the cylinder one can think of the field as produced by an array of real Magnetic Dipoles (plane circular current loops) aligned one after the other.

\subsection*{36.10.04.02 A Uniformly Magnetized Sphere}

This § is referenced at pages:
[1833, 1833, 1834, 1834, 1875, 1875]
Compare with § 35.10.07.02 - Electric Properties of Matter
The field inside a Magnetized sphere is uniform, while the external field is exactly a Dipole field.
The \(\mathbf{H}\) field has sources at the surface of the sphere, therefore the density of field lines changes crossing the surface.
The \(\mathbf{B}\) field has no sources at the surface of the sphere and its flux is conserved, so the density of flux lines is.

Figure 36.4: The B field has never sources, but it may have vortexes. The \(\mathbf{H}\) field has sources at the surface of the sphere, therefore the density of field lines changes crossing the surface.

\section*{Direct Calculation}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Example 5.11||
Use the results of § 33-029-Basic Laws of ElectroMagnetism and integrate the Magnetization surface current density \(\mathbf{M} \times \mathbf{n}\).

\section*{A Purely Formal Calculation}

Start from equation (36.03.01), with \(\mathbf{M}\) uniform,
\[
\mathbf{A}[\mathbf{x}]=\frac{\mu_{0}}{4 \pi} \iiint_{\tau} \frac{\mathbf{M}[\mathbf{y}] \times(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\frac{\mu_{0}}{4 \pi} \mathbf{M} \times \iiint_{\tau} \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\frac{\mu_{0}}{4 \pi} \mathbf{M} \times \mathbf{I}[\mathbf{x}] .
\]

Read § 38-014 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for the calculation of \(\mathbf{I}[\mathbf{x}]\).
It follows:
\[
\mathbf{A}[\mathbf{x}]=\frac{\mu_{0}}{4 \pi} \mathbf{M} \times \mathbf{I}[\mathbf{x}]=\left\{\begin{array}{lc}
\frac{\mu_{0}}{3} \mathbf{M} \times \mathbf{x} & \text { for }|\mathbf{x}| \leq R \\
\frac{\mu_{0}}{4 \pi} \frac{\mathbf{M} \times \mathbf{x}}{x^{3}} \tau & \text { for }|\mathbf{x}|>R
\end{array}\right.
\]
\[
\text { with } \tau=\frac{4}{3} \pi R^{3}
\]

The vector potential A is the same as a Magnetic Dipole, outside the sphere. It is the vector potential of a uniform field, inside the sphere. The field lines of \(\mathbf{A}\) inside the sphere are lines perpendicular to the direction of \(\mathbf{M}\), running in circumferences centered on the axis of the sphere (the diameter of the sphere parallel to \(\mathbf{M}\) ). Remember that the vector potential, in static conditions, is defined to within the gradient of an arbitrary function.

\section*{Analogy With the Electric Case}

Use the definition of magnetic charges, generated by the field \(\mathbf{H}\) and the formal analogy between \(\mathbf{E}\) and \(\mathbf{H}\). It follows that the equations for \(\mathbf{H}\) are formally the same equations as the ones for the electric field produced by a uniformly Polarized sphere, to within, possibly, the dimensional constants \(\epsilon_{\mathrm{R}}\) and \(\mu_{\mathrm{R}}\).
The external magnetic field is written from the analogy with the electric field of an electric Dipole taking again into account the correspondence described in § 38.03.05 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology and the fact that \(\mathrm{M}_{\mathrm{E}}=0\) :
\[
\mathbf{H}_{\mathrm{E}}=\frac{1}{4 \pi}\left(3 \frac{(\mathrm{~m} \cdot \mathbf{r})}{r^{5}} \mathbf{r}-\frac{\mathrm{m}}{r^{3}}\right) \quad \Longrightarrow \quad \mathbf{B}_{\mathrm{E}}=\frac{\mu_{0}}{4 \pi}\left(3 \frac{(\mathrm{~m} \cdot \mathbf{r})}{r^{5}} \mathbf{r}-\frac{\mathrm{m}}{r^{3}}\right)
\]

The expression of the magnetic field, deduced by analogy, is the same as the expression of the magnetic field produced by a Magnetic Dipole moment: \(\mathrm{m}=\Delta \tau \mathrm{M}\).
Use the correspondence described in § 38.03.05 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology to find the internal magnetic fields:
\[
\mathbf{H}_{\mathrm{I}}=-\frac{\mathbf{M}}{3} \quad \mathbf{B}_{\mathrm{I}} \equiv \mu_{0}\left(\mathbf{H}_{\mathrm{I}}+\mathbf{M}\right)=+\frac{2 \mu_{0}}{3} \mathbf{M}
\]

Note that the internal magnetic field is such that:
\[
\mathbf{B}_{\mathrm{I}} \cdot \mathbf{M} \geq 0
\]
and compare with the analogous electrical situation in § 35.10.07.02 - Electric Properties of Matter. The difference of the two cases is a reflection of the fundamentanl difference, at small distances, between the fields produced by a real Electric Dipole and a real Magnetic Dipole (read § 38.01 - ElectroMagnetism Miscellaneous Complements Applications and Phenomenology).

\subsection*{36.10.05 A Sphere of LHI Material in a Uniform and Constant External Magnetic Field}

This § is referenced at pages:
[1835, 1835, 1835, 1835, 1875, 1875, 1920, 1920]
©|J.P.Pérez et al., 5 Vol.
.Ed., WEB - URL.|22.V.4||
Compare with § 35.10.08 - Electric Properties of Matter.
It can be shown that, for any LHI sphere or ellipsoid, the induced Magnetization is uniform in an external uniform field.
For a sphere of LHI material with magnetic susceptibility \(\chi_{\mathrm{M}}^{*}\) in an external magnetic field \(\mathbf{B}_{0}\) the following relations apply.
Be careful to distinguish between the external applied field \(\mathbf{B}_{0}\) and the average field inside the sphere \(B\).
The internal field can be calculated as follows.
\[
\begin{gathered}
\mathbf{M} \equiv \chi_{M}^{*} \mathbf{H}, \\
\mathbf{H}=\mathbf{H}_{0}-\frac{\mathbf{M}}{3} \quad, \\
\mathbf{M}=\left(\frac{3 \chi_{M}^{*}}{3+\chi_{M}^{*}}\right) \frac{\mathbf{B}_{0}}{\mu_{0}}, \\
\mathbf{B}=\frac{3\left(1+\chi_{M}^{*}\right)}{3+\chi_{M}^{*}} \mathbf{B}_{0} \Longrightarrow|\mathbf{B}| \geq\left|\mathbf{B}_{0}\right| \quad \text { if } \chi_{M}^{*}>0 \quad, \quad|\mathbf{B}| \leq\left|\mathbf{B}_{0}\right| \quad \text { if } \chi_{M}^{*}<0 \quad \text { B } \cdot \mathbf{B}_{0} \geq 0 \quad, \\
\mathbf{H}=\frac{3}{3+\chi_{M}^{*}} \mathbf{H}_{0} \Longrightarrow|\mathbf{H}| \leq\left|\mathbf{H}_{0}\right| \quad \text { if } \chi_{M}^{*}>0 \quad, \quad|\mathbf{H}| \geq\left|\mathbf{H}_{0}\right| \quad \text { if } \chi_{M}^{*}<0 \quad \mathbf{H} \cdot \mathbf{H}_{0} \geq 0 \quad,
\end{gathered}
\]

Expressions in terms of the magnetic susceptibility follow.
\[
\begin{gathered}
\hline \mathbf{M} \equiv \chi_{\mathbf{M}} \mathbf{B} / \mu_{0} \\
\hline \mathbf{B}=\mathbf{B}_{0}+\frac{2}{3} \mu_{0} \mathbf{M} \\
\mathbf{M}=\frac{3 \chi_{\mathrm{M}}}{3-2 \chi_{\mathrm{M}}} \frac{\mathbf{B}_{0}}{\mu_{0}} \\
\hline \mathbf{B}=\frac{3}{3-2 \chi_{\mathrm{M}}} \mathbf{B}_{0} \leq \mathbf{B}_{0} \\
\hline \mathbf{H}=\frac{3-3 \chi_{\mathrm{M}}}{3-2 \chi_{\mathrm{M}}} \frac{\mathbf{B}_{0}}{\mu_{0}} \\
\hline
\end{gathered}
\]

The meaning of deMagnetizing field \(\mathbf{H}\) is clear when noting that the internal \(\mathbf{H}\) field is always smaller that the external (applied) field for \(\chi_{M}^{*}>0\) (but not for \(\chi_{M}^{*}<0\) ).
Note that in any case \(\mathbf{H}\) is parallel to \(\mathbf{H}_{0}\) and \(\mathbf{B}\) is parallel to \(\mathbf{B}_{0}\) (the coefficients are always positive). The case of a strictly non Magnetizable object (such as vacuum) is found for \(\chi_{M}^{*}=\chi_{M}=0\).
A paramagnetic medium attracts the field lines: in fact \(|\mathbf{B}| \geq\left|\mathbf{B}_{0}\right|\), if \(\chi_{M}^{*}>0\).
A diamagnetic medium expels the field lines: in fact \(|\mathbf{B}| \leq\left|\mathbf{B}_{0}\right|\), if \(\chi_{\mathbf{M}}^{*}<0\).
The case of a perfect paramagnet is found for \(\chi_{M}^{*}=+\infty\left(\chi_{M}=1\right): \mathbf{H}=0, \mathbf{B}=3 \mathbf{B}_{0}\).
The case of a perfect diamagnet is found for \(\chi_{M}^{*}=-1\left(\chi_{M}=-\infty\right): \mathbf{B}=0, \mathbf{H}=-\mathbf{M}=3 / 2 \mathbf{H}_{0}\).
The Magnetization is parallel to the external (applied) field for \(\chi_{\mathrm{M}}^{*}>0\).
The Magnetization is anti-parallel to the external (applied) field for \(\chi_{M}^{*}<0\).

The magnetisability of the sphere is:
\[
\begin{equation*}
\alpha_{\mathrm{m}}=\frac{3 \chi_{\mathrm{M}}^{*}}{3+\chi_{\mathrm{M}}^{*}} \Delta V=\frac{3\left(\mu_{\mathrm{R}}-1\right)}{2+\mu_{\mathrm{R}}} \Delta V \tag{36.10.02}
\end{equation*}
\]
and it is not strictly proportional to the magnetic susceptibility \(\chi_{\mathrm{M}}^{*}\).
Note that for most typical materials, whose magnetic susceptibility is very close to zero, the difference between the \(\mathbf{B}\) and \(\mathbf{H}\) fields is very small.
The formal analogy, \(\mathbf{H} \Leftrightarrow \mathbf{E}\), with the case of the sphere in an external electric field (section § 35.10.08 - Electric Properties of Matter) is obvious, the only basic difference being that the electrical susceptibility is non negative while the magnetic susceptibility \(\left(\chi_{\mathbb{M}}^{*}\right)\) is constrained to be greater or equal -1 .

Figure 36.5: A LHI sphere with \(\mu_{R}=100\) in an external uniform and constant field (B field lines)

\subsection*{36.10.06.02 Spherical Cavity}

Read § 38.03.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

\subsection*{36.10.07 Non-Circular Toroidal Coil}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Example 5.10||
A toroidal coil is made of a circular ring (donut) around which a long wire is tightly wrapped. The winding is uniform and tight enough so that each turn can be considered a closed loop and the current as a surface current. The cross-sectional shape of the coil is not important, the results do not change as long as the shape remains the same all around the ring, that is the toroidal coil is a solid of revolution. In that case it can be shown that the magnetic field of the toroidal coil is circumferential at all points, both inside and outside the toroidal coil.

\section*{SOLUTION}

The magnetic field is:
\(\mathbf{B}=\frac{\mu_{0} N I}{2 \pi r} \hat{\mathbf{e}}_{\theta} \quad\) inside the toroidal coil; the magnetic field is zero outside the toroidal coil

\section*{Exercises Problems and Physical Applications}

\section*{36-002 D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....}

All problems from D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ...., chapter 6 .

\section*{36-003 A Cubic Magnetizable Material With rigid|frozen-in Magnetization}

A cube of Magnetizable material of side \(d\), with one vertex at the origin and sides parallel to the Cartesian planes, carries a rigid|frozen-in Magnetization \(\mathbf{M}=k \mathbf{r}\) where \(k\) is a constant.
1. Determine the dimensions of \(k\).
2. Find all the Magnetization currents.
3. Write the expression of the magnetic field at large distances.

\section*{36-004 A Magnetic Material on the Axis of a Solenoid: Force|Torque}

Consider a small piece of LHI Magnetizable material on the axis of a circular solenoid. Where is the force on the piece maximum? What is the torque?

\section*{36-005 Magnetic Dipole Moment of Iron Atoms}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.12||
The Magnetic Dipole moment of an iron atom in a piece of iron is \(\mathrm{m}=2.22 \mu_{\mathrm{B}}\). Suppose that all the Dipoles are aligned in a bar \(L=4.86 \mathrm{~m}\) long and with a sectional area \(S=1.31 \mathrm{~cm}^{2}\).
1. Calculate the Magnetic Dipole moment of the bar.
2. What is the torque required to keep the bar perpendicular to a uniform external magnetic field \(B=1.53 \mathrm{~T}\) ?

\section*{36-006 A Solenoid With a Chrome Core}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.14 CHECK||
A solenoid has a number of windings per unit lengthh \(n=16 \mathrm{w} / \mathrm{cm}\) and a current \(I=1.3\) A.
1. A chrome bar is inserted, filling completely the interior of the solenoid: what is the magnetic field increase?
2. What is the Magnetization of the bar?

36-007 Saturation Magnetization of Nickel
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|37.22||
The saturation Magnetization of nickel is \(M=511 \mathrm{kA} / \mathrm{m}\). Calculate the Magnetic Dipole moment of a nickel atom, knowing that Nickel has \(Z=28, \mathcal{M}_{0}=58.7 \mathrm{~g} / \mathrm{mol}\) and \(\eta_{\mathrm{M}}=8.9 \mathrm{~g} / \mathrm{cm}^{3}\).

\section*{SOLUTION}
\[
m=\frac{M \mathcal{M}_{0}}{\rho \mathcal{N}_{\mathrm{A}}}=0.6 \mu_{\mathrm{B}}
\]

\section*{36-008 magnetic susceptibility and Magnetic-Permeability for Non-Linear Media}

Show that for non linear (but isotropic for simplicity) media, using the differential definitions of magnetic susceptibility and Magnetic-Permeability, it is still valid that:
\[
\mu_{\mathrm{R}}=\frac{\partial}{\partial H}\left(\frac{B}{\mu_{0}}\right)=1+\frac{\partial M}{\partial H}=1+\chi_{\mathrm{M}}^{*}
\]

What are the limits at saturation?

\section*{SOLUTION}
\[
\begin{gathered}
\quad \chi_{\mathrm{M}}^{*} \longrightarrow 0 \quad \mu_{\mathrm{R}} \longrightarrow 1 \\
\mathbf{B} \simeq \mu_{0} \mathbf{H} \quad \text { when }|H| \gg|M| \text { and } \mid \text { or }|B| / \mu_{0} \gg|M|
\end{gathered}
\]

\section*{36-009 Magnetization Curve of Iron}

The measured first Magnetization curve of some piece of ferro-magnetic iron ( \(\eta_{\mathrm{M}}=7.87 \mathrm{~kg} / \mathrm{dm}^{3}\) and \(\left.\mathcal{M}_{0}=55.8 \mathrm{~g} / \mathrm{mol}\right)\) is described by the function:
\[
M[H]=\alpha \arctan [\beta H]
\]
with \(\alpha=1.11 \cdot 10^{6} \mathrm{~A} / \mathrm{m}\) and \(\beta^{-1}=10 \mathrm{~A} / \mathrm{m}\).
Determine the saturation Magnetization.
Determine the magnetic susceptibility at \(H=H_{0}=0 \mathrm{~A} / \mathrm{m}\) and \(H=H_{1}=1500 \mathrm{~A} / \mathrm{m}\).
Calculate the number of Bohr-magnetons per iron atom contributing to the saturation Magnetization.

\section*{SOLUTION}
\[
\begin{gathered}
M_{\text {sat }} \lim _{H \rightarrow+\infty} M[H]=\frac{\pi \alpha}{2} \Longrightarrow M_{\text {sat }}=1.74 \cdot 10^{6} \mathrm{~A} / \mathrm{m} \\
\chi_{\mathrm{M}}^{*}=\frac{\alpha \beta}{1+\beta^{2} H^{2}} \quad \chi_{\mathrm{M}}^{*}\left[H=H_{0}\right]=1.11 \cdot 10^{5} \quad \chi_{\mathrm{M}}^{*}\left[H=H_{1}\right]=4.93
\end{gathered}
\]

Average number of contributing electrons per iron atom (g-factor):
\[
g=\frac{M_{\mathrm{sat}} \mathcal{M}_{0}}{\mu_{\mathrm{B}} N_{A} \eta_{\mathrm{M}}}=2.22
\]

\section*{36-010 Magnetic Field Inside a Solenoid}

A long and thin solenoid is filled with a ferro-magnetic material. Inside the material there are two small cavities, coaxial with the solenoid. Inside the first cavity, shaped as a large and thin disk, one measures a B field \(B_{1}=7.54 \cdot 10^{-2} \mathrm{~T}\). In the second cavity, shaped as a long and thin cylinder, one measures a B field \(B_{2}=1.26 \cdot 10^{-3} \mathrm{~T}\).

Calculate the susceptibility and Magnetization of the ferromagnetic material.

\section*{SOLUTION}
\[
\chi_{\mathrm{M}}^{*}=59 ; M=5.9 \cdot 10^{4} \mathrm{~A} / \mathrm{m}
\]

\section*{36-011 Force on a Magnetic Sample on the Axis of a Ideal Circular Finite Solenoid}

Use the results of § 33.18.58 - Basic Laws of ElectroMagnetism to determine the force acting on a small sample (volume \(\tau\) ) of a homogeneous, isotropic and linear magnetic material with susceptibility \(\chi_{M}^{*}\) located on the axis ( \(z\) axis) of a circular finite-length solenoid (of radius \(r\) ), as a function of the position.
Does the reasoning and results change if the material is ferromagnetic ?
Consider the sample located at the center of one of the basis of the solenoid and find the expression if the force in this case if \(\left|\mathbf{j}_{\mathrm{S}}\right|=10^{3} \mathrm{~A} / \mathrm{m}, r=5 \mathrm{~cm}\) and \(\tau=1.0 \mathrm{~cm}^{3}\).

\section*{SOLUTION}
\[
f[z]=\frac{\chi_{M}^{*}}{\mu_{0}\left(1+\chi_{\mathrm{M}}^{*}\right)} \tau B_{z}[z] \frac{\mathrm{d} B_{z}}{\mathrm{~d} z}[z] \simeq \frac{\chi_{\mathrm{M}}^{*}}{\mu_{0}} \tau B_{z}[z] \frac{\mathrm{d} B_{z}}{\mathrm{~d} z}[z] .
\]

\section*{36-012 An Ideal Circular Solenoid Filled With a Non Uniform Magnetic Material}

This § is referenced at pages:
[1888, 1888]
Determine the capacity of an ideal circular solenoid, with number of windings per unit length \(n\), radius \(R\) and length \(l\), filled with an isotropic and non uniform magnetic material with relative MagneticPermeability depending on the distance from the axis of the solenoid only. Let \(r\) be the radial distance form the axis of the solenoid. The relative Magnetic-Permeability is the function \(\mu_{\mathrm{R}}[r]\) for \(0 \leq r \leq R\).

Calculate the Magnetization current (both volume and surface currents).

\section*{SOLUTION}
\[
\begin{gathered}
H=\left|\mathrm{j}_{\mathrm{s}}^{\mathrm{F}}\right| \\
L \equiv \frac{|\Phi|}{|I|}=2 \pi \mu_{0} n^{2} l \int_{r=0}^{r=R} \mu_{\mathrm{R}}[r] r \mathrm{~d} r
\end{gathered}
\]

Order of magnitude: for \(n=10^{3} \mathrm{~m}^{-1}, R=3 \mathrm{~cm}\) and \(l=10 \mathrm{~cm}\) one has \(L=0.36 \mathrm{mH}\).
Alternative method of solution.

\section*{36-013 An Ideal Circular Solenoid Filled With Two Uniform Magnetic Materials}

Solve problem § 36-012 - Magnetic Properties of Matter with two magnetic materials with different Magnetic-Permeability whose interface is at constant distance from the axis.
Calculate the Magnetization currents.

\section*{36-014 A Current Wire With Non Zero Magnetic-Permeability}
©|Lim Yung-Kuo, Problems And Solutions On Electromagnetism, 1993, World Scientific, ...Ed., ....|2001||
A straight circular cylindrical wire has radius \(R\) and carries a current \(I\). If the material of the wire has Magnetic-Permeability \(\mu_{\mathrm{R}}\) find the expression of the magnetic field and the \(\mathbf{H}\) field inside and outside the wire. Assume that the Magnetic-Permeability outside the wire is 1 .

\section*{36-015 Lamina in External Magnetic Field}
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P22-7||
A thin lamina with palne parallel faces is made of LHI magnetic material with magnetic susceptibility \(\chi_{M}\) is immersed in a uniform externla magnetic field, \(\mathbf{B}=B_{x} \hat{\mathbf{e}}_{1}+B_{y} \hat{\mathbf{e}}_{2}\). The lamina lies in the \(y z\) plane. Calculate \(\mathbf{B}, \mathbf{M}\) and \(\mathbf{H}\), assumed to be uniform, internally to the lamina and the Magnetization currents.

In this section we will always deal with ElectroMagnetic relations in free space, which are the basic law of nature and always valid, and never ever the description in presence of matter, nor the \(\mathbf{D}\) and \(\mathbf{H}\) fields, will be used. In the rest of this section we will consider ElectroMagnetic fields interacting with charges and currents. We will use interchangeably the words particles and matter.

EM fields store and transport energy, linear momentum and angular momentum.
Note that, in order to simplify the formulas, the result:
\[
\varepsilon_{0} \mu_{0} c^{2}=1
\]
which turns out from the solution of Maxwell Equations for ElectroMagnetic waves, will be often used.

See the important comment in § 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order Multipoles.

\subsection*{37.01.02.01 Introduction}
- Capacitors and inductors demonstrate that ElectroMagnetic fields can store energy.
- Heating by ElectroMagnetic radiation (including light) shows that ElectroMagnetic radiation can transport energy.
- The ElectroMagnetic braking effect shows how kinetic energy can be converted into internal energy and transferred as heat via ElectroMagnetic fields (the magnetic field in this case).

\subsection*{37.01.02.02 Expression of the Energy of the ElectroMagnetic Fields}

We know, from the energy equations of mechanics, that energy changes are related to the total power applied by both internal and external interactions.
One needs to start from the expression of the work per unit time (that is power) done by ElectroMagnetic fields on matter, in order to derive the expression of the energy balance, that is the first principle of thermodynamics:
\[
\Pi \equiv \frac{\mathrm{d} \mathcal{W}_{\mathrm{EM} \longrightarrow \mathrm{MAT}}}{\mathrm{~d} t}
\]

The work per unit time (that is power) per unit volume done by the ElectroMagnetic fields on charges and currents (that is matter) is:
\[
\frac{\mathrm{d} \Pi}{\mathrm{~d} \Omega}=\rho \mathbf{v} \cdot(\mathbf{E}+\mathbf{v} \times \mathbf{B})=\mathbf{j} \cdot \mathbf{E}
\]

By using the 4th Maxwell Equation to replace \(\mathbf{j}\) and the identity:
\[
\operatorname{div}(E \times B)=B \cdot \operatorname{rot} E-E \cdot \operatorname{rot} B,
\]
one finds Poynting theorem which expresses the conservation of energy in local form at any point:
\[
\begin{equation*}
\frac{\mathrm{d} \Pi}{\mathrm{~d} \Omega}=\mathbf{j} \cdot \mathbf{E} \equiv k^{0}=-\partial_{t} u-\frac{\partial S_{k}}{\partial x_{k}}=-\partial_{t} u-\operatorname{div} \mathbf{S} \tag{37.01.01}
\end{equation*}
\]
\(\rightarrow\)
\[
1894
\]

ElectroMagnetic field energy density (energy per unit volume) is:
\[
\begin{equation*}
u[\mathbf{x}, t]=\frac{\varepsilon_{0} \mathbf{E}^{2}[\mathbf{x}, t]}{2}+\frac{\mathbf{B}^{2}[\mathbf{x}, t]}{2 \mu_{0}} . \tag{37.01.02}
\end{equation*}
\]

The expression for the energy density (37.01.02), which in elementary and static cases is shown to be the energy stored in ElectroMagnetic fields, is assumed to be a valid expression for the energy stored in ElectroMagnetic fields in all situations, following Poynting theorem.
In static conditions only, it can be shown that an alternative form for the ElectroMagnetic field energy density (energy per unit volume) can be written in terms of the potentials as:
\[
\begin{equation*}
U_{\mathrm{EM}}=\frac{1}{2} \iiint \rho[\mathbf{r}] \Phi[\mathbf{r}] \mathrm{d} V+\frac{1}{2} \iiint \mathbf{j}[\mathbf{r}] \cdot \mathbf{A}[\mathbf{r}] \mathrm{d} V \quad \text { in static conditions only - total ElectroMagnetic energy } \tag{37.01.03}
\end{equation*}
\]

In presence of matter the above relations apply only in case of a linear relation between the charge and scalar potential (for the first term) and the current and the vector potential (for the second term). The above relation, equation 37.01.03, is the total energy required to build the full configuration; note, in fact, the factor \(1 / 2\).

\subsection*{37.01.02.03 Poynting Vector and Its Non-Uniqueness}

The ElectroMagnetic field energy flux (energy crossing a unit area perpendicular to the direction of energy flow per unit time) is given by Poynting vector:
\[
\begin{equation*}
\mathbf{S}[\mathbf{x}, t]=\frac{\mathbf{E}[\mathbf{x}, t] \times \mathbf{B}[\mathbf{x}, t]}{\mu_{0}} \tag{array}
\end{equation*}
\]

The Poynting vector describes the energy flux: energy per unit time per unit area perpendicular to the direction of energy flow. This is evident from the form of equation (37.01.01), which is a balance equation, reducing to the equation for the conservation of ElectroMagnetic energy in case no work is exchanged with matter by ElectroMagnetic fields. In fact equation (37.01.01) has the form of a typical balance law, with a non zero Sources|Sinks term: - \(\mathbf{j} \cdot \mathbf{E}\).
The time-averaged value of the Poynting vector thus describes the time-averaged energy flux: average energy per unit time per unit area perpendicular to the direction of energy flow); this is called the intensity of ElectroMagnetic radiation.

Note that only the entire surface-integral of the Poynting vector, on a closed surface, has a clear physical meaning. In fact one has to be careful with the strict identification of the Poynting vector at a point with the local energy flux per unit time per unit area perpendicular to the direction of energy flow at that point. In fact the Poynting vector is defined to within a divergence-less field, by Poynting theorem. No troubles arise when one uses the theorem (37.01.01) in integral form, applied to an arbitrary volume, without attempting to localize the energy flux in space. On the other hand the differential form is correct at any point. In fact Poynting theorem defines, in a unambiguous way, only the divergence of \(\mathbf{S}\), that is the infinitesimal flux per unit volume, not \(\mathbf{S}\) itself.
One needs to postulate that the Poynting vector, equation (37.01.04) represent the local energy flux.

\subsection*{37.01.02.04 Local Conservation of Energy}

It must be emphasized that equation (37.01.01) implies that energy conservation is a local energy conservation, that is whenever there is a change of energy inside a certain volume the energy must be either given to (received from) matter or has to flow across the boundaries of the surface.
Equation (37.01.01) can be written \({ }^{1}\), in integral form and for the fixed integration domain \(\Omega\) (Poynting theorem for the energy), as:
\[
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \iiint_{\Omega} u \mathrm{~d} V+\iiint_{\Omega} \mathbf{j} \cdot \mathbf{E} \mathrm{d} V=-\oiint_{\partial \Omega} S_{k} \mathrm{~d} \mathbf{S}_{k}=-\oiiint_{\partial \Omega} \mathbf{S} \cdot \mathrm{d} \mathbf{S} \tag{37.01.05}
\end{equation*}
\]

\footnotetext{
\(\rightarrow\) 18941895
}
with
\[
U_{\mathrm{EM}}[t] \equiv \iiint_{\Omega} u[\mathbf{x}, t] \mathrm{d} V
\]

Equation (37.01.05) represents the energy balance for the system made of the ElectroMagnetic fields inside volume \(\Omega\). It shows that, in non-stationary situations, ElectroMagnetic energy can be stocked in ElectroMagnetic fields and not only transformed into other forms of energy via its transformation into mechanical energy. In fact the immediate effect of the ElectroMagnetic fields on matter is to transform ElectroMagnetic energy into kinetic energy of the particles. This energy can then be transformed into other forms of energy.
The balance is only the balance for EM fields inside volume \(\Omega\) : if other sources of energies or work are present as well as other parts, they should be taken into account in the balance of the overall system by writing the energy balance for any component.

\footnotetext{
\({ }^{1}\) One has to be obviously careful not to mix the symbols for the Poynting vector, \(\mathbf{S}\), and the one of the integration surface, \(\mathbf{S}\) in these relations
}

\subsection*{37.01.02.05 Some Particular Cases}
- steady conditions:
\[
\partial_{t} u=0 .
\]
- No work by/to ElectroMagnetic fields:
\[
\mathbf{j} \cdot \mathbf{E}=0 .
\]
- Localized fields: there exists a large enough sphere of radius \(R\) enclosing volume \(\Omega_{0}\) such that outside it any field is zero:
\[
\oiint_{\partial \Omega \mid \Omega_{0} \subset \Omega} \mathbf{S} \cdot \mathrm{~d} \mathbf{S}=0 .
\]

\subsection*{37.01.02.06 Matter and ElectroMagnetic Fields Only}

Note that:
\[
\iiint_{\Omega} \mathbf{j} \cdot \mathbf{E} \mathrm{d} V \equiv \frac{\mathrm{~d} \mathcal{W}_{\mathrm{EM} \longrightarrow \mathrm{MAT}}}{\mathrm{~d} t} \equiv \frac{\mathrm{~d} U_{\mathrm{MAT}}}{\mathrm{~d} t}
\]

Therefore the integrated form of equation (37.01.05) can be also written as:
\[
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t}\left(U_{\mathrm{EM}}+U_{\mathrm{MAT}}\right)=-\oiiint_{\partial \Omega} S_{k} \mathrm{~d} \mathbf{S}_{k}=-\oiiint_{\partial \Omega} \mathbf{S} \cdot \mathrm{d} \mathbf{S} \tag{37.01.06}
\end{equation*}
\]
showing that the energy (of the ElectroMagnetic fields plus matter) inside the volume can change because energy flows into or out of the volume across the surface.
If the fields are localized inside a finite spatial region the volume can be taken as large as it is required to contain all the fields. This implies the conservation of the total energy:
\[
\frac{\mathrm{d}}{\mathrm{~d} t}\left(U_{\mathrm{EM}}+U_{\mathrm{MAT}}\right)=0 \quad \text { (localized fields) }
\]

Note that in general, for radiation fields, the surface contribution cannot be neglected, even taking the surface at infinity, because for radiation fields the Electric|Magnetic fields decrease only as \(r^{-1}\) at infinity.

\subsection*{37.01.02.07 Ohmic Conductors}

Note that in the case of a Ohmic conductor the power per unit volume transferred by the fields to matter is the positive quantity (Joule effect):
\[
\frac{\mathrm{d} \Pi}{\mathrm{~d} \Omega}=\mathbf{j} \cdot \mathbf{E}=\frac{\mathbf{j}^{2}}{\sigma}
\]

This is the Joule effect. Read § 37.02.01 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum for the description of the energy transfers.

\subsection*{37.01.02.08 Energy Balance With External Generators (Batteries)}
©|S.Bobbio \& E.Gatti, Elettromagnetismo E Ottica, 1991, Bollati-Boringhieri, ...Ed., ....|9.10||
Consider the case when a battery, providing a linear EM-motive field \(\mathbf{E}^{\prime}\), of non ElectroMagnetic origin, different from zero only inside the battery, is feeding energy to matter inside the batteries to recover energy lost by matter in other parts of the circuit. One has:
\[
\mathbf{j}=\sigma\left(\mathbf{E}+\mathbf{E}^{\prime}\right) \Longrightarrow \mathbf{j} \cdot \mathbf{E}=\frac{\mathbf{j}^{2}}{\sigma}-\mathbf{j} \cdot \mathbf{E}^{\prime}
\]
\[
\mathbf{E}^{\prime} \neq 0 \text { only inside the battery }
\]

The power per unit volume transferred by the ElectroMagnetic fields to matter is: \(\mathbf{j} \cdot \mathbf{E}\).
The power per unit volume transferred by the EM-motive fields to matter is: \(\mathbf{j} \cdot \mathbf{E}^{\prime}\).

The energy balance, for ElectroMagnetic fields plus conduction charges plus battery, becomes:
\[
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \iiint_{\Omega} u \mathrm{~d} V+\oiint_{\partial \Omega} \mathbf{S} \cdot \mathrm{d} \mathbf{S}+\iiint_{\Omega} \frac{\mathbf{j}^{2}}{\sigma} \mathrm{~d} V=\iiint_{\Omega} \mathbf{j} \cdot \mathbf{E}^{\prime} \mathrm{d} V \tag{37.01.07}
\end{equation*}
\]

The above equation means that ElectroMagnetic energy is transferred out of the ElectroMagnetic fields via the Joule effect, taking out energy from the ElectroMagnetic fields, and that the linear EM-motive field feeds energy into the ElectroMagnetic fields.

See the important comment in § 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order multipoles.

\subsection*{37.01.03.01 Introduction}

ElectroMagnetic fields can carry linear momentum.
The following example motivates the above statement. Consider two identical point charges constrained to move at constant speed along the \(x\) and \(y\) axis, both of them moving in the negative direction and approaching the origin, that is still at \(x>0\) and \(y>0\). It can be shown that the electric field is radial and that the magnetic field is purely tangential to circumferences perpendicular and concentric to the velocity. The ElectroMagnetic force between the charges would tend to drive them off the axes but we can assume that the charges are mounted on tracks and forced to maintain the same direction and the same speed by some external agent. The electric force between them is repulsive, and the two forces are equal and opposite. The magnetic field produced by the charge on the \(x\) axis points in the negative direction of the \(z\) axis, on the \(y\) at \(y>0\), so that the force is in the positive direction of the \(x\) axis. The magnetic field produced by the charge on the \(y\) axis points in the positive direction of the \(z\) axis, on the \(x\) at \(x>0\), so that the force is in the positive direction of the \(y\) axis.
All, in all, the ElectroMagnetic forces on the two charges are equal but not opposite, in violation of Newton third law. As Newton third law is linked to linear momentum conservation this results challenges linear momentum conservation.
The problem is solved once one realizes that the ElectroMagnetic field carry a linear momentum.
Even perfectly static ElectroMagnetic fields can harbor linear momentum and angular momentum, as long as \(\mathbf{E} \times \mathbf{B}\) is non-zero. It is only when these contributions from ElectroMagnetic fields are included that the classical conservation laws hold.
Linear momentum conservation for isolated systems is maintained if and only if the linear momentum carried by the ElectroMagnetic fields is accounted for, and experiments have shown that ElectroMagnetic waves can carry and transport linear momentum.

\subsection*{37.01.03.02 Expression of the Linear Momentum of the ElectroMagnetic Fields}

This § is referenced at pages:
[1898, 1898, 1899, 1899]
linear momentum is a vector, its volume density must be a vector. A local conservation law implies that one must take the divergence of the flux. But the flux must be a quantity capable to provide the flux of all the three components of the linear momentum, that is we need one flux for each component of the linear momentum. In other words the divergence of the linear momentum flux must be a vector, it cannot be a scalar. Therefore the flux of linear momentum must be a second-rank tensor.
Consider the linear momentum balance in vacuum in presence of a charge density \(\rho\) and current density j. The ElectroMagnetic fields loose linear momentum which is transferred to the charges. We know, from the first Cardinal Equation of mechanics, that linear momentum changes are connected to the total external force. The linear momentum per unit volume per unit time given by the ElectroMagnetic fields to matter can be written, after using the Maxwell Equations, as:
\[
\begin{equation*}
\frac{\mathrm{d} \mathbf{F}}{\mathrm{~d} \Omega}=(\rho \mathbf{E}+\mathbf{j} \times \mathbf{B}) \equiv \mathbf{k}=-\partial_{t} \mathbf{g}-\frac{\partial \Theta_{i k} \mathbf{e}_{i}}{\partial x^{k}}=-\partial_{t} \mathbf{g}-\frac{\partial \boldsymbol{\Theta}_{k}}{\partial x^{k}}, \tag{37.01.08}
\end{equation*}
\]
in terms of the force \(\mathbf{F}\) applied by the ElectroMagnetic fields to matter.
ElectroMagnetic field linear momentum density (linear momentum per unit volume) and linear momentum flux (linear momentum crossing a unit area perpendicular to the direction of linear momentum flow per unit time) are:
\[
\begin{equation*}
\mathbf{g}[\mathbf{x}, t]=\varepsilon_{0} \mathbf{E}[\mathbf{x}, t] \times \mathbf{B}[\mathbf{x}, t]=\frac{\mathbf{S}[\mathbf{x}, t]}{c^{2}} \tag{37.01.09}
\end{equation*}
\]
\[
\Theta_{i j}^{\because i}[\mathbf{x}, t]=-\left(\varepsilon_{0} E_{i} E_{j}+\frac{B_{i} B_{j}}{\mu_{0}}-\frac{1}{2} \delta_{i j}\left(\varepsilon_{0} E^{2}+\frac{B^{2}}{\mu_{0}}\right)\right)=-\left(\varepsilon_{0} E_{i} E_{j}+\frac{B_{i} B_{j}}{\mu_{0}}-\delta_{i j} u\right)
\]

The vector \(\mathbf{g}\) is the volume density of the ElectroMagnetic linear momentum and it describes the linear momentum density (linear momentum per unit volume). ElectroMagnetic radiation (see section § 42 - ElectroMagnetic Waves) is given by the propagation of ElectroMagnetic fields. The EM fields in ElectroMagnetic radiation are time-varying. The time-averaged value of the \(\mathbf{g}\) vector thus describes the linear momentum density (linear momentum per unit volume) of EM radiation.

The tensor \(\Theta_{i j}^{\prime \prime}\) is a tensor describing the flux of linear momentum out of the volume defining the system, that is the linear momentum per unit area perpendicular to the direction of the flow per unit time. It is analogous of the Poynting vector for linear momentum and as the Poynting vector it conventionally describe a positive flux when the flux is out-going. The tensor \(-\Theta_{i j}^{\bullet \ddot{ }}\) (note the minus sign) is the ElectroMagnetic stress tensor (Maxwell stress tensor). The linear momentum flux per unit time out any surface \(\Sigma\) can thus be written as:
\[
\frac{\mathrm{d} \mathbf{P}}{\mathrm{~d} t}=\mathbf{e}_{i} \oiint_{\Sigma} \Theta_{i j}^{\because} \mathrm{d} \mathbf{S}_{j} .
\]

Note that only the entire surface-integral of the ElectroMagnetic stress tensor has a clear physical meaning. One has to be careful with the identification of the ElectroMagnetic stress tensor with the local linear momentum flux per unit area per unit time. In fact the ElectroMagnetic stress tensor is defined to within a divergence-less field. No troubles arise when one uses the theorem (37.01.08) in integral form, applied to an arbitrary volume without attempting to localise the linear momentum flow in space. On the other hand the differential form is correct at any point, as the derivation provide the divergence of the linear momentum flow.
It must be emphasised that equation (37.01.08) implies that linear momentum conservation is a local linear momentum conservation, that is whenever there is a change of linear momentum inside a certain volume the linear momentum must be either given to (received from) matter or has to flow across the boundaries of the surface.

Note also the equation (37.01.08) has the form of a typical balance law, with a non zero source term. Equation (37.01.08) can be written, in integral form (Poynting theorem for the linear momentum), as:
\[
\begin{equation*}
\left.\frac{\mathrm{d}}{\mathrm{~d} t} \iiint_{\Omega} \mathbf{g}[\mathbf{x}] \mathrm{d} \mathbf{x}+\iiint_{\Omega} \mathbf{k}[\mathbf{x}] \mathrm{d} \mathbf{x}=-\oiiint_{\partial \Omega} \mathbf{e}_{i} \Theta_{i j} \ddot{\ddot{x}}\right] \mathrm{d} \mathbf{S}_{j} \tag{37.01.10}
\end{equation*}
\]
with
\[
\mathbf{P}_{\mathrm{EM}} \equiv \iiint_{\Omega} \mathbf{g} \mathrm{d} V
\]

Equation (37.01.10) represents the linear momentum balance for the system made of the ElectroMagnetic fields inside volume \(\Omega\).

The left side gives the rate of change of ElectroMagnetic linear momentum inside the volume \(\Omega\).
Note that:
\[
\iiint_{\Omega}(\rho \mathbf{E}+\mathbf{j} \times \mathbf{B}) \mathrm{d} V \equiv \mathbf{F}_{\mathrm{EM} \longrightarrow \mathrm{MAT}}=\frac{\mathrm{d} \mathbf{P}_{\mathrm{MAT}}}{\mathrm{~d} t}
\]

Therefore the integral form can be also written as:
\[
\frac{\mathrm{d}}{\mathrm{~d} t}\left(\mathbf{P}_{\mathrm{EM}}+\mathbf{P}_{\mathrm{MAT}}\right)=-\oiiint_{\partial \Omega} \mathbf{e}_{i} \Theta_{i j} \ddot{\mathrm{~d}} \mathbf{S}_{j}
\]
showing that the linear momentum (of the ElectroMagnetic fields plus matter) inside the volume can change because linear momentum flows into or out of the volume across the surface.
If the fields are localized inside a finite spatial region the volume can be taken as large as it is required to contain all the fields. This implies the conservation of the total linear momentum:
\[
\frac{\mathrm{d}}{\mathrm{~d} t}\left(\mathbf{P}_{\mathrm{EM}}+\mathbf{P}_{\mathrm{MAT}}\right)=0 \quad \text { (localized fields) }
\]

Note that in general, for radiation fields, the surface contribution cannot be neglected, even taking the surface at infinity, because for radiation fields the Electric|Magnetic fields decrease only as \(r^{-1}\) at infinity. Compare the analogous behavior of the Poynting vector.

\subsection*{37.01.03.04 Maxwell Stress Tensor}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|6.8||
©|W.K.H.Panoffsky \& M.Phillips, Classical Electricity And Magnetism, 1962, Addison-Wesley, 2ndEd., ....|6||
A slightly different approach, equivalent to the general one presented above when one limits to static situations, leads directly to Maxwell stress tensor as follows.

Maxwell stress tensor describes, in static situations, the forces acting on the matter enclosed inside a certain volume. When the situation is not static one needs to revert to the general expressions in section § 37.01.03.02 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum.

See the very important comment in \(\S\) 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order Multipoles.

The total force acting on the matter enclosed inside a certain volume \(\Omega\) is given by:
\[
\mathbf{F}=\iiint_{\Omega}(\rho \mathbf{E}+\mathbf{j} \times \mathbf{B}) \mathrm{d} V
\]

In static situations, using Maxwell Equations for static situations, one can rewrite it as:
\[
\partial_{t}\{\ldots\}=0 \Longrightarrow \mathbf{F}=\mathbf{e}_{i} \iiint_{\Omega} \partial_{k} \Xi_{i k} \mathrm{~d} V
\]
where Maxwell stress tensor is given by:
\[
\begin{equation*}
\Xi_{i j} \equiv \varepsilon_{0}\left(E_{i} E_{j}-\frac{1}{2} \delta_{i j} E^{2}\right)+\frac{1}{\mu_{0}}\left(B_{i} B_{j}-\frac{1}{2} \delta_{i j} B^{2}\right) . \tag{37.01.11}
\end{equation*}
\]

Maxwell stress tensor gives the ElectroMagnetic stresses in a static situation.
The total ElectroMagnetic force acting on the matter enclosed inside a a volume \(\Omega\) can be also expressed in terms of a surface integral as:
\[
\mathbf{F}=\mathbf{e}_{i} \iiint_{\Omega} \partial_{k} \Xi_{i k}^{\because} \mathrm{d} V=\mathbf{e}_{i} \oiint_{\partial \Omega} n_{k} \Xi_{i k} \ddot{\mathrm{~d}} \mathbf{S}
\]

It is rather amazing that the total ElectroMagnetic force acting on the matter enclosed inside the volume \(\Omega\) can be expressed in terms of the ElectroMagnetic fields on the boundary of the volume only without any reference to the Charge|Current inside the volume. The reason why this makes sense is that the ElectroMagnetic fields on the boundary of the volume includes also the contribution generated by the Charge|Current inside the volume themselves.
Note that the resulting ElectroMagnetic pressure is not isotropic.
Note also that the result is unambiguous when the total ElectroMagnetic force acting on the matter enclosed inside the volume \(\Omega\) is considered. If one tries to give a meaning to the Maxwell stress tensor limiting to a part of the surface only the objection might arise that Maxwell stress tensor can be changed by adding any divergence-less function to it. As for the case of Poynting vector only the integral on a closed surface is unambiguous.
Note that Maxwell stress tensor gives the ElectroMagnetic stresses in a static situation acting on the system, that is the flux of linear momentum entering the volume. Therefore it has the opposite sign with respect to the tensor \(\Theta_{i j}^{\bullet \bullet}\) introduced in § 37.01.03.02 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum (Read also § 30.03.02.02 - Introduction to the Mechanics of Continuous Media).
The stress tensor is conventionally defined to be positive for a traction (acting on the system) while it is negative for a compression (acting on the system).
Special case, when \(\mathbf{B}=0\) :
\[
\begin{equation*}
\mathbf{F}_{\mathrm{E}}=\varepsilon_{0} \oiint_{\partial \Omega}\left((\mathbf{n} \cdot \mathbf{E}) \mathbf{E}-\frac{1}{2} \hat{\mathbf{n}} E^{2}\right) \mathrm{d} \mathbf{S} \tag{37.01.12}
\end{equation*}
\]

Special case, when \(\mathbf{E}=0\) :
\[
\begin{equation*}
\mathbf{F}_{\mathrm{B}}=\frac{1}{\mu_{0}} \oiint_{\partial \Omega}\left((\mathbf{n} \cdot \mathbf{B}) \mathbf{B}-\frac{1}{2} \hat{\mathbf{n}} B^{2}\right) \mathrm{d} \mathbf{S} \tag{37.01.13}
\end{equation*}
\]

Diagonalization of the two expressions (37.01.12), (37.01.13) provides:
\[
\Xi_{i k}[\mathbf{E}, \mathbf{0}]=\frac{\varepsilon_{0}}{2}\left(\begin{array}{ccc}
+E^{2} & 0 & 0 \\
0 & -E^{2} & 0 \\
0 & 0 & -E^{2}
\end{array}, \quad, \quad \Xi_{i k}[\mathbf{0}, \mathbf{B}]=\frac{1}{2 \mu_{0}}\left(\begin{array}{ccc}
+B^{2} & 0 & 0 \\
0 & -B^{2} & 0 \\
0 & 0 & -B^{2}
\end{array},\right\}\right.
\]
where the positive eigenvalue corresponds to an eigenvector along the direction of the field.
This shows that a tension is transmitted along the direction of the field and a transverse pressure is transmitted perpendicularly to the direction of the field, in both cases.
Note that the diagonalized stress tensor can be considered as the superposition of one isotropic stress tensor, giving rise to a uniform pressure, plus a stress tensor giving rise to a tension along the field equal to twice the pressure.

The effect of Maxwell stress tensor can be understood as follows. Consider a small circular cylinder coaxial with the field at some point. The expressions (37.01.12), (37.01.13) show that the contribution to the surface integral at the two bases and at the lateral surface are (with \(\mathbf{V}=\{\mathbf{E}, \mathbf{B}\}\) ):
lateral surface \(\Longrightarrow \mathbf{n} \cdot \mathbf{V}=0 \Longrightarrow \mathrm{~d} \mathbf{F} \propto-\hat{\mathbf{n}} \Longrightarrow \quad\) compression on the lateral sides ,
bases \(\Longrightarrow \mathbf{V}(\mathbf{n} \cdot \mathbf{V})=\hat{\mathbf{n}} V^{2} \Longrightarrow \mathrm{~d} \mathbf{F} \propto\left(\hat{\mathbf{n}} V^{2}-\hat{\mathbf{n}} V^{2} / 2\right)=\hat{\mathbf{n}} V^{2} / 2 \Longrightarrow \quad\) traction on both bases.
As a comment to the previous relations one should note that the term \(\mathbf{V}(\mathbf{n} \cdot \mathbf{V})\) is invariant for changing \(\mathbf{V} \rightarrow-\mathbf{V}\).

When summing all the contributions on the whole surface the balance of the different contribution will give the overall force.

Stresses on the Surface Charge at the Surface of a Closed Conductor
It always tends to expand the surface charge.

See the important comment in § 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order Multipoles.

\subsection*{37.01.04.01 Introduction}

ElectroMagnetic fields can carry angular momentum.
Even perfectly static ElectroMagnetic fields can harbor linear momentum and angular momentum, as long as \(\mathbf{E} \times \mathbf{B}\) is non-zero. It is only when these contributions from ElectroMagnetic fields are included that the classical conservation laws hold.
The Feynman Cylinder paradox is solved by taking into account the angular momentum of ElectroMagnetic fields.
Angular momentum conservation for isolated systems is maintained if and only if the angular momentum carried by the ElectroMagnetic fields is accounted for, and experiments have shown that ElectroMagnetic waves can carry and transport angular momentum.

\subsection*{37.01.04.02 Expression of the Angular Momentum of the ElectroMagnetic Fields}

This § is referenced at pages:
[Never referenced.]
\[
\begin{equation*}
\frac{\mathrm{d} \boldsymbol{\Gamma}}{\mathrm{~d} \Omega}=\mathbf{x} \times(\rho \mathbf{E}+\mathbf{j} \times \mathbf{B}) \tag{37.01.14}
\end{equation*}
\]

The density of angular momentum and the angular momentum of the ElectroMagnetic fields are:
\[
\begin{equation*}
\frac{\mathrm{d} \mathbf{J}}{\mathrm{~d} \Omega}[\mathbf{x}, t]=\mathbf{x} \times \mathbf{g} \quad \mathbf{J}[t]=\iiint_{\Omega} \mathbf{x} \times \mathbf{g} \mathrm{d} \mathbf{x} \tag{37.01.15}
\end{equation*}
\]

This angular momentum density equation (37.01.15) includes both spin and orbital angular momenta of the ElectroMagnetic fields. That is, whether the angular momentum is produced by circular Polarization (spin) or by vorticity (orbital), equation (37.01.15) yields the total angular momentum density at any point in space and any instant in time, regardless its appearance seemingly suggesting an orbital part only.

- The Feynman cylinder paradox \({ }^{\text {a }}\).
- A variation on the Feynman cylinder paradox. Consider a cylindrical capacitor immersed in a magnetic field parallel to the axis.
First case. If the capacitor is discharged there is an average current in the radial direction which interacts with the magnetic field. This generates an overall torque on the capacitor which tends to put it into rotation: angular momentum of the ElectroMagnetic field is transferred into mechanical angular momentum.
Second case. If the magnetic field is reduced to zero a circular electric field is induced, whose modulus depends on the distance form the axis. Therefore the torques acting on the two charged faces of the capacitor are not balanced and the capacitor acquires angular momentum: angular momentum of the ElectroMagnetic field is transferred into mechanical angular momentum.

37.01.05 General Expressions in Presence of Matter
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
The expressions in presence of matter, using the macroscopic description, leads to some complications.
The Abraham-Minkowski controversy, over the form of the ElectroMagnetic Energy-LinMomentum tensor in a dielectric medium, has been resolved by the recognition that division of the total EnergyLinMomentum tensor into ElectroMagnetic and matter parts is arbitrary.

\section*{Examples and Physical Applications}

\subsection*{37.02.01 Energy Balance for a Resistive Wire}

This § is referenced at pages:
[1895, 1895]
Consider a circular cylindrical wire of radius \(R^{2}\) whose axis is the \(z\) axis, where a constant and uniform current \(I\) flows. Consider a finite part of the wire, of length \(L\), and apply the energy balance to it.
Consider the microscopic picture for a typical solid conductor, where free electrons move inside a fixed lattice of positive ions. The power per unit volume given by the ElectroMagnetic fields to free electrons first goes into kinetic energy of the free electrons. The kinetic energy gained by the free electrons is then given to the lattice of ions, as potential and kinetic energy of the ions in the lattice, thanks to collisions. Both the kinetic energy of the free electrons and the total energy of the lattice contribute to the internal energy of the resistive material. All in all the ElectroMagnetic field transfers some energy into internal energy of the material, which is eventually given to the surrounding ambient as heat.

We will first consider the integral balance for a whole piece of wire and later the differential balance at the internal points.

The equipotential surfaces and the electric field for the very idealized situation of a long rectilinear and cylindrical coaxial wire with circular cross-section are shown in figures 37.1 and 37.2. The external shell is kept at zero potential and it is assumed to have zero resistance, while the difference of potential is applied at the two bases of the wire. Note that in general at the surface of the wire there is both a normal component of the electric field and a surface charge.

Figure 37.1: A toy coaxial cable (potential)

\footnotetext{
\({ }^{2}\) Not to be confused with the resistance of the wire, which will not be used.
}

\subsection*{37.02.01.01 Integral Balance}

Under steady conditions the Poynting theorem shows that the energy given by the ElectroMagnetic fields into internal energy of the resistor (the Joule effect) can be considered to enter from the lateral perimeter of the wire, feeded by the ElectroMagnetic fields. However it should be kept in mind that the Poynting vector is not unique and therefore the spatial localisation of the energy flux is not relevant, but only the divergence of the Poynting vector is as well as the integral on a closed surface are.
It is important to stress that the EM-motive field of the battery does not intervene here, because the battery is outside the volume where the energy balance is applied.
Consider, in fact, a circular cylinder surface, \(\Sigma\), coaxial with the wire and with radius \(r>R\), just slightly larger than \(R\). Inside the wire the electric field is parallel to the axis of the wire, thanks the steady situation, and therefore, its tangential component, thanks to its continuity, has the same value just outside the wire. Note that, a priori, a normal component of the electric field is present at the surface of the wire, as well as a corresponding surface charge density. The normal component of the electric field, only present externally to the wire, is not relevant because it does not affect the energy balance as it provides a component of the Poynting vector parallel to the wire, whose flux across the cylindrical surface is zero. To avoid complications with this normal component at the two bases of the cylinder it is necessary to choose the surface \(\Sigma\) just slightly bigger that the wire in such a way that the part of the cylinder basis outside the wire has a negligible area, tending to zero, as the normal component has a non-zero contribution there. In fact, a priori the normal components of the electric field at the two bases are different because \(\rho_{\mathrm{S}}\) may be different.
The radial component of the Poynting vector is directed towards the interior of the wire. It has the value, at \(r=R\) :
\[
\mathbf{S}=\varepsilon_{0} c^{2} \mathbf{E} \times \mathbf{B} \Longrightarrow|S|=\varepsilon_{0} c^{2}\left(\frac{|j|}{\sigma}\right)\left(\frac{\mu_{0}|I|}{2 \pi R}\right)=\frac{j^{2} R}{2 \sigma} \quad \text { and } \quad \mathbf{S}=-\frac{j^{2} R}{2 \sigma} \hat{\mathbf{e}}_{r}
\]

The negative flux of the Poynting vector across the surface \(\Sigma\) is thus:
\[
-\oiiint \mathbf{S} \cdot \mathrm{d} \mathbf{S}=\frac{j^{2} R}{2 \sigma}(2 \pi R L)=\frac{\pi j^{2} R^{2} L}{\sigma}=|I \Delta V|=\iiint \mathbf{j} \cdot \mathbf{E} \mathrm{d} V
\]

The negative flux of the Poynting vector implies that ElectroMagnetic energy is entering the volume.

\subsection*{37.02.01.02 Differential Balance at the Internal Points}

The internal Electric|Magnetic fields and the Poynting vector are:
\[
\mathbf{E}=E_{z} \hat{\mathbf{e}}_{3} \quad \mathbf{B}=\frac{\mu_{0} j_{z} r}{2} \hat{\mathbf{e}}_{\psi} \quad \mathbf{S}=-\frac{E_{z} j_{z} r}{2} \hat{\mathbf{e}}_{r} .
\]

It follows:
\[
-\operatorname{div} \mathbf{S}=-\frac{\partial S_{r}}{\partial r}-\frac{S_{r}}{r}=+E_{z} j_{z}=+\frac{j_{z}^{2}}{\sigma}>0
\]

This shows clearly in a non-ambiguous way the meaning of Poynting theorem in differential form: at any point internal to the wire the ElectroMagnetic fields are feeding a power per unit volume to matter, energy which is then dissipated by the Joule effect.

\subsection*{37.02.01.03 Differential Balance at the External Points}

The calculation of the Poynting vector outside the wire is difficult but Poynting theorem allows to state that, in steady conditions, \(\operatorname{div} \mathbf{S}=0\) because \(\mathbf{j}=0\).

\subsection*{37.02.01.04 Energy Transfers}

Inside the wire the electric field gives energy to the free charges (electrons), which becomes kinetic energy of the free charges. The free charges (electrons) collide with the fixed particles (positive ions) giving them mechanical energy. The energy of all the particles contributes to the internal energy. In steady conditions the work done by the electric field is thus totally transferred into internal energy, which is then possibly given to the external world as heat.
Poynting theorem, in steady conditions, reads:
\(\{\) Work done by ElectroMagnetic fields on free electrons inside the wire \(\}=\iiint \mathbf{j} \cdot \mathbf{E} \mathrm{d} V\),
\(\{E M\) Energy entering the system from outside \(\}=\oint \mathbf{S} \cdot \mathrm{d} \mathbf{S} \quad\),
\[
\iiint \mathbf{j} \cdot \mathbf{E} \mathrm{d} V+\oint \mathbf{S} \cdot \mathrm{d} \mathbf{S}=0
\]

In fact in steady conditions the energy of the ElectroMagnetic fields inside the system does not change and therefore any energy must come from outside.

\subsection*{37.02.02 Hidden Linear Momentum and Angular Momentum}

Hidden momentum is perfectly ordinary relativistic mechanical momentum, as the example above indicates; it occurs in systems with internally moving parts, such as current-carrying loops, and it is "hidden" only in the sense that it not associated with motion of the objects a whole.

\title{
Mansuripur's paradox
}

\author{
David J. Griffiths* \\ Department of Physics, Reed College, Portland, Oregon 97202 \\ V. Hnizdo \\ National Institute for Occupational Safety and Health, Morgantown, West Virginia 26505
}

A recent article claims that the Lorentz force law is incompatible with special relativity. We discuss the "paradox" on which this claim is based. The resolution depends on whether one assumes a "Gilbert" model for the magnetic dipole (separated monopoles) or the standard "Ampère" model (a current loop). The former case was treated in these pages many years ago; the latter, as several authors have noted, constitutes an interesting manifestation of "hidden momentum."

\section*{I. INTRODUCTION}

On May 7, 2012, a remarkable article appeared in Physical Review Letters. \({ }^{1}\) The author, Masud Mansuripur, claimed to offer "incontrovertible theoretical evidence of the incompatibility of the Lorentz [force] law with the fundamental tenets of special relativity," and concluded that "the Lorentz law must be abandoned." The Lorentz law,
\[
\begin{equation*}
\mathbf{F}=q[\mathbf{E}+(\mathbf{v} \times \mathbf{B})] \tag{1}
\end{equation*}
\]
tells us the force \(\mathbf{F}\) on a charge \(q\) moving with velocity \(\mathbf{v}\) through electric and magnetic fields \(\mathbf{E}\) and \(\mathbf{B}\). Together with Maxwell's equations, it is the foundation on which all of classical electrodynamics rests. If it is incorrect, 150 years of theoretical physics is in serious jeopardy.

Such a provocative proposal was bound to attract attention. Science \({ }^{2}\) published a full-page commentary, and within days several rebuttals were posted. \({ }^{3}\) Critics pointed out that since the Lorentz force law can be embedded in a manifestly covariant formulation of electrodynamics, it is guaranteed to be consistent with special relativity, \({ }^{4}\) and and some of them identified the specific source of Mansuripur's error: neglect of "hidden momentum." Nearly a year later Physical Review Letters published four rebuttals, \({ }^{5}\) and Science printed a followup article declaring the "purported relativity paradox resolved." \({ }^{6}\)

Mansuripur's argument is based on a "paradox" that was explored in this journal by Victor Namias and others \({ }^{7}\) many years ago: a magnetic dipole moving through an electric field can experience a torque, with no accompanying rotation. In Section II we introduce Mansuripur's version of the paradox, in simplified form, and explain Namias's resolution. The latter is based on a "Gilbert" model of the dipole (separated magnetic monopoles); it does not work for the (realistic) "Ampère" model (a current loop). For Amperian dipoles the resolution involves "hidden" momentum, so in Section III we discuss the physical nature of this often-misunderstood phenomenon. Mansuripur himself treated the dipole as the point limit of a magnetized object, so in Section IV we repeat the calculations in that context (for both models), and confirm our earlier results. In Section V we discuss
the Einstein-Laub force law, which Mansuripur proposed as a replacement for the Lorentz law, and in Section VI we offer some comments and conclusions.

\section*{II. GILBERT DIPOLES: NAMIAS'S RESOLUTION}

First the paradox: In \(\mathcal{S}^{\prime}\) (the "proper" frame) there is an ideal magnetic dipole \(\mathbf{m}=m_{0} \hat{\mathbf{x}}\) at \((0,0, d)\), and a point charge \(q\) at the origin, both at rest. The torque on \(\mathbf{m}\) is (obviously) zero. Now examine the same configuration in \(\mathcal{S}\) (the "lab" frame), with respect to which \(\mathcal{S}^{\prime}\) moves at constant speed \(v\) in the \(z\) direction (Fig. 1). In \(\mathcal{S}\) the (moving) point charge generates electric and magnetic fields
\[
\begin{gathered}
\mathbf{E}(x, y, z, t)=\frac{q}{4 \pi \epsilon_{0}} \frac{\gamma}{R^{3}}(x \hat{\mathbf{x}}+y \hat{\mathbf{y}}+(z-v t) \hat{\mathbf{z}}), \\
\mathbf{B}(x, y, z, t)=\frac{q}{4 \pi \epsilon_{0}} \frac{v \gamma}{c^{2} R^{3}}(-y \hat{\mathbf{x}}+x \hat{\mathbf{y}}), \\
\left(\gamma \equiv 1 / \sqrt{1-(v / c)^{2}}, R \equiv \sqrt{x^{2}+y^{2}+\gamma^{2}(z-v t)^{2}}\right), \text { and }
\end{gathered}
\] the (moving) magnetic dipole acquires an electric dipole moment \({ }^{8}\)
\[
\begin{equation*}
\mathbf{p}=\frac{1}{c^{2}}(\mathbf{v} \times \mathbf{m})=\frac{1}{c^{2}} v m_{0} \hat{\mathbf{y}} . \tag{4}
\end{equation*}
\]

The torque on the dipole is
\[
\begin{equation*}
\mathbf{N}=(\mathbf{m} \times \mathbf{B})+(\mathbf{p} \times \mathbf{E})=\frac{q m_{0}}{4 \pi \epsilon_{0}} \frac{v}{c^{2} d^{2}} \hat{\mathbf{x}} \tag{5}
\end{equation*}
\]

FIG. 1. Electric charge ( \(q\) ) and magnetic dipole ( \(\mathbf{m}\) ) in proper (primed) and lab (unprimed) frames.

FIG. 2. "Gilbert" magnetic dipole.
(by Lorentz transformation, \(d=\gamma(z-v t)\); the magnetic contribution is zero, because \(\mathbf{B}\) vanishes on the \(z\) axis). The torque is zero in one inertial frame, but non-zero in the other! Mansuripur concludes that the Lorentz force law (on which Eq. 5 is predicated) is inconsistent with special relativity.
This "paradox" was resolved years ago by Victor Namias. \({ }^{7}\) The standard torque formulas \((\mathbf{p} \times \mathbf{E}\) and \(\mathbf{m} \times \mathbf{B}\) ) apply to dipoles at rest, but they do not hold, in general, for dipoles in motion. Suppose we model the magnetic dipole as separated monopoles (Fig. 2). The "Lorentz force law" for a magnetic monopole \(q^{*}\) reads \({ }^{9}\)
\[
\begin{equation*}
\mathbf{F}=q^{*}\left[\mathbf{B}-\left(1 / c^{2}\right) \mathbf{v} \times \mathbf{E}\right], \tag{6}
\end{equation*}
\]
so the torque \({ }^{10}\) on a moving dipole \(\mathbf{m}=q^{*}\left(\mathbf{r}_{+}-\mathbf{r}_{-}\right)\)is
\[
\begin{aligned}
\mathbf{N} & =\left(\mathbf{r}_{+} \times \mathbf{F}_{+}\right)+\left(\mathbf{r}_{-} \times \mathbf{F}_{-}\right) \\
& =(\mathbf{m} \times \mathbf{B})-\frac{1}{c^{2}} \mathbf{m} \times(\mathbf{v} \times \mathbf{E}) .
\end{aligned}
\]

But \(\mathbf{m} \times(\mathbf{v} \times \mathbf{E})=\mathbf{v} \times(\mathbf{m} \times \mathbf{E})+(\mathbf{m} \times \mathbf{v}) \times \mathbf{E}\), so
\[
\begin{align*}
\mathbf{N} & =(\mathbf{m} \times \mathbf{B})-\frac{1}{c^{2}}(\mathbf{m} \times \mathbf{v}) \times \mathbf{E}-\frac{1}{c^{2}} \mathbf{v} \times(\mathbf{m} \times \mathbf{E}) \\
& =(\mathbf{m} \times \mathbf{B})+(\mathbf{p} \times \mathbf{E})-\frac{1}{c^{2}} \mathbf{v} \times(\mathbf{m} \times \mathbf{E}) . \tag{7}
\end{align*}
\]

There is a third term, missing in Eq. 5, which (it is easy to check) exactly cancels the offending torque; the net torque is zero in both frames.

\section*{III. AMPÈRE DIPOLES: HIDDEN MOMENTUM}

Namias believed that his formula (Eq. 7) applies just as well to an Ampère dipole as it does to a Gilbert dipole. He was mistaken. An Ampère dipole in an electric field carries "hidden" momentum, \({ }^{11}\)
\[
\begin{equation*}
\mathbf{p}_{h}=\frac{1}{c^{2}}(\mathbf{m} \times \mathbf{E}) \tag{8}
\end{equation*}
\]

Because it is crucial in understanding the resolution to Mansuripur's paradox, we pause to review the derivation of this formula, in a simple model.

Imagine a rectangular loop of wire carrying a steady current. Picture the current as a stream of noninteracting positive charges that move freely within the wire. \({ }^{12}\) When

FIG. 3. Current loop in an external electric field.
a uniform electric field \(\mathbf{E}\) is applied (Fig. 3), the charges accelerate up the left segment, and decelerate down the right one. Question: What is the total momentum of all the charges in the loop? The left and right segments cancel, so we need only consider the top and bottom. Say there are \(N_{t}\) charges in the top segment, going to the right at speed \(v_{t}\), and \(N_{b}\) charges in the lower segment, going at (slower) speed \(v_{b}\) to the left. The current \((I=\lambda v)\) is the same in all four segments (otherwise charge would be piling up somewhere). Thus
\[
\begin{equation*}
I=\frac{q N_{t}}{l} v_{t}=\frac{q N_{b}}{l} v_{b}, \quad \text { so } \quad N_{t} v_{t}=N_{b} v_{b}=\frac{I l}{q} \tag{9}
\end{equation*}
\]
where \(q\) is the charge of each particle, and \(l\) is the length of the rectangle. Classically, the momentum of a single particle is \(p=m v\), where \(m\) is its mass, so the total momentum (to the right) is
\[
\begin{equation*}
p_{\text {classical }}=m N_{t} v_{t}-m N_{b} v_{b}=m \frac{I l}{q}-m \frac{I l}{q}=0 \tag{10}
\end{equation*}
\]
as one would certainly expect (after all, the loop as a whole is not moving). But relativistically the momentum of a particle is \(p=\gamma m v\), and we get
\[
\begin{equation*}
p_{\text {relativistic }}=\gamma_{t} m N_{t} v_{t}-\gamma_{b} m N_{b} v_{b}=\frac{m I l}{q}\left(\gamma_{t}-\gamma_{b}\right) \tag{11}
\end{equation*}
\]
which is not zero, because the particles in the upper segment are moving faster. In fact, the gain in energy \(\left(\gamma m c^{2}\right)\), as a particle goes up the left side, is equal to the work done by the electric force, \(q E w\), where \(w\) is the height of the rectangle, so
\[
\begin{equation*}
\gamma_{t}-\gamma_{b}=\frac{q E w}{m c^{2}}, \quad \text { and hence } \quad p_{\mathrm{rel}}=\frac{I l E w}{c^{2}} \tag{12}
\end{equation*}
\]

Now \(I l w\) is the magnetic dipole moment of the loop; as vectors, \(\mathbf{m}\) points into the page and \(\mathbf{p}\) is to the right, so
\[
\begin{equation*}
\mathbf{p}_{\mathrm{rel}}=\frac{1}{c^{2}}(\mathbf{m} \times \mathbf{E}) \tag{13}
\end{equation*}
\]

This is the "hidden" momentum in Eq. 8.

The term "hidden momentum" was coined by Shockley; \({ }^{11}\) it was an unfortunate choice. The phenomenon itself was first studied in the context of static electromagnetic systems with nonzero field momentum \(\left(\mathbf{p}_{\text {field }}=\epsilon_{0} \int(\mathbf{E} \times \mathbf{B}) d^{3} \mathbf{r}\right)\). In such configurations the hidden momentum exactly cancels the field momentum \(\left(\mathbf{p}_{h}=-\mathbf{p}_{\text {field }}\right)\), leaving a total of zero, as required by the "center of energy theorem." \({ }^{13}\) This has created the impression that hidden momentum is something artificial and ad hoc-invented simply to rescue an abstract theorem. \({ }^{14}\) Nothing could be farther from the truth. Hidden momentum is perfectly ordinary relativistic mechanical momentum, as the example above indicates; it occurs in systems with internally moving parts, such as current-carrying loops, and it is "hidden" only in the sense that it not associated with motion of the object as a whole. A Gilbert dipole in an electric field, having no moving parts, harbors no hidden momentum (and the fields-with the crucial delta-function term in \(\mathbf{B}\) included-carry no compensating momentum). \({ }^{15}\)

Returning to the configuration in Fig. 1, the hidden momentum in \(\mathcal{S}^{\prime}\) is
\[
\begin{equation*}
\mathbf{p}_{h}=\frac{1}{c^{2}}\left[\left(m_{0} \hat{\mathbf{x}}\right) \times\left(\frac{1}{4 \pi \epsilon_{0}} \frac{q}{d^{2}} \hat{\mathbf{z}}\right)\right]=-\frac{q m_{0}}{4 \pi \epsilon_{0} c^{2} d^{2}} \hat{\mathbf{y}} . \tag{14}
\end{equation*}
\]

Because \(\mathbf{p}_{h}\) is perpendicular to \(\mathbf{v}\), and transverse components are unaffected by Lorentz transformations, this is also the hidden momentum in \(\mathcal{S}\). It is constant (in time), so there is no associated force. But the hidden angular momentum,
\[
\begin{equation*}
\mathbf{L}_{h}=\mathbf{r} \times \mathbf{p}_{h} \tag{15}
\end{equation*}
\]
is not constant (in the lab frame), because \(\mathbf{r}\) is changing. In fact,
\[
\begin{equation*}
\frac{d \mathbf{L}_{h}}{d t}=\mathbf{v} \times \mathbf{p}_{h}=\frac{q m_{0}}{4 \pi \epsilon_{0}} \frac{v}{c^{2} d^{2}} \hat{\mathbf{x}} \tag{16}
\end{equation*}
\]

This increase in angular momentum requires a torque,
\[
\begin{equation*}
\mathbf{N}=\frac{q m_{0}}{4 \pi \epsilon_{0}} \frac{v}{c^{2} d^{2}} \hat{\mathbf{x}} \tag{17}
\end{equation*}
\]
and this is precisely what we found in Eq. 5.
Recapitulating: In the Gilbert model there is an extra term in the torque formula (Eq. 7); the total torque is zero, there is no hidden angular momentum, and nothing rotates. In the Ampère model there is no third term in the torque formula (Eq. 5\()^{16}\); the torque is not zero, and drives the increasing hidden angular momentumbut still nothing rotates. \({ }^{17}\) It helps to separate the angular momentum into two types: "overt" (associated with actual rotation) and "hidden" (so called because it is not associated with any overt rotation of the object). Torque is the rate of change of the total angular momentum:
\[
\begin{equation*}
\mathbf{N}=\frac{d \mathbf{L}_{o}}{d t}+\frac{d \mathbf{L}_{h}}{d t} \tag{18}
\end{equation*}
\]

In both models \(d \mathbf{L}_{o} / d t=\mathbf{0}\). In the Gilbert model \(\mathbf{N}\) and \(d \mathbf{L}_{h} / d t\) are also zero; in the Ampère model they are equal but non-zero.

\section*{IV. MAGNETIZED MATERIALS}

It is of interest to see how this plays out in Mansuripur's formulation of the problem. He treats the dipole as magnetized medium, and calculates the torque directly from the Lorentz force law, without invoking \(\mathbf{p} \times \mathbf{E}\) or \(\mathbf{m} \times \mathbf{B}\). In the proper frame, he takes
\[
\begin{equation*}
\mathbf{M}^{\prime}\left(x^{\prime}, y^{\prime}, z^{\prime}, t^{\prime}\right)=m_{0} \delta\left(x^{\prime}\right) \delta\left(y^{\prime}\right) \delta\left(z^{\prime}-d\right) \hat{\mathbf{x}} \tag{19}
\end{equation*}
\]

Now, \(\mathbf{M}\) and \(\mathbf{P}\) constitute an antisymmetric second-rank tensor:
\[
P^{\mu \nu}=\left(\begin{array}{cccc}
0 & c P_{x} & c P_{y} & c P_{z}  \tag{20}\\
-c P_{x} & 0 & -M_{z} & M_{y} \\
-c P_{y} & M_{z} & 0 & -M_{x} \\
-c P_{z} & -M_{y} & M_{x} & 0,
\end{array}\right)
\]
and the transformation rule is \({ }^{18}\)
\[
\begin{aligned}
& P_{z}=P_{z}^{\prime}, P_{x}=\gamma\left(P_{x}^{\prime}+\frac{v}{c^{2}} M_{y}^{\prime}\right), P_{y}=\gamma\left(P_{y}^{\prime}-\frac{v}{c^{2}} M_{x}^{\prime}\right) \\
& M_{z}=M_{z}^{\prime}, M_{x}=\gamma\left(M_{x}^{\prime}-v P_{y}^{\prime}\right), M_{y}=\gamma\left(M_{y}^{\prime}+v P_{x}^{\prime}\right)
\end{aligned}
\]
(for motion in the \(z\) direction). In the present case, then, the polarization and magnetization in the "lab" frame are
\[
\begin{align*}
\mathbf{M}(x, y, z, t) & =m_{0} \delta(x) \delta(y) \delta(z-v t-(d / \gamma)) \hat{\mathbf{x}}  \tag{21}\\
\mathbf{P}(x, y, z, t) & =\frac{m_{0} v}{c^{2}} \delta(x) \delta(y) \delta(z-v t-(d / \gamma)) \hat{\mathbf{y}} . \tag{22}
\end{align*}
\]

According to the Lorentz law, the force density is
\[
\begin{equation*}
\mathbf{f}=\rho \mathbf{E}+\mathbf{J} \times \mathbf{B} \tag{23}
\end{equation*}
\]
where \(\rho=-\boldsymbol{\nabla} \cdot \mathbf{P}\) is the bound charge density and \(\mathbf{J}=\) \(\partial \mathbf{P} / \partial t+\boldsymbol{\nabla} \times \mathbf{M}\) is the sum of the polarization current and the bound current density. Using Eqs. 2, 3, 21, and 22 , we obtain
\[
\begin{align*}
\mathbf{f} & =-(\boldsymbol{\nabla} \cdot \mathbf{P}) \mathbf{E}+(\boldsymbol{\nabla} \times \mathbf{M}) \times \mathbf{B}+\frac{\partial \mathbf{P}}{\partial t} \times \mathbf{B} \\
& =-\frac{q m_{0} v}{4 \pi \epsilon_{0} c^{2}} \frac{d}{R^{3}} \delta(x) \delta^{\prime}(y) \delta(z-v t-d / \gamma) \hat{\mathbf{z}} \tag{24}
\end{align*}
\]
(where a prime denotes the derivative). The net force on the dipole is
\[
\begin{equation*}
\mathbf{F}=\int \mathbf{f} d x d y d z=\left.\frac{q m_{0} v d}{4 \pi \epsilon_{0} c^{2}} \frac{d}{d y}\left[\frac{1}{\left(y^{2}+d^{2}\right)^{3 / 2}}\right]\right|_{y=0} \hat{\mathbf{z}}=\mathbf{0} \tag{25}
\end{equation*}
\]

Meanwhile, the torque density is
\[
\begin{equation*}
\mathbf{n}=\mathbf{r} \times \mathbf{f}=-\frac{q m_{0} v d}{4 \pi \epsilon_{0} c^{2}} \frac{y}{R^{2}} \delta(x) \delta^{\prime}(y) \delta(z-v t-d / \gamma) \hat{\mathbf{x}} \tag{26}
\end{equation*}
\]
so the net torque on the dipole is
\[
\begin{align*}
\mathbf{N} & =\int \mathbf{n} d x d y d z \\
& =-\left.\frac{q m_{0} v d}{4 \pi \epsilon_{0} c^{2}}\left\{-\frac{d}{d y}\left[\frac{y}{\left(y^{2}+d^{2}\right)^{3 / 2}}\right]\right\}\right|_{y=0} \hat{\mathbf{x}} \\
& =\frac{q m_{0} v}{4 \pi \epsilon_{0} c^{2} d^{2}} \hat{\mathbf{x}} \tag{27}
\end{align*}
\]
confirming Eq. 5. This is the torque required to account for the increase in hidden angular momentum.

What if we run Mansuripur's calculation for a dipole made out of magnetic monopoles? The bound charge, bound current, and magnetization current are \({ }^{19}\)
\[
\begin{equation*}
\rho_{b}^{*}=-\boldsymbol{\nabla} \cdot \mathbf{M}, \quad \mathbf{J}_{b}^{*}=-c^{2} \boldsymbol{\nabla} \times \mathbf{P}, \quad \mathbf{J}_{p}^{*}=\frac{\partial \mathbf{M}}{\partial t} \tag{28}
\end{equation*}
\]
so the force density on the magnetic dipole (again invoking Eqs. 2, 3, 21, and 22) is \({ }^{20}\)
\[
\begin{align*}
\mathbf{f} & =\rho^{*} \mathbf{B}-\frac{1}{c^{2}} \mathbf{J}^{*} \times \mathbf{E} \\
& =-(\boldsymbol{\nabla} \cdot \mathbf{M}) \mathbf{B}+(\boldsymbol{\nabla} \times \mathbf{P}) \times \mathbf{E}-\frac{1}{c^{2}}\left(\frac{\partial \mathbf{M}}{\partial t}\right) \times \mathbf{E} \\
& =\mathbf{0} \tag{29}
\end{align*}
\]

The total force is again zero, but this time so too is the torque density \((\mathbf{n}=\mathbf{r} \times \mathbf{f})\), and hence the total torque. As before, the torque is zero in the Gilbert model-and there is no hidden angular momentum.

\section*{V. THE EINSTEIN-LAUB FORCE LAW}

Having concluded that the Lorentz force law is unacceptable, Mansuripur proposes to replace Eq. 24 with an expression based on the Einstein-Laub law: \({ }^{21}\)
\[
\begin{align*}
\mathbf{f}_{\mathrm{EL}}= & (\mathbf{P} \cdot \boldsymbol{\nabla}) \mathbf{E}+\frac{\partial \mathbf{P}}{\partial t} \times\left(\mu_{0} \mathbf{H}\right)+(\mathbf{M} \cdot \boldsymbol{\nabla}) \mu_{0} \mathbf{H} \\
& -\frac{1}{c^{2}} \frac{\partial \mathbf{M}}{\partial t} \times \mathbf{E} \\
= & \frac{m_{0} q v \gamma}{4 \pi \epsilon_{0} c^{2}} \frac{1}{R^{3}} \delta(x) \delta(y)[2 \delta(z-v t-d / \gamma) \\
& \left.-(z-v t) \delta^{\prime}(z-v t-d / \gamma)\right] \hat{\mathbf{y}} \tag{30}
\end{align*}
\]

The total force on the dipole still vanishes:
\[
\begin{align*}
\mathbf{F}_{\mathrm{EL}} & =\frac{m_{0} q v \gamma}{4 \pi \epsilon_{0} c^{2}} \hat{\mathbf{y}}\left\{\frac{2}{d^{3}}+\left.\frac{1}{\gamma^{3}} \frac{d}{d z}\left[\frac{1}{(z-v t)^{2}}\right]\right|_{z-v t=d / \gamma}\right\} \\
& =\mathbf{0} \tag{31}
\end{align*}
\]

The torque density should be \(\mathbf{r} \times \mathbf{f}_{\mathrm{EL}}\) :
\[
\begin{align*}
\mathbf{n}_{\mathrm{EL}}=- & \frac{m_{0} q v \gamma}{4 \pi \epsilon_{0} c^{2}} \frac{z}{R^{3}} \delta(x) \delta(y)[2 \delta(z-v t-d / \gamma) \\
& \left.-(z-v t) \delta^{\prime}(z-v t-d / \gamma)\right] \hat{\mathbf{x}} \tag{32}
\end{align*}
\]
giving a total torque
\[
\begin{align*}
\mathbf{N}_{\mathrm{EL}} & =-\frac{m_{0} q v \gamma}{4 \pi \epsilon_{0} c^{2}} \hat{\mathbf{x}}\left\{\frac{2(v t+d / \gamma)}{d^{3}}+\frac{1}{\gamma^{3}} \frac{d}{d z}\left[\frac{z}{(z-v t)^{2}}\right]\right\} \\
& =-\frac{m_{0} q v}{4 \pi \epsilon_{0} c^{2} d^{2}} \hat{\mathbf{x}} \tag{33}
\end{align*}
\]
(the derivative is again evaluated at \(z-v t=d / \gamma\) ). It's not zero! In fact, it's minus the "Lorentz" torque, Eq. 27.

But Mansuripur argues that, "To guarantee the conservation of angular momentum, [Eq. 32] must be supplemented..."
\[
\begin{equation*}
\mathbf{n}_{\mathrm{EL}}^{\prime}=\mathbf{n}_{\mathrm{EL}}+(\mathbf{P} \times \mathbf{E})+(\mathbf{M} \times \mathbf{B}) \tag{34}
\end{equation*}
\]

In our case the extra terms are
\[
(\mathbf{P} \times \mathbf{E})+(\mathbf{M} \times \mathbf{B})=\frac{m_{0} q v}{4 \pi \epsilon_{0} c^{2} d^{2}} \delta(x) \delta(y) \delta(z-v t-d / \gamma) \hat{\mathbf{x}}
\]
and their contribution to the total torque is
\[
\begin{equation*}
\int[(\mathbf{P} \times \mathbf{E})+(\mathbf{M} \times \mathbf{B})] d x d y d z=\frac{m_{0} q v}{4 \pi \epsilon_{0} c^{2} d^{2}} \hat{\mathbf{x}} \tag{35}
\end{equation*}
\]
which is just right to cancel Eq. 33, yielding a net torque of zero (which Mansuripur takes to be the correct answer).

What are we to make of this argument? In the first place, the Einstein-Laub force density was derived assuming that the medium is at rest, \({ }^{21}\) which in this case it is not. More important, the magnetization terms implicitly assume a Gilbert model for the magnetic dipole:
\[
\begin{equation*}
(\mathbf{M} \cdot \boldsymbol{\nabla}) \mathbf{B}=-\boldsymbol{\nabla} \times(\mathbf{M} \times \mathbf{B})+(\mathbf{B} \cdot \boldsymbol{\nabla}) \mathbf{M}-(\boldsymbol{\nabla} \cdot \mathbf{M}) \mathbf{B} \tag{36}
\end{equation*}
\]
as long as the magnetization is localized, the first two terms yield vanishing surface integrals, \({ }^{22}\) leaving \(-(\boldsymbol{\nabla} \cdot \mathbf{M}) \mathbf{B}-\left(1 / c^{2}\right)[(\partial \mathbf{M} / \partial t) \times \mathbf{E}]\) for the net force density on the object, the same as in the Gilbert model (Eq. 29). \({ }^{23}\) There may be some contexts in which the Einstein-Laub force law is valid and useful, but this is not one of them. Mansuripur is quite explicit in writing that the magnetic dipole he has in mind is "a small, charge neutral loop of current," which is to say, an Ampère dipole.

\section*{VI. CONCLUSION}

The resolution of Mansuripur's "paradox" depends on the model for the magnetic dipole:
- If it is a Gilbert dipole (made from magnetic monopoles), the third term in Namias's formula (Eq. 7) supplies the missing torque. In Mansuripur's formulation (using a polarizable medium), it comes from a correct accounting of the bound charge/current (Eq. 28). The net torque is zero in the lab frame, just as it is in the proper frame.
- If it is an Ampère dipole (an electric current loop), the third term in Namias's equation is absent, and the torque on the dipole is not zero. It is, however, just right to account for the increasing hidden angular momentum in the dipole.

In either model the Lorentz force law is entirely consistent with special relativity.

\({ }^{10}\) We calculate all torques（in the lab frame）with respect to the origin．But because the net force on the dipole is zero in all cases，it does not matter－we could as well use any fixed point，including the（instantaneous）position of the dipole．
\({ }^{11}\) W．Shockley and R．P．James，＂＇Try simplest cases＇discov－ ery of＇hidden momentum＇forces on＇magnetic currents，＂＂ Phys．Rev．Lett．18，876－879（1967）；W．H．Furry，＂Ex－ amples of momentum distributions in the electromagnetic field and in matter，＂Am．J．Phys．37，621－636（1969）； L．Vaidman，＂Torque and force on a magnetic dipole，＂ Am．J．Phys．58，978－983（1990）；V．Hnizdo，＂Conserva－ tion of linear and angular momentum and the interaction of a moving charge with a magnetic dipole，＂Am．J．Phys． 60，242－246（1992）；V．Hnizdo，＂Hidden mechanical mo－ mentum and the field momentum in stationary electromag－ netic and gravitational systems，＂Am．J．Phys．65，515－518 （1997）．
\({ }^{12}\) This is of course an unrealistic model for an actual current－ carrying wire．Vaidman（Ref．11）explores more plausible models，but the result is unchanged．
\({ }^{13}\) If the center of energy of a closed system is at rest，the total momentum of the system must be zero．See，for example， S．Coleman and J．H．Van Vleck，＂Origin of＇Hidden Mo－ mentum Forces＇on Magnets，＂Phys．Rev．171，1370－1375 （1968）；M．G．Calkin，＂Linear momentum of the source of a static electromagnetic field，＂Am．J．Phys．39，513－516 （1971）．
\({ }^{14}\) Mansuripur variously calls hidden momentum an＂ab－ surdity＂（M．Mansuripur，＂Resolution of the Abraham－ Minkowski controversy，＂Opt．Commun．283，1997－2005 （2010），p．1999），a＂problem＂to be＂solved＂（Ref．1）and ＂as applied to magnetic materials ．．．an unnecessary bur－ den＂（Ref．6）．
\({ }^{15}\) D．J．Griffiths，＂Dipoles at rest，＂Am．J．Phys．60，979－ 987 （1992）．The magnetic field of a point dipole is \(\mathbf{B}=\) \(\left(\mu_{0} / 4 \pi\right)\left(1 / r^{3}\right)[3(\mathbf{m} \cdot \hat{\mathbf{r}}) \hat{\mathbf{r}}-\mathbf{m}]+\alpha \mu_{0} \mathbf{m} \delta^{3}(\mathbf{r})\) ，where \(\alpha=2 / 3\) for Ampère dipoles and \(-1 / 3\) for Gilbert dipoles．The delta function term leads，for example，to hyperfine splitting in the ground state of hydrogen，and provides experimental confirmation that the proton is an Ampére dipole．
\({ }^{16}\) We do not know a simple way to prove this directly，but we will confirm it implicitly in Section IV．
\({ }^{17}\) This is certainly not the first time such issues have arisen． How can there be a torque in the lab frame，when there is none in the proper frame？See J．D．Jackson，＂Torque or no torque？Simple charged particle motion observed in different inertial frames，＂Am．J．Phys．72，1484－1487 （2004）．How can there be a torque，with no accompanying rotation？See D．G．Jensen，＂The paradox of the L－shaped object，＂Am．J．Phys．57，553－555（1989）．
\({ }^{18}\) See，for instance，Ref．9，Eq．12．118．
19 The minus sign in \(\mathbf{J}_{b}^{*}\) is due to the switched sign in ＂Ampère＇s law＂for magnetic monopoles（see Ref．9， Eq．7．44）．Note that in Eq． 28 （and hence also Eq．29），M and \(\mathbf{P}\) are the densities of the dipole moments of magnetic monopoles and magnetic－monopole currents，respectively．
\({ }^{20}\) There is some dispute as to the correct form of the Lorentz force law for magnetic monopoles in the pres－ ence of polarizable and magnetizable materials，but not when（as here）the polarization／magnetization is
itself due to monopoles. See K. T. McDonald, "Poynting's Theorem with Magnetic Monopoles," (11 pp),〈http://puhep1.princeton.edu/~mcdonald/examples/poynting.pdf〉 (2013).
\({ }^{21}\) A. Einstein and J. Laub, "Über die im elektromagnetischen Felde auf ruhende Körper ausgeübten ponderomotorischen Kräfte," Ann. Phys. (Leipzig) 26, 541-550 (1908); English translation in The Collected Papers of Albert Einstein, Vol. 2 (Princeton University Press, Princeton, NJ, 1989). In evaluating the force, Mansuripur uses the field \(\mathbf{H}\) due to \(q\) (see Eq. 12b in Ref. 1); his \(\mu_{0} \mathbf{H}\) is our B (Eq. 3).
\({ }^{22}\) The \(i\) th component of the second term is \((\mathbf{B} \cdot \boldsymbol{\nabla}) M_{i}=\) \(\boldsymbol{\nabla} \cdot\left(M_{i} \mathbf{B}\right)-M_{i} \boldsymbol{\nabla} \cdot \mathbf{B}=\boldsymbol{\nabla} \cdot\left(M_{i} \mathbf{B}\right)\).
\({ }^{23}\) B. D. H. Tellegen, "Magnetic-dipole models," Am. J. Phys. 30, 650-652 (1962). Tellegen's force (6), which assumes a Gilbert magnetic dipole, can be obtained by integrating the magnetization-dependent terms in the Einstein-Laub force density in which it is assumed that \(\mathbf{M}=\mathbf{m} \delta^{3}\left(\mathbf{r}-\mathbf{r}_{0}\right)\). Another derivation of the force on a Gilbert magnetic dipole is by A. D. Yaghjian, "Electromagnetic forces on point dipoles," IEEE Anten. Prop. Soc. Symp. 4, 2868-2871 (1999).

\section*{Electric|Magnetic Dipole Moments}

This § is referenced at pages:
[1812, 1812, 1834, 1834, 1854, 1854, 1878, 1878, 2632, 2632]
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|5.6||
The Electric Dipole moment is independent from the origin of the Coordinate System for all systems with zero total charge: \(\iiint \rho \mathrm{d} V=0\).
The Magnetic Dipole moment is independent from the origin of the Coordinate System for all systems with \(\iiint \mathbf{j} \mathrm{d} V=0\). A sufficient condition is a steady current distribution ( \(\mathbf{d i v} \mathbf{j}=0\) ) with compact support. The Electric|Magnetic field of ideal Electric|Magnetic Dipoles are identical.
The Electric|Magnetic field of real Electric|Magnetic Dipoles are identical at large distances. At short distances the fields are very different. In particular the fields at and near the center are opposite in the two cases. See figure 38.1.
Read § 61.12 - Thermodynamics in Action for a general discussion of the energetic aspects.

Figure 38.1: Difference of near fields between real Electric|Magnetic Dipoles.

© ©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|23||
According to the statements in §33.05.02 - Basic Laws of ElectroMagnetism the forces on Dipoles in external (applied) fields, in a static situation and away from the Charge|Current producing the external ElectroMagnetic fields, can be written as the equivalent expressions:
\begin{tabular}{|ll|}
\hline \(\mathbf{f}_{\mathrm{E}}=(\mathrm{p} \cdot \operatorname{grad}) \mathbf{E}\) & \(\mathbf{f}_{\mathrm{E}}=\operatorname{grad}(\mathrm{p} \cdot \mathbf{E})\) \\
\hline \hline \(\mathbf{f}_{\mathrm{M}}=(\mathrm{m} \cdot \operatorname{grad}) \mathbf{B}\) & \(\mathbf{f}_{\mathrm{M}}=\operatorname{grad}(\mathrm{m} \cdot \mathbf{B})\) \\
\hline
\end{tabular}
where in the right-most expressions the Dipole moments must always be considered fixed with respect to the gradient operator, that is non differentiated.
It must be emphasized that in the above expressions the fields are the external fields, excluding the fields produced by the Dipoles themselves.
The equivalence of the two expressions under the given hypotheses is ensured by the fact that the hypotheses imply that both the external Electric|Magnetic fields are irrotational:
\[
\frac{\partial E_{k}}{\partial x_{j}}=\frac{\partial E_{j}}{\partial x_{k}} \quad \frac{\partial B_{k}}{\partial x_{j}}=\frac{\partial B_{j}}{\partial x_{k}}
\]
and by the fact that the Dipole moments are considered as fixed constants, that is non differentiated.
Read § 61.12 - Thermodynamics in Action for a general discussion of the energetic aspects.

\subsection*{38.02.01 Linearly Polarizable|Magnetizable Entities in Static Conditions}

This § is referenced at pages:
[1785, 1785]
Consider electrically neutral linearly Polarizable|Magnetizable entities, with no intrinsic Dipole moment and whose induced Dipole moment is written in terms of the external (applied) fields, \(\mathbf{E}\) and|or \(\mathbf{B}\), as:
\[
\mathrm{p}=\left(\alpha_{\mathbf{E}} \varepsilon_{0}\right) \mathbf{E} \quad \mathrm{m}=\left(\alpha_{\mathrm{M}} / \mu_{0}\right) \mathbf{B}
\]

It must be clear that the external (applied) fields, \(\mathbf{E}\) and|or \(\mathbf{B}\), are the total fixed fields acting on the entity and produced by external and far-away generators, producing the fixed external fields that is fixed charges and|or fixed currents.
As the generators of the external (applied) fields are outside the region of interest and the situation is a static one the forces can be written as:
\[
\begin{aligned}
\mathbf{f}_{\mathrm{E}} & =(\mathrm{p} \cdot \mathbf{g r a d}) \mathbf{E}=\left(\varepsilon_{0} \alpha_{\mathrm{E}}\right)(\mathbf{E} \cdot \mathbf{g r a d}) \mathbf{E}, \\
\mathbf{f}_{\mathrm{M}} & =(\mathrm{m} \cdot \mathbf{g r a d}) \mathbf{B}=\left(\alpha_{\mathrm{M}} / \mu_{0}\right)(\mathbf{B} \cdot \mathbf{g r a d}) \mathbf{B}, \\
\left\{\mathbf{f}_{\mathrm{E}}\right\}_{k} & =\mathrm{p}_{r} \boldsymbol{\nabla}_{r} E_{k}=\left(\varepsilon_{0} \alpha_{\mathrm{E}}\right) E_{r} \boldsymbol{\nabla}_{r} E_{k}=\left(\varepsilon_{0} \alpha_{\mathrm{E}}\right) E_{r} \boldsymbol{\nabla}_{k} E_{r}=\frac{\varepsilon_{0} \alpha_{\mathrm{E}}}{2} \nabla_{k} \mathbf{E}^{2} \Longrightarrow \mathbf{f}_{\mathrm{E}}=\frac{\varepsilon_{0} \alpha_{\mathrm{E}}}{2} \nabla \mathbf{E}^{2}, \\
\left\{\mathbf{f}_{\mathrm{M}}\right\}_{k} & =\mathrm{m}_{r} \boldsymbol{\nabla}_{r} B_{k}=\left(\alpha_{\mathrm{M}} / \mu_{0}\right) B_{r} \nabla_{r} B_{k}=\left(\alpha_{\mathrm{M}} / \mu_{0}\right) B_{r} \boldsymbol{\nabla}_{k} B_{r}=\frac{\alpha_{\mathrm{M}}}{2 \mu_{0}} \nabla_{k} \mathbf{B}^{2} \Longrightarrow \mathbf{f}_{\mathrm{M}}=\frac{\alpha_{\mathrm{M}}}{2 \mu_{0}} \nabla \mathbf{B}^{2} .
\end{aligned}
\]

First note that the gradient of the square of a field is always directed pointing to where the module of the field increases.

The above results imply that:
- Polarizable media are always attracted towards the region where the electric field is most intense, as the polarisability is always positive;
- Magnetizable media are attracted towards the region where the magnetic field is most intense, if their magnetisability is positive (paramagnetic media), while they are repelled away from the region where the magnetic field is most intense, if their magnetisability is negative (diamagnetic media).
The energy energy of a Polarizable|Magnetizable Dipole in an external (applied) field is thus:
\[
\mathrm{p} \propto \mathbf{E} \Longrightarrow U_{\mathrm{E}}=-\frac{\mathrm{p} \cdot \mathbf{E}}{2} \quad \mathrm{~m} \propto \mathbf{B} \Longrightarrow U_{\mathrm{M}}=-\frac{\mathrm{m} \cdot \mathbf{B}}{2}
\]

The factor 2 with respect to the case of a fixed Dipole should be noted.
It is also important to stress that:
- in the electric case, this is the total energy, not the potential energy, because, while building the system, some energy is stored as internal energy;
- in the magnetic case, this is not the total energy, because, in order to keep the external magnetic field fixed while building the system, the external generator must do some work which has not been accounted here.
© - QUOTE
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|§ 15.1, 15.2|Full explanation
The magnetic energy of a Dipole \(U=-\mathrm{m} \cdot \mathbf{B}\) may not include all the energy of the system (it is a fake kind of energy) but it gives the correct expression for the forces on a steady current distribution!
The total (true) energy of the world is: \(+\mathrm{m} \cdot \mathbf{B}\). It is only if we assume that all currents are constant that we can use only a part of the total energy, \(-\mathrm{m} \cdot \mathbf{B}\), to find the mechanical forces.

Read § 35.10.08 - Electric Properties of Matter and section § 36.10.05 - Magnetic Properties of Matter for the Polarizability|Magnetizability of a spherical piece of material.

\subsection*{38.02.01.01 Energy Balance}

This § is referenced at pages:
[2630, 2630]

\section*{Energy Balance for a Model Polarizable Molecule}

Model the Polarized molecule as two opposite-sign charge distributions and the restoring force between the positive and negative charges of the molecule by a linear (elastic spring-like) restoring force, which is actually of ElectroMagnetic origin. In fact, the stable equilibrium condition of the molecule, corresponding to zero Polarization, is distorted by the external electric field, and the restoring force is linear for small displacements.
Define the system as the Polarized molecule with an induced Electric Dipole, that is, the two equal and opposite charge distributions have absolute value \(|q|\), and centers of charge separated by a distance \(\Delta \ell\).
The change of total energy of the system is given by the total work made on the system: the work done by the external forces plus the work done by the internal forces. The spring models the internal restoring force, of ElectroMagnetic origin. The contribution of the spring can be accounted for either as work done by the internal forces, modeled by the elastic spring or as internal (elastic-like) potential energy of the spring, \(U_{\mathrm{k}}\).
Consider the work, \(\mathrm{d} \mathcal{W}_{\mathrm{E}}\), made by an external agent to build the system, by a quasi-static process. The molecule, when un-Polarized, has zero internal (elastic-like) potential energy.

The first principle of thermodynamics gives:
\[
\mathrm{d} U_{\mathrm{EM}}=\mathrm{d} \mathcal{W}_{\mathrm{E}}+\mathrm{d} \mathcal{W}_{\mathrm{I}} \Longrightarrow \mathrm{~d} U_{\mathrm{EM}}-\mathrm{d} \mathcal{W}_{\mathrm{I}}=\mathrm{d} U_{\mathrm{EM}}+\mathrm{d} U_{\mathrm{k}}=\mathrm{d} \mathcal{W}_{\mathrm{E}}=\mathbf{f} \cdot \mathrm{d} \mathbf{r}+\boldsymbol{\gamma} \cdot \mathrm{d} \boldsymbol{\theta}
\]
where \(\mathbf{f}, \gamma\) and \(\mathrm{d} \mathcal{W}_{\mathrm{E}}\) are the force, torque and work by the external agent to keep the system at equilibrium at any time (a quasi-static process), that is to say the opposite of the Force|Torque acted on the system by the external field; \(\mathrm{d} U_{\mathrm{EM}}\) is the ElectroStatic interaction energy between the Dipole and the external field.
At equilibrium, with the induced Dipole aligned with the external field, every charge is in equilibrium under the effect of the electric field (assumed to be the same at the position of the two charges) and the force of the spring. One has:
\[
\begin{gathered}
k \Delta \ell=|q| E, \\
\mathrm{p} \| \mathbf{E}, \\
\mathcal{W}_{\mathrm{E}}=\frac{1}{2} k(\Delta \ell)^{2}+q\left(\Phi\left[\mathbf{r}_{+}\right]-\Phi\left[\mathbf{r}_{-}\right]\right)=\frac{1}{2} k(\Delta \ell)^{2}-\mathrm{p} E=\frac{1}{2} \frac{(k \Delta \ell)^{2}}{k}-\mathrm{p} E=\frac{1}{2} \frac{(q E)^{2}}{k}-\mathrm{p} E=\frac{1}{2} \mathrm{p} E-\mathrm{p} E=-\frac{1}{2} \mathrm{p} E, \\
\mathcal{W}_{\mathrm{E}}=-\frac{1}{2} \mathrm{p} E=U_{\mathrm{k}}+U_{\mathrm{EM}} .
\end{gathered}
\]

The pure ElectroStatic energy is the same for both a rigid and a Polarizable Dipole: it is, in fact, a purely positional potential energy and it cannot depend on the way the configuration was obtained.
The internal elastic energy, of ElectroMagnetic origin and modeled as spring, is a part of the internal energy.
In the energy balance, the total energy must be considered, as the Dipole is unavoidably Polarized when going into the external field. The addition of the spring, modeling the internal energy, provides the overall energy balance.
The above approach is often called the virtual work principle. Therefore in the use of the virtual work principle the total energy of the system must be used.
The expression above with \(k\) at denominator allow to recover the case of the rigid Dipole, \(k \rightarrow \infty\), where the first term (spring potential energy) is negligible.

\subsection*{38.02.02 Forces on a Linearly Polarizable|Magnetizable Entities in Static External (Applied) Fields}

This § is referenced at pages:
[1321, 1321, 1321, 1321, 1695, 1695, 1696, 1696, 1833, 1833, 1935, 1935]
Read § 38.05 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.
Consider a static situation with the generators of the external (applied) fields outside the region of interest.
In a static situation a Polarized/Magnetized medium placed inside an external field, \(\mathbf{E}_{0}\) or \(\mathbf{B}_{0}\), produced by fixed Charge|Currents located far-away from the region where the bodies are placed, is acted on by a total force per unit volume given by:
\[
\begin{aligned}
& \frac{\mathrm{d} \mathbf{F}_{\mathrm{E}}}{\mathrm{~d} V}=(\mathbf{P} \cdot \mathbf{g r a d}) \mathbf{E}_{0} \\
& \frac{\mathrm{~d} \mathbf{F}_{\mathrm{M}}}{\mathrm{~d} V}=(\mathbf{M} \cdot \mathbf{g r a d}) \mathbf{B}_{0} .
\end{aligned}
\]

Note that the fields produced by the bodies do not enter the expression for the total force because they give rise to internal forces with zero sum. However, if the bodies are not rigid, the internal forces may contribute to the deformation of the bodies.
38.02.03 Examples

\subsection*{38.02.03.01 Microscopic Explanation of Attraction of Linear Media Towards Intense Fields}

Any piece of LHI Polarizable material is attracted into a free-space capacitor because of the net force on the induced Electric Dipoles. In fact the electric field outside the capacitor Polarized the material and every induced microscopic Electric Dipole is attracted towards the regions where the field is most intense.
The same explanation obviously apply to attraction of paramagnetic materials towards a magnet.

38.03.01 Free/Polarization Charges and Free/Polarization|Magnetization Currents

This § is referenced at pages:
[1789, 1789, 1789, 1789, 1925, 1925]
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|pag. 347||

Read also § 34.02.02 - Electric|Magnetic Properties of Matter.
Read also § 38.11.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.

The distinction between free and Polarization charges and among free, Polarization and Magnetization currents has some degree of arbitrariness. That is: different choices may be possible, all of them giving rise to the same macroscopic Electric|Magnetic fields. In fact macroscopic Electric|Magnetic fields are observable physical quantities, only depending on the Charge|Currents distributions, not on the way we choose to describe Charge|Current distributions.

Usually Polarization and Magnetization refer to inaccessible charges and|or currents.
Note that after introducing the Polarization charge density and Magnetization current, consistency between Maxwell Equations and charge conservation forces to introduce a Polarization current, as in section \(\S 35.02 .04\) - Electric Properties of Matter.

In general one decides which charges are described as Polarization charges, normally bound, that is inaccessible charges, and all the remaining charges must then be treated as free charges. One has to be careful to count all charges one and only one time. The definition of free and Polarization currents follows consequently.

Consider the following examples.
- Consider for instance a ionic crystal, away from external electric fields.

It can be described as zero Polarization.
However, it can be also described in terms of a Polarization vector, that is a density of Electric Dipole moment, plus free charges. In fact there can be different groupings of one positive ion with one negative ion to produce an Electric Dipole. Different groupings give rise to different Polarization vectors. All groupings leave some ungrouped ions at the surface, that is a surface distribution of free charges. The volume density is zero for these uniform Polarization. The surface Polarization charge density is calculated from the Polarization and it is at any point equal and opposite to the surface free charge density.
- Consider a solid metallic conductor.

One possibility is to define all the charges as Polarization charges, with the free conduction electrons considered as bound electrons with a vanishingly small bound strength.
A second possibility is to describe the free conduction electrons as free charge. In this case, however, it is appropriate to include in the free charges also the positive charge of the reticular ions necessary to make the overall free charges a neutral one; that is, one positive charge from nuclei for each free electron. In this way also the remaining charges, that is the bound electrons plus the corresponding positive charges, constitute a neutral system, the Electric Dipole moment is independent of the origin. The free current is thus given by the electron drift velocity plus the positive ion charge drift
velocity, often equal to zero.
- A similar discussion might apply to an electrolytic solutions, with the positive ion charge drift velocity different from zero.
A similar type of arbitrariness exists for the Magnetization currents, normally bound, that is inaccessible currents, whose charges are not accounted for as free charges. One might, for instance, describe the currents produced by the orbital electrons not only as a Magnetization currents but also as a free currents, if the electrons are considered, and accounted for, as free charges.

\subsection*{38.03.01.01 Model Dependence}

In the end it is worth noting that the separation into free/bound Charge|Current ultimately requires a model for the medium, and hence the introduction of \(\mathbf{D}\) and \(\mathbf{H}\) is model dependent. Accordingly, the validity Maxwell equations written in terms of \(\mathbf{D}\) and \(\mathbf{H}\) is model dependent, it relies on assumptions about the properties of the medium and requires supplementary information to give it a meaning.

\subsection*{38.03.02 Maxwell Equations in Presence of Matter}

The Maxwell Equations in presence of matter, written in differential form and applicable in all the cases when the fields and Charge|Current producing the ElectroMagnetic fields are, from the mathematical point of view, sufficiently well-behaved functions, read:

The Maxwell Equations must be complemented with the charge conservation law, equation (33.07.09), which is, however, implied by Maxwell Equations:
\[
\begin{equation*}
\operatorname{div} \mathbf{j}^{\mathrm{F}}+\partial_{t} \rho^{\mathrm{F}}=0 \tag{38.03.01}
\end{equation*}
\]

Moreover, by definition of Polarization Charge|Current and Magnetization currents, one has always the identities:
\[
\begin{array}{c|} 
\\
\hline \boldsymbol{\operatorname { d i v }} \mathbf{j}^{\mathrm{P}}+\partial_{t}{ }_{\mathrm{t}}^{\mathrm{P}}=0 \\
\quad \text { by definition of } \mathbf{j}^{\mathrm{M}} \text { as a rotor }
\end{array}
\]

The above relations make clear that all charges must be partitioned into the two sets of free/Polarization charges and can never change it. Moreover, Magnetization currents ar not linked to any Magnetization charge.
Note that when writing Maxwell equations, ((38.03.02), (38.03.02), (38.03.02), (38.03.02)), in terms of \(\mathbf{D} / \mathbf{H}\) and free Charge|Current (as in equations (38.03.02), (38.03.02), (38.03.02), (38.03.02)) the charge continuity equation is written in terms for the free Charge|Current and not in terms of the total Charge|Current.

\subsection*{38.03.03 Auxiliary ElectroMagnetic Fields Vectors}

\subsection*{38.03.03.01 Practical Use}

The auxiliary vector \(\mathbf{D}\) is of little practical usage because what one normally controls is the macroscopic potential difference, which is linked to the electric field \(\mathbf{E}\).
The auxiliary vector \(\mathbf{H}\) is more useful because what one normally controls is the macroscopic current, which is linked to the vector field \(\mathbf{H}\).
38.03.03.02 Case of Magnetic Field: The Two Magnetic Field Vectors

This § is referenced at pages:
[1683, 1683]
Several facts support the idea of \(\mathbf{B}\) begin the fundamental magnetic field, justifying naming it the magnetic field.
- The fields \(\mathbf{E}\) and \(\mathbf{B}\) appear in the Lorentz force.
- The fields \(\mathbf{E}\) and \(\mathbf{B}\) appear in the two homogeneous Maxwell equations, those defining the structural properties of the ElectroMagnetic fields, with no reference to Charge|Current; as a consequence, \(\mathbf{E}\) and \(\mathbf{B}\) are related to the ElectroMagnetic potentials and to the ElectroMagnetic field tensor.
- The appearance of \(\mathbf{D}\) and \(\mathbf{H}\) in Maxwell equations is in the presence of free Charge|Current; however, it is known that the separation of Charge|Current into free and bound Charge|Current can be ambiguous, at least in some circumstances; see for instance § 38.03.01 - ElectroMagnetism Miscellaneous Complements Applications and Phenomenology. So, for instance, different legitimate choices for what is free/bound may lead to different \(\mathbf{D} / \mathbf{H}\) fields.

\section*{Relativistic Covariance}
© \(\mid\) M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|1.1||
The four Maxwell Equations can be divided into two sets: the homogeneous equations (involving \(\mathbf{E}\) and B) and the non-homogeneous ones (involving \(\mathbf{D}\) and \(\mathbf{H}\) as well as the charge and current densities).

If a Lorentz Transformation is carried on, and charge and current densities transform as a four-vector, the two sets of equations keep the same form and do not mix provided the two pairs \(\{\mathbf{E}, \mathbf{B}\}\) and \(\{\mathbf{D}, \mathbf{H}\}\) form a anti-symmetrical four-tensor of rank two (read §56-ElectroMagnetism and Relativity).
Since the non-homogeneous set contains Charge|Current, which represent the influence of matter, one is forced to attribute the corresponding pair \(\{\mathbf{D}, \mathbf{H}\}\) to the influence of matter.

\subsection*{38.03.04 Electric-Permittivity Versus Magnetic-Permeability in LHI Media}

The Electric-Permittivity | Magnetic-Permeability of LHI media show a basic difference.

\section*{Electric LHI Materials}

It can be shown that the Electric-Permittivity must be, for static fields:
\[
\epsilon_{\mathrm{R}} \geq 1
\]

This implies:
\[
\chi_{\mathrm{E}} \geq 0
\]

Note that \(\mathbf{P}\) and \(\mathbf{E}\) are always parallel as \(\chi_{\mathrm{E}} \geq 0\).
Note that \(\mathbf{D}\) and \(\mathbf{E}\) are always parallel as \(\epsilon_{\mathrm{R}} \geq 1\).

\section*{Magnetic LHI Materials}

It can be shown that the Magnetic-Permeability must be, for static fields:
\[
\mu_{\mathrm{R}} \geq 0
\]

This implies, with equation (36.06.04):
\[
\chi_{M}^{*} \geq-1 \quad \Leftrightarrow \quad \chi_{M} \leq+1
\]

Equation (36.06.04) implies that \(\chi_{M}\) and \(\chi_{M}^{*}\) always have the same sign:
\[
\chi_{\mathrm{M}} \chi_{\mathrm{M}}^{*}>0
\]

A diamagnetic material has thus:
\(-1 \leq \chi_{\mathrm{M}}^{*} \leq 0 \quad\) and \(\quad-\infty \leq \chi_{\mathrm{M}} \leq 0 \quad \mathbf{M}\) anti-parallel to both \(\mathbf{H}\) and \(\mathbf{B}\), diamagnetic

A paramagnetic material has thus:
\[
0 \leq \chi_{M}^{*} \leq+\infty \quad \text { and } \quad 0 \leq \chi_{M} \leq+1 \quad \text { M parallel to both } \mathbf{H} \text { and } \mathbf{B}, \text { paramagnetic }
\]

Note that \(\mathbf{H}\) and \(\mathbf{B}\) are always parallel as \(\mu_{R} \geq 0\) :
\[
\mathbf{H} \cdot \mathbf{B} \geq 0
\]

\subsection*{38.03.05 Comparison Between the Equations of ElectroStatics and MagnetoStatics}

This § is referenced at pages:
[1719, 1719, 1719, 1719, 1878, 1878, 1878, 1878]

\subsection*{38.03.05.01 Rigid Polarization|Magnetization}

A genreric material may have a rigid, that is independent of external (applied) fields, Polarization and|or Magnetization (ferro-electric materials and ferro-magnetic materials).

In this case the three electric vectors, \((\mathbf{E}, \mathbf{P}\) and \(\mathbf{D})\), and or the three magnetic vectors, \((\mathbf{B}, \mathbf{M}\) and \(\mathbf{H})\), need not be parallel, and are not parallel in general, like in ferro-electric materials and ferro-magnetic materials.
Let us denote by \(\mathbf{F}_{\mathrm{R}} \rightarrow\) rigid field a rigid field, that is independent of external (applied) fields, and by \(\mathbf{F}_{\mathrm{I}} \rightarrow\) induced field and induced field.

We can write:
\[
\begin{array}{rlrl}
\mathbf{P} & =\mathbf{P}_{\mathrm{I}}+\mathbf{P}_{\mathrm{R}} & \mathbf{M} & =\mathbf{M}_{\mathrm{I}}+\mathbf{M}_{\mathrm{R}}, \\
\mathbf{P}_{\mathrm{I}} & =\left(\varepsilon_{0}-1\right) \varepsilon_{0} \mathbf{E} \equiv \chi_{\mathbf{E}} \varepsilon_{0} \mathbf{E} & \mathbf{M}_{\mathrm{I}} & =\left(1-\frac{1}{\mu_{\mathrm{R}}}\right) \frac{\mathbf{B}}{\mu_{0}} \equiv \chi_{\mathrm{M}} \frac{\mathbf{B}}{\mu_{0}}, \\
\mathbf{D} & =\varepsilon_{0} \mathbf{E}+\mathbf{P}=\epsilon_{\mathrm{R}} \varepsilon_{0} \mathbf{E}+\mathbf{P}_{\mathrm{R}} & \mathbf{H}=\frac{\mathbf{B}}{\mu_{0}}-\mathbf{M}=\frac{\mathbf{B}}{\mu_{\mathrm{R}} \mu_{0}}-\mathbf{M}_{\mathrm{R}} .
\end{array}
\]

\subsection*{38.03.05.02 ElectroStatics and MagnetoStatics Without Free Charge|Current}

The equations of ElectroStatics and MagnetoStatics in absence of free Charge|Current show a formal correspondence, to within the dimensional constants \(\varepsilon_{0}\) and \(\mu_{0}\). In order to simplify the correspondence getting rid of the irrelevant dimensional constants, one might consider the re-scaled ElectroMagnetic fields:
\[
\mathbf{E}^{\prime} \equiv \varepsilon_{0} \mathbf{E} \quad \mathbf{B}^{\prime} \equiv \mathbf{B} / \mu_{0}
\]

The equations of ElectroStatics and MagnetoStatics in absence of free charges and currents read:
\[
\begin{aligned}
& \mathbf{D}=\varepsilon_{0} \mathbf{E}+\mathbf{P} \equiv \mathbf{E}^{\prime}+\mathbf{P} \Longrightarrow \varepsilon_{0} \mathbf{E} \equiv \mathbf{E}^{\prime}=\mathbf{D}-\mathbf{P}, \\
& \mathbf{H}=\mathbf{B} / \mu_{0}-\mathbf{M} \equiv \mathbf{B}^{\prime}-\mathbf{M} \Longrightarrow \mathbf{B} / \mu_{0} \equiv \mathbf{B}^{\prime}=\mathbf{H}+\mathbf{M} \quad, \\
& \operatorname{rot} \mathrm{E}^{\prime}=0 \Longrightarrow \operatorname{rot} \mathrm{D}=\operatorname{rot} \mathbf{P}, \\
& \operatorname{rot} \mathrm{H}=0 \Longrightarrow \operatorname{rot}^{\prime}=\boldsymbol{\operatorname { r o t }} \mathrm{M} \text {, } \\
& \begin{aligned}
\operatorname{div} \mathbf{D} & =0 \Longrightarrow \operatorname{div} \mathbf{E}^{\prime}=-\operatorname{div} \mathbf{P} \\
\operatorname{div} \mathbf{B}^{\prime} & =0 \Longrightarrow \operatorname{div} \mathbf{H}=-\operatorname{div} \mathbf{M}
\end{aligned},
\end{aligned}
\]

These equations can be applied at any point except where there are discontinuities in the physical properties of the media and|or discontinuities of the fields.

The formal correspondence is obvious:
\begin{tabular}{|lll|}
\hline \begin{tabular}{|lll}
\hline \(\mathbf{E}^{\prime}\) & \(\Leftrightarrow\) & \(\mathbf{H}\) \\
\hline \(\mathbf{P}\) & \(\Leftrightarrow\) & \(\mathbf{M}\) \\
\hline \(\mathbf{D}\) & \(\Leftrightarrow\) & \(\mathbf{B}^{\prime}\) \\
\hline
\end{tabular},
\end{tabular}

Thanks to the formal parallel between \(\mathbf{E}\) and \(\mathbf{H}\) the standard definitions of Electric|Magnetic susceptibility and Magnetic-Permeability |Electric-Permittivity are formally symmetrical even if from the physical point of view the analogy is between the basic fields \(\mathbf{E}\) and \(\mathbf{B}\).

\subsection*{38.03.05.03 Fictitious Magnetic Charge}

The formal parallelism can be pushed forward from equation (38.03.05.02), equation (38.03.05.02) and equations (38.03.05.02). The concept of magnetic charge (source of \(\mathbf{H}\) ) can be formally introduced in parallel with the concept of (total) electric charge (source of \(\mathbf{E}\) ):
\begin{tabular}{|c|}
\hline\(\tilde{\rho}=-\operatorname{div} \mathbf{M}\) \\
\(\tilde{\rho}_{\mathrm{S}}=\mathbf{M} \cdot \mathbf{n}\) \\
\end{tabular}

This concept is useful, for instance, in order to understand the behavior of field lines in permanent magnets.
One should keep in mind that the magnetic charge is just a fictitious and formal entity. As far as we now today real magnetic charges do not exist.
When the concept of magnetic charge is introduced the concept of de-Magnetizing \(\mathbf{H}\) field becomes obvious and parallel to the electric case.

\subsection*{38.03.05.04 Generators of the Auxiliary Fields in ElectroStatics and MagnetoStatics}

Note that equations (38.03.05.02), (38.03.05.02) show clearly that the auxiliary fields \(\mathbf{D}\) and \(\mathbf{H}\) do not depend only on the free charges and currents but, in general, they also depend on the Polarization and Magnetization. In fact to determine any vector field, in general, the knowledge of both divergence and rotor is required and equations (38.03.05.02), (38.03.05.02) show indeed the dependence of \(\mathbf{H}\) on the Magnetization and the dependence of \(\mathbf{D}\) on the Polarization.
However it is possible that some problems with a high degree of symmetry allow their solution by using only one of the two equations: either divergence or rotor equation, in differential form; either flux or circulation equation, in integral form.

\subsection*{38.03.06 ElectroMagnetic Fields Inside a Cavity in a Material Medium}

This § is referenced at pages:
[1836, 1836, 1836, 1836, 1885, 1885, 1885, 1885]
Note that carving out a cavity in a Polarized/Magnetized medium is equivalent to superimposing an object of the same shape of the cavity but with opposite Polarization|Magnetization.

\subsection*{38.03.06.01 Electric Case}

The electric field inside an ideal cavity in a Polarizable medium, \(\mathbf{E}_{c}\), can be expressed in terms of the average macroscopic field in matter, \(\mathbf{E}\), as
\[
\mathbf{E}_{\mathrm{c}}=\mathbf{E}+\gamma \frac{\mathbf{P}}{\varepsilon_{0}} \quad \mathbf{D}_{\mathrm{c}}=\mathbf{D}+\gamma_{D} \mathbf{P}
\]
where \(\gamma\) is a factor depending on the shape of the cavity:
\begin{tabular}{|c|c|c|} 
long thin cylinder (pipe or needle) parallel to \(\mathbf{E}\) & \begin{tabular}{c}
\(\gamma=0\) \\
sphere
\end{tabular} & \(\gamma_{D}=-1\) for \(\mathbf{D}\) \\
short large cylinder (disk or wafer) perpendicular to \(\mathbf{E}\) & \(\gamma=1 / 3\) & \(\gamma_{D}=-2 / 3\) for \(\mathbf{D}\) \\
\(\gamma=1\) & \(\gamma_{D}=0\) for \(\mathbf{D}\)
\end{tabular}

It can be easily shown that:
\[
\gamma_{D}=\gamma-1 .
\]

\subsection*{38.03.06.02 Magnetic Case}

The magnetic field inside an ideal cavity in a Magnetizable medium, \(\mathbf{B}_{\mathbf{c}}\), can be expressed in terms of the average macroscopic field in matter, \(\mathbf{B}\), as
\[
\mathbf{B}_{\mathrm{c}}=\mathbf{B}+\gamma \mu_{0} \mathbf{M} \quad \mathbf{H}_{\mathbf{c}}=\mathbf{H}+\gamma_{H} \mathbf{M}
\]
where \(\gamma\) is a factor depending on the shape of the cavity:
\begin{tabular}{|c|c|c|} 
long thin cylinder (pipe or needle) parallel to \(\mathbf{B}\) & \(\gamma=-1\) & \(\gamma_{H}=0\) for \(\mathbf{H}\) \\
sphere & \(\gamma=-2 / 3\) & \(\gamma_{H}=1 / 3\) for \(\mathbf{H}\) \\
short large cylinder (disk or wafer) perpendicular to \(\mathbf{B}\) & \(\gamma=0\) & \(\gamma_{h}=1\) for \(\mathbf{H}\)
\end{tabular}

It can be easily shown that:
\[
\gamma_{D}=\gamma+1
\]

\subsection*{38.03.06.03 Analogies and Differences Between the Electric and the Magnetic Case}

For a Polarized sphere the electric field generated by the matter inside the sphere is always anti-parallel to the Polarization:
\[
\mathbf{E}_{\mathrm{I}}=-\frac{\mathbf{P}}{3 \varepsilon_{0}}
\]

For a Magnetized sphere the magnetic field generated by the matter inside the sphere is always parallel to the Magnetization:
\[
\mathbf{B}_{\mathrm{I}}=+\frac{2 \mu_{0} \mathbf{M}}{3}
\]

For a sphere of an LHI material in an external uniform Electric|Magnetic field the field inside the sphere is given by:
\[
\begin{equation*}
\mathbf{E}=\frac{3}{\epsilon_{\mathrm{R}}+2} \mathbf{E}_{0} \quad \mathbf{B}=\frac{3 \mu_{\mathrm{R}}}{\mu_{\mathrm{R}}+2} \mathbf{B}_{0} \tag{38.03.02}
\end{equation*}
\]

Note the following two limiting cases, from equations (38.03.02).
A perfect conductor can be considered as a electric material with infinite polarisability: equations (38.03.02) implies \(\mathbf{E}=0\), when \(\chi_{\mathrm{E}} \rightarrow+\infty\left(\epsilon_{\mathrm{R}} \rightarrow+\infty\right)\). In a perfect conductor free charges move in such a way to cancel the internal electric field.
A perfect diamagnet can be considered as a magnetic material with zero magnetisability: equations (38.03.02) implies \(\mathbf{B}=0\), when \(\chi_{\mathrm{M}} \rightarrow-\infty\left(\mu_{\mathrm{R}} \rightarrow 0\right)\). In a perfect diamagnet free currents start in such a way to cancel the internal magnetic field.

\subsection*{38.03.07 Properties of LH Media}

The following properties only apply to linear and homogeneous media. They do not apply to media with other constitutive relations, such as media with rigid Polarization|Magnetization.
Note that isotropy is not required but we will only consider, for simplicity, the case of an isotropic medium, as the generalization is straightforward.

\subsection*{38.03.07.01 Volume Charge|Current Density in LH Media}

In electric LH media one can easly show that:
\[
\rho^{\mathrm{F}} \propto \rho^{\mathrm{P}} \propto \rho
\]

In magnetic LH media, in static conditions (this is an essential hypotesis), one can easly show that:
\[
\text { in static conditions: } \partial_{t}=0 \quad \Longrightarrow
\]
\[
\mathbf{j}^{\mathrm{F}} \propto \mathbf{j}^{\mathrm{M}} \propto \mathbf{j} \quad \text { in static conditions, such that } \mathbf{j}^{\mathrm{P}}=\partial_{t} \mathbf{P}=0 \text { and } \partial_{t} \mathbf{D}=0 \text {. }
\]

In conducting LH media (homogeneous Ohmic media), for harmonic dependence with frequency \(\omega\), one can easily show that:
\[
\mathbf{j}^{\mathrm{P}} \propto \omega \mathbf{E} \text {. }
\]
38.03.08 Non-Isotropic Media

It can be shown that the Electric|Magnetic susceptibility tensors are symmetrical. They can be diagonalized but note that a diagonal form of the susceptibility tensors in general does not imply at all that the \(\mathbf{E} / \mathbf{B}\) fields are parallel to the \(\mathbf{P} / \mathbf{M}\) fields, unless the coefficients are all identical. Actually when starting from non parallel fields a change of bases which just diagonalizes the matrix cannot make the two vector fields parallel.
©|A.Moliton|Basic Electromagnetism and Materials, § 4|Many Phenomenological Detalis|

\subsection*{38.04.01 Rigidly Polarized/Magnetized Bodies}

Rigid constitutive relations: \(\mathbf{P}\) and \(\mid\) or \(\mathbf{M}\) are fixed, independent of the external (applied) fields (permanent Polarization|Magnetization: ferro-electric and|or ferro-magnetic materials).

\subsection*{38.04.02 Time-Invariant Systems}

Even if not often stated, most constitutive relations concern time-invariant systems, read § 17.07 Linear Systems. This clearly excludes such phenomena as hysteresis and ageing.

\subsection*{38.04.03 Linearity}

Linearity does not require proportionality of the fields at any point is space or time but it is sufficient to have proportionality of the space and time Fourier components, that is to say the result is given by a convolution, for a generic scalar field:
\[
W[\mathbf{x}, t]=\iiint \int \chi\left[\mathbf{x}^{\prime}, t^{\prime}\right] V\left[\mathbf{x}-\mathbf{x}^{\prime}, t-t^{\prime}\right] \mathrm{d} t^{\prime} \mathrm{d} \mathbf{x}^{\prime}
\]
where \(\chi\left[\mathbf{x}^{\prime}, t^{\prime}\right]\) is non zero only near some region around \(\mathbf{x}^{\prime}=0\) and \(t^{\prime}=0\).

\subsection*{38.04.03.01 Time Dispersion}

This § is referenced at pages:
[Never referenced.]
The value of the field W at time \(t\) may depend on the values of the field V at all the times before \(t\), \(t^{\prime}<t\).

Causality implies:
\[
\chi\left[\mathbf{x}^{\prime}, t^{\prime}<0\right]=0
\]

\subsection*{38.04.03.02 Space Dispersion}

This § is referenced at pages:
[Never referenced.]
The value of the field W at point x may depend on the values of the field V at all the points around \(\mathbf{x}\), \(\left|\mathbf{x}^{\prime}-\mathbf{x}\right|<\Delta\). Spatial dispersion is normally negligible in ElectroMagnetic phenomena, except for special situations.

\subsection*{38.04.04 Hysteresis}

There are materials in which the Polarization|Magnetization depends not only on the actual Electric|Magnetic field intensity but on the sequence of preceding states as well: this phenomenon is called hysteresis.

\subsection*{38.04.05 General Constitutive Relations}

This § is referenced at pages:
[1201, 1201]

\subsection*{38.04.05.01 Macroscopic ElectroMagnetism}

In general:
\(\mathbf{P}=\mathbf{P}\{\mathbf{E}, \mathbf{B}\} \quad \mathbf{M}=\mathbf{M}\{\mathbf{B}, \mathbf{E}\} \quad \mathbf{j}=\mathbf{j}\{\mathbf{E}, \mathbf{B}\} \quad\) for conducting materials \(\quad\), (38.04.01)
The rotory brackets mean that the connections are not necessarily simple and may be nonlinear, non local in space or non local in time (for instance they may depend on past history: hysteresis). Read § 19.03 Some Miscellaneous Topics.
Therefore, To be generally correct, equations (38.04.01), should be understood as holding for the Fourier transforms in space and time of the field quantities, because the basic linear connections can be non-local.
Read § 19.03 - Some Miscellaneous Topics.

\subsection*{38.04.05.02 Microscopic ElectroMagnetism}

Including electro-magnetic and magneto-electric effects, equation (35.02.01.01), (36.02.01.01), the relations among local ElectroMagnetic fields and induced dipoles become:
\[
\binom{\mathrm{p} / \varepsilon_{0}}{\mathrm{~m} \mu_{0}}=\left(\begin{array}{cc}
\alpha_{\mathrm{ee}} & \alpha_{\mathrm{em}}  \tag{38.04.02}\\
\alpha_{\mathrm{me}} & \alpha_{\mathrm{mm}}
\end{array}\right)\binom{\mathbf{E}_{\mathrm{LOC}}}{\mathbf{B}_{\mathrm{LOC}}} .
\]

\subsection*{38.04.06 Molecules With a Permanent Electric|Magnetic Dipole Moment - Langevin Equation}

This § is referenced at pages:
[1809, 1809, 1824, 1824, 1852, 1852, 1869, 1869, 1948, 1948, 1948, 1948, 1950, 1950, 2632, 2632]
© |Am.J.Phys, , ..., ..., ...Ed., ...., Vol. 45, No. 10, October 1977 922|Polarization of a polar gas by external and internal electric fields||
The Clausius-Mossotti equation (sections § 35.09-Electric Properties of Matter and § 36.09 - Magnetic Properties of Matter) gives the relation between the susceptibility and Polarizability|Magnetizability based on the relation between the local field (acting on the single molecule) and the average macroscopic fields. It applies to substances which are isotropic on the macroscopic scale.
The Clausius-Mossotti equation was applied in sections § 35.09-Electric Properties of Matter and § 36.09-Magnetic Properties of Matter to substances whose molecules do not have a permanent Electric|Magnetic Dipole moment, but the final results, equations (35.09.01), (36.09.01), can be applied to the Polarizability|Magnetizability by orientation as well.
The Langevin equation gives the susceptibility of substances whose molecules have a permanent Electric|Magnetic Dipole moment. If the nearest neighbor interaction energies are small, a material made of molecules with a permanent Electric|Magnetic moments will normally have the Dipoles oriented randomly in the absence of an Electric|Magnetic field.

In a very strong field all the Dipoles will align with the Electric|Magnetic field, giving a maximum (saturation) Polarization/Magnetization. At smaller field strengths the thermal randomizing will oppose the alignment to some extent. The average Polarization/Magnetization may be found from statistical physics.
The Polarizability|Magnetizability by orientation follows the general definition in equations (35.02.01.01), (36.02.01.01). Clearly, in this case, the induced Polarizability|Magnetizability will be parallel to the external local field. In general one should use the local field, not the average macroscopic field, except for very low-density materials. However, for the sake of simplicity, let us consider, for simplicity, the case of very low-density materials: the generalization to dense LI materials is given by Clausius-Mossotti equations.

The energy of a single Dipole in an external field \(\mathbf{E} / \mathbf{B}\) is \(\varepsilon[\theta, \phi]=-\mathrm{p} \cdot \mathbf{E} / \varepsilon[\theta, \phi]=-\mathrm{m} \cdot \mathbf{B}\) which ranges from \(-\mathrm{p} E /-\mathrm{m} B\) to \(+\mathrm{p} E /+\mathrm{m} B\), depending on the orientation of the Dipole with respect to the field.

Statistical physics says that for any system in equilibrium at absolute temperature \(T\), the probability for having energy \(\varepsilon[\theta, \phi]\) is proportional to the Boltzmann factor (Boltzmann statistics):
\[
\exp \left[-\varepsilon / k_{\mathrm{B}} T\right] \quad \text { in terms of the fundamental constant } k_{\mathrm{B}}=1.38 \cdot 10^{-23} \mathrm{~J} / \mathrm{K}
\]

Consider an isotropic material whose molecules have a permanent Dipole moment.
The average energy, for a generic Dipole of moment \(g\) in an external field \(\mathbf{W}\), directed along the \(z\) axis, is then:
\[
\langle\varepsilon\rangle=\frac{\iint \varepsilon \exp \left[-\varepsilon / k_{\mathrm{B}} T\right] \mathrm{d} \varepsilon}{\iint \exp \left[-\varepsilon / k_{\mathrm{B}} T\right] \mathrm{d} \varepsilon} \quad \varepsilon=\varepsilon[\theta, \phi]
\]

The average Dipole moment along the \(z\) axis for a generic Dipole of moment \(g\) in an external field \(\mathbf{W}\), directed along the \(z\) axis, is then found by integrating on the solid angle:
\[
\left\langle\mathrm{g}_{z}\right\rangle=\langle\mathrm{g} \cos \theta\rangle=\frac{\iint \mathrm{g} \cos \theta \exp \left[\mathrm{~g} W \cos \theta / k_{\mathrm{B}} T\right] \mathrm{d} \phi \mathrm{~d}(\cos \theta)}{\iint \exp \left[\mathrm{g} W \cos \theta / k_{\mathrm{B}} T\right] \mathrm{d} \phi \mathrm{~d}(\cos \theta)}
\]

Langevin equation follows:
\[
\left\langle\mathrm{p}_{z}\right\rangle=\mathrm{p}\left(\operatorname{cth}\left[\frac{\mathrm{p} E}{k_{\mathrm{B}} T}\right]-\frac{k_{\mathrm{B}} T}{\mathrm{p} E}\right)
\]
\[
\left\langle\mathrm{m}_{z}\right\rangle=\mathrm{m}\left(\mathrm{cth}\left[\frac{\mathrm{~m} B}{k_{\mathrm{B}} T}\right]-\frac{k_{\mathrm{B}} T}{\mathrm{~m} B}\right) .
\]

It is common usage to introduce the dimensionless variable \(x\) :
\(\left\langle\mathrm{g}_{z}\right\rangle=\mathrm{g}\left(\operatorname{cth}[x]-\frac{1}{x}\right) \equiv \mathrm{g} L[x] \quad\) where \(L\) is the so-called Langevin Function \(\quad x=\left\{\frac{\mathrm{p} E}{k_{\mathrm{B}} T}, \frac{\mathrm{~m} B}{k_{\mathrm{B}} T}\right\}\)
At large fields and|or at low temperatures, all the molecules are lined-up and the material has thus a non-linear response. Ordinarily \(k_{\mathrm{B}} T\) is much greater than \(\mathrm{p} E / \mathrm{m} B\). In this regime the material has a linear response, and the first-order development of the Langevin Function gives:
\[
\left\langle\mathrm{g}_{z}\right\rangle \simeq \frac{\mathrm{g} x}{3}
\]

At low fields (and low-density) the Polarizability|Magnetizability follow:
\[
\alpha_{\mathrm{e}}=\frac{\mathrm{p}^{2}}{3 \varepsilon_{0} k_{\mathrm{B}} T} \quad \alpha_{\mathrm{m}}=\frac{\mu_{0} \mathrm{~m}^{2}}{3 k_{\mathrm{B}} T}
\]

The temperature dependence \(1 / T\) gives the so-called Curie law. Clearly Polarization|Magnetization by orientation has a strong temperature dependence, at variance with the Polarization|Magnetization by deformation.

In general the Polarizability|Magnetizability is the sum of the one due to deformation (always present) plus the one due to the permanent moment.

At high fields all Dipoles are aligned and the Polarization/Magnetization saturates.
In dense materials the distinction between the average field and the local field must be accounted for, as for Clausius-Mossotti equation.

The total energy, for \(N\) Dipoles, is given by:
\[
\mathscr{U = N \langle \varepsilon \rangle = - N \langle \mathrm { g } _ { z } \rangle W} \Longrightarrow\left\{\begin{array}{l}
\frac{\Delta \mathcal{U}}{\frac{\Delta V}{\Delta U}=-\left\langle P_{z}\right\rangle E} \\
\frac{\Delta \mathcal{U}}{\Delta V}=-\left\langle M_{z}\right\rangle B \\
\hline
\end{array}\right.
\]

\section*{Charges and Currents in External Static ElectroMagnetic Fields}

This \(\S\) is referenced at pages:
[1825, 1825, 1870, 1870, 1921, 1921]
Read § 38.02.02 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.
When one considers the effects of external ElectroMagnetic fields on either a charge or a current distribution as a whole one must neglect the effects of the ElectroMagnetic fields produced by the Charge|Current distribution on the same Charge|Current distribution itself. In fact the fields produced by the Charge|Current distribution itself have no effect on the global motion of the system, according to the cardinal equation of mechanics, as the resultant of the internal forces and the resultant of the internal torques are zero. These fields may actually have an effect on the internal dynamics of the Charge|Current distribution, unless the system is a rigid one, but they do not influence the linear momentum nor the angular momentum of the Charge|Current distribution. Their effect, in case of a non-rigid system, may cause deformation of the Charge|Current distribution.
Note also that a static electric field in a region without charges has the same mathematical properties of a static magnetic field in a region without currents. In fact both are fields with zero divergence and zero rotor.

Consider a localized stationary charge distribution in an external ElectroStatic field. The external ElectroStatic field is supposed to be stationary, that is the generators do what is required to keep it constant, whatever happens.
By direct computation the total force, due to the external electric field \(\mathbf{E}[\mathbf{r}]\), acting on a system of two point charges of equal magnitude and opposite sign, separated by \(\Delta \mathbf{r}\), and carrying a fixed Electric Dipole moment equal to p , is found to be:
\[
\begin{equation*}
F_{k}[\mathbf{r}]=p_{s} \frac{\partial E_{k}}{\partial x_{s}}[\mathbf{r}] \quad \Leftrightarrow \quad \mathbf{F}=(\mathrm{p} \cdot \mathbf{g r a d}) \mathbf{E} \tag{38.05.01}
\end{equation*}
\]

It is assumed that the two charges are in equilibrium, separated by a fixed distance \(\Delta r \equiv|\Delta \mathbf{r}|\), due to the action of some other force, internal to the pair of charges.
Note that the vector expression is not ambiguous if one takes literally the dot of the scalar product, whose meaning is to point out that scalar product is between p and \(\operatorname{grad}(\).\() . This is the force exerted\) by the external electric field \(\mathbf{E}\).

The torque, with respect to an arbitrary pole \(O\), taken as the origin of the Coordinate System, can be evaluated as follows. Let \(\mathbf{r}\) the location of the center of the Dipole, and let \(\mathbf{E}\) the electric field at the center of the Dipole, let \(\mathbf{r}_{+}\)the location of the positive charge, let \(\mathbf{r}_{-}\)the location of the negative charge, and let \(\mathbf{E}_{+}\)and \(\mathbf{E}_{-}\)the external electrical field at the position of the positive and negative charges respectively. One finds:
\[
\begin{aligned}
\boldsymbol{\Gamma}_{0} & \equiv|q|\left(\mathbf{r}_{+} \times \mathbf{E}_{+}-\mathbf{r}_{-} \times \mathbf{E}_{-}\right), \\
& =|q|\left((\mathbf{r}+\Delta \mathbf{r} / 2) \times \mathbf{E}_{+}-(\mathbf{r}-\Delta \mathbf{r} / 2) \times \mathbf{E}_{-}\right) \\
& =|q|\left(\mathbf{r} \times\left(\mathbf{E}_{+}-\mathbf{E}_{-}\right)+(\Delta \mathbf{r} / 2) \times\left(\mathbf{E}_{+}+\mathbf{E}_{-}\right)\right)
\end{aligned}
\]

Taking the limit of the ideal (point) Electric Dipole one finds:
\[
\boldsymbol{\Gamma}_{0}=|q|(\mathbf{r} \times((\Delta \mathbf{r} \cdot \text { grad }) \mathbf{E})+\Delta \mathbf{r} \times \mathbf{E})=\mathbf{r} \times((\mathbf{p} \cdot \text { grad }) \mathbf{E})+\mathrm{p} \times \mathbf{E}=\mathbf{r} \times \mathbf{F}+\mathrm{p} \times \mathbf{E}
\]

For an ElectroStatic external field, as \(\operatorname{rot} \mathbf{E}=0\), the expression of the force (as long as p is treated as a constant vector) is equivalent to:
\[
\begin{align*}
& F_{k}=p_{s} \frac{\partial E_{s}}{\partial x_{k}}=\frac{\partial}{\partial x_{k}}\left(p_{s} E_{s}\right)=\frac{\partial}{\partial x_{k}}(\mathrm{p} \cdot \mathbf{E})  \tag{38.05.02}\\
& \Leftrightarrow \quad \text { F }=\operatorname{grad}(\mathrm{p} \cdot \mathbf{E}) \\
& \rightarrow \\
& 1936
\end{align*}
\]

In fact:
\[
0=\mathrm{p} \times \operatorname{rot} \mathbf{E} \quad \Longrightarrow \quad p_{j} \partial_{i} E_{j}=p_{j} \partial_{j} E_{i}
\]

Note however that equation (38.05.01) applies in all circumstances, including the case of induced Dipoles. On the other hand equation (38.05.02) applies to ElectroStatics fields only and, moreover, the expression of the Electric Dipole moment must be kept constant when it is taken inside/outside the gradient.
Read § 33-049 - Basic Laws of ElectroMagnetism for an alternative way of writing the force formula.
In an ElectroStatic field (as long as p is treated as a constant) the force can be derived from the potential energy:
\[
\begin{equation*}
U[\mathbf{r}]=-\mathrm{p} \cdot \mathbf{E} . \tag{38.05.03}
\end{equation*}
\]
\(\rightarrow\)

Note that the expression (38.05.02) means that force is equal to the gradient of the projection of the magnetic field along the Dipole.
Both the Force|Torque can be derived from the potential energy (as long as p is treated as a constant vector):
\[
\mathbf{F}=(\mathrm{p} \cdot \text { grad }) \mathbf{E} \quad \boldsymbol{\Gamma}_{0}=\mathbf{r} \times \mathbf{F}+\mathrm{p} \times \mathbf{E}
\]

Note that in a uniform field there is no net force on the Electric Dipole, \(\mathbf{F}=0\), and therefore the moment, \(\Gamma_{0}\), is independent of the pole, \(O\).

In the general case of an arbitrary static charge distribution in an external static electrostatic field, the following approach applies.
Static distribution means that the multipole moments are assumed to be fixed, independent from the external field.
Note that the formula below is the energy in an external fixed field, not the total energy (no factor \(1 / 2\) ). Energia della distribuzione di cariche localizzata attorno ad \(\mathbf{x}_{0}\) :
\[
\begin{equation*}
U=\int_{V} \rho[\mathbf{x}] \Phi[\mathbf{x}] \mathrm{d} \mathbf{x}=q \Phi\left[\mathbf{x}_{0}\right]-\mathrm{p} \cdot \mathbf{E}\left[\mathbf{x}_{0}\right]+\frac{1}{6} Q_{j k} \frac{\partial^{2} \Phi}{\partial x_{j} \partial x_{k}}\left[\mathbf{x}_{0}\right]+\ldots=q \Phi\left[\mathbf{x}_{0}\right]-\mathrm{p} \cdot \mathbf{E}\left[\mathbf{x}_{0}\right]-\frac{1}{6} Q_{j k} \frac{\partial E_{j}}{\partial x_{k}}\left[\mathbf{x}_{0}\right]+\ldots \tag{38.05.04}
\end{equation*}
\]
dove si è usato il fatto che \(\operatorname{div} \mathbf{E}=0\) per il campo esterno per passare dal tensore di quadrupolo cartesiano a quello a traccia nulla.
Si ricavano le equazioni per forze e momenti su dipoli e multipoli superiori.

38.05.02.01 Force|Torque on a Magnetic Dipole in an External MagnetoStatic Field

This § is referenced at pages:
[1692, 1692, 1693, 1693, 1696, 1696]
©|Am.J.Phys, , ..., ..., ...Ed., .... 67, 45 (1999);|WEB - URL||
The total force, due to the external magnetic field \(\mathbf{B}[\mathbf{r}]\), acting on a plane circuit carrying a steady current of Magnetic Dipole moment equal to \(m\) is found to be, by direct computation:
\[
F_{k}[\mathbf{r}]=m_{s} \frac{\partial B_{k}}{\partial x_{s}}[\mathbf{r}] \quad \Leftrightarrow \quad \mathbf{F}=(\mathrm{m} \cdot \mathbf{g r a d}) \mathbf{B}
\]

One can limit the derivation to a small plane square circuit and deduce the result for any general shape by decomposing the generic plane circuit into infinitesimal square circuits.
For a MagnetoStatic external field, and away from the currents generating the extrrnal magnetic field, as \(\boldsymbol{\operatorname { r o t }} \mathbf{B}=0\), the expression of the force (as long as \(m\) is treated as a constant vector) is equivalent to:
\[
F_{k}=m_{s} \frac{\partial B_{s}}{\partial x_{k}}=\frac{\partial}{\partial x_{k}}\left(m_{s} B_{s}\right) .
\]

In fact the currents generating the external MagnetoStatic field, most likely, shall have zero current density at the points where the current loop is located.

Therefore:
\[
0=\mathrm{m} \times \operatorname{rot} \mathbf{B} \quad \Longrightarrow \quad m_{j} \partial_{i} B_{j}-m_{j} \partial_{j} B_{i}
\]

Read § 33-049 - Basic Laws of ElectroMagnetism for an alternative way of writing the force formula.
In an MagnetoStatic field (as long as \(m\) is treated as a constant) the force can be derived from the potential energy:
\[
U[\mathbf{r}]=-\mathrm{m} \cdot \mathbf{B}
\]

Both the Force|Torque can be derived from the potential energy (as long as \(m\) is treated as a constant):
\[
\mathbf{F}=(\mathrm{m} \cdot \mathbf{g r a d}) \mathbf{B} \quad \boldsymbol{\Gamma}_{0}=\mathbf{r} \times \mathbf{F}+\mathrm{m} \times \mathbf{B}
\]

Note that in a uniform field there is no net force on the Magnetic Dipole, \(\mathbf{F}=0\), and therefore the moment, \(\boldsymbol{\Gamma}_{0}\), is independent of the pole, \(O\).

The torque can be also derived by direct computation.

\subsection*{38.05.02.02 Force|Torque on a Steady Current Distribution in an External MagnetoStatic Field}

This § is referenced at pages:
[1693, 1693, 1696, 1696]
©|F.Wegner, Classical Electrodynamics, 2003, ..., ...Ed., WEB - URL.|§ 10.c||
©|J.P.Pérez et al., 5 Vol., , ..., ..., ...Ed., WEB - URL.|13.3.2, 13.5||
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|§ \(5.7|\mid\)
Consider a localized steady current distribution in an external MagnetoStatic field. The external MagnetoStatic field is supposed to be stationary, that is the generators do what is required to keep it constant, whatever happens.
A system of forces acts on the system of currents. The total Force|Torque are given by:
\[
\mathbf{F}=\iiint \mathbf{j}[\mathbf{x}] \times \mathbf{B}[\mathbf{x}] \mathrm{d} \mathbf{x} \quad \boldsymbol{\Gamma}_{0}=\iiint\left(\mathbf{x}-\mathbf{x}_{0}\right) \times(\mathbf{j}[\mathbf{x}] \times \mathbf{B}[\mathbf{x}]) \mathrm{d} \mathbf{x}
\]

If the magnetic field varies of a little amount inside the volume occupied by the current distribution one can use a series development around a convenient origin, \(\mathbf{x}_{0}\) :
\[
\mathbf{B}[\mathbf{x}] \simeq \mathbf{B}\left[\mathbf{x}_{0}\right]+(\Delta \mathbf{x} \cdot\lceil\mathbf{g r a d}) \mathbf{B}\rfloor_{\mathbf{x}_{0}} .
\]

After some calculations (see \({ }^{1}\) ), also exploiting the fact that the volume integral of the divergenceless \(\mathbf{j}\) is null for steady currents and the fact that the magnetic field is divergence-less, one finds, as a function of the Magnetic Dipole moment of the distribution,
\[
\begin{equation*}
\mathrm{m}=\frac{1}{2} \iiint \mathbf{x} \times \mathbf{j}[\mathbf{x}] \mathrm{d} \mathbf{x} \tag{38.05.05}
\end{equation*}
\]
the expression of the force on the current distribution (as long as \(m\) is treated as a constant):
\[
\begin{equation*}
\mathbf{F}=\operatorname{grad}(\mathrm{m} \cdot \mathbf{B}) \tag{38.05.06}
\end{equation*}
\]

The previous result is totally general, it also applies to time-dependent external fields.
For a MagnetoStatic external field and away from the currents generating the external magnetic field, as \(\boldsymbol{\operatorname { r o t }} \mathrm{B}=0\), the expression of the force (as long as m is treated as a constant vector) is equivalent to:
\[
\begin{equation*}
\mathbf{F}=(\mathrm{m} \cdot \mathrm{grad}) \mathbf{B} \tag{38.05.07}
\end{equation*}
\]

In fact the currents generating the external MagnetoStatic field, most likely, shall have zero current density at the points where the current loop is located.
Note however that equation (38.05.06) applies in all circumstances, including the case of induced Dipoles. On the other hand equation (38.05.07) applies to MagnetoStatics fields only and, moreover, the expression of the Magnetic Dipole moment must be kept constant when it is taken inside/outside the gradient.

\footnotetext{
\({ }^{1}\) J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....
}

In a similar manner one can deduce the torque on the current distribution (see \({ }^{2}, \S 5.7\) ):
\[
\Gamma_{\mathbf{x}_{0}}=\mathrm{m} \times \mathbf{B}\left[\mathbf{x}_{0}\right]
\]

\subsection*{38.05.02.03 Multipole Development of the Energy of a Steady Current Distribution in an External MagnetoStatic Field}

This § is referenced at pages:
[Never referenced.]
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|5.7||
In the general case of an arbitrary steady current distribution in an external static magnetostatic field, the following approach applies.
Static distribution means that the multipole moments are assumed to be fixed, independent from the external field.
Note that the formula below is the energy in an external fixed field, not the total energy (no factor \(1 / 2\) ).

\footnotetext{
\({ }^{2}\) J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....
}

©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
The concepts used to describe lumped-components circuits, such as resistance, capacitance, inductance and impedance, can be extended to the general case where the dimensions of the circuits are not negligible with respect to the vacuum wavelength, as is the case for high-frequency cases.
They can be defined in a general fashion from the fields concepts. To do that, one starts with the assumption that the sources and fields have a harmonic time dependence, exploiting the linearity of Maxwell Equations.

\subsection*{38.06.01 Poynting Theorem for Harmonics Fields}

In the case of harmonic fields, assuming that only linear media are present, one finds, with a procedure exactly identical to the one in \(\S 37.01\) - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum an expression for the energy balance written in terms of the complex Poynting vector, \(\mathbf{S}\), and the complex harmonic densities of electric, \(w_{e}\), and magnetic energy, \(w_{m}\), and starting from the expression of the time-averaged power spent by the ElectroMagnetic field inside the region, \(W_{E M}\) :
\[
\begin{aligned}
\mathbf{S} & \equiv \frac{1}{2} \mathbf{E} \times \mathbf{H}^{\star}, \\
w_{e} & \equiv \frac{1}{2} \mathbf{E} \cdot \mathbf{D}^{\star}, \\
w_{m} & \equiv \frac{1}{2} \mathbf{B} \cdot \mathbf{H}^{\star}, \\
W_{E M} & =\frac{1}{2} \iiint \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{d} \mathbf{x}
\end{aligned}
\]

The result is:
\[
\frac{1}{2} \iiint_{V} \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{d} \mathbf{x}+2 \beth \omega \iiint_{V}\left(w_{e}-w_{m}\right) \mathrm{d} \mathbf{x}+\oiiint_{\partial V} \mathbf{S} \cdot \mathbf{n} \mathrm{~d} \mathbf{S}=0
\]

The real part of equation (38.06.01) gives the time-averaged energy conservation while the imaginary part is connected to the oscillating behavior of the stored energy, the reactive part of the energy.
If the harmonic densities of electric, \(w_{e}\), and magnetic energy, \(w_{m}\), have a real volume integral (as it happens with lossless Polarizable material and ideal conductors)
the real part of equation (38.06.01) becomes:
\[
\frac{1}{2} \iiint \operatorname{Re}\left(\mathbf{j}^{\star} \cdot \mathbf{E}\right) \mathrm{d} \mathbf{x}+\oiiint \operatorname{Re}(\mathbf{S} \cdot \mathbf{n}) \mathrm{d} \mathbf{S}=0
\]

This equation means that in steady conditions the work done by the ElectroMagnetic fields inside the volume is equal to the average energy flux entering the surface. If the system is dissipative this is represented by the second term in equation (38.06.01), which has, in this case, a real part also.

\subsection*{38.06.02 Impedance in Terms of Fields}

The complex Poynting theorem, equation (38.06.01), can be used to define the input impedance of a general two-terminal, linear and passive, ElectroMagnetic system.

Suppose that all the system is enclosed inside a volume \(V\), bounded by a surface \(S \equiv \partial V\) and that only the two terminal of the Dipole are exiting from this volume. Moreover, let \(S_{i}\) be the small portion of the surface \(S\) from which the energy is allowed to enter the volume (for instance the section of the connecting cable), the only part of the boundary of \(V\) where energy is allowed to be transferred in. Note however that energy can exits the surface from the portion \(S-S_{i}\) of the surface \(S\). Let \(V_{i}\) and \(I_{i}\) be the input (harmonic) voltage and current. Apply equation (38.06.01) to all the space external to \(S\) one finds:
\[
\begin{equation*}
\frac{V_{i} I_{i}^{\star}}{2}=-\oiint_{S_{i}} \mathbf{S} \cdot \mathbf{n} \mathrm{~d} \mathbf{S} \tag{38.06.02}
\end{equation*}
\]

One can now use equation (38.06.01) in equation (38.06.02) to find:
\[
\begin{equation*}
\frac{V_{i} I_{i}^{\star}}{2}=\frac{1}{2} \iiint_{V} \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{d} \mathbf{x}+2 \beth \omega \iiint_{V}\left(w_{e}-w_{m}\right) \mathrm{d} \mathbf{x}+\oiint_{S-S_{i}} \mathbf{S} \cdot \mathbf{n} \mathrm{~d} \mathbf{S} \tag{38.06.03}
\end{equation*}
\]

If the surface \(S-S_{i}\) is brought to infinity the integral is real.
and it represents the radiated energy. This is normally negligible at low frequencies and moreover no distinction is required any more between the two surfaces \(S\) and \(S-S_{i}\). Equation (38.06.03) can be split into its real and imaginary parts, introducing the resistance and reactance and assuming that the energy flux across \(S\) is real:
\[
\begin{aligned}
& R=\frac{1}{I_{i}^{2}}\left(\operatorname{Re}\left(\iiint_{\mathrm{V}} \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{d} \mathbf{x}\right)+2 \oiint_{S-S_{i}} \mathbf{S} \cdot \mathbf{n} \mathrm{~d} \mathbf{S}+4 \omega \operatorname{Im}\left(\iiint_{\mathrm{V}}\left(\mathrm{w}_{\mathrm{e}}-\mathrm{w}_{\mathrm{m}}\right) \mathrm{d} \mathbf{x}\right)\right) \\
& X=\frac{1}{I_{i}^{2}}\left(4 \omega \operatorname{Re}\left(\iiint_{\mathrm{V}}\left(\mathrm{w}_{\mathrm{e}}-\mathrm{w}_{\mathrm{m}}\right) \mathrm{d} \mathbf{x}\right)-\operatorname{Im}\left(\iiint_{\mathrm{V}} \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{d} \mathbf{x}\right)\right)
\end{aligned}
\]

The term \(\iiint \mathbf{j}^{\star} \cdot \mathbf{E} \mathrm{dx}\) represents the radiation resistance, important at high frequencies. At low frequencies and in those cases when the Ohmic losses are the only causes of energy dissipation only the first term in each of the two equations survive.
38.06.03 Lumped Components

\section*{Phenomenology}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
©|S.Bobbio \& E.Gatti, Elettromagnetismo E Ottica, 1991, Bollati-Boringhieri, ...Ed., ....|||
©|C.Kittel, Introduction To Solid State Physics, 1996, J.Wiley \& Sons, ...Ed., ....|||

Note: linearity requires \(E \ll E_{\text {atomic }} \approx 10^{11} \mathrm{~V} / \mathrm{m}\).
1. Polarization goes via two main phenomena:
- Deformation.

Always present. Normally no temperature dependence.
- Orientation.

Strong dependence on the temperature. \(\chi_{\mathrm{E}}\) decreases while increasing the temperature.
Energy scale for thermal agitation effects: \(E \approx k T \approx 0.025 \mathrm{eV}\).
2. Ferro-Electricity. Example: \(\mathrm{BaTiO}_{3}\), spontaneous symmetry breaking below the critical temperature. Surface Polarization charges are quickly neutralized. Any electric field produced attracts neutralizing charges. If Polarization is changed the external charges need time for neutralization: an effect is visible. Ferroelectric materials possess domains, called ferroelectric, inside which dipole moments are coupled with each other, thus giving rise to spontaneous Polarization.
3. Piezo-Electricity. A change of the mechanical stress will induce a change of the Polarization and vice-versa. The piezo-electric constant, relating the Polarization vector to the strain tensor, forms a third-rank tensor. Example from: C.Kittel, Introduction To Solid State Physics, 1996, J.Wiley \& Sons, ...Ed., ....: an elementary cell made as three/four identical Dipoles with total Dipole moment equal to zero; when stressed the directions deform and do not sum to zero any longer. Most used material: Quartz. Used for piezo-electric transducers (deformation to electrical signal). A piezoelectric transducer is a device that uses the piezoelectric effect to convert a deformation to an electrical signal. It can be used to measure pressure, strain, force,... If the changes of strain is very fast, such as in a collision, the resulting Polarization might be so high to start sparks.
4. Pyro-Electricity. Changes of temperature imply change of dimensions of the crystalline solid which can change the Polarization of the solid if the change of dimensions shifts the center of charge of the elementary cells. Used for infrared radiation detection (motion sensors).
5. Electro-Striction.
6. Super-Dielectrics: artificial materials made of an insulating porous substrate filled with a ionic liquid. It behaves as the model in § 35-013 - Electric Properties of Matter.

\subsection*{38.07.02 Phenomenology of Magnetization}
1. Diamagnetism. Always present. It opposes to the applied external (applied) field. Normally no temperature dependence.
2. Paramagnetism. Strong dependence on the temperature. \(\chi_{M}\) decreases while increasing the temperature. Energy scale for thermal agitation effects: \(E \approx k T \approx 0.025 \mathrm{eV}\). Curie law:
\[
\chi_{\mathrm{M}}=C \frac{\rho}{T-T_{\mathrm{C}}} .
\]
\(T_{\mathrm{C}}\), the Curie temperature, is a characteristic of the material. Exception: Paramagnetism from electrons in metal having no temperature dependence.
- Mu-metal is a nickel-iron alloy ( 0.75 nickel, 0.15 iron, plus copper and molybdenum) that has very high Magnetic-Permeability. The high Magnetic-Permeability makes mu-metal effective for screening static or low-frequency magnetic fields, which cannot be attenuated by other methods.
- Permalloy is the term for a nickel iron magnetic alloy. It refers to an alloy with about 0.20 iron and 0.80 nickel content. Permalloy has a high Magnetic-Permeability, low coercivity, near zero magneto-striction, and significant anisotropic magneto-resistance.
3. Ferromagnetic phenomena. Non-linear, history dependence of the field (hysteresis). Strong effect: \(\chi_{\mathrm{M}}^{*} \approx 10^{5}\). Above the Curie temperature it becomes paramagnetic. The locking process of \(\mathrm{BaTiO}_{3}\) is not possible due to the faint magnetic interaction energy with respect to the electric interaction energy. QM effect.
- Ferromagnetism.
- Ferrimagnetism.
- Antiferromagnetism.
4. MagnetoStriction.

\section*{38-001 Properties of Material Media}

Find a few examples of material media which are, from the point of view of their ElectroMagnetic properties:
- homogeneous and isotropic;
- homogeneous and non-isotropic;
- non-homogeneous and isotropic;
- non-homogeneous and non-isotropic,

Explain and motivate your answers.
Try first to find the above examples among materials with a linear response, as for small enough ElectroMagnetic fields the response is always linear.

\section*{38-002 Typical Values}

Assume the following data: \(E=1.0 \cdot 10^{6} \mathrm{~V} / \mathrm{m} ; B=1.0 \cdot 10^{1} \mathrm{~T} ; \mathrm{p}=1.0 \cdot 10^{-30} \mathrm{C} \cdot \mathrm{m} ; \mathrm{m}=1 \mu_{\mathrm{B}} ; T=300 \mathrm{~K}\); \(\eta_{\mathrm{N}} \approx 1.0 \cdot 10^{28}\) molecules \(/ \mathrm{m}^{3}\).
One finds:
\[
\begin{gathered}
\frac{\mathrm{p} E}{k_{\mathrm{B}} T}=2 \cdot 10^{-2}, \\
\frac{\mathrm{~m} B}{k_{\mathrm{B}} T}=2 \cdot 10^{-2}, \\

\section*{38-003 Determination of Permanent Moments and the Polarisability}

Exploiting the fact that the Polarizability|Magnetizability is the sum of the one due to deformation (always present) plus the one due to the permanent moment one can measure the value of the Polarizability|Magnetizability due to deformation by measuring and plotting the linear dependence on the inverse of the temperature.
Starting from the Clausius-Mossotti equations § 35.09 - Electric Properties of Matter and § 36.09 Magnetic Properties of Matter one should replace the Polarizability|Magnetizability as the sum of the one due to deformation and the one due to the permanent Dipole moment:
\[
\frac{\alpha_{\mathrm{g}}}{3} \longrightarrow \frac{1}{3}\left(\left(\alpha_{\mathrm{g}}\right)_{\text {deformation }}+\left(\alpha_{\mathrm{g}}\right)_{\text {orientation }}\right)
\]

The orientation term depends on the temperature and therefore one can plot the linear dependence on the inverse of the temperature.

\section*{38-004 Order of Magnitude of the Polarisability}
1. Estimate the order of magnitude of the polarisability, by charge density deformation, of a molecule. A safe way, if no other method helps, is to deduce it from the measured values of electric susceptibilities. Read § 35.10.03 - Electric Properties of Matter.
2. Estimate the order of magnitude of the polarisability by orientation, read § 38.04.06-ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.
3. Compare the above results.

\section*{38-005 Order of Magnitude of the Magnetisability}
1. Estimate the order of magnitude of the magnetisability, by current density deformation, of a molecule (diamagnetism). A safe way, if no other method helps, is to deduce it from the measured values of magnetic susceptibilities. See any textbook for semi-classical models of diamagnetism.
2. Estimate the order of magnitude of the magnetisability by orientation, read § 38.04.06 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology.
3. Compare the above results.

\section*{38-006 D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd. \\ \(\qquad\) - Problem 5.49}

Show that the two forces between two arbitrary current loops are equal and opposite.

\section*{38-007 Polarizable Sphere in an External Electric Monopole Field}

Show that:
\[
|\mathrm{p}| \propto 1 / r^{2} \quad \mathrm{p} \cdot \mathbf{E} \propto 1 / r^{4} \quad \mathrm{p} \cdot \boldsymbol{\operatorname { g r a d }} \mathbf{E} \propto 1 / r^{5} .
\]

\section*{38-008 Polarization Surface Charge Density}

Consider a circular cylindrical piece of matter which is Polarized along the axis of the cylinder.
Assume it is made of molecules, with a Electric Dipole moment, all perfectly aligned and Polarized along the axis of the cylinder. Assume every molecule carries a Electric Dipole moment as for one molecule of water.
1. Estimate, as a function of the density of the material, the surface charge density at the two bases of the cylinder.
2. If all the molecular Dipoles in a cup of water could be made to point down what would be the magnitude of the surface charge density at the upper water surface.

\section*{38-009 Mangetization Surface Current Density}

Consider a circular cylindrical piece of matter which is Magnetized along the axis of the cylinder.
Assume it is made of molecules, with a Magnetic Dipole moment, all perfectly aligned and Magnetized along the axis of the cylinder. Assume every molecule carries a Magnetic Dipole moment given by one Bohr-magneton.
1. Estimate, as a function of the density of the material, the surface current density at the lateral surface of the cylinder.
2. If all the molecular Dipoles in a cup of water could be made to point down what would be the magnitude of the surface current density at the lateral water surface.

\section*{38-010 Relaxation Time Inside a Conducting Electric Material}

Read also § 33.18.18 - Basic Laws of ElectroMagnetism.
Suppose that at a certain time a free charge density \(\rho_{0}\) exists inside a small region of a homogeneous and isotropic medium having conductibility \(\sigma\) and relative Electric-Permittivity \(\epsilon_{\mathrm{R}}\). Determine the time development of the free charge density.

\section*{SOLUTION}
\[
\rho[\mathbf{x}, t]=\rho_{0}[\mathbf{x}] \exp \left[-\frac{\sigma}{\varepsilon_{0} \epsilon_{\mathrm{R}}} t\right] \quad \tau=\frac{\varepsilon_{0} \epsilon_{\mathrm{R}}}{\sigma}
\]

\section*{38-011 Hall Effect}

A steady current \(I\) is flowing in a metal strip of rectangular section with width \(L\) and thickness \(D\). The metal has \(n_{e}\) free electrons per unit volume. If a magnetic field \(\mathbf{B}\) penetrates the metal strip, perpendicular to the width of the strip, determine the expression of the potential difference between the two sides of the strip.
\begin{tabular}{|l|}
\hline SOLUTION \\
\hline\(\Delta \Phi=\frac{I B}{n_{e} e d}\). \\
\hline
\end{tabular}

\section*{38-012 A Rotating Cylinder}

A long cylinder made of a conducting material with radius \(R=5 \mathrm{~cm}\) rotates around its axis with an angular velocity \(\omega=100\) turns/s in a stationary and uniform magnetic field \(B=1 \mathrm{~T}\) parallel to the axis. Assume that the fringe effects at the edges of the cylinder are negligible.
1. Compare \(\omega\) with the cyclotron frequency of the free electrons inside the conductor.
2. Determine, as a function of \(\omega\) and \(B\), the volume charge density, the surface charge density, the Polarization and the Electric Dipole moment per unit length of the cylinder.
3. Determine the volume current density, the surface current density, the Magnetization and the Magnetic Dipole moment per unit length of the cylinder.
4. Determine the electric field and the Polarization in all the space.

\section*{38-013 Langevin Equation}

Refer to § 38.04.06 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology. Show that the Polarizability|Magnetizability in any direction perpendicular to the external field is zero.

\section*{38-014 A Useful Integral}

This § is referenced at pages:
[1834, 1834, 1878, 1878]
The following integral
\[
\mathbf{I}[\mathbf{x}] \equiv \iiint_{\tau} \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y} \quad \text { with volume } \tau \text { such that }|\mathbf{y}|<R
\]
appears in some different situations, so that it is useful to calculate it for the simple case of a spherical volume.

Let us calculate the integral in the case of a spherical volume centered at the origin. To do that, note that the integral is just proportional to the electric field produced by a uniform volume charge distribution inside volume \(\tau\). If this is a sphere, the result is well-known as it follows from application of Gauss law:
\(\mathbf{I}[\mathbf{x}] \equiv \iiint_{\tau} \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\left\{\begin{array}{ll}\frac{4 \pi}{3} \mathbf{x} & \text { for }|\mathbf{x}| \leq R \\ \frac{4 \pi R^{3}}{3} \frac{\mathbf{x}}{x^{3}} & \text { for }|\mathbf{x}|>R\end{array} \quad, \quad\right.\) with \(\tau\) a sphere of radius \(R\) located at the origin \(\quad\).

\section*{SOLUTION}

Let \(\mathbf{E}[\mathbf{x}]\) be the electric field produced by a charge, uniformly distributed with volume density \(\rho\), inside a sphere of radius \(R\). We then have:
\[
\mathbf{I}[\mathbf{x}] \equiv \iiint_{\tau} \frac{(\mathbf{x}-\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{3}} \mathrm{~d} \mathbf{y}=\frac{4 \pi \varepsilon_{0}}{\rho} \mathbf{E}[\mathbf{x}]=\left\{\begin{array}{lr}
\frac{4 \pi}{3} \mathbf{x} & \text { for }|\mathbf{x}| \leq R \\
\frac{4 \pi R^{3}}{3} \frac{\mathbf{x}}{x^{3}} & \text { for }|\mathbf{x}|>R
\end{array}\right.
\]

\section*{38-015 Torque From the Potential Energy}

Show that the torque with respect to the position of the Dipole can be derived from the potential energy (38.05.03).

\section*{38-016 Magnetic Mirrors}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|5.7||
Consider a charged particle spiraling in a slow-changing magnetic field. That is: the Larmor Radius of the particle is much smaller than the distance scale over which the magnetic field changes in a significant way. Under these conditions the time-averaged force on the particle can be evaluated by considering the force over the Magnetic Dipole moment generated by the current.
Show qualitatively that, by taking into account the sign of the forces and Magnetic Dipole moments, the result is that all particles are pushed away from regions were the flux lines of the magnetic field are denser.

\section*{38-017 Polarisability of a Conducting Sphere}

Show that the polarisability of a conducting sphere of radius \(R\) is \(\propto R^{3}\).

The concept of wave is fundamental in all physics.
In this section the general properties of all waves are discussed, valid for any kind of wave. These properties do not depend on any specific kind of wave, even if different kinds of waves are used as examples. Specific properties, different for different kinds of waves, must be discussed in the specific case. Most of what is discussed in this section can only be better understood after studying all the following topics in waves as well as specific cases of waves.
Everywhere, if not specified otherwise, the wave equation is implicitly assumed to be the classical non-dispersive d'Alembert wave PDE-(Partial Differential Equation), either homogeneous or non-homogeneous.
Note that an equation describing waves, as it must involve both time and spatial coordinates, is necessarily a PDE, called in short, the wave equation; many types of wave equations do exist; read § 40.01.04 - General Properties of Waves.

\subsection*{40.01.01 Physical Systems Leading to d'Alembert Classical Non-Dispersive Wave Equation}

Often, wave phenomena are described by the ubiquitous d'Alembert Classical Non-Dispersive wave equation. For this reason, sometimes, wave phenomena are identified with all and only the phenomena described by d'Alembert wave equation. However, even if d'Alembert wave phenomena is the simplest and a very common case in physics, it is not the full story. Read section § 40.01.04-General Properties of Waves.
The following examples of physical systems lead, at least to a first approximation, to the d'Alembert wave equation.
- From Maxwell Equations in vacuum one deduces the ElectroMagnetic wave equation in vacuum (d'Alembert wave equation, read § 42.01 - ElectroMagnetic Waves).
- From Maxwell Equations in a neutral perfect medium one deduces the ElectroMagnetic wave equation in a neutral perfect medium (d'Alembert wave equation, read § 42.02 - ElectroMagnetic Waves).
- The equations for the ElectroMagnetic potentials in the Lorenz Gauge (read § 45.01 - Radiation of ElectroMagnetic Waves) is d'Alembert wave equation.
- The linear spring-mass chain (read § 23.07.04-Oscillations of a few mass points) gives, in the continuum limit, d'Alembert wave equation.
- The small transverse vibrations of an ideal string (read § 25.07.07 - Introduction to Mechanics of Elastic Solids) give d'Alembert wave equation, read § 41.03.01 - Mechanical Waves.
- The small longitudinal vibrations of any piece of matter (sound) give d'Alembert wave equation.
- Small waves on a liquid surface are described, to a first approximation, by d'Alembert wave equation.

\subsection*{40.01.02 Waves}
©|G.B.Whitham|Linear and Nonlinear Waves|WEB - URL - Advanced|
©|D.A.Russell|WEB - URL|Many excellent demos!|
Waves appear under many aspects in common experience. A few general concepts about waves are summarized in this section. Their understanding will improve when discussing specific examples.
There is no general precise definition of wave in physics, as the broad use of the term wave makes it difficult to produce a precise definition which would not be limiting.
Sort of definition of wave can be as follows.
A wave is a signal (or perturbation, or disturbance), possibly (but not necessarily) impulsive or periodical, produced by some well-defined source and traveling with a well-defined kinematics (speed, in particular). The traveling signal, with the above characteristics, is a signal modifying the equilibrium conditions of some physical field, describing some property of some physical system. The signal may distort and|or attenuate/amplify as long as it remains recognizable. Superposition of different signals, not necessarily a linear superposition, can lead to more and more complex behavior, also different from a qualitative point of view. There is no overall movement of matter.
The terms signal, source, traveling, physical field/system and the others terms above are used in a sufficiently broad manner to allow a wide range of interpretation of what constitutes a wave.
This generic definition may seem to be a too vague, but it turns out to be perfectly adequate; moreover, any attempt to be more precise appears to be too restrictive; in fact, different features are important in different types of waves.
The first question to ask when dealing with waves is: which physical quantity is oscillating?
A wonderful introduction to waves is available at WEB - URL and WEB - URL \({ }^{1}\).

\footnotetext{

}

\subsection*{40.01.03 Additional Examples of General Wave Phenomena}

This § is referenced at pages:
[1978, 1978]
- A large crowd of people at a stadium during a soccer, football or baseball game often does the wave (or the Mexican wave): some people jump up and sit down and then some other nearby people see them and they also jump up and sit down, and so on with everybody jumping up and sitting down as soon as they see their neighboring sitting down. We then have a traveling wave around the stadium. The wave is the Perturbation|Disturbance|Signal made by people jumping up and sitting down. The wave travels around the stadium with a definite speed and trajectory. None of the individual people at the stadium is moving while the wave travels: they all remain at their place. Note that it is essential that everybody moves at the right time, by following the kinematics of his/her neighboring spectators. If this is not the case and everybody moves at random we have no wave but just a random movement. Note that nobody is moving, so that the wave may travel at a very large speed with respect to the speed a single person might rush around the stadium. Note also that the speed the wave is moving has nothing to do with the speed each spectator is jumping-up/sitting-down.
- Sound waves in matter: longitudinal oscillations of matter particles with respect to their equilibrium position (music, for instance).
- Elastic waves in solid matter (both longitudinal and transversal): longitudinal and transverse oscillations of matter particles with respect to their equilibrium position (seismic waves, for instance).
- Shock waves in gases: an abrupt change of pressure propagating in the gas.
- EM waves: oscillating ElectroMagnetic fields (light, radio-waves and micro-waves, for instance).
- Surface waves on water: oscillating water particles.
- Gravitational waves: oscillating gravitational field.
- Quantum Physics describe particle mechanics by means of Schrödinger waves.
- Some examples from outside physics:
- Traffic-lights waves: a long straight road having identical traffic-lights at equal distances, with disturbances given by the traffic-lights changing color. If traffic-lights are properly synchronized for a certain speed the wise car-driver can get all greens.
- Traffic waves \({ }^{\text {a }}\) : car traffic on a road with disturbances, given by possibly abrupt changes in traffic density, produced by traffic lights or other traffic obstacles. As simple model is described by a first-order PDE.
- Blood Wave propagation in arteries \({ }^{\text {b }}\) : pressure waves of blood in arteries.
- Epizootic waves, that is geographic spread of diseases: a population susceptible to contracting a disease with disturbances given by the density of infectives.
- Grass waves \({ }^{\text {c }}\).

\({ }^{c}\) WEB - URL

\subsection*{40.01.04 Different Wave Equations for Different Physical Systems}

This § is referenced at pages:
[1960, 1960, 1961, 1961]
Waves in physics may either involve oscillations of a material medium (mechanical waves) or not (such as ElectroMagnetic, gravitational and Schrödinger waves).
The term wave equation, except when specified otherwise, will mean the d'Alembert Classical NonDispersive wave equation. The one-dimensional and three-dimensional wave equations for a quantity, \(\xi[\mathbf{x}, t]\), in terms of the propagation speed of waves, \(v\), the so-called phase-velocity and for a source function \(s[\mathbf{r}, t]\), read:
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial z^{2}}-\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}}=s[z, t] \quad \nabla^{2} \xi-\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}}=s[\mathbf{r}, t] \tag{40.01.01}
\end{equation*}
\]

However it must be emphasized that different wave phenomena may be described by other wave equations, that is the concept of wave is not at all linked to d'Alembert Classical Non-Dispersive wave equation. Phenomena described by d'Alembert Classical Non-Dispersive wave equation are very common.
In general, \(\xi[\mathbf{x}, t]\) is any oscillatory physical quantity associated with the wave.

\subsection*{40.01.04.01 PDE Wave Equations and Conditions for Solutions}

Every wave phenomenon is described by its own wave equation, a PDE-(partial differential equation) in space and time coordinates, possibly a non linear one (see section § 40.03-General Properties of Waves). The problem of finding solutions, and understanding their existence and uniqueness, is a very complex mathematical problem, in general. As for ODE one must add conditions, to ensure uniqueness of the solutions, but not too many conditions, to ensure existence of some solutions. Broadly speaking two types of conditions are used:
- initial conditions: at a certain time, the values of the unknown function at all points is given, and|or for some of the derivatives;
- boundary conditions: for all the times, the values of the unknown function at all points of some surface are given, and|or for some of the derivatives;
- mixed conditions: a mixture of initial and boundary conditions.

\subsection*{40.01.04.02 ElectroMagnetic Waves in Ohmic Conducting Media}

As an example of a wave phenomenon which is not described by d'Alembert wave equation one can mention the case of ElectroMagnetic waves in Ohmic conducting media (see section § 42.06 - ElectroMagnetic Waves). In this case there is one more additional term added to d'Alembert Classical Non-Dispersive wave equation which introduces energy dissipation in the system:
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial z^{2}}-\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}}-b^{2} \partial_{t} \xi=s[z, t] \quad \nabla^{2} \xi-\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}}-b^{2} \partial_{t} \xi=s[\mathbf{r}, t] \tag{40.01.02}
\end{equation*}
\]

The added term has the physical interpretation of being related to some kind of friction.
The name dissipative d'Alembert wave equation will be used.
It is, in fact, a special case of the telegraph wave-equation.

\subsection*{40.01.04.03 Schrödinger Wave Equation}

In non-relativistic quantum physics the dynamics of a particle of mass \(m\) in an external potential \(V[\mathbf{r}]\), is given, in terms of the wave-function \(\psi[\mathbf{r}, t]\), by the Schrödinger wave equation:
\[
\begin{equation*}
\beth \hbar \partial_{t} \psi[\mathbf{r}, t]=-\frac{\hbar^{2}}{2 m} \nabla^{2} \psi[\mathbf{r}, t]+V[\mathbf{r}] \psi[\mathbf{r}, t] . \tag{40.01.03}
\end{equation*}
\]

Schrödinger wave equation is, in general, a non-linear one.
Note also that Schrödinger wave equation is intrinsically a complex equation.

\subsection*{40.01.04.04 Advection Wave Equation}

\subsection*{40.01.04.05 Korteweg-deVries Wave Equation}

An example of a non-linear wave equation is the Korteweg-deVries wave-equation. It describes smallamplitude, shallow, confined water waves, called solitons. A soliton looks like a wave pulse that retains its shape as it travels.

Read section § 62.05.04 - Elements of Kinetic Theory and Transport Phenomena.

\subsection*{40.01.04.07 Airy Equation}

A non-linear PDE with dispersion relation:
\[
\omega / k=-k^{2} .
\]

\subsection*{40.01.04.08 Vibrating Beam Wave Equation}

Read § 41.03.01 - Mechanical Waves, § 41.03.02 - Mechanical Waves, § 23.07.04 - Oscillations of a few mass points, \(\S 23.07 .05\) - Oscillations of a few mass points.
The Vibrating Beam Wave Equation is a fourth-Order PDE.
The major difference between the transverse vibrations of an ideal string (read § 25.07.07- Introduction to Mechanics of Elastic Solids) and the transverse vibrations of a thin beam is that the beam offers some resistance to bending, at variance of the ideal string which is assumed to be perfectly flexible.
The wave equation becomes:
\[
\ddot{\xi}[z, t] \propto-\xi^{\prime \prime \prime \prime}[z, t] .
\]

See a vibrating beam at WEB - URL.
See the mode shapes for the first four modes of a vibrating cantilever beam at WEB - URL.

\subsection*{40.01.05 Linear and Non-Linear Wave Equations}

Very often, phenomena describe by non-linear wave-equation can be treated by approximating the wave equation to a linear wave equation, under the appropriate conditions. This is called linearization. Typical example: water waves on the surface of sea/lake/pool....

This § is referenced at pages:
[1966, 1966]
© \(\mid\) R.Knobel|||
Waves can be roughly divided into two broad categories, depending on their kinematics.
- Standing waves (also called normal modes).

Typically when the region of space is limited and waves are near boundaries and boundaries have a very important effect on the behavior of waves (read § 40.02.03.05-General Properties of Waves). At any point in space all the oscillations have the same time dependence, that is space and time variables are separated:
\[
\xi[\mathbf{r}, t]=g[\mathbf{r}] f[t]
\]

Example, a Sinusoidal|Cosinusoidal standing wave in one dimensional bounded region \(0 \leq z \leq L\), with \(\xi[z=0, t]=\xi[z=L, t]=0\) :
\[
\xi[z, t]=\xi_{0} \sin \pi z / L \cos \omega t \quad \text { or } \quad \xi[z, t]=\xi_{0} \sin 2 \pi z / L \cos \omega t .
\]

Show that it satisfies the wave equation (40.01.01)
Example, a attenuating Sinusoidal|Cosinusoidal standing wave in one dimensional bounded region \(0 \leq z \leq L\), with \(\xi[z=0, t]=\xi[z=L, t]=0\) :
\[
\xi[z, t]=\xi_{0} \exp [-t / \tau] \sin \pi z / L \cos \omega t \quad \text { or } \quad \xi[z, t]=\xi_{0} \exp [-t / \tau] \sin 2 \pi z / L \cos \omega t .
\]

Show that it does not satisfy the wave equation (40.01.01)
Example: the plucked string of a guitar.
Standing waves (also called normal modes) do not propagate at all.
Standing waves do not transport, on average, Energy, Linear Momentum, Angular Momentum. This means that, while there is a local transport of Energy, Linear Momentum, Angular Momentum, on average, Energy, Linear Momentum, Angular Momentum, move forth and back, so that on average there is no global transport.
- Traveling waves (also called progressive waves).

Typically when the region of space is large and waves are far away from boundaries (read § 40.02.02 - General Properties of Waves and § 40.02.03 - General Properties of Waves).

In general, the solutions of PDE are functions of space and time variables independently. Traveling waves are so-called whenever they are function of combinations of the variables only:
\[
\xi[\mathbf{r}, t]=H[k[\mathbf{r}] \pm v t]
\]

Example: a Gaussian pulse in one dimension:
\[
\xi[z, t]=\frac{\xi_{0}}{\sigma \sqrt{2 \pi}} \exp \left[-\frac{(z \pm v t)^{2}}{2 \sigma^{2}}\right]
\]

Show that it satisfies the wave equation (40.01.01).
Example: an attenuating Gaussian pulse in one dimension:
\[
\xi[z, t]=\exp [-t / \tau] \frac{\xi_{0}}{\sigma \sqrt{2 \pi}} \exp \left[-\frac{(z \pm v t)^{2}}{2 \sigma^{2}}\right] .
\]

Show that it does not satisfy the wave equation (40.01.01); it satisfies a different wave-equation. Example: waves in open water.
Traveling waves transport Energy, Linear Momentum, Angular Momentum.
Technically, the difference between traveling and standing waves is in the average, Energy, Linear Momentum, Angular Momentum, transport velocity being either different or equal to zero. Read § 41.08 - Mechanical Waves, § 42.05 - ElectroMagnetic Waves for the specific case of mechanical and

\section*{ElectroMagnetic waves.}

Additional nomenclature: asymptotically constant wave disturbances are defined as follows.
Assume that for any fixed \(t\),
\[
\begin{cases}\xi[x, t] \rightarrow k_{1} & \text { as } x \rightarrow-\infty \\ \xi[x, t] \rightarrow k_{2} & \text { as } x \rightarrow+\infty\end{cases}
\]
for some constants \(k_{1}\) and \(k_{2}\). In general, the values \(k_{1}\) and \(k_{2}\) are not necessarily the same.
- Wave-front \({ }^{a}: k_{1} \neq k_{2}\).
- Pulse: \(k_{1}=k_{2}\).

A pulse temporarily changes the value of \(\xi\) at position \(x\) before it settles back to its original value.
\({ }^{\text {a }}\) Beware this name is not universally used for this kind of waves
Superposition, not necessarily a linear one, among different waves can lead to more complex behavior, also different from a qualitative point of view. For instance, a suitable superposition of different traveling waves may give rise to standing waves (read § 40.01.06-General Properties of Waves), as well as the other way round.

\subsection*{40.01.07 Some Important Types of Simple Waves}

Let us consider 3D waves only in a unbounded domain.
Beware that the nomenclature about waves is not universal and often sloppy....
- Harmonic wave: any wave whose time dependence is harmonic.
- Plane Waves-(PW): waves such that either amplitude and|or phase are uniform on all the planes perpendicular to some fixed direction in space; strictly speaking: harmonic PW with constant phase on all the planes perpendicular to some fixed direction in space; for non-harmonic waves the latter definition does not make any sense, so it is sometimes used to refer to waves such that the amplitude is uniform on all the planes perpendicular to some fixed direction in space; note that MPW do not necessarily have constant amplitude planes corresponding to the constant phase planes.
- MPW: harmonic PW with homogeneous amplitude, sometimes, defined just as harmonic PW; the latter have a distinguished importance as in quantum mechanics represent particle with fixed energy and linear momentum.
- Attenuated|Amplificated MPW: varying (decreasing|increasing) amplitude; energy is dissipated|absorbed.
- Non-homogeneous MPW: constant amplitude planes and constant phase planes are not parallel to each other.
- Spherical Waves-(SW): waves such that either amplitude and|or phase are uniform on all the spheres centered at the same point; strictly speaking: harmonic SW with constant phase on all the spheres centered at the same point; for non-harmonic waves the latter definition does not make any sense, so it is is sometimes used to refer to waves such that the amplitude is uniform on all the spheres centered at the same point; note that MSW do not necessarily have constant amplitude spheres corresponding to the constant phase spheres.
- MSW: harmonic SW with homogeneous amplitude, sometimes, defined just as harmonic SW; the latter have a distinguished importance as in quantum mechanics represent particle with fixed energy and angular momentum.
- Cylindrical Waves-(CW): waves such that either amplitude and|or phase are uniform at fixed distance from a fixed axis; same distinction as for PW and SW.
Note that all the above names are often used in a sloppy and non universal way.
40.01.08 What Is a Wave?
©|J.A.Scales \& R.Snieder|What is a wave?|NATURE 401, 21 OCTOBER 1999, pag. 739

\section*{© - QUOTE}

Most people assume that a wave, being central to all the phenomena we observe, has a uniform definition. But defining this basic concept isn't so easy.

Taking all these examples into account, we stick with our definition of a wave as an organized propagating imbalance; just don't ask us to define 'organized'.

\title{
d'Alembert Classical Non-Dispersive Wave Equation
}
© \(\mid\) A.D.Polyanin et al.|Handbook of Linear Partial Differential Equations for Engineers and Scientists|Chapman Hall/CRC Press, Boca Raton, 2002

The term wave equation, except when specified otherwise, will mean the d'Alembert Classical NonDispersive wave equation.

The general solution of the wave equation for a non-dispersive wave is discussed in this section. A non-dispersive wave is by definition such that the phase-velocity, \(v\), is a fixed constant which does not depend, in particular, on the frequency of MW.

Solutions of d'Alembert wave equation that are initially zero outside some limited region propagate out from the region at a fixed speed in all spatial directions, as do physical waves from a localized disturbance: traveling waves. Another class of solutions represent standing waves, or normal modes, defined inside a limited region.

The equation alone does not specify a solution: a unique solution is usually obtained by setting a problem with further conditions, such as:
1. initial conditions, which prescribe the value and velocity of the wave on a suitable surface;
2. or values on a closed surface (boundary conditions).

The effect of boundaries, giving rise to boundary conditions, reflection and refraction of waves will be introduced later.

The phase-velocity must not be confused with the velocity of the movement of the Perturbation|Disturbance|Signal: \(\dot{\xi}\).

We consider here the wave equation for a scalar quantity, \(\xi\). When the physical field is a vector or tensor field the general discussion in this section is still valid but additional properties may come into play, which are specific of the physical field and cannot be discussed in general.

In all the cases, solutions to the wave equation will be found and studied but in no case the problem of finding all the solutions will be studied, as this is a complex problem left to Mathematics for Physics.

However it is known that the Fourier Series|Integral (read § 16 - Some Elements of Fourier Analysis) makes Monochromatic Plane Waves-(MPW) the basic elements for solving the wave equation. In fact the Fourier Series|Integral allows one to write any and all the solutions as a sum/integral over MPW. It is therefore sensible, thanks to the linearity of d'Alembert wave equation, to consider only MPW solutions, to start with, and study them in detail as the basic building block of any solution to the wave equation.

\subsection*{40.02.01 Linearity and Superposition of Classical d'Alembert Waves}

The classical homogeneous d'Alembert wave equations (40.01.01) (Read also sections (40.02.01), (40.02.07)) are linear and homogeneous. Therefore any sum of solutions of the equation is still a solution of the equation and the Perturbation|Disturbance|Signal caused by any one solution sum to the Perturbation|Disturbance|Signal produced by all the other Perturbation|Disturbance|Signals in a linear way.

When there is a source the equation becomes a non-homogeneous one (read § 41-004 - Mechanical Waves). The classical non-homogeneous d'Alembert wave equation is linear and non-homogeneous. In this case the sum of the Perturbation|Disturbance|Signal caused by two sources is the sum of the two Perturbation|Disturbance|Signals.

\subsection*{40.02.02 One-Dimensional d'Alembert Non-Dispersive Wave Equation}

This § is referenced at pages:
[1965, 1965]
The one-dimensional wave equation for the scalar quantity \(\xi[z, t]\), whatever the meaning of the physical quantity \(\xi\), is:
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial z^{2}}=\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}} \tag{40.02.01}
\end{equation*}
\]
where \(v\) is the propagation speed of the waves, the so-called phase-velocity.
Only non-dispersive waves such that the phase-velocity, \(v\), is a fixed constant independent of the frequency of MW, will be considered here.

\subsection*{40.02.02.01 General Solution for Non-Dispersive Waves in Unbounded Media}

This § is referenced at pages:
[1970, 1970]
A traveling one-dimensional solution is a any function with argument \(k z-\omega t\).
The general solution of the one-dimensional wave equation in free space without boundaries is easy to write, as long as the phase-velocity \(v \equiv|\mathbf{v}|>0\) is a fixed number, that is the phase-velocity is same for every MW (a so-called non-dispersive wave). In this case the general solution is:
\[
\begin{equation*}
\xi[z, t]=f_{\oplus}[z-v t]+f_{\ominus}[z+v t], \tag{40.02.02}
\end{equation*}
\]
in terms of any two arbitrary functions: \(f_{\oplus}\) and \(f_{\ominus}\).
It can be easily shown by direct calculation that the above function (40.02.02) satisfy the wave equation for any \(f_{\oplus}\) and \(f_{\ominus}\).
The solution of equation (40.02.01) can be found by direct construction with the change of variables:
\[
w_{\oplus} \equiv z-v t \quad w_{\ominus} \equiv z+v t
\]
in terms of which equation (40.02.01) takes the form, in case the phase-velocity \(v\) is a fixed number:
\[
\frac{\partial^{2} \xi}{\partial w_{\oplus} \partial w_{\ominus}}=0
\]
whose solution is equation (40.02.02)
It can be shown that the latter formula gives all the solutions.
The special form of solution (40.02.02) means that, for a non-dispersive wave, any Perturbation|Disturbance|Signal travels keeping the same shape.
Any generic functions \(f_{\oplus}\) and \(f_{\ominus}\) satisfies the equation. However any specific physical problem will have initial/boundary conditions so that the specific solution will be determined in terms of the functions specifying initial/boundary conditions.

\subsection*{40.02.02.02 Rigidly Traveling MPW Solutions in 1D}

This § is referenced at pages:
[1392, 1392, 1974, 1974]
Read also § 40.02.03.02-General Properties of Waves.
As we have a general solution (read \(\S 40.02 .02 .01\) - General Properties of Waves) we can move to studying MPW in 1D.
Read § 17.02 - Linear Systems for the important and useful relations about the sum of harmonic functions with the same frequency.
Consider non-dispersive waves in unbounded one-dimensional media, that is fixed \(v\), in the whole onedimensional space.
Guided by the example of the oscillations of of the surface of a water pool Let us try to find a solution such that a space-harmonic profile rigidly moves at constant speed, \(v\). A function of type:
\[
\xi[z, t] ?=? C \cos \pm z-v t
\]
cannot be used as the argument of the cosinus must be dimensionless. Therefore we need to introduce a constant, \(k\), with dimensions of inverse length, and obtain (after adding also a generic phase constant, \(\phi\) ):
\[
\begin{array}{|l|ll|}
\hline \xi[z, t]=C \cos k( \pm z-v t)-\phi & v \equiv \omega[k] / k & \text { phase-velocity }  \tag{40.02.03}\\
\hline
\end{array}
\]
with the defining relation of the phase-velocity in terms of time frequency and wave-number. As in the previous case the quantity \(k\) is called the wave-number as it is linked to the space behavior of the solution. The constants \(C\) and \(\phi\) must be determined from the initial/boundary conditions.
Replacing the above tentative solution in the above equation one finds the necessary conditions for the above function to be a solution, which is the dispersion relation:
\[
\omega[k]=k v \quad \text { dispersion relation } .
\]

In this case, for waves described by d'Alembert Classical Non-Dispersive wave equation with fixed \(v\), the dispersion relation is somewhat of a trivial dispersion relation, in the sense that there is no dispersion at all: these waves are non-dispersive waves, that is, waves whose phase-velocity is independent of \(\omega\) and \(k\), read \(\S 40.03 .08\) - General Properties of Waves. One should not be confused by the fact that, in this case, the dispersion relation is identical to the definition of the phase-velocity: this is because we are dealing with d'Alembert Classical Non-Dispersive wave equation with fixed \(v\). The two concepts are totally distinct concepts.

As the Fourier Series|Integral allows us to use Sinusoid|Cosinusoid to describe any function it is worthwhile to study better the behavior of Sinusoid|Cosinusoid harmonic waves.
In order to use harmonic waves it is necessary to use the dimensionless phase (40.02.09). As a particular case d'Alembert wave equation always admits harmonic solutions:
\[
\begin{equation*}
\xi[z, t]=\xi_{0} \cos \pm k z-\omega t-\phi \quad \text { with } k>0 \text { and } \omega>0 \tag{40.02.04}
\end{equation*}
\]
where \(\omega>0\) is the angular frequency of the time oscillation at a fixed space point, linked to the time period of the oscillation, \(k>0\) is the wave number, linked to the wavelength \(\lambda\) of the space oscillation at a fixed time and corresponding to the space traveled in a period by any part of the wave at fixed phase.
The corresponding phase-velocity, that is the speed of travel of the planes of constant phase (as it is demonstrated in § 40.02.02.03-General Properties of Waves) is:
\[
\begin{equation*}
v \equiv \omega[k] / k \tag{40.02.05}
\end{equation*}
\]

The Sinusoid|Cosinusoid wave (40.02.04) represents a Sinusoid|Cosinusoid vibration in time, at any fixed location \(z\), and a Sinusoid|Cosinusoid vibration in space, at any fixed time, \(t\).

The following general relations apply:
\[
\begin{array}{|c|}
\hline \omega=\frac{2 \pi}{T} \equiv 2 \pi \nu \\
k=\frac{2 \pi}{\lambda} \equiv 2 \pi \sigma \\
\lambda=v T
\end{array},
\]

The latter relation shows the link among the spatial period, the time period and the phase-velocity: it is in fact a direct consequence of the phase-velocity equation (40.02.05).
MPW are characterized by a double periodicity: in time and in space. The dispersion relation (40.03.02) is the link among the two periodicities. It depends on the particular physical phenomena under study, that is on the wave equation. The relation (40.03.02) provides, by means of the solution to the wave equation, the relation between \(\omega\) and \(k\) for a given MPW (the dispersion relation). The first task of the solution of any problem with waves is to find the dispersion relation between the frequency, \(\omega\), and the wave-number, \(k\).
The existence of the dispersion relation comes from the fact that the one-dimensional wave-equation has only one parameter, the velocity \(v\). When one introduces the solution in the form of equation (40.02.04) the two parameters, \(k\) and \(\omega\), turn out to be linked by the wave equation. The link is actually the relation between the space and time periodicity of the wave.

\subsection*{40.02.02.03 Phase-Velocity}

This § is referenced at pages:
[1970, 1970]
The special form of equation (40.02.02) means that the Perturbation|Disturbance|Signal \(\xi[x, t]\) takes the same value at all times-points where \((v>0)\) :
\(z-v t=\) constant \(\quad\) for the part \(f_{\oplus}[z-v t] \quad\) and \(\quad z+v t=\) constant \(\quad\) for the part \(f_{\ominus}[z+v t]\)

In other words the two perturbations/disturbances, \(f_{\oplus}\) and \(f_{\ominus}\) travel rigidly with velocity, the phasevelocity, \(+v\), for the part \(f_{\oplus}[z-v t]\), and \(-v\), for the part \(f_{\ominus}[z+v t]\). In fact:
\[
z \pm v t=\text { constant } \Longrightarrow z_{2} \pm v t_{2}=z_{1} \pm v t_{1} \Longrightarrow \Delta z=\mp v \Delta t \Longrightarrow \frac{\Delta z}{\Delta t}=\mp v .
\]

Clearly the total Perturbation|Disturbance|Signal is not moving rigidly unless either \(\xi=f_{\oplus}\) or \(\xi=f_{\ominus}\).
Note that it is essential that the phase-velocity is a fixed constant in order to have a rigid propagation of the wave-form. The phase-velocity could reasonably be called the argument velocity, because \(v\) is the speed with which a point with constant argument, \(z \pm v t\), of the function \(f\) moves. However, not all systems have the property that the phase-velocity \(\pm \omega / k\) is constant, that is, independent of \(\omega\) and \(k\) : waves described by d'Alembert Classical Non-Dispersive equation with fixed \(v\) have this property, that is they are non-dispersive waves.

The case of an exactly non-dispersive waves is important, in practice, because it includes many important phenomena, such as ElectroMagnetic waves propagating in vacuum or in a perfect medium.

\subsection*{40.02.02.04 Time-Harmonic Solutions (Standing Waves or Normal Modes)}

This § is referenced at pages:
[2131, 2131, 2133, 2133]
Guided by the example of the oscillations of the plucked string of a guitar, Let us try to find a solution such that all the parts, which are labeled by the coordinate \(z\), oscillate with the same time dependence, a harmonic one (this kind of solutions is called a standing wave or normal mode):
\[
\xi[z, t] \quad ?=? \quad A[z] \cos \omega t-\phi
\]

Note: there is no propagation of the wave at all in this case.
In other words the space and time dependence are factorized (see section §40.02.03.05 - General Properties of Waves) and all oscillators oscillate with the same time dependence, a time-harmonic one in this case.

Replacing the above tentative solution into the wave equation one finds the necessary conditions for the above function to be a solution:
\[
\begin{equation*}
\frac{\mathrm{d}^{2} A[z]}{\mathrm{d} z^{2}}=-\frac{\omega^{2}}{v^{2}} A[z] \equiv-k^{2} A[z] \tag{40.02.06}
\end{equation*}
\]
\(\rightarrow\)
with the necessary condition given by the dispersion relation:
\[
\omega=\omega[k] \equiv k v
\]

In this case, for waves described by d'Alembert Classical Non-Dispersive wave equation with fixed \(v\), the dispersion relation is somewhat of a trivial dispersion relation, in the sense that there is no dispersion at all: these waves are non-dispersive waves, that is, waves whose phase-velocity is independent of \(\omega\) and \(k\), read § 40.03.08-General Properties of Waves.
The quantity \(k\) is called the wave-number as it is linked to the space behavior of the solution. In fact the general solution for \(A[z]\) is given by:
\[
A[z]=b_{c} \cos k z+b_{s} \sin k z .
\]

In summary:
\[
\begin{gathered}
\xi[z, t]=\left(b_{c} \cos k z+b_{s} \sin k z\right) \cos \omega t-\phi, \\
\omega=\omega[k] \quad \text { the dispersion relation }
\end{gathered}
\]

The constants \(b_{c}, b_{s}\) and \(\phi\) must be determined from the initial/boundary conditions.
In this case, for waves described by d'Alembert Classical Non-Dispersive wave equation with fixed \(v\), the dispersion relation is somewhat of a trivial dispersion relation, in the sense that there is no dispersion at all: these waves are non-dispersive waves, that is, waves whose phase-velocity is independent of \(\omega\) and \(k\), read § 40.03.08-General Properties of Waves.
Consider the plucked string of a guitar, whose ends are fixed, so that \(\xi[z=0, t]=0\) and \(\xi[z=L, t]=0\) :
\[
\begin{gathered}
\xi[z=0, t]=0 \Longrightarrow b_{c}=0, \\
\xi[z=L, t]=0 \Longrightarrow \sin k L=0, \\
\Longrightarrow k=q \frac{\pi}{L} \quad q \in \mathbb{Z} \quad k \text { is quantized } \Longrightarrow \omega=q v \frac{\pi}{L} \quad \omega \text { is quantized }, \\
b_{s} \quad \text { is arbitrary } .
\end{gathered}
\]

\subsection*{40.02.02.05 Standing Waves With Arbitrary Time Dependence}

The phenomena in one dimension described so far concerns waves propagating in an infinite medium. If the system is bounded (closed) in such a way that the energy must remain inside a finite volume some other different phenomena appear.
Standing waves in one dimension (also called normal modes) are separable solutions of the wave equations, that is solutions such that the space and time parts are separated:
\[
\xi[z, t]=f[z] g[t]
\]

In normal modes of oscillations all the oscillators oscillate with the same time dependence but different amplitudes.
For a separable solution one finds that:
\[
\frac{1}{f[z]} \frac{\mathrm{d}^{2} f}{\mathrm{~d} z^{2}}=\frac{1}{v^{2} g[t]} \frac{\mathrm{d}^{2} g}{\mathrm{~d} t^{2}}=-k^{2} .
\]

In fact as the two members depend on a priori different variables they must be constant and the constant is negative because of the oscillatory character of the phenomena.
It follows:
\[
\frac{\mathrm{d}^{2} f}{\mathrm{~d} z^{2}}+k^{2} f[z]=0 \quad \frac{\mathrm{~d}^{2} g}{\mathrm{~d} t^{2}}+\omega^{2} g[t]=0
\]
so that the solution for the standing wave is:
\[
\xi[z, t]=A \cos k z+\phi_{z} \cos \omega t+\phi_{t} .
\]

Boundary conditions must be satisfied, imposed by the specific problem.
Examples of standing waves in one dimension include the following.
- Standing waves on a string, like on a guitar.
- In quantum physics wave-functions are solutions to Schrödinger equation.

\subsection*{40.02.02.06 Oscillations of a Closed System: Standing Waves in Bounded 1D Regions}

Read § 43 - Waves in Bounded Regions.
Example: the vibrating string with fixed ends.

\subsection*{40.02.03 Three-Dimensional d'Alembert Non-Dispersive Wave Equation}

This § is referenced at pages:
[1965, 1965]
The three-dimensional wave equation for the scalar quantity \(\xi[x, t]\), whatever the meaning of the physical quantity \(\xi\), is:
\[
\begin{equation*}
\nabla^{2} \xi=\frac{1}{v^{2}} \frac{\partial^{2} \xi}{\partial t^{2}} \tag{40.02.07}
\end{equation*}
\]
\(\rightarrow\) 19681974 1976
where \(v\) is the propagation speed of the waves, the so-called phase-velocity.
Here, only non-dispersive waves such that the phase-velocity, \(v\), is a fixed constant independent of the frequency of monochromatic wave, will be considered here.

\subsection*{40.02.03.01 Rigidly Traveling PW Solutions in 3D}

\section*{This § is referenced at pages:}
[Never referenced.]
Read § 40.02.02.02 - General Properties of Waves.
Consider non-dispersive waves in unbounded media, that is fixed \(v\), in the whole three-dimensional space.
Let us consider general PW solutions, not necessarily monochromatic: this is the simplest generalization of the traveling wave in higher dimensions.
Strictly speaking, MPW do not exist in nature as they are made of a Sinusoidal|Cosinusoidal time-space behavior of infinite extent both in space and in time. However they are often a very useful approximation.
Similarly, strictly speaking, PW do not exist in nature as well, as they are made of fronts of infinite extent. However they are often a very useful approximation.
In the three-dimensional case any expression of the type
\[
\begin{equation*}
\xi[\mathbf{x}, t]=f[\mathbf{n} \cdot \mathbf{x}-v t] \quad \text { a scalar wave }, \tag{40.02.08}
\end{equation*}
\]
where \(f\) is any arbitrary function, \(\hat{\mathbf{n}}\) is any arbitrary fixed unit vector and is a PW .
In fact:
\[
f \equiv f[s] \Longrightarrow \operatorname{grad} \xi=\hat{\mathbf{n}} \frac{\mathrm{d} f}{\mathrm{~d} s} \quad \nabla^{2} \xi \equiv \operatorname{div} \operatorname{grad} \xi=(\mathbf{n} \cdot \mathbf{n}) \frac{\mathrm{d}^{2} f}{\mathrm{~d} s^{2}}=\frac{\mathrm{d}^{2} f}{\mathrm{~d} s^{2}}
\]

Therefore for any function \(f\) and any \(\hat{\mathbf{n}}\) the expression (40.02.08) is a solution, as long as \(v\) is a fixed constant.
While for the one-dimensional equation two arbitrary functions give all the (PW) solutions, for the threedimensional equation one can have an infinite number of solutions by choosing any arbitrary function and any arbitrary unit vector, \(\hat{\mathbf{n}}\).
It is more convenient to write the phase as a dimensionless quantity, as it was done for the other cases discussed before, also adding a generic phase constant, \(\phi\) :
\[
\begin{equation*}
\Phi \equiv \mathbf{k} \cdot \mathbf{x}-\omega t-\phi \tag{40.02.09}
\end{equation*}
\]

As the d'Alembert equation has only one parameter, the velocity \(v\), the two quantities \(\mathbf{k}\) and \(\omega\) must be related in order to represent a solution to the wave equation. By direct substitution in equation (40.02.07) one finds the basic relation between the two quantities \(k\) and \(\omega\), the dispersion relation:
\[
v^{2}(\mathbf{k} \cdot \mathbf{k})=v^{2} k^{2}=\omega^{2} \Longrightarrow v \equiv \frac{\omega}{k}
\]

In this case, for waves described by d'Alembert Classical Non-Dispersive wave equation with fixed \(v\), the dispersion relation is somewhat of a trivial dispersion relation, in the sense that there is no dispersion at all: these waves are non-dispersive waves, that is, waves whose phase-velocity is independent of \(\omega\) and \(k\), read § 40.03.08-General Properties of Waves.
The dimensionless phase of the wave, is the function of position and time
\[
\Phi[\mathbf{r}, t] \equiv \mathbf{k} \cdot \mathbf{x}-\omega t-\phi=k(\mathbf{n} \cdot \mathbf{x}-v t)-\phi \quad \hat{\mathbf{n}} \equiv \mathbf{k} /|\mathbf{k}|
\]
giving, at any time, the locus of the points in space where the value of the Perturbation|Disturbance|Signal has the same fixed value. At any time the locus of constant phase is a plane perpendicular to the unit vector \(\hat{\mathbf{n}}\) : the unit vector \(\hat{\mathbf{n}}\) defines the direction in space.
Note: \(\phi\) is the dimensionless phase constant, a fixed number; \(\Phi[\mathbf{r}, t]\) is the dimensionless phase of the wave, (phase, in short) a function of space and time coordinates. Obviously one can add any integer multiple of \(2 \pi\) to the phase constant without changing the value of the function. Normally one uses a value in the range \(0 \leq \phi \leq 2 \pi\).
The phase-velocity, that is the velocity of movement of constant-phase planes, is still \(v\).

\section*{SOLUTION}

The phase-velocity can be calculated as follows.
Consider one specific constant-phase wave-front, defined by a certain values of the phase, \(c\). The phase of the wave will keep the same value, \(c\), after a certain time interval \(\Delta t\), at all the points of a plane which can be calculated as follows:
\[
\begin{aligned}
c=\Phi[\mathbf{r}, t]= & \mathbf{k} \cdot \mathbf{x}-\omega t-\phi=\mathbf{k} \cdot \mathbf{x}+\mathbf{k} \cdot \Delta \mathbf{x}-\omega t-v \Delta t-\phi=c, \\
& \Longrightarrow \mathbf{k} \cdot \Delta \mathbf{x}-\omega \Delta t=|\mathbf{k}| \hat{\mathbf{n}} \cdot \Delta \mathbf{x}-\omega \Delta t=0, \\
& \Longrightarrow v=\omega /|\mathbf{k}| .
\end{aligned}
\]

As the quantity \(\hat{\mathbf{n}} \cdot \Delta \mathrm{x}\) represent the distance between the two planes with the same phase the above relation shows that \(v\) is the phase-velocity.
In the special case of \(\Delta t=T\) one has \(\hat{\mathbf{n}} \cdot \Delta \mathbf{x}=\lambda\).
An alternative derivation follows.
Consider any two points, \(\mathbf{x}_{1}\) and \(\mathbf{x}_{2}\), on two planes with the same phase at different times \(t_{1}\) and \(t_{2}\). That is the second plane is the first one moved between \(t_{1}\) and \(t_{2}\). One has:
\[
\hat{\mathbf{n}} \cdot\left(\mathbf{x}_{2}-\mathbf{x}_{1}\right)-v\left(t_{2}-t_{1}\right)=0
\]
where \(\hat{\mathbf{n}} \cdot\left(\mathbf{x}_{2}-\mathbf{x}_{1}\right)\) is the distance between the two planes and the above equation describes the kinematics of the planes at constant phase. If the above relation is satisfied then \(\xi\) has the same values at the two points \(\left\{\mathbf{x}_{1}, t_{1}\right\}\) and \(\left\{\mathbf{x}_{2}, t_{2}\right\}\).
Q.E.D.

Note that at large distance from the source, whatever the source, all waves can be approximated as PW.

\subsection*{40.02.03.02 Rigidly Traveling MPW Solutions in 3D}

This § is referenced at pages:
[1970, 1970, 2033, 2033]
Let us now consider MPW solutions.
Consider non-dispersive waves in unbounded media, that is fixed \(v\), in the whole three-dimensional space.
It is any PW as in equation 40.02 .08 with \(f[w]=\sin w-\phi_{s}\) or \(f[w]=\cos w-\phi_{s}\). It is harmonic in both space and time.

\subsection*{40.02.03.03 Isotropic Cylindrical Waves Solutions for Non-Dispersive Waves in Unbounded Media}

This § is referenced at pages:
[1980, 1980]
© \(\mathbb{E}\) E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|§ 2||
Consider non-dispersive waves in unbounded media, that is fixed \(v\), in the whole three-dimensional space.
Consider a isotropic two-dimensional traveling wave propagation (water waves on a water surface, for instance): the amplitude decreases as energy is spread along the circumference.
Consider either cylindrical waves in a three-dimensional problem or circular waves in a two-dimensional problem. Assume waves isotropic in the plane perpendicular to the axis of the cylinder.
A isotropic cylindrical wave profile, moving rigidly in the radial direction with constant amplitude, is described by:
\[
\xi[r, t]=f[r \pm v t],
\]
where the \(\pm\) sign describes ingoing/outgoing waves. Following the one-dimensional case we can try this kind of solution.

However if energy is proportional to the square of the amplitude then energy conservation makes the latter relation inconsistent and requires
\[
\xi[r, t] \approx \frac{\xi_{0}}{\sqrt{r}}
\]

The Laplacian in cylindrical coordinates for systems with cylindrical symmetry reads
\[
\nabla^{2} \xi=\frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial \xi}{\partial r}\right)=\frac{\partial^{2} \xi}{\partial r^{2}}+\frac{1}{r} \frac{\partial \xi}{\partial r}
\]

The exact solutions in this case are given in terms of the so-called Bessel functions \({ }^{2}\), which typically arise in problems with cylindrical symmetry. It can be shown that, for \(k r \gg 1\), they can be approximated as
\[
\xi[r, t] \sim \frac{\xi_{0}}{\sqrt{r}} \cos k r \pm \omega t-\phi
\]

Note that, unlike the plane and spherical waves, cylindrical waves cannot assume an arbitrary functional form.

\subsection*{40.02.03.04 Isotropic Spherical Waves Solutions for Non-Dispersive Waves in Unbounded Media}

This § is referenced at pages:
[1980, 1980]
©|E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|§ 2||
Consider non-dispersive waves in unbounded media, that is fixed \(v\), in the whole three-dimensional space.
Consider a isotropic three-dimensional traveling wave propagation (acoustic waves in three dimensions, for instance): the amplitude decreases as energy is spread along the sphere.
Consider spherical waves in a three-dimensional problem. Assume isotropic waves. A isotropic spherical wave profile, moving rigidly in the radial direction with constant amplitude, is described by:
\[
\xi[r, t]=f[r \pm v t]
\]
where the \(\pm\) sign describes ingoing/outgoing waves. Following the one-dimensional case we can try this kind of solution.
If energy is proportional to the square of the amplitude of the wave energy conservation makes the latter relation inconsistent and implies
\[
\xi[r, t] \approx \frac{\xi_{0}}{r}
\]

The latter result is made more precise by solving the three-dimensional wave equation (40.02.07) in spherical coordinates for a isotropic scalar function: \(\xi[r, t]\).
The Laplacian in spherical coordinates for systems with spherical symmetry reads
\[
\boldsymbol{\nabla}^{2} \xi[r, t] \longrightarrow \frac{1}{r} \frac{\partial^{2} 1}{\partial r^{2}}(r \xi[r, t])=\frac{\partial^{2} \xi}{\partial r^{2}}+\frac{2}{r} \frac{\partial \xi}{\partial r}
\]

The general solution follows from the general solution of the wave equation, in terms of two arbitrary functions:
\[
\xi[z, t]=\frac{f_{\oplus}[r-v t]+f_{\ominus}[r+v t]}{r}
\]

40.02.03.05 Oscillations of a Closed System: Standing Waves in Bounded 3D Regions

This § is referenced at pages:
[1965, 1965, 1972, 1972, 2128, 2128]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., .... 2.3|||
©|J.P.Pérez et al., Optique, ..., DUNOD, ...Ed., WEB - URL.|19.6||
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 6||
Read § 43 - Waves in Bounded Regions.
Examples: transmission lines, ElectroMagnetic cavities, water waves on a swimming pool.
Consider non-dispersive waves in bounded media, that is fixed \(v\), in a bounded (limited) threedimensional region, such that it is contained inside some sphere.
The phenomena in three dimensions described so far concerns waves propagating in an infinite medium. If the system is bounded (closed) in such a way that the energy must remain inside a finite volume some other different phenomena appear.
Standing waves in three dimensions (also called normal modes) are separable solutions of the wave equations, that is solutions such that the space and time parts are separated:
\[
\xi[\mathbf{r}, t]=f[\mathbf{r}] g[t] .
\]

In normal modes of oscillations all the oscillators oscillate with the same time dependence but different amplitudes.
Boundary conditions must be satisfied, imposed by the specific problem.
Examples of standing waves in three dimensions include the following.
- Standing waves on a drum.
- Wave-guides and resonant cavities.
- In quantum physics wave-functions are solutions to Schrödinger equation.

\section*{Understanding Waves - Real Wave Phenomena}

\section*{This § is referenced at pages:}
[1963, 1963]
In this section some general properties and phenomena related to waves are just mentioned and introduced, while their study, for the different types of waves, is postponed to the next sections.
Wave phenomena arise everywhere in the world, but the phenomena are often much more complex than the simple d'Alembert Classical Non-Dispersive wave equation can describe. The main complications are non-linearity, which is absent for linear d'Alembert waves, and dispersion.

\subsection*{40.03.01 Oscillators at Different Places With Defined Relative Phase}

The concept of wave can be better understood starting from a set of localized oscillating systems as follows.
An oscillating system is something physically localized in space and characterized by some physical property oscillating in time (a particular and important case is that of harmonic oscillations). Physical waves can be considered to be built from many (possibly infinite) different oscillators, distributed at in some space region, with some oscillating physical property.
Neighboring oscillators oscillate with a well-defined relative relationship among each-other, described by the wave equation.
In fact any wave consists of oscillations both in space and in time.
The oscillating physical property might be periodic both in time and in space.
In any case the wave equation implies a well-defined relation between the time-oscillation of oscillators located at neighboring points in space and the variation in space of the oscillating physical property.
The Mexican wave (read § 40.01.03 - General Properties of Waves) is clarifying: each supporter must stand-up and sit-down at the right moment, depending on what his neighboring supporters are doing.

\subsection*{40.03.02 Scalar Vector and Tensor Waves}

The case when the physical quantity propagated by the wave is a scalar quantity will be mainly considered in the exemplifications.

\subsection*{40.03.02.01 MP Scalar Vector and Tensor Waves}

Consider a generic wave-field, \(W, \mathbf{W}, \mathbb{W}\) :
\[
\begin{gathered}
W[\mathbf{r}, t]=W_{0} \cos \mathbf{k} \cdot \mathbf{r}-\omega t-\delta, \\
\mathbf{W}[\mathbf{r}, t]=\mathbf{W}_{0} \cos \mathbf{k} \cdot \mathbf{r}-\omega t-\delta \Longrightarrow W_{i}[\mathbf{r}, t]=\left(W_{i}\right)_{0} \cos \mathbf{k} \cdot \mathbf{r}-\omega t-\delta, \\
\mathbb{W}[\mathbf{r}, t]=\mathbb{W}_{0} \cos \mathbf{k} \cdot \mathbf{r}-\omega t-\delta \Longrightarrow W_{i j}[\mathbf{r}, t]=\left(W_{i j}\right)_{0} \cos \mathbf{k} \cdot \mathbf{r}-\omega t-\delta .
\end{gathered}
\]

Whenever vector/tensor waves are considered the vector/tensor nature of the physical quantity usually imposes additional relations/constraints. Examples:
- scalar waves: longitudinal elastic waves (acoustic waves);
- vector waves: ElectroMagnetic (transverse) waves, transverse vibrations on a string;
- tensor waves: gravitational waves.

\subsection*{40.03.03 Velocity of the Oscillating Field}

Let the oscillating physical quantity, that is the propagating disturbance, be \(\xi[\mathbf{r}, t]\) : the quantity \(\dot{\xi}[\mathbf{r}, t]\) represents a velocity. If the quantity \(\boldsymbol{\xi}[\mathbf{r}, t]\) represents a displacement, this velocity is the velocity associated to the displacement (as for mechanical waves); in other cases the velocity may have a different meaning, for instance in EM waves where it is the time-derivative of the electric or magnetic field.
The \(\dot{\xi}[\mathbf{r}, t]\) velocity must not be confused with any propagation velocity of the associated wave, such as phase-velocity or group-velocity.

\subsection*{40.03.04 Longitudinal and Transverse Vector Waves}

When the physical field is a vector field (which includes the two important cases of mechanical waves and ElectroMagnetic waves) one can introduce the distinction between longitudinal waves and transverse waves. In the simplest case of PW this is defined with respect to the direction of propagation of the wave, \(\mathbf{k}\), that is for any given wave-vector \(\mathbf{k}\), as follows.
- If the field, \(\boldsymbol{\xi}\), of the PW is parallel to \(\mathbf{k}\) we say the wave is longitudinal (such as: acoustic waves).
- If the field, \(\boldsymbol{\xi}\), of the PW is perpendicular to \(\mathbf{k}\) we say the wave is transverse (such as: transverse waves on a string, plane ElectroMagnetic waves, torsion waves on a bar).
Transverse waves require the additional concept of Polarization to be described, because, for a transverse vector field, all directions in the plane perpendicular to \(\mathbf{k}\) are allowed, in principle, so that the concept of Polarization is required to fully describe the field (that is, one has to describe the two degrees of freedom in the plane perpendicular to \(\mathbf{k}\) ). Read \(\S 42.03\) - ElectroMagnetic Waves for the full description of the concept of Polarization introduced for the case of ElectroMagnetic waves; the same applies to transverse waves on a string.
There are cases of waves which have both a longitudinal and a transverse component, such as: water waves and elastic waves in solid media. For elastic waves in solid media: In the most general case:
- longitudinal waves are defined as waves such that: \(\boldsymbol{\operatorname { r o t }} \boldsymbol{\xi}=0\);
- transverse waves are defined as waves such that: \(\operatorname{div} \boldsymbol{\xi}=0\).
40.03.05 Harmonic Waves
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|§ \(1.3|\mid\)
Harmonic waves are waves such that at any fixed point in space the time dependence of the wave disturbance is harmonic
\[
\xi[\mathbf{r}, t]=G[\mathbf{r}] \exp F[\mathbf{r}]-\omega t \equiv G[\mathbf{r}] \exp \Phi[\mathbf{r}, t]
\]
\begin{tabular}{|c}
\hline\(\frac{\partial \Phi[\mathbf{r}, t]}{\partial t} \equiv-\omega \quad\) if and only if harmonic wave \(\quad \operatorname{grad} \Phi[\mathbf{r}, t] \equiv \mathbf{k} \quad\) if and only if harmonic wave. \\
\hline
\end{tabular}
(40.03.01)

MPW is a special case of harmonic waves, such that also the space dependence is sinusoidal.
Read § 17.02 - Linear Systems for the important and useful relations about the sum of harmonic functions with the same frequency.
Also Read § 40.04.02 - General Properties of Waves.
Consider harmonic waves \({ }^{3}\).

\footnotetext{
\({ }^{3}\) In the literature there is a variety of nomenclature. Here, we will use wave-front and front as generic nouns, while reserving CPWF and CAWF for a more precise/technical usage.
}

\subsection*{40.03.05.01 Constant-Phase Surfaces for Harmonic Waves}

A CPWF-(constant-phase wave-front) is defined as the locus of points in space such that the phase in time of the different oscillators in space is the same. Different CPWF are defined by all possible different values of the phase, between zero and \(2 \pi\). Harmonic Waves propagates such that any CPWF, moves in space with a well-defined kinematics (speed). The velocity of CPWF is the so-called phase-velocity.
Note that the phase-velocity does not, in general, represent the velocity information, signals, energy or other physical quantities are moving. The problem of the velocity of transport of information, signals, energy or other physical quantities is a very complex one and the concept of phase-velocity is not sufficient to describe all the complexity.

Note that a CPWF is the locus of points with equal phase of the time oscillation, not equal amplitude. In fact, for waves propagating in more than one dimension the amplitude decreases even when there is no absorption.

\subsection*{40.03.05.02 Constant-Amplitude Surfaces for Harmonic Waves}

The surfaces \(G[\mathbf{r}]=\) constant are called CAWF-(constant-amplitude wave-front).
In general, CPWF and CAWF do not coincide.Such a wave is said to be a non-homogeneous one.

\subsection*{40.03.06 Energy Linear Momentum and Angular Momentum}

Waves may carry energy, linear momentum and angular momentum. As a well-known example it is common experience that water waves on the ocean carry energy as they are capable both to set into oscillation a ship (that is they impart kinetic energy to the ship) and to raise the quota of the ship (that is they impart gravitational potential energy to the ship). Water waves can also set in motion surfers, imparting them a significant speed provided the surfer can catch the right kinematics. Energy must be put into the system to cause the initial disturbance and it is this energy that is then transmitted by the wave.

\subsection*{40.03.07 Shape and Energy}

Energy is clearly related the amplitude of the oscillations.
In case of two-dimensional and three-dimensional traveling waves it is common experience that the amplitude of the wave decreases with the distance from the source and this is due to the energy spreading over larger and larger regions of space. In fact, in two or three dimensions, while the wave spreads out, its amplitude will decrease in order to conserve the energy.
In presence of absorption, even in one dimension, the wave will decrease its amplitude as it moves. However, waves with absorption are not described by d'Alembert wave equation.
Water waves and the plucked string of a guitar, as a common example, show clearly that often (but not always) waves, at least to a first approximation, are perturbations/disturbances either moving or stationary without changing their shape or keeping the same shape but with a progressively decreasing amplitude or even changing (often slowly) their shape.
A rather reasonable assumption is that a wave carries an energy per unit area per unit time proportional to the square of the amplitude of the wave. In fact we know that kinetic energy is proportional to the square of the speed and elastic potential energy is proportional to the square of the deformation; moreover the energy of ElectroMagnetic fields depends on the square of the ElectroMagnetic field intensity. Read § 40.02.03.03 - General Properties of Waves, § 40.02.03.04-General Properties of Waves.

\subsection*{40.03.08 Dispersion Relation Phase-Velocity Group-Velocity}

This § is referenced at pages:
[1970, 1970, 1972, 1972, 1972, 1972, 1974, 1974, 2135, 2135, 2135, 2135]
Read § 16.04.05.01 - Some Elements of Fourier Analysis.
The following basic fact must be stressed, as it might be confusing for the special case of the d'Alembert wave equation with fixed \(v\) : there is a neat distinction between the dispersion relation and the phasevelocity relation.

The dispersion relation is always, for any kind of MPW, whatever its wave equation, the relation between frequency and wave-vector:
\[
\begin{equation*}
\omega=\omega[\mathbf{k}] \tag{40.03.02}
\end{equation*}
\]
which is obtained replacing any MPW into the wave equation and imposing the MPW to be a solution.
An equation is dispersive if \(\omega[k]\) is real and its second derivative is different from zero: \(\omega^{\prime \prime}[k] \neq 0\). If \(\omega[k]\) is complex, the equation is diffusive.

Note that, for a isotropic medium:
\[
\begin{equation*}
\omega=\omega[|\mathbf{k}|] \quad \text { isotropic medium } \tag{40.03.03}
\end{equation*}
\]

In general, a complex exponential solution must be used to replace in the wave equation and find the dispersion relation:
\[
\bar{\xi}[\mathbf{r}, t]=\bar{A} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)] \Longrightarrow \omega=\omega[\overline{\mathbf{k}}]
\]
where the wave-vector and amplitude are complex (read § 40.04.01 - General Properties of Waves and references therein). A complex wave-vector allows to describe harmonic solutions which are either attenuating or amplificating waves.

The phase-velocity relation is always, in 1D, for any kind of MPW, whatever its wave equation:
\[
v_{p} \equiv \frac{\omega[k]}{k} \quad \text { one dimension only }
\]

It is therefore derived from the dispersion relation.
In the special case of the d'Alembert wave equation with fixed \(v\) the definition of the phase-velocity and the dispersion relation coincide and this may lead to some confusion.

If the wave is dispersive then MPW with different frequencies will travel at different speeds so that a generic waveform might not keep the same shape as it moves.

The group velocity of a wave is defined by:
\[
v_{g} \equiv \frac{\mathrm{~d} \omega[k]}{\mathrm{d} k} \quad \text { one dimension only }
\]
and it represents, to a first approximation, the speed of propagation of the energy of a wave (for moderately dispersive media and packets localized enough). Read §40.03.11 - General Properties of Waves and § 16.04.05.01 - Some Elements of Fourier Analysis.

\subsection*{40.03.09 Dispersion and Dispersion Relation}
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....||A nice introduction.|
© \(\mid\) King \(|§ 8| A\) nice introduction.|
©|L.D.Landau et al., Electrodynamics of continuous media, ..Ed., ....|§ 103||
©|D.Morin|WEB - URL OR WEB - URL|Very nice and clear introduction to dispersion.|
©|G.B.Whitham|Linear and Nonlinear Waves|WEB - URL - Advanced|
The speed of ElectroMagnetic waves in a vacuum does not depend on the frequency of the MPW: ElectroMagnetic waves in vacuum are exactly non-dispersive.

Also ElectroMagnetic waves in a perfect medium are exactly non-dispersive.
In matter, often to a good approximation, almost-MPW ElectroMagnetic waves suffer low dispersion and low attenuation.
However, in general, ElectroMagnetic waves in matter suffer dispersion and attenuation.
To a very good approximation the velocity of sound waves in air is independent of the frequency of the MPW. If that would not be the case, people at different distances from the center of an auditorium would hear a different musical experience.
However, the idealization that MPW of any frequency will travel at the same speed will fail, to some extent, for most real physical systems.
Dispersion is the dependence of the phase-velocity on the frequency of the MPW. Dispersion has a profound effect on the behavior of a wave. For instance, dispersion of light causes such effects as the rainbow.
In order to get the dispersion relation for any linear homogeneous system of partial differential equations: replace a Sinusoid|Cosinusoid into the equation, use the boundary conditions and ask for the relation to be identically satisfied. This requirement implies a relation on some coefficients: this is the dispersion relation.

Non trivial examples we will study are the following: EM waves in Ohmic media; EM waves in plasma; EM waves in a wave-guide.

\subsection*{40.03.09.01 Dispersion Relation for ElectroMagnetic Waves in Vacuum}

These are exactly described by the classical d'Alembert wave equation.
They show, exactly, a simple dispersion relation, the frequency is strictly proportional to the wavenumber and the proportionality constant in the speed of light in vacuum:
\[
\omega=\omega[k]=k c \text {. }
\]

\subsection*{40.03.09.02 Dispersion Relation for ElectroMagnetic Waves in Matter}

These are not described, in general, by the classical d'Alembert wave equation.
In general, ElectroMagnetic waves in matter are dispersive. In fact, matter is made by charges in motion, which can have a resonant response at different frequencies; therefore it is to be expected that waves of different frequencies travel with different kinematics. Read § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter.
In Ohmic neutral LHI media, the ElectroMagnetic wave equation reads (read § 42.06 - ElectroMagnetic Waves):
\[
\begin{array}{|c|}
\hline \nabla^{2} \mathbf{E}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{E}-\epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{\mathrm{R}} \mu_{0} \frac{\partial^{2} \mathbf{E}}{\partial t^{2}}=0 \\
\nabla^{2} \mathbf{B}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{B}-\epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{\mathrm{R}} \mu_{0} \frac{\partial^{2} \mathbf{B}}{\partial t^{2}}=0 \\
\hline
\end{array}
\]

The resulting dispersion relation is equation (50.02.04).

\subsection*{40.03.09.03 Dispersion Relation for ElectroMagnetic Waves in a Plasma}

These are not described by the classical d'Alembert wave equation.
The dispersion relation of ElectroMagnetic waves propagating through an unMagnetized plasma is:
\[
\omega= \pm \sqrt{k^{2} c^{2}+\omega_{p}^{2}},
\]
in term of the so-called plasma frequency, \(\omega_{p}\), which depends on the properties of the plasma.

\subsection*{40.03.09.04 Dispersion Relation for ElectroMagnetic Waves in Wave-Guides}

Read § 43.03.03 - Waves in Bounded Regions, § 43.03.04-Waves in Bounded Regions.

\subsection*{40.03.09.05 Dispersion Relation for Surface Water Waves}

This § is referenced at pages:
[2023, 2023]
These are not described by the classical d'Alembert wave equation.
For pure gravity waves, that is waves characterized by a negligible effect of the surface tension, the dispersion relation, in the linear regime, is given by:
\[
\omega^{2}=g k \operatorname{tah}[k h] \Longrightarrow\left\{\begin{array}{l}
k h \gg 1 \Longrightarrow \omega=\sqrt{g k} \quad \\
k h \ll 1 \Longrightarrow \omega=k \sqrt{g h}
\end{array} \quad \text { deep-water waves, dispersive }, ~\right. \text { shallow-water waves, non dispersive }
\]
as a function of the sea depth, \(h\).
In general, the dispersion relation, in the linear regime, is given by:
\[
\omega^{2}=\left(g k+k^{3} \frac{\gamma}{\rho}\right) \operatorname{tah}[k h]
\]
as a function of the sea depth, \(h\), and surface tension \(\gamma\).

\subsection*{40.03.09.06 Dispersion Relation for Linear Mass-Spring Chain}

Consider the linear mass-spring chain of \(\S\) 23.07.04- Oscillations of a few mass points and its dispersion relation (equations (23.07.01), (23.07.02), (23.07.03)). In that case the wavelength, \(\lambda_{p}=2 \pi / k_{p}\), associated to the mode \(p\), but the corresponding frequency, \(\omega_{p}\), is not simply proportional to \(p\). In fact:
\[
\begin{gathered}
\omega_{p} \propto 2 \omega_{0} \sin \frac{a k_{p}}{2} \quad k_{p} \propto p / a \quad p=1, \ldots N \\
v_{p} \propto \frac{2 \omega_{0}}{k_{p}} \sin \frac{a k_{p}}{2} \\
p \ll N \Longrightarrow a k_{p} \ll 1 \Longrightarrow v_{p} \simeq a \omega_{0}
\end{gathered}
\]

The above relations show that in general the phase-velocity is different for different modes, that is frequency. Only for low-frequency modes the phase velocity are about the same. It is physically clear that, for a number \(N\) of points in the chain, it is not possible to have Sinusoidal|Cosinusoidal waves with \(p>N\). This phenomenon is known as cut-off frequency: the maximum possible frequency is \(2 \omega_{0}\).
All the previous discussion shows that one has to be careful when modeling a real system made of a large number of entities as a continuous system.

\subsection*{40.03.09.07 Dispersion Relation for a Real Vibrating String}

For a non-ideal string, where stiffness is taken into account, the dispersion relation is written as:
\[
\omega^{2}=k^{2}\left(T / \rho_{l}+a k^{2}\right)
\]
where \(a\) is a constant that depends on the string, \(T\) is the tension of the string and \(\rho_{l}\) the linear mass density.

\subsection*{40.03.09.08 Dispersion Relation for Free Schrödinger Equation}

The dispersion relation for a free non-relativistic particle, \(V=0\), is:
\[
\omega=\frac{\hbar}{2 m} k^{2}
\]
see equation (40.01.03).

\subsection*{40.03.09.09 Dispersion Relation for Free Klein-Gordon Equation}

The Klein-Gordon equation, which arises in relativistic quantum physics, gives the dispersion relation for a free particle:
\[
\omega= \pm \sqrt{\alpha^{2} k^{2}+\beta^{2}}
\]
with constants \(\alpha\) and \(\beta\).

\subsection*{40.03.09.10 Dispersion and High-Frequency Cut-Off}
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 7||

\section*{© - QUOTE}
A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....

Dispersion is linked to the effect known as cut-off. It is the inability of a dispersive system to transmit waves above or below a certain critical (cut-off) frequency. The effect high-frequency cut-off is clear in the analysis of the normal modes of the spring-mass chain, read § 23.07.04Oscillations of a few mass points and in the case of ElectroMagnetic wave-guides, read § 42.09 ElectroMagnetic Waves.
No frequency higher that the maximum frequency can exist. However nothing prevents us from applying a forcing at an higher frequency. What does happen in this case?
It can be shown that for \(\omega>\omega_{0}\) the wave is damped and for \(\omega \gg \omega_{0}\) it is strongly damped so that the structure behaves like a rigid structure.

\subsection*{40.03.10 Attenuation/Dissipation}

Attenuation/dissipation refers to the wave loosing energy while it propagates. The wave might possibly increase its energy if something is pumping energy into the wave, such as in a LASER.
Suppose \(\omega\) is real but the dispersion relation leads to a complex \(\mathbf{k}\) : the wave is attenuated or, possibly, enhanced depending on the sign of the imaginary part of the complex wave-vector.
If \(\mathbf{k}\) is purely imaginary there is no oscillation at all but the wave is exponentially damped (or, possibly, enhanced).

\subsection*{40.03.11 Modulation and Beats}

This § is referenced at pages:
[1150, 1150, 1981, 1981, 1986, 1986, 1993, 1993, 2135, 2135, 2216, 2216]
Consider the superposition between two one-dimensional MPW with different frequencies and same amplitude (the phase constant is ignored as it is not essential in this problem) traveling in the same direction, in case the dispersion relation \(\omega=\omega[k]\) is just a generic function, depending on the physical problem:
\[
\begin{gathered}
\omega=\omega[k] \\
\xi[z, t]=A \cos k_{1} z-\omega_{1} t+A \cos k_{2} z-\omega_{2} t=, \\
2 A \cos \frac{k_{1}-k_{2}}{2} z-\frac{\omega_{1}-\omega_{2}}{2} t \cos \frac{k_{1}+k_{2}}{2} z-\frac{\omega_{1}+\omega_{2}}{2} t=2 A \cos k_{\text {MOD }} z-\omega_{\text {MOD }} t \cos \bar{k} z-\bar{\omega} t \equiv \\
\xi[z, t]=A_{\text {MOD }}[z, t] \cos \bar{k} z-\bar{\omega} t \\
k_{\text {MOD }} \equiv \frac{k_{1}-k_{2}}{2} \quad \omega_{\text {MOD }} \equiv \frac{\omega_{1}-\omega_{2}}{2}
\end{gathered}
\]

Note that the assumption of equal amplitudes it is not necessary at all, it only makes the mathematics simpler.
If \(\omega_{\text {MOD }} \ll \bar{\omega}\), that is \(\omega_{1} \simeq \omega_{2}\), the combination is a fast Sinusoid|Cosinusoid, at the high frequency \(\langle\omega\rangle\), whose amplitude is modulated by a slowly varying Sinusoidal|Cosinusoidal amplitude \(A_{\text {MOD }}[z, t]\), at a low-frequency \(\omega_{\text {MOD }}\). The so-called carrier frequency, \(\bar{\omega} \equiv\langle\omega\rangle\), has about the same frequency as the two components, \(\omega_{1} \simeq \bar{\omega} \simeq \omega_{2}\) and a Sinusoidal|Cosinusoidal amplitude slowly varying.

By superposition of many frequencies one can get different wave-forms for the amplitude, thus generating complex signals via the amplitude of a basic frequency, the carrier. This is the basis of amplitude modulation techniques.
The amplitude moves at a velocity, the so-called group velocity:
\[
\begin{equation*}
v_{g} \equiv \frac{\omega_{\text {MOD }}}{k_{\text {MOD }}}=\frac{\omega_{2}-\omega_{1}}{k_{2}-k_{1}} \simeq \frac{\mathrm{~d} \omega}{\mathrm{~d} k}+\ldots \tag{40.03.04}
\end{equation*}
\]

If the two disturbances are very close in frequency the combined disturbance exhibits the so-called called beats: the combined vibration is basically a disturbance with a frequency equal to the average of the two frequencies and an amplitude which varies sinusoidally with time with one wavelength including many wavelengths of the fast oscillation.

Note that depending on the group velocity being smaller or larger than the phase velocity the oscillations inside the envelope may go either backward or forward with respect to the envelope. The waveform travels as a rigid profile if and only if the group velocity and phase-velocity are identical.
While mathematically the result is always valid the physical interpretation in terms of beats is only meaningful whenever the condition \(\mathrm{f} \omega_{\text {MOD }} \ll \bar{\omega}\) is satisfied.
The intensity is:
\[
I \propto\left(A_{\text {MOD }}\right)^{2}[z, t] \cos ^{2} \bar{k} z-\bar{\omega} t .
\]

The envelope travels with a frequency \(\Delta \omega\), as the square doubles the frequency. This gives rise to beats: at an fixed point in space the intensity increases and decreases with a frequency determined by the difference of the original frequencies.

\section*{Example: Amplitude Modulation in Radio-Communications}

\subsection*{40.03.12 Wave Impedance}

This § is referenced at pages:
[2011, 2011, 2011, 2011, 2145, 2145, 2145, 2145]
Typically two properties characterize wave propagation (at least for classical d'Alembert waves).
- EM waves in LHI media:
\[
\epsilon_{\mathrm{R}} \oplus \mu_{\mathrm{R}} \quad \Leftrightarrow \quad Z \oplus v=c / n .
\]

For ElectroMagnetic waves the interpretation is: large/small wave impedance means that the electric field \(\mathbf{E}\) is large/small with respect to the field \(\mathbf{H}\).
- The impedance of mechanical waves is, in all generality, defined as the ratio between the force and the velocity of the oscillating part: it has therefore dimensions of \(\mathrm{N} /(\mathrm{m} / \mathrm{s})=\mathrm{kg} / \mathrm{s}\) :
- Mechanical longitudinal waves:
\[
Y \oplus \rho \quad \Leftrightarrow \quad Z=S \sqrt{\rho Y} \oplus v=\sqrt{\frac{Y}{\rho}}
\]
- Mechanical transverse waves on a string:
\[
T \oplus \lambda \quad \Leftrightarrow \quad Z=\sqrt{\lambda T} \oplus v=\sqrt{\frac{T}{\lambda}}
\]

For mechanical waves, according to definition (41.08.05), a medium with large/small \(Z\) is a hard/soft medium as far as the propagation of waves is concerned, because for a given force the resulting velocity is small/large.
In both cases the wave equation gives a relation between the pair of quantities entering the definition of the wave impedance and the two quantities enter the expression of the power/intensity carried by the wave. This, in the end, explains the motivation for introducing the concept and its usefulness.

\subsection*{40.03.13 MPW Versus Real Waves}

This § is referenced at pages:
[2113, 2113]
MPW are the basic building blocks to build any kind of waves, that is any solution to the wave equation. In fact, linearity implies that any superposition of solutions MPW is still a solution. However, real waves are more complicated than MPW.
- The CPWF of real waves are not planes, in general. However at a distance \(R\) very far enough from the source of dimension \(D, R \gg D\), any CPWF can be approximated by a spherical wave. Furthermore, if one studies only a small part of the CPWF of size \(L\), with \(L \ll R\), it can be approximated by a PW.
Therefore, when one studies waves far away from the source, either PW or spherical waves can be assumed.
Note that a plane/spherical wave is not necessarily monochromatic but the concept of CPWF is defined for any MW.
- Transverse waves are often the superposition of waves with different states of Polarization. Read § 42.15.01 - ElectroMagnetic Waves.
- A strictly MPW does not exist, as it is infinite both in space and in time. A better model is a finite sinusoid, a so-called wave-train lasting for times \(\Delta \tau\). Read § 16 - Some Elements of Fourier Analysis.
- A non-MPW can be made by superposition of different frequencies. Superposition of two MPW at two different frequencies may give rise to: non-rigid movement of the waveform, whenever the phase-velocity of the two MPW are different; amplitude modulation; the concept of group velocity. Read § 40.03.11 - General Properties of Waves.
- In general any waveform can be expressed, via the Fourier Series|Integral (see section § 16 - Some Elements of Fourier Analysis) as a Series|Integral of MPW with complex coefficients of the different MPW.

\subsection*{40.03.14 Doppler Effect}
©|H.J. Pain, The physics of vibrations and waves, John Wiley and Sons, 2005.|§ 15||
The Doppler effect is a general wave phenomenon showing up when the source of the waves and the observer/receiver have a relative motion.
The Doppler effect consists in the fact that the frequency of the wave perceived by the observer/receiver is, in general, different from the frequency of the wave emitted by the source.
The effect exists for all types of waves but it may differ, from the quantitative point of view, for different types of waves. In particular there is a difference between the case of mechanical waves and the case of ElectroMagnetic waves.
The Doppler effect is a very important physical phenomenon, with many applications and uses.
The Doppler effect for mechanical waves is presented in § 41.10 - Mechanical Waves.
The Doppler effect for ElectroMagnetic waves is presented in § 42.12 - ElectroMagnetic Waves.

\subsection*{40.03.15 Interference and Diffraction}

Interference and diffraction are closely-related characteristic phenomena of waves.
Interference is discussed in § 46 - Interference. Basic evidence: Young experiment and similar.
Diffraction is discussed in § 47 - Diffraction. Basic evidence: limited resolution of optical instruments.
Interference and diffraction have been fundamental concepts in the historical evolution of the waveparticle duality saga.
40.03.16 Classification of PDE Solutions
©|A.D.Polyanin et al.|Handbook of non Linear Partial Differential Equations|Chapman Hall/CRC Press, 2012, 2nd Ed|
Assume \(z\) and \(t\) variables (similar discussion for more than one space variable). Some specific types of solutions:
\begin{tabular}{|c|c|}
\hline Traveling Wave & \(\xi[z, t]=F[w] \quad w=\alpha z+\beta t \quad \alpha \beta \neq 0\) \\
\hline Additive separable solution & \(\xi[z, t]=\phi[z]+\psi[t]\) \\
\hline Multiplicative separable solution & \(\xi[z, t]=\phi[z] \psi[t]\) \\
\hline Steady solution ( \(\psi_{T}\) periodic) & \(\xi[z, t]=\phi[z] \psi_{T}[t]\) \\
\hline Generalized traveling wave (1) & \(\xi[z, t]=F[w] \quad w=t \psi[z]+\phi[z]\) \\
\hline Generalized traveling wave (2) & \(\xi[z, t]=F[w] \quad w=z \psi[t]+\phi[t]\) \\
\hline Generalized separable solution & \(\xi[z, t]=\phi_{1}[z] \psi_{1}[t]+\phi_{2}[z] \psi_{2}[t]+\ldots\) \\
\hline Functional separable solution & \(\xi[z, t]=F[w] \quad w=\phi_{1}[z] \psi_{1}[t]+\phi_{2}[z] \psi_{2}[t]+\ldots\) \\
\hline
\end{tabular}

Useful and extensive data tables for dealing with wave phenomena in matter, EM waves in matter and mechanical waves, can be found at: WEB - URL.

\section*{Examples and Physical Applications}

\subsection*{40.04.01 MPW Solutions With the Complex Formalism}

This § is referenced at pages:
[1981, 1981]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|Appendix||
Read also sections § 17.04-Linear Systems, § 17.05-Linear Systems, § 23.06-Oscillations of a few mass points.
MPW are the simplest general wave solutions to d'Alembert wave equation.
It is convenient to introduce the complex notation as a convenient tool to simplify the calculations. In fact, once it is understood that we deal with linear systems where Sinusoids|Cosinusoids have a distinguished role, it is worth noting that a Sinusoid|Cosinusoid at a given frequency is characterized by two parameters: its amplitude and its phase. It is possible to pack the two parameters together into a single entity by using a complex number.
It has to be clear that the complex number has no physical significance at all, but it is only a useful way to treat two different real quantities as a single complex entity. Other advantages will become clear at the end of this section.
Both the two harmonic functions
\[
b_{c} \cos \mathbf{k} \cdot \mathbf{x}-\omega t \quad b_{s} \sin \mathbf{k} \cdot \mathbf{x}-\omega t
\]
as well as
\[
A \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi \quad A \sin \mathbf{k} \cdot \mathbf{x}-\omega t-\phi
\]
where \(b_{c}, b_{s}, A\) and \(\phi\) are all constants, are solutions of the d'Alembert wave equation, provided the dispersion relation is satisfied.
Thanks to the linearity also the linear combination with complex coefficients
\[
A \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t-\phi)] \equiv A \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi+\beth A \sin \mathbf{k} \cdot \mathbf{x}-\omega t-\phi \equiv \bar{A} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)],
\]
is a solution, where the definition
\[
\bar{A} \equiv A \exp [-\beth \phi]
\]
has been introduced.
One can now appreciate two more advantages: the first one is that both time and space derivation became just a multiplication; secondly the time and space parts are factorised.
It is important to stress that one can use the complex formalism without problems as long as only operations which do not mix the real and imaginary parts of complex numbers are involved, such as addiction, subtraction, derivation and integration. In this case the real art of the complex result is the results for the physical fields. When one carries on operations mixing the real and imaginary parts of complex numbers, such as multiplication and division of complex numbers, this is not true any more and the complex formalism cannot be used without taking countermeasures.

\subsection*{40.04.02 Velocity for a General Wave}

This § is referenced at pages:
[1979, 1979]
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|§ 1.3||

Consider a generic wave defined by the implicit wave equation:
\[
f[\mathbf{r}, t]=c \quad \text { where } c \text { is a constant }
\]

The time-dependence is not harmonic, in general.
1. Show that the velocity of the constant amplitude surfaces (CAWF) can be expressed as:
\[
v=-\frac{\partial_{t} f}{\left|\operatorname{grad}_{\mathbf{r}} f\right|}
\]
2. What happens when applying the formula to a steady solution such as (40.02.06)?

\subsection*{40.04.03 Relation Between Energy Flux and Energy Density}

This § is referenced at pages:
[2010, 2010, 2050, 2050]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|2.2||

It can be shown that, in general, the time-averaged energy volume density at any point in space, \(\langle u\rangle\), is linked to the time-averaged energy flux at that point (intensity), \(I \equiv\langle S[\mathbf{r}, t]\rangle\), by the relation:
\[
\begin{equation*}
\langle\mathbf{S}[\mathbf{r}, t]\rangle \equiv \mathbf{v}_{E}\langle u[\mathbf{r}, t]\rangle \tag{40.04.01}
\end{equation*}
\]
in terms of the speed of energy transport, \(v_{E}\).
In fact, if energy travels at a speed \(\mathbf{v}_{E} \equiv \hat{\mathbf{n}} v_{E}\), the time-averaged energy crossing any small plane surface defined by the vector \(d \mathbf{S}\) is:
\[
\frac{\mathrm{d} E}{\mathrm{~d} t}=\frac{\langle u\rangle(\hat{\mathbf{n}} \cdot \mathrm{d} \mathbf{S})\left(v_{E} \mathrm{~d} t\right)}{\mathrm{d} t}
\]

Therefore equation (40.04.01) can be actually taken as the definition of speed of energy transport.
It is important to stress that the speed energy travels is not, in general, the phase-velocity and not, in general, the group-velocity.

\subsection*{40.04.04 Standing Waves as Superposition of Traveling Waves}

Consider the general solution to the one-dimensional wave equation for a on an elastic string with fixed extremes, in the case of small oscillations. Consider two harmonic solutions, with velocity \(\pm v\), at fixed frequency and same amplitude:
\[
\xi[z, t]=A \cos \left(k z+\omega t+\phi_{\oplus}\right)+A \cos \left(k z-\omega t+\phi_{\ominus}\right)=2 A \cos k z+\frac{\phi_{\oplus}+\phi_{\ominus}}{2} \cos \omega t+\frac{\phi_{\oplus}-\phi_{\ominus}}{2}
\]

The solution is a standing wave solution, because there is nothing traveling but only standing solutions.
Standing waves are appropriate in those cases where the wave is limited to a closed volume, that is energy cannot escape.
40.04.05 Monochromatic Quasi-PW Solutions to the d'Alembert Wave Equation
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|||
©|J.P.Pérez et al., Optique, ..., DUNOD, ...Ed., WEB - URL.|||
Write the solution to the d'Alembert wave equation as follows:
\[
\Phi[\mathbf{r}, t]=\phi[\mathbf{r}] \exp -\beth \omega t \Longrightarrow \quad \nabla^{2} \phi+\frac{\omega^{2}}{v^{2}} \phi=0 \quad \text { Helmholtz equation } \quad \phi[\mathbf{r}] \equiv A[\mathbf{r}] \exp \beth \psi[\mathbf{r}] .
\]

It is time periodic, but non periodic in space.
Often the amplitude, \(A[\mathbf{r}]\) changes less rapidly than the phase, \(\psi[\mathbf{r}]\), so that is is sensible to neglect variations of the amplitude with respect to variations of the phase. The resulting phase-velocity and wave-vector are:
\[
v=\frac{\omega}{|\operatorname{grad} \psi|} \quad \mathbf{k} \equiv \operatorname{grad} \psi
\]
40.04.06 PW Approximation of Spherical Waves
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|9.30||
Show that a spherical wave of wavelength \(\lambda\) can be approximated by a plane wave, over a circular fenditure of radius \(R\) transverse with respect to the radial direction and placed at distance \(L\) from the source, as long as \(R^{2} \ll \lambda L\), that is roughly the area of the fenditure is small with respect to \(\lambda L\).

\subsection*{40.04.07 Examples of Interference/Diffraction}
- Interference causes the superposition of two (or more) waves with the same amplitude at some point to give a resulting wave amplitude ranging from a minimum of zero (totally destructive interference) to a maximum of twice (or the number of sources) the amplitude (maximally constructive interference).
- Interference is particularly interesting for light. In fact if light were similar to the flux of a beam of classical particles it would not be possible to add two beams and produce zero effect (that is to cancel the effects). This is what happens in the milestone Young two-slits experiment.
- The beam of a laser maintains, to a first approximation, the same diameter but it actually spreads a little bit. This is not due to any imperfection but to inherent diffraction.
- Any optical instrument has a limiting performance due to diffraction, which might prevent two point sources close enough to be seen as distinct sources by optical instruments.
- Sounds can be heard after obstacles thanks to interference/diffraction.
- Interference/Diffraction just differ for the type of sources:
- a finite or infinite countable set of sources of finite intensity is called interference (sum over the sources is involved);
- a continuum infinite set of sources of infinitesimal intensity is called diffraction (integration over the sources is involved).

\section*{Exercises Problems and Physical Applications}

Show that the equations (17.02.01) make sense that is the two ratios defining \(\cos \phi\) and \(\sin \phi\)
\[
\cos \phi=\frac{A_{1} \cos \phi_{1}+A_{2} \cos \phi_{2}}{A} \quad \sin \phi=\frac{A_{1} \sin \phi_{1}+A_{2} \sin \phi_{2}}{A},
\]
are always smaller than one.

\section*{40-005 Synchronization of Traffic Lights}

A straight road has identical traffic lights at equal distance of \(D=300 \mathrm{~m}\).
If the traffic lights are synchronized at \(v=37 \mathrm{~km} / \mathrm{h}\) what is the frequency of oscillation of the traffic lights?

What is the phase-velocity and wavelength of the traffic light wave?

\section*{40-006 One Wave}
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 7||
Show that the following expressions all describe the same traveling wave:
\[
\begin{gathered}
\xi[z, t]=A \sin 2 \pi(z-v t) / \lambda, \\
\xi[z, t]=A \sin 2 \pi(k z-v t)), \\
\xi[z, t]=A \sin 2 \pi((x / \lambda)-(t / T)), \\
\xi[z, t]=-A \sin \omega(t-x / v), \\
\xi[z, t]=A \operatorname{Im}(\exp [2 \pi \beth(\mathrm{kz}-\nu \mathrm{t})]) .
\end{gathered}
\]

\section*{40-007 One Sound Wave}
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 7||
1. What is the equation for a longitudinal wave traveling in the negative \(z\) direction with amplitude \(A=0.003 \mathrm{~m}\), frequency \(\nu=5 \mathrm{~Hz}\), and phase speed \(v=3000 \mathrm{~m} / \mathrm{s}\) ?
2. Which kind of wave it is? In which material is it traveling?
3. Find the maximum speed of any particle.
4. How far apart are two points whose displacements are \(30^{\circ}\) apart in phase?
5. At a given point, what is the phase difference between two displacements occurring at times separated by \(\Delta t=0.01 \mathrm{~s}\) ?

\section*{40-008 Another Wave}
©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 7||
Two points on the surface of a lake are observed as a traveling water wave passes them. The two points are at \(x_{1}=0\) and \(x_{2}=L\). The transverse motions of the two points are found to be: \(y_{1}=0.2 \sin 3 \pi t\) and \(y_{2}=0.2 \sin 3 \pi t+\pi / 8\).
What is the frequency and wavelength?
What is the phase speed?
Which way is the wave traveling?

\section*{40-009 Superposition of Two Harmonic Oscillations}

Consider two harmonic oscillations at different frequencies, \(\omega_{1}\) and \(\omega_{2}\), for instance the oscillations in time of two waves at a fixed point is space.
Under what conditions the resulting oscillation is periodic and what is the period?

\section*{40-010 Modulation With Different Amplitude Waves}

Carry on the exercise of \(\S 40.03 .11\) - General Properties of Waves without assuming that the two amplitudes are equal.

\section*{Some Mechanical Wave Phenomena}

This § is referenced at pages:
[2004, 2004]
General definition of mechanical wave: a wave propagating as a Perturbation|Disturbance|Signal|Deformation of a material medium.

In any mechanical wave, there are real pieces of matter, particles in the end, oscillating. There is no overall motion of matter, that is the Center-Of-Mass position of any piece of the oscillating matter keeps on average the same position.

In most cases, mechanical waves have a more or less pronounced energy dissipation inside the medium. Only only non-dispersive and non-dissipative mechanical waves are considered in this section.

\section*{Longitudinal Waves in an LHI Medium (Acoustic Waves)}

This § is referenced at pages:
[Never referenced.]

\subsection*{41.02.01 Elastic Force in a Solid}

Consider a cylindrical String|Bar with non uniform deformations.
Imagine to cut the cylindrical String|Bar by an imaginary plane perpendicular to its length. By definition, the stress exerted by one part of the String|Bar on the other nearby part is the tension per unit area, aka the normal stress. The tension can also be defined as the two equal and opposite forces needed to keep the two sides of the cut cylindrical String|Bar in place after cutting.
All the above discussion neglects the sign of the tension, which need careful evaluation as follows.
Consider a small piece of the cylindrical bar, so short that one can assume that its longitudinal deformation is approximately uniform. The rest length, \(\Delta z\), will be left tend to zero at the end of the calculation. Its generic elongation is: \(\Delta \xi[z, z+\Delta z] \equiv \xi[z+\Delta z]-\xi[z]\). The force along \(z\) it exerts at its two extremes, which is equal and opposite to the force exerted on it by the nearby parts of the bar, thanks to the action-reaction principle, is:
\[
F_{z}= \pm Y S \frac{\Delta \xi[z, z+\Delta z]}{\Delta z}= \pm Y S \frac{\xi[z+\Delta z]-\xi[z]}{\Delta z} \rightarrow \pm Y S \frac{\partial \xi}{\partial z}[z, t]
\]
where the sign is determined by which of the two ends one considers and depending on whether one considers the force on one of the bases of the bar or the force one of the two bases of the bar exerts on the nearby parts.
When the String|Bar is longitudinally deformed, the force acting on the piece of the bar after \(z\) due to the part of the bar before \(z\), is:
\[
\begin{equation*}
F_{\ominus}=-Y S \frac{\partial \xi}{\partial z}[z, t] \tag{41.02.01}
\end{equation*}
\]
force on the piece after \(z\) due to the part before \(z\),
the force acting on the piece of the bar before \(z\) due to the part of the bar after \(z\), is:
\[
\begin{equation*}
F_{\oplus}=+Y S \frac{\partial \xi}{\partial z}[z+\Delta z, t] \tag{41.02.02}
\end{equation*}
\]

The sign of the two contributions is readily evaluated when considering the piece of elongated/contracted.

\subsection*{41.02.02 Acoustic Waves in a Solid Bar}

\section*{This § is referenced at pages:}
[1651, 1651, 1651, 1651, 2000, 2000]
Read § 30.08.02 - Introduction to the Mechanics of Continuous Media and § 41.11.03 - Mechanical Waves.
The derivation in this section is based on the Young module: it applies to solids.
Consider a cylindrical solid bar, of rest length \(L\) and cross sectional area \(S\), made of a LHI solid. Consider the longitudinal deformations of the bar. Let the \(z\) axis be on the axis of the bar. The bar is supposed to undergo longitudinal deformations in a non necessarily uniform way. Assume that the change in the transverse dimensions is negligible, that is the Poisson module is zero.

Denote by \(\xi[z, t]\) the displacement from the reference position of the part of the bar which is located, when at rest, at \(z\).

Note that:
- \(z\) is just a label to identify the different elementary constituents of the bar;
- \(\xi[z, t]\) is the dynamical variable: an equation for it must be found and solved.

Consider a piece of the bar located, at rest, between \(z\) and \(z+\Delta z \geq z\) and apply the equations of mechanics to this system. When the bar is longitudinally deformed the force acting on the piece of the bar, due to the part of the bar before \(z\), is:
\[
F_{\ominus}=-Y S \frac{\partial \xi}{\partial z}[z, t]
\]
force on the piece of the bar at \(z\) from the part before \(z\),
while the force acting on the piece of the bar, due to the part of the bar after \(z+\Delta z\), is:
\[
F_{\oplus}=+Y S \frac{\partial \xi}{\partial z}[z+\Delta z, t]
\]
force on the piece of the bar at \(z+\Delta z\) from the part after \(z+\Delta z\).
as from equation (41.02.02) and (41.02.01).
Note that the two forces will not have the same module unless the deformation is uniform, which would implies:
\[
\frac{\partial \xi}{\partial z}[z, t]=\text { constant } \quad \Longrightarrow \quad \xi[z, t]=\alpha+\beta z \quad \text { with } \alpha \text { and } \beta \text { constants }
\]

The first Cardinal Equation applied to the piece of the bar reads:
\[
\left(f_{\mathrm{V}}[z, t] S \Delta z\right)+Y S\left(\frac{\partial \xi}{\partial z}[z+\Delta z, t]-\frac{\partial \xi}{\partial z}[z, t]\right)=\rho_{0} S \Delta z \frac{\partial^{2} \xi_{\mathrm{CM}}}{\partial t^{2}}\left[z_{\mathrm{CM}}, t\right]
\]
in terms of the rest density of the bar, \(\rho_{0}\), the location of the Center-Of-Mass of the system when at rest, \(z_{\mathrm{CM}}\), with \(z \leq z_{\mathrm{CM}} \leq z+\Delta z\) and the displacement of the Center-Of-Mass, \(\xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right]\).

Note that in general:
\[
\xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right] \neq \xi\left[z_{\mathrm{CM}}\right]
\]
because if the Center-Of-Mass corresponds to same piece of matter when at rest, in general the Center-Of-Mass of the deformed piece of bar will correspond to some other piece of matter so that in general the displacement of a piece of matter, \(\xi[z]\), is different from the displacement of the Center-Of-Mass, \(\xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right]\). Remember in fact that the Center-Of-Mass is a gometrical point, not a mass-point.

Taking the limit for \(\Delta z \longrightarrow 0\) of the first Cardinal Equation above one finds:
\[
\begin{gathered}
z \leq z_{\mathrm{CM}} \leq z+\Delta z \\
z+\xi[z] \leq z_{\mathrm{CM}}+\xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right] \leq z+\Delta z+\xi[z+\Delta z] \\
\text { for } \Delta z \longrightarrow 0 \Longrightarrow \\
z \leq z_{\mathrm{CM}} \leq z \\
z+\xi[z] \leq z+\xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right] \leq z+\xi[z] \Longrightarrow \xi[z] \leq \xi_{\mathrm{CM}}\left[z_{\mathrm{CM}}\right] \leq \xi[z]
\end{gathered}
\]

Therefore the equation becomes:
\[
\begin{equation*}
\rho_{0} \frac{\partial^{2} \xi}{\partial t^{2}}[z, t]-Y \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=f_{\mathrm{V}}[z, t] \tag{41.02.03}
\end{equation*}
\]

This is the non-homogeneous one-dimensional d'Alembert wave equation with propagation speed:
\[
\begin{equation*}
c_{\mathrm{L}}=\sqrt{\frac{Y}{\rho_{0}}} \tag{41.02.04}
\end{equation*}
\]
\(\rightarrow\) 1413

Note that this kind of derivation is based on the assumption of validity of Hooke law, that is a linear constitutive equation between stress and strain. This is why it gives a linear wave equation. A derivation without this assumption is given in § 41.02.03 - Mechanical Waves.

The expression for \(c_{\mathrm{L}}\) shows that the stiffer the solid the highest the speed of sound.

\subsection*{41.02.03 General Acoustic Waves in Fluids/Solids}

This § is referenced at pages:
[1646, 1646, 1646, 1646, 1998, 1998]
Read \(\S 30.08 .02\) - Introduction to the Mechanics of Continuous Media and \(\S 41.11 .03\) - Mechanical Waves.

The derivation in this section is based on the normal stress: it applies to both solids and fluids. The general non-linear equation will be derived, with the linear limit at the end.

Consider a long cylindrical tube, in the \(z\) direction, filled with a uniform and homogeneous fluid or, alternatively, a long cylindrical solid bar. Let the cross-sectional dimension of the tube be much shorter than its length and let its cross-sectional area be \(A\). Assume that any motion is only along \(z\).

Consider a macroscopically small, but finite, part of the mass delimited by two planes perpendicular to the \(z\) axis, of rest length \(\Delta z_{0}\), and follow its motion under the action of the pressure (that is the normal stress) exerted by the neighboring masses. The volume is macroscopically small, so that its properties are assumed not to change inside it. This allows to write for the density:
\[
\rho_{0}[z] \equiv \frac{\Delta m}{\Delta z_{0}}
\]
which might be in principle non uniform.
The mass one follows is always made by the same particles (this is the so-called Lagrangian approach). In the Lagrangian approach \(\mathbf{r}\) is just a label for an infinitesimal mass of the medium and therefore independent of time. It is not the dymamical variable.

Label each infinitesimally small part of fluid by its location in the reference configuration of the fluid, \(\mathbf{r}\). Let \(\xi_{z}[z] \equiv \xi[z]\) be the displacement along \(z\) from the reference position of the particles of fluid lying at \(z\) in the reference configuration. Let \(\rho[z]\) and \(p[z]\) be, respectively, the linear mass density and pressure, in the disturbed state, of the small region of fluid lying at \(z\) in the reference configuration. They are the functions describing the properties of the part of mass which stay at \(z\) in the undisturbed state.

We follow the particles, and so the functions do, in a sense.
The value of any quantity in any configuration can be calculated rigorously via the Lagrange theorem of analysis. Infinitesimals of higher order than the lowest order will vanish when letting \(\Delta z_{0}\) go to zero.

The following kinematics equations apply, where the time dependence is normally omitted from the formulas. The limit of small displacements or, better, small strains, to be precise,
\[
\left|\frac{\partial \xi}{\partial z}\right| \ll 1
\]
is considered and the limit for \(\Delta z_{0}\) go to zero is taken in the end.

One has:
\[
\begin{gathered}
\Delta z=\Delta z_{0}+\xi\left[z+\Delta z_{0}\right]-\xi[z]=\Delta z_{0}\left(1+\frac{\partial \xi}{\partial z}[\bar{z}]\right) \quad z \leq \bar{z} \leq z+\Delta z_{0} \quad \lim _{\Delta z_{0} \longrightarrow 0} \bar{z}=z \\
\Delta z_{0} \longrightarrow \Delta z \equiv \Delta z_{0}+\Delta \xi=\Delta z_{0}\left(1+\frac{\partial \xi}{\partial z}[\bar{z}]\right)=\Delta z_{0}\left(1+\frac{\partial \xi}{\partial z}[z]\right)+\mathcal{O}\left[\left(\Delta z_{0}\right)^{2}\right] \\
\rho_{0}[z] \equiv \lim _{\Delta z_{0} \longrightarrow 0} \frac{\Delta m}{\Delta z_{0}} \longrightarrow \rho[z] \equiv \lim _{\Delta z_{0} \longrightarrow 0} \frac{\Delta m}{\Delta z}
\end{gathered}
\]
\(\rho[z]=\lim _{\Delta z_{0} \longrightarrow 0} \frac{\rho_{0}[z]}{\partial \xi}=\frac{\rho_{0}[z]}{\partial \xi}=\frac{\rho_{0}[z]}{\partial \xi} \quad\) for \(\Delta z_{0} \longrightarrow 0\) an exact equation ,
\[
\begin{aligned}
\rho[z] & \simeq \rho_{0}[z]\left(1-\frac{\partial \xi}{\partial z}[z]\right)
\end{aligned} \quad \text { approximate relation for }\left|\frac{\partial \xi}{\partial z}\right| \ll 1 \text { and } \Delta z_{0} \longrightarrow 0
\]

As the medium is homogeneous the Center-Of-Mass, at reference, will be at the middle of the cylinder. It is assumed that \(\Delta z_{0}\) is so small that it remains homogeneous at any time, so that the Center-Of-Mass is still in the middle of the piece at any time. The limit for \(\Delta z_{0}\) go to zero is taken in the end, in any case. The first Cardinal Equation applied to the small piece of mass, as a function of the pressure, gives:
\[
z_{\mathrm{CM}} \equiv z+\frac{\Delta z_{0}}{2}+\xi\left[z+\frac{\Delta z_{0}}{2}\right] \quad \text { the small piece of mass is so small that it is uniform at any time }
\]
\[
A\left(p[z]-p\left[z+\Delta z_{0}\right]\right)=\rho_{0}[z] \Delta z_{0} A \frac{\partial^{2} z_{\mathrm{CM}}}{\partial t^{2}}
\]
\[
\frac{\partial^{2} z_{\mathrm{CM}}}{\partial t^{2}}[z]=\frac{\partial^{2} \xi}{\partial t^{2}}[z]+\frac{\Delta z_{0}}{2} \frac{\partial}{\partial z}\left(\frac{\partial^{2} \xi}{\partial t^{2}}\right)[\bar{z}]
\]
for \(\Delta z_{0} \longrightarrow 0\) an exact equation.
\[
z_{\mathrm{CM}}=z+\frac{\Delta z_{0}}{2}+\xi[z]+\frac{\Delta z_{0}}{2} \frac{\partial \xi}{\partial z}[\bar{z}] \quad z \leq \bar{z} \leq z+\Delta z_{0} \quad \lim _{\Delta z_{0} \longrightarrow 0} \bar{z}=z
\]
\[
-\frac{\partial p}{\partial z}[z] \Delta z_{0}=\rho_{0}[z] \Delta z_{0} \frac{\partial^{2} \xi}{\partial t^{2}}[z]+\mathcal{O}\left[\left(\Delta z_{0}\right)^{2}\right]
\]
\[
-\frac{\partial p}{\partial z}[z]=\rho_{0}[z] \frac{\partial^{2} \xi}{\partial t^{2}}[z]
\]

We have now collected two basic exact equations (that is no approximation in the limit for \(\Delta z_{0} \longrightarrow 0\) ), the equation for the density (41.02.03) and the first cardinal equation (41.02.03):
\[
-\frac{\partial p}{\partial z}[z, t]=-\frac{\partial p}{\partial \rho}[\rho[z, t]] \frac{\partial \rho}{\partial z}[z, t]=\rho_{0} \frac{\partial p}{\partial \rho}[\rho[z, t]] \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=\rho_{0} \frac{\partial^{2} \xi}{\partial t^{2}}[z, t]
\]

We know have three unknown functions: \(\xi[z, t], \rho[z, t]\) and \(p[z, t]\). We only have two equations: equation (41.02.03) and equation (41.02.03).

The third equation must be in fact the constitutive equation (or equation of state) of the medium, as the relation between \(\rho[z, t]\) and \(p[z, t]\) is actually the constitutive equation (equation of state). The constitutive equation allows one to calculate the derivative of pressure with respect to density.
In the problem discussed in § 41.02.02-Mechanical Waves the third equation, the constitutive equation, is given by the assumption that the solid is elastic, so that normal stress and strain are proportional.

Finally, within the small strain approximation, the derivative of pressure with respect to density is calculated at the reference configuration, thus becoming a constant and the classical wave equation is found:
\[
\begin{equation*}
\left.\frac{\partial p}{\partial \rho}\right|_{0} \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=\frac{\partial^{2} \xi}{\partial t^{2}}[z, t] \quad \text { for }\left|\frac{\partial \xi}{\partial z}\right| \ll 1 \tag{41.02.05}
\end{equation*}
\]

It must be stressed again that, in this Lagrangian approach, the meaning of \(p[z, t], \rho[z, t]\) as well as other functions is: the value at time \(t\) of the quantity at those infinitesimal piece of matter whose reference position is at \(z\).
It must be stressed again that equations (41.02.03), (41.02.03) are mathematically exact, as it was shown in the derivation, in the limit for \(\Delta z_{0} \longrightarrow 0\). Derivations of this kind are often carried on without all those precise mathematical passages, by employing the first-order Taylor series development without further details, as it is implicit that the limit process implied will make the approximate relations exact.
Note also that:
\[
\frac{\Delta \rho}{\rho} \simeq-\left.\frac{\Delta V}{V} \longrightarrow c_{\mathrm{L}}^{2} \simeq \frac{\Delta p}{\Delta \rho}\right|_{0}=\frac{B}{\rho_{0}}
\]
so that, after adding the external volume forces:
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial t^{2}}[z, t]-\left.\frac{B}{\rho}\right|_{0} \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=f_{\mathrm{V}} \quad \text { for }\left|\frac{\partial \xi}{\partial z}\right| \ll 1 . \tag{41.02.06}
\end{equation*}
\]

Read section § 41-003 - Mechanical Waves, § 41-003 - Mechanical Waves, § 41-004 - Mechanical Waves.

\section*{Transverse Waves in an LHI Medium}

Transverse waves cannot exist in fluids as the shear modulus is zero.

\subsection*{41.03.01 Transverse Elastic Waves on a Stretched Ideal String}

This § is referenced at pages:
[1961, 1961, 1964, 1964]
Consider a stretched ideal string, with linear mass density at rest \(\lambda\), whose tension, \(T\), is kept constant by two suitable forces at the extremes. Let the \(z\) axis coincide with the string when at rest.

Consider the transverse (but plane) oscillations of the string.
Assume:
- Small displacements, in the transverse dimensions only (no longitudinal displacement).
- Small angles with respect to the \(z\) axis. Note that this is not related to the condition of small displacements, but it is an independent assumption. One might in fact have small displacements with large derivatives of the displacement function.
- Constant tension. Actually one may consider the tension changing according to Hooke law. For small displacements and small angles the change of length is of second-order so that to first-order the tension does not change.
Note: the string can only be stretched, not compressed. This is basically different from the case of the elastic solid, and orthogonal to the case of a fluid.
Consider a small piece of the string when deformed in a plane (the \(z y\) plane). Let transverse displacement, along \(y\), with respect to the reference position of the piece located at \(z\) when the string is at rest be \(\xi[z, t]\). In the present problem this is actually a displacement along the \(y\) direction.
The first Cardinal Equation applied to a small piece of string whose length at rest is \(\Delta z\), when projected on the \(z\) and \(y\) directions, read:
\[
\begin{gathered}
F_{z}=T \cos \alpha+\Delta \alpha-T \cos \alpha=0, \\
F_{y}=T \sin \alpha+\Delta \alpha-T \sin \alpha=\lambda \Delta z \frac{\partial^{2} \xi}{\partial t^{2}}[\bar{z}, t] .
\end{gathered}
\]

Under the given assumptions one can approximate the angles to first-order to obtain:
\[
\begin{aligned}
F_{z} & =T-T=0 \quad \text { as } \cos \alpha \simeq 1 \text { and } \cos \alpha+\Delta \alpha \simeq 1 \text { to first-order }, \\
F_{y}=T \Delta \alpha & =\lambda \Delta z \frac{\partial^{2} \xi}{\partial t^{2}}[\bar{z}, t] \quad \text { as } \sin \alpha \simeq \alpha \text { and } \sin \alpha+\Delta \alpha \simeq \alpha+\Delta \alpha \text { to first-order } .
\end{aligned}
\]

When one takes the limit for \(\Delta z \longrightarrow 0\) one obtains (time dependence of all quantities is implicit in all the equations):
\[
\begin{gathered}
\alpha[z, z+\Delta z] \simeq \frac{\xi[z+\Delta z]-\xi[z]}{\Delta z} \longrightarrow \frac{\partial \xi}{\partial z}[z], \\
\Delta \alpha[z, z+\Delta z] \equiv \alpha[z+\Delta z]-\alpha[z], \\
\frac{\Delta \alpha[z, z+\Delta z]}{\Delta z}=\frac{\alpha[z+\Delta z]-\alpha[z]}{\Delta z} \longrightarrow \frac{\partial \alpha[z]}{\partial \Delta z}=\frac{\partial^{2} \xi}{\partial z^{2}}[z] .
\end{gathered}
\]

Therefore:
\[
\frac{\partial^{2} \xi}{\partial z^{2}}=\frac{\lambda}{T} \frac{\partial^{2} \xi}{\partial t^{2}}
\]

This is the one-dimensional wave equation with propagation speed:
\[
\begin{equation*}
c_{\mathrm{T}}=\sqrt{\frac{T}{\lambda}} \tag{41.03.01}
\end{equation*}
\]

\subsection*{41.03.02 Transverse Elastic Waves on a Elastic Bar}

This § is referenced at pages:
[1964, 1964]
The phase-velocity of transverse elastic waves on a elastic bar is:
\[
c_{\mathrm{T}}=\sqrt{\frac{G}{\rho}}
\]

Read \(\S 30.06\) - Introduction to the Mechanics of Continuous Media for a more complete discussion.

\subsection*{41.04.01 General Longitudinal Waves in Unbounded Homogeneous Isotropic and Elastic Media}

This § is referenced at pages:
[1486, 1486]
This type of wave is also often called a dilatation wave, a irrotational wave, a pressure wave, or a P-wave ( P for: primary or pressure). The displacement is always parallel to the wave-vector:
\[
\boldsymbol{\xi}[\mathbf{r}, t]=\boldsymbol{\xi}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t-\phi)] \quad \mathbf{k} \times \boldsymbol{\xi}_{0}=0
\]

The derivations in § 41.01 - Mechanical Waves were based on the fact that the system was not undergoing any lateral shrinkage/expansion, that is the Poisson module was assumed to be zero. In the more general case it can be shown that the velocity of longitudinal waves is:
\[
\begin{equation*}
c_{c_{\mathrm{L}}^{2}=\frac{(1-\Sigma)}{(1+\Sigma)(1-2 \Sigma)} \frac{Y}{\rho_{0}}}^{c_{\mathrm{L}}^{2}=\frac{3 B+4 G}{3 \rho_{0}}}, \tag{41.04.01}
\end{equation*}
\]
\[
\begin{gathered}
\overrightarrow{ } \overrightarrow{2004} \\
\vec{~} \\
20042028
\end{gathered}
\]

Note that, according to the relations in section § 25.02.04 - Introduction to Mechanics of Elastic Solids, the two expressions \((41.04 .01),(41.04 .02)\) are totally equivalent.

The two different ways of writing the same result are more or less suitable depending on the required application. Equation (41.04.01) gives the result for the case when there is no lateral shrinkage/expansion using \(\Sigma=0\). Refer to \(\S 25.07 .06\) - Introduction to Mechanics of Elastic Solids for an example with \(\Sigma \neq 0\) but longitudinal only displacements, thanks to the presence of forces perpendicular to the wave-vector which forbid displacements perpendicular to the wave-vector.

Equation (41.04.02) is useful to consider the case of a fluid, which has \(G=0\).
Read also § 30 - Introduction to the Mechanics of Continuous Media.

\subsection*{41.04.02 General Transverse Waves in Unbounded Homogeneous Isotropic and Elastic Media}

This § is referenced at pages:
[Never referenced.]
This type of wave is also often called a rotational wave, a shear wave, or an S-wave (S for: secondary or shear). The displacement is always perpendicular to the wave-vector:
\[
\boldsymbol{\xi}[\mathbf{r}, t]=\boldsymbol{\xi}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t-\phi)] \quad \mathbf{k} \cdot \boldsymbol{\xi}_{0}=0
\]

The displacement can have any direction in a plane normal to the wave-vector, so that they two independent states of Polarization are present.
\[
\begin{gather*}
c_{\mathrm{T}}^{2}=\frac{Y}{\rho_{0}} \frac{1}{2(1+\Sigma)}  \tag{41.04.03}\\
c_{\mathrm{T}}^{2}=\frac{G}{\rho_{0}} \tag{41.04.04}
\end{gather*}
\]

Note that, according to the relations in section § 25.02.04 - Introduction to Mechanics of Elastic Solids, the two expressions (41.04.03), (41.04.04) are totally equivalent.

The two different ways of writing the same result are more or less suitable depending on the required application.

Equation (41.04.04) is useful to consider the case of a fluid, which has \(G=0\).
Read also § 30 - Introduction to the Mechanics of Continuous Media.

As mechanical waves are oscillations of parts of matter, sources of mechanical waves are in principle any thing which can set matter in motion.

\section*{Energy Linear Momentum and Angular Momentum of Mechanical Waves}

This § is referenced at pages:
[1965, 1965]
It is a common experience that mechanical waves carry energy even if they transport no matter. For instance a ship is set into motion by water waves, that is it can gain both kinetic and gravitational potential energy. Acoustic waves carry mechanical energy from the source to the ear.

\subsection*{41.08.01 Longitudinal Mechanical Waves in LHI Solids}
©|W.C.Elmore \& M.A.Heald, \(\qquad\) .Ed., ....|general discussion, § su mezzi elastici||

\subsection*{41.08.01.01 Energy of Longitudinal Mechanical Waves in LHI Solids}

This § is referenced at pages:
[2050, 2050]
The case of purely longitudinal mechanical waves along the \(z\) axis (that is one-dimensional waves) will be considered in this section, for a material with \(\Sigma=0\).

Consider a cylindrical bar with cross-sectional area \(S\), made of an LHI material, with volume mass density \(\rho\) and Young modulus \(Y\). Let the deformation along the \(z\) direction be \(\xi[z, t]\).

The kinetic energy per unit volume/length is:
\[
\frac{\mathrm{d} K}{\mathrm{~d} V}=\frac{\rho}{2}(\dot{\boldsymbol{\xi}})^{2} \Longrightarrow \frac{\mathrm{~d} K}{\mathrm{~d} z}=\frac{\rho S}{2}\left(\partial_{t} \xi\right)^{2}
\]

The general calculation of elastic potential energy in a LHI solid is rather complex and therefore here we limit to a very simplified, far from general, derivation. Consider a short piece of the system such that the deformation can be considered as uniform, that is the normal stress is uniform. Let the rest length of the piece be \(\Delta z\). The piece of system can be assimilated to a spring and the potential energy written down by analogy:
\[
\begin{gathered}
k=\frac{Y S}{\Delta z} \quad \Delta U=\frac{k}{2} \Delta \xi^{2} \Longrightarrow \frac{\Delta U}{\Delta V}=\left(\frac{Y}{2 \Delta z}\right) \frac{\Delta \xi^{2}}{\Delta z} \\
\frac{\mathrm{~d} U}{\mathrm{~d} V}=\frac{Y}{2}\left(\frac{\partial \xi}{\partial z}\right)^{2} \Longrightarrow \frac{\mathrm{~d} U}{\mathrm{~d} z}=\frac{Y S}{2}\left(\frac{\partial \xi}{\partial z}\right)^{2}
\end{gathered}
\]

The elastic potential energy per unit volume|length is thus:
\[
\frac{\mathrm{d} U}{\mathrm{~d} V}=\frac{Y}{2}\left(\frac{\partial \xi}{\partial z}\right)^{2} \Longrightarrow \frac{\mathrm{~d} U}{\mathrm{~d} z}=\frac{Y S}{2}\left(\frac{\partial \xi}{\partial z}\right)^{2}
\]

Note that energies are not expressed in terms of second derivatives but in terms of first derivatives.

\subsection*{41.08.01.02 Energy of Longitudinal Monochromatic Mechanical Waves in LHI Solids}

Consider a MPW with wave-vector module \(k>0\), angular frequency \(\omega\) and amplitude \(\xi_{0}\). Let the phase-velocity be \(v_{z} \gtreqless 0\) and its module be \(v \equiv\left|v_{z}\right|\). We have:
\[
\begin{array}{rcc}
\xi[z, t]=\xi_{0} \cos [ \pm k z-\omega t] & \dot{\xi}[z, t]=\omega \xi_{0} \sin [ \pm k z-\omega t] & \frac{\partial \xi}{\partial z}=\mp k \xi_{0} \sin [ \pm k z-\omega t] \\
\omega \omega=k v & v^{2}=\frac{Y}{\rho} &
\end{array}
\]

The elastic potential energy per unit volume and its time-average are:
\[
\begin{equation*}
\frac{\mathrm{d} U}{\mathrm{~d} V}=\frac{1}{2} Y \xi_{0}^{2} k^{2} \sin ^{2}[ \pm k z-\omega t] \Longrightarrow\left\langle\frac{\mathrm{d} U}{\mathrm{~d} V}\right\rangle=\frac{1}{4} Y \xi_{0}^{2} k^{2} \tag{41.08.02}
\end{equation*}
\]

The mechanical energy per unit volume and its time-average are:
\[
\begin{gathered}
\frac{\mathrm{d} E}{\mathrm{~d} V}=\frac{\xi_{0}^{2}}{2}\left(\rho \omega^{2}+Y k^{2}\right) \sin ^{2}[ \pm k z-\omega t]=\frac{\rho \xi_{0}^{2}}{2}\left(\omega^{2}+v^{2} k^{2}\right) \sin ^{2}[ \pm k z-\omega t] \\
\left\langle\frac{\mathrm{d} E}{\mathrm{~d} V}\right\rangle=\frac{1}{4} \xi_{0}^{2}\left(\rho \omega^{2}+Y k^{2}\right)=\frac{1}{2} \rho \xi_{0}^{2} \omega^{2}=\frac{1}{2} Y \xi_{0}^{2} k^{2}
\end{gathered}
\]

The power transmitted along the system from a smaller \(z\) to a larger \(z\) (from left to right, in short) across any surface perpendicular to the \(z\) direction is calculated from the expression of the force from left to right of any section of the system,
\[
\begin{equation*}
F_{\ominus}=-Y S \frac{\partial \xi}{\partial z} \tag{41.08.03}
\end{equation*}
\]
and therefore one finds:
\[
\Pi_{\ominus} \equiv \partial_{t} \xi F_{\ominus}=-Y S \frac{\partial \xi}{\partial z} \partial_{t} \xi= \pm Y S \xi_{0}^{2} k \omega \sin ^{2}[ \pm k z-\omega t]
\]

Note that the latter is the power produced by the force \(F_{\ominus}\), that is the force, from left to right, of any section of the system on the piece at its right. A positive power then means that positive work, and therefore energy, is transmitted from left to right and vice-versa. The power is positive for waves traveling in the positive direction (that is power runs from left to right) and it is negative for waves traveling in the negative direction (that is power runs from right to left).
The time-averaged power transmitted along the system from left to right across any surface perpendicular to the system is:
\[
\left\langle\Pi_{\ominus}\right\rangle= \pm \frac{1}{2} Y S \xi_{0}^{2} k \omega= \pm \frac{1}{2} Y S \xi_{0}^{2} \frac{\omega^{2}}{v}= \pm \frac{1}{2} \rho S \xi_{0}^{2} v \omega^{2}=\frac{1}{2} \rho S \xi_{0}^{2} \omega^{2} v_{z}
\]
in terms of \(v_{z}\), the signed component of the phase velocity along \(z\). The intensity is thus:
\[
\begin{equation*}
I_{\ominus} \equiv \frac{\left\langle\Pi_{\ominus}\right\rangle}{S}= \pm \frac{1}{2} \rho \xi_{0}^{2} \omega^{2} v \tag{41.08.04}
\end{equation*}
\]

\subsection*{41.08.01.03 Linear Momentum of Longitudinal Mechanical Waves in LHI Solids}
©|K.Y.Bliokh \& F.Nori|Spin and orbital angular momenta of acoustic beams|DOI: WEB - URL - and references.|
Linear momentum, along \(z\), of one piece of length \(\Delta z\) :
\[
\Delta P_{z}=\rho S \Delta z \partial_{t} \xi .
\]

The first Cardinal Equation of mechanics allows to recover the wave equation:
\[
F_{\ominus}[z, t]+F_{\oplus}[z+\Delta z, t]=\partial_{t} \Delta P_{z}=\rho S \Delta z \frac{\partial^{2} \xi}{\partial t^{2}} \Longrightarrow \quad \text { in the limit } \Delta z \rightarrow 0 \quad \Longrightarrow Y \frac{\partial^{2} \xi}{\partial z^{2}}=\rho \frac{\partial^{2} \xi}{\partial t^{2}}
\]

\subsection*{41.08.01.05 Wave Impedance of Longitudinal Mechanical Waves in LHI Solids}

This § is referenced at pages:
[2145, 2145]
Read also § 40.03.12 - General Properties of Waves for other comments on the wave impedance.
As the expression of the power involves the force and the speed it is useful to introduce the waveimpedance of longitudinal mechanical waves, considering all quantities along \(z\) :
\[
\xi \equiv \xi_{z}[z, t] \Longrightarrow\left|\partial_{t} \xi\right| Z \equiv\left|F_{z}\right|
\]

It turns out to depend on the properties of the medium only, by using equations (41.08.01.02), (41.08.03):
\[
Z=\frac{Y S}{v}=\rho S v=S \sqrt{Y \rho} \quad[\mathrm{Z}]=M L T^{-1}
\]

Note: sometimes in this problem the wave impedance is defined as the quantity \(Z / S\) above. This happens when in the definition in equation (41.08.05) one uses the stress instead of the force.
It turns out:
\[
\left\langle\Pi_{\ominus}\right\rangle= \pm \frac{1}{2} Z \xi_{0}^{2} \omega^{2}
\]

As the mechanical power is force times velocity, the impedance allows one to express the intensity as a function of force/velocity multiplied/divided by the impedance, read § 44.03.01-Reflection and Refraction of Waves and § 40.03.12 - General Properties of Waves.

\subsection*{41.08.02 Transverse Mechanical Waves}

Transverse mechanical waves need, for a complete definition, the specification of their Polarization state, as for ElectroMagnetic waves § 42.03 - ElectroMagnetic Waves.

\subsection*{41.08.02.01 Energy and Intensity of Transverse Mechanical Waves}

This § is referenced at pages:
[2023, 2023]
The same expressions derived for longitudinal mechanical waves, with the suitable reinterpretation of symbols and expressed only in terms of density, frequency wave-number and phase-velocity, apply, as in equation (41.08.01), equation (41.08.02), equation (41.08.01.02), and equation (41.08.04), provided the Polarization state is taken into account.

\subsection*{41.10.01 Source at Rest With Respect to the Medium and Observer in Motion}

In this case the Doppler effect is just a matter of relative velocity, because the relative velocity between the observer and any CPWF is just \(\mathbf{v}_{0}-\mathbf{c}\).

\subsection*{41.10.01.01 Slow Motion of the Observer}

Consider a PW with wave-vector \(\mathbf{k} \equiv k \hat{\mathbf{n}}\) and phase-velocity \(\mathbf{c}\). When the source, emitting at frequency \(\nu\), is at rest with respect to the material medium and the observer is in motion with velocity \(\mathbf{v}_{0}\) with respect to the material medium, the observer measures a frequency \(\nu^{\prime}\) :
\[
\begin{equation*}
\nu^{\prime}=\nu\left(1-\frac{\hat{\mathbf{n}} \cdot \mathbf{v}_{0}}{c}\right)=\nu\left(1-\frac{v_{0} \cos \theta_{0}}{c}\right) \quad \text { for } v_{0}\left|\cos \theta_{0}\right| \leq c \tag{41.10.01}
\end{equation*}
\]

This relation is valid in the case \(v_{0}\left|\cos \theta_{0}\right|<c\) and, in particular, in the limit \(\mathbf{v}_{0} \longrightarrow \mathbf{0}\).
Consider in fact the special case of collinear and equi-verse \(\mathbf{c}\) and \(\mathbf{v}_{0}\) and any specific phase of the wave (its maximum amplitude, for instance). Start from the instant of time when the observer is coincident with the maximum amplitude of the wave. The next maximum amplitude of the wave will reach the observer after a time
\[
T^{\prime}=\frac{\lambda}{\left(c-v_{0}\right)}=\frac{T c}{\left(c-v_{0}\right)}=\frac{T c}{\left|c-v_{0}\right|}
\]
as given by the relative velocity between the wave and the observer, giving the new frequency of equation (41.10.01).

\subsection*{41.10.01.02 Fast Motion of the Observer}

In the case \(v_{0}\left|\cos \theta_{0}\right|>c\) the observer moves faster than the wave and the two above relations become:
\[
\begin{equation*}
\nu^{\prime}=\nu\left(\frac{\hat{\mathbf{n}} \cdot \mathbf{v}_{0}}{c}-1\right)=\nu\left(\frac{v_{0} \cos \theta_{0}}{c}-1\right) \quad \text { for } v_{0}\left|\cos \theta_{0}\right|>c . \tag{41.10.02}
\end{equation*}
\]
and
\[
\begin{equation*}
T^{\prime}=\frac{\lambda}{\left(v_{0}-c\right)}=\frac{T c}{\left(v_{0}-c\right)}=\frac{T c}{\left|c-v_{0}\right|} \tag{41.10.03}
\end{equation*}
\]

In this case the sequence of wave-crests seen by the observer is inverted with respect to the sequence of a fixed observer.
41.10.01.03 Summary
\[
\begin{aligned}
& \nu^{\prime}=\nu\left|1-\frac{\hat{\mathbf{n}} \cdot \mathbf{v}_{0}}{c}\right|=\nu\left|1-\frac{v_{0} \cos \theta_{0}}{c}\right| \\
& T^{\prime}=\frac{\lambda}{\left(v_{0}-c\right)}=\frac{T c}{\left(v_{0}-c\right)}=\frac{T c}{\left|v_{0}-c\right|}
\end{aligned}
\]
41.10.02 Source in Motion With Respect to the Medium and Observer at Rest
©|D.A.Russel|WEB - URL||

Consider a PW with wave-vector \(\mathbf{k} \equiv k \hat{\mathbf{n}}\) and phase-velocity \(\mathbf{c}\). When the source, emitting at frequency \(\nu\), is in motion with respect to the material medium with velocity \(\mathbf{v}_{\mathrm{S}}\) and the observer is at rest with respect to the material medium, the observer measures a frequency \(\nu^{\prime}\) :
\[
\begin{equation*}
\nu^{\prime}=\nu \frac{1}{\left(1-\hat{\mathbf{n}} \cdot \mathbf{v}_{\mathrm{S}} / c\right)}=\nu \frac{1}{\left(1-v_{\mathrm{S}} \cos \theta_{\mathrm{S}} / c\right)} \quad \text { for } v_{\mathrm{S}}\left|\cos \theta_{\mathrm{S}}\right| \leq c \tag{41.10.05}
\end{equation*}
\]

Consider in fact the special case of collinear and equi-verse \(\mathbf{c}\) and \(\mathbf{v}_{S}\) and any specific phase of the wave (the maximum amplitude, for instance).

\section*{A first derivation}

Start from the instant of time when the source is emitting the maximum amplitude of the wave. After one period the maximum amplitude of the wave will have traveled by \(c T\), where we suppose the observer is located, while the source will have traveled by \(v_{\mathrm{S}} T\). The new maximum amplitude of the wave will reach the observer after a time
\[
T^{\prime}=T \frac{c-v_{\mathrm{S}}}{c}
\]
giving the new frequency of equation (41.10.05).

\section*{A second derivation}

When the source is moving the wavelength seen at the observer, \(\lambda^{\prime}\), is changed with respect to the wavelength of the wave when the source is standing, \(\lambda\). The relations among the two wavelengths are:
\[
\lambda \equiv c T=\lambda^{\prime}+v_{\mathrm{S}} T
\]

\subsection*{41.10.02.01 Summary}

In case the source moves with a velocity larger than the phase-velocity of the wave a shock-wave is generated, read \(\S 41.10 .04\) - Mechanical Waves.

\subsection*{41.10.03 General Case}

The Doppler effect for mechanical waves is non-symmetrical under the interchange of the velocity of the observer and source. This is due to the fact that the medium sets a kind of privileged Reference Frame. The speed of the wave, as it is seen by the observer, is not the same in the two cases.
In the general case of both source and observer moving at velocity, respectively, \(\mathbf{v}_{\mathrm{S}}\) and \(\mathbf{v}_{\mathbf{0}}\), with respect to the medium the expression is:
\[
\begin{equation*}
\nu^{\prime}=\nu \frac{\left(c-\hat{\mathbf{n}} \cdot \mathbf{v}_{0}\right)}{\left(c-\hat{\mathbf{n}} \cdot \mathbf{v}_{\mathbf{S}}\right)} \tag{41.10.06}
\end{equation*}
\]

For low velocities the results only depends on the relative velocity of source and observer, as it becomes:
\[
\begin{equation*}
\nu^{\prime} \simeq \nu+\hat{\mathbf{n}}\left(\frac{\mathbf{v}_{\mathrm{S}}-\mathbf{v}_{0}}{c}\right) \tag{41.10.07}
\end{equation*}
\]

It is implicit in equation (41.10.06) that the phase-velocity of the wave is larger in module of both the module of the source velocity and the module of the observer velocity.
Note that in the case \(\hat{\mathbf{n}} \cdot \mathbf{v}_{0}=\hat{\mathbf{n}} \cdot \mathbf{v}_{\mathrm{S}}\) there in no change in frequency, showing that only the relative motion is relevant. However the two different cases in equations (41.10.04), (41.10.05) are not symmetrical due to the presence of the propagation medium. Note however that in the case either the source velocity or the observer velocity are very small with respect to the phase-velocity the results from the two equations (41.10.04), (41.10.05) are not distinguishable for the same relative velocity.

Table 41.1 summarizes the characteristics of mechanical Doppler effect. All velocities are with respect to the medium. In the first case the observer sees a different phase-velocity of the wave because it is
\begin{tabular}{|c|c|c|c|}
\hline\(\nu \neq \nu^{\prime}\) & \multicolumn{3}{|c|}{ as seen by the observer } \\
\hline Source at rest, observer moving with \(\mathbf{v}_{0}:\) & \(\lambda^{\prime}=\lambda\) & \(\mathbf{c}^{\prime}=\mathbf{c}-\mathbf{v}_{\mathbf{0}} \neq \mathbf{c}\) & \(\left|\mathbf{v}_{\mathbf{0}}\right| \leq c\) \\
Observer at rest, source moving with \(\mathbf{v}_{\mathbf{S}}:\) & \(\lambda^{\prime}=T\left|\mathbf{c}-\mathbf{v}_{\mathbf{S}}\right| \neq \lambda\) & \(\mathbf{c}^{\prime}=\mathbf{c}\) & \(\left|\mathbf{v}_{\mathbf{S}}\right| \leq c\) \\
\hline
\end{tabular}

Table 41.1: Doppler effect for mechanical waves; the two cases.
moving with respect to the medium which sets the phase-velocity. In the second case the observer sees the same phase-velocity of the wave because it is not moving with respect to the medium which sets the phase-velocity.
In the first case the observer sees the same wavelength of the wave because that is set by the stationary source and phase-velocity. The wavelength is measured on water and it does not change. In the second case the observer sees a different wavelength of the wave because that is set by the moving source and phase-velocity. The wavelength is measured on water but it does change because the sources emits the different phases of the waves at different points.
Note that in all cases the physical quantity relevant to the observer is the frequency of the wave it receives because this will set the frequency of the oscillations at the observer, both in case of a stationary observer or in in the case of observer in motion.
Compare with the Doppler effect for ElectroMagnetic waves § 42.12 - ElectroMagnetic Waves.

\subsection*{41.10.04 Source Faster Than Wave}

This § is referenced at pages:
[2015, 2015]
If the source moves with a velocity which is larger than the phase-velocity of the wave inside the medium peculiar phenomena happen.

The CPWF have an envelope which is a conical surface. It is the locus of the equal-phase points for the waves emitted by the source during its motion and it constitutes itself a kind of shock-wave. This conical front is the shock-wave. The source lies at the vertex of the conical front.

The ratio between the speed of the source and the speed of the wave defines the Mach ratio (or Mach number):
\[
\mathcal{M} \equiv \frac{v_{\mathrm{S}}}{c}
\]

From geometric considerations one can easily show that the front of the shock-wave moves at an angle with the velocity of the source, \(\theta\), given by:
\[
\cos \theta=\frac{c}{v_{\mathrm{S}}}=\frac{1}{\mathcal{M}}
\]

In the case of mechanical waves, that is waves propagating as Perturbation|Disturbance|Signal of a material medium, the movement itself of some object is the source of the Perturbation|Disturbance|Signal and it is not necessary that a real wave-emitting source exists. This is the case, for instance, of the sonic shock-wave produced by a plane moving at a speed larger than the speed of sound in air.

\section*{Examples and Physical Applications}

\subsection*{41.11.01 Conveyor Belt Example}

The conveyor belt gives an excellent analogy to Doppler effect. The speed of the conveyor belt corresponds to the phase speed of the wave in the medium.

A men putting stones, at regular time intervals, on the belt corresponds to the source.
A men taking out stones corresponds to the observer.
The frequencies corresponds to the rate stones are put on the belt (by the source) and to the rate stones are taken out by the observer.

\subsection*{41.11.02 SONAR}

\subsection*{41.11.03 Speed of Sound in a Ideal Gas}

This § is referenced at pages:
[1997, 1997, 1999, 1999]
Calculate the speed of sound in a ideal gas with adiabatic index equal to \(\gamma\).
Assume both cases of adiabatic and isothermal transformation, and discuss which of them is best suited to the problem.

\section*{SOLUTION}

One should assume an adiabatic transformation because, normally, the compression/rarefaction of the gas are so fast and the thermal conductivity of the gas so low that there is negligible heat transfer between neighboring parts of the gas.
For adiabatic transformations one finds:
\[
\begin{gathered}
p=\rho \frac{R T}{M} \quad \text { equation of state of a ideal gas }, \\
p=k \rho^{\gamma} \quad \text { adiabatic transformation, } k \text { is a constant }, \\
\frac{\partial p}{\partial \rho}=k \gamma \rho^{\gamma-1}=p \rho^{-\gamma} \gamma \rho^{\gamma-1}=\gamma \frac{p}{\rho}=\gamma \frac{R T}{M}, \\
c^{2}=p^{\prime}\left[\rho_{0}\right]=\frac{\partial p}{\partial \rho}=\gamma \frac{p}{\rho}=\gamma \frac{R T}{M} .
\end{gathered}
\]

For isothermal trnasformations one would find:
\[
c^{2}=p^{\prime}\left[\rho_{0}\right]=\frac{\partial p}{\partial \rho}=\frac{p}{\rho}=\frac{R T}{M} \quad \text { as it formally corresponds to } \gamma=1
\]

Medical ultra-sonography.

\subsection*{41.11.05 Doppler Ultra-Sonography}

\subsection*{41.11.06 Dynamics of an LHI String|Bar Hanging in the Gravity Field With a Suspended Mass}

This § is referenced at pages:
[1488, 1488, 1488, 1488]
©|W.C.Elmore \& M.A.Heald,
..Ed., ....|4.8||
Read section § 25.07.09 - Introduction to Mechanics of Elastic Solids for the statics.
Consider an elastic string, made of an homogeneous and isotropic material, hanging in the gravity field from one extreme. The rest length is \(L\), its sound speed is \(c\) and its total mass \(m\). A small mass \(M\) is appended to the free extreme.
Determine the configuration of equilibrium assuming small strain and no lateral change of dimensions.
Show that the fundamental angular frequency of the small oscillations, \(\omega\), can be approximated, for \(m \ll M\), as
\[
\begin{equation*}
\frac{\omega^{2}}{\omega_{0}^{2}}=\frac{3 M}{(m+3 M)}=\frac{1}{(1+\alpha / 3)}, \tag{41.11.01}
\end{equation*}
\]
where \(\omega_{0}\) is the fundamental angular frequency of the small oscillations for negligible mass of the spring. Compare the approximate formula (41.11.01) with the exact result for a few values of the ratio \(m / M\).

\section*{SOLUTION}

Introduce a vertical \(z\) axis, oriented downwards, with origin at the point where the string is hanging. The equation of motion is equation (41.12.03):
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial t^{2}}[z, t]-c^{2} \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=g \tag{41.11.02}
\end{equation*}
\]
let us first determine the equilibrium condition. The boundary conditions at equilibrium are:
\[
\begin{equation*}
\xi[z=0]=0 \quad \text { fixed extreme } \tag{41.11.03}
\end{equation*}
\]
\[
\frac{\partial \xi}{\partial z}[z=L]=\frac{M g}{Y A} \quad \text { positive because it is elongated, it is required to sustain the mass }
\]

The static solution is found from the static equation
\[
-c^{2} \frac{\partial^{2} \xi}{\partial z^{2}}[z, t]=g
\]
in terms of two integration constants, \(\beta_{0}\) and \(\beta_{1}\), as:
\[
\begin{equation*}
\xi[z]=-\frac{g}{2 c^{2}} z^{2}+\beta_{1} z+\beta_{0} \tag{41.11.04}
\end{equation*}
\]

And the boundary conditions give the static solution:
\[
\bar{\xi}[z]=-\frac{g}{2 c^{2}} z^{2}+\left(\frac{g L}{c^{2}}+\frac{M g}{Y A}\right) z=\frac{g}{Y}\left(-\frac{\rho_{0}}{2} z^{2}+\left(L \rho_{0}+\frac{M}{A}\right) z\right)
\]

The stress exerted by a part on the part at larger \(z\) is:
\[
\frac{F}{A}=S_{z z}=-Y A \frac{\partial \xi}{\partial z}
\]

The stress exerted by a part on the part at smaller \(z\) is:
\[
\frac{F}{A}=S_{z z}=+Y A \frac{\partial \xi}{\partial z}
\]

We can check the stress at the mass and at the hanging point.
\[
\begin{aligned}
& \frac{F}{A}[z=0]=S_{z z}[z=0]=-Y A \frac{\partial \xi}{\partial z}[z=0]=-(M+m) g \\
& \frac{F}{A}[z=L]=S_{z z}[z=L]=-Y A \frac{\partial \xi}{\partial z}[z=L]=-M g
\end{aligned}
\]

Both stresses are negative as the chain is hanging the mass and itself.
The general solution can be found by finding the general solution of the homogeneous equation and adding a particular solution of the complete equation, for instance the static solution determined above.
The generic boundary conditions are:
\[
\begin{equation*}
\xi[z=0, t]=0 \tag{41.11.05}
\end{equation*}
\]
\[
\begin{equation*}
M \frac{\partial^{2} \xi}{\partial t^{2}}[z=L, t]=-Y A \frac{\partial \xi}{\partial z}[z=L, t]+M g \quad \text { the equation of motion for the mass } M \tag{41.11.06}
\end{equation*}
\]

Consider now the general solution as:
\[
\xi[z, t]=\widetilde{\xi}[z, t]+\bar{\xi}[z, t]
\]
where \(\widetilde{\xi}[z, t]\) is the general solution of the homogeneous equation. As \(\bar{\xi}[z, t]\) is a particular solution of the full equation \(\widetilde{\xi}[z, t]\) satisfies:
\[
\begin{equation*}
\frac{\partial^{2} \widetilde{\xi}}{\partial t^{2}}[z, t]-c^{2} \frac{\partial^{2} \widetilde{\xi}}{\partial z^{2}}[z, t]=0 \tag{41.11.07}
\end{equation*}
\]

The frequency spectrum of the homogeneous equation and of the non-homogeneous equations are the same.
We can then solve the homogeneous equation.
The dispersion relation:
\[
\omega=k c
\]
is derived from the homogeneous equation for \(\widetilde{\xi}\), equation (41.11.07).
The boundary conditions for \(\widetilde{\xi}\) become:
\[
\widetilde{\xi}[z=0]=\xi[z=0]-\bar{\xi}[z=0]=0-0=0
\]
and
\[
\begin{gathered}
M \frac{\partial^{2} \xi}{\partial t^{2}}[z=L, t]=-Y A \frac{\partial \xi}{\partial z}[z=L, t]+M g \\
M \frac{\partial^{2} \bar{\xi}}{\partial t^{2}}[z=L, t]+M \frac{\partial^{2} \widetilde{\xi}}{\partial t^{2}}[z=L, t]=-Y A \frac{\partial \bar{\xi}}{\partial z}[z=L, t]-Y A \frac{\partial \widetilde{\xi}}{\partial z}[z=L, t]+M g \\
\frac{\partial^{2} \bar{\xi}}{\partial t^{2}}[z, t]=0 \quad \bar{\xi} \text { is a static solution }
\end{gathered}
\]
\[
-Y A \frac{\partial \bar{\xi}}{\partial z}[z=L, t]+M g=0 \quad \text { from the boundary condition }
\]
\[
M \frac{\partial^{2} \widetilde{\xi}}{\partial t^{2}}[z=L, t]=-Y A \frac{\partial \widetilde{\xi}}{\partial z}[z=L, t]
\]
\[
\widetilde{\xi}_{\mathrm{M}} \equiv \widetilde{\xi}[z=L]
\]
having used equation (41.11.06). Consider a solution for \(\widetilde{\xi}[z, t]\) of type:
\[
\widetilde{\xi}[z, t]=B \sin k z \cos \omega t
\]
with \(B\) arbitrary constant. This already satisfies the boundary condition:
\[
\widetilde{\xi}[z=0]=\xi[z=0]-\bar{\xi}[z=0]=0-0=0
\]

The second boundary condition must take into account the motion of the mass, described by the displacement \(\widetilde{\xi}_{\mathrm{M}}\) :
\[
\begin{gathered}
\widetilde{\xi}_{\mathrm{M}}=\widetilde{\xi}[z=L]=B \sin k L \cos \omega t \\
F[z=L]=-Y A \frac{\partial \widetilde{\xi}}{\partial z}[z=L]=M \frac{\partial^{2} \xi_{\mathrm{M}}}{\partial t^{2}} \\
-Y A B k \cos k L \cos \omega t=-M \omega^{2} B \sin k L \cos \omega t \\
-Y A k \cos k L=-M \omega^{2} \sin k L \\
\omega^{2}=k^{2} c^{2}=k^{2} \frac{Y}{\rho_{0}}, \\
\tan k L=(k L) \frac{Y A}{M \omega^{2} L}=(k L) \frac{Y A \rho_{0}}{M k^{2} Y L}=(k L) \frac{Y A \rho_{0}}{M k^{2} Y L} \\
\Longrightarrow(k L) \tan k L=\frac{m}{M}
\end{gathered}
\]

Therefore the allowable wave numbers are given by:
\[
(k L) \tan k L=\frac{m}{M}
\]

Note that, due to the form of the equation, the different modes will not be multiple of each other. The equation always has one and only one solution in the interval
\[
0 \leq k L \pi / 2 \quad \text { first mode }
\]
that is the smallest solution describing the first oscillation mode.
Let \(\theta \equiv k L\) and \(\alpha \equiv m / M\).
The transcendental equation cannot be solved exactly in closed form. The equation has infinite solutions, corresponding to the infinite normal modes of the oscillations of the chain.
Consider the limiting case \(M \ll m\). In this case the solutions can be approximated by:
\[
M \ll m \Longrightarrow \theta \equiv k L \simeq \frac{\pi}{2}+q \pi \quad \text { with } q \text { any integer positive number }
\]

This is coherent with the fact that in this case the effect of the mass is negligible, and we have the oscillations of a chain free at its unconstrained extreme. Note that the first mode corresponds to
\[
k L=\frac{\pi}{2} \Longrightarrow \lambda=4 L
\]
as it is expected for a chain with one fixed extreme and the second one free.
Consider the limiting case \(m \ll M\). In this case the fundamental mode can be determined by noting that \(\theta\) must be small and therefore the tangent can be developed in Taylor series around \(\theta=0\) :
\[
\begin{gathered}
m \ll M \Longrightarrow \theta \tan \theta \simeq \theta\left(\theta+\frac{\theta^{3}}{3}+\mathcal{O}\left[(\theta)^{5}\right]\right)=\alpha \ll 1 \quad, \\
\theta^{4}+3 \theta^{2}-3 \alpha=0 \Longrightarrow \theta^{2}=\frac{-3 \pm \sqrt{9+12 \alpha}}{2} \longrightarrow \theta^{2}=\frac{-3+\sqrt{9+12 \alpha}}{2} \quad \text { positive solution acceptable }
\end{gathered}
\]

As \(\alpha \ll 1\) we can develop the solution around \(\alpha=0\) :
\[
\theta^{2}=\frac{-3+\sqrt{9+12 \alpha}}{2}=\alpha-\frac{\alpha^{2}}{3}+\frac{2 \alpha^{3}}{9}+\mathcal{O}\left[(\alpha)^{4}\right]
\]

By taking the lowest order term we find:
\[
\begin{gathered}
\theta^{2}=\alpha \Longrightarrow k^{2} L^{2}=\frac{m}{M} \\
\Longrightarrow \omega^{2}=k^{2} c^{2}=\frac{\alpha}{L^{2}} \frac{Y}{\rho_{0}}=\frac{m}{M} \frac{Y}{L^{2}} \frac{A L}{m}=\frac{Y A}{M L}=\frac{k_{\mathrm{E}}}{M} \\
k_{\mathrm{E}} \equiv \frac{Y A}{L} \quad \text { the equivalent elastic constant of the chain }
\end{gathered}
\]

Note that this level of approximation amount to \(\operatorname{take}: \tan \theta=\theta\).
By taking the second to lowest order term we find:
\[
\begin{gathered}
\theta^{2}=\alpha-\frac{\alpha^{2}}{3} \Longrightarrow k^{2} L^{2}=\alpha-\frac{\alpha^{2}}{3} \\
\Longrightarrow \omega^{2}=k^{2} c^{2}=\frac{1}{L^{2}}\left(\alpha-\frac{\alpha^{2}}{3}\right) \frac{Y}{\rho_{0}}=\frac{1}{L^{2}} \alpha \frac{Y}{\rho_{0}}\left(1-\frac{\alpha}{3}\right)= \\
\frac{k_{\mathrm{E}}}{M}\left(1-\frac{\alpha}{3}\right)=\frac{k_{\mathrm{E}}}{M}\left(1-\frac{m}{3 M}\right) \simeq \frac{k_{\mathrm{E}}}{M} \frac{1}{\left(1+\frac{m}{3 M}\right)}=\frac{k_{\mathrm{E}}}{M+m / 3} \\
k_{\mathrm{E}} \equiv \frac{Y A}{L} \quad \text { the equivalent elastic constant of the chain }
\end{gathered}
\]

Therefore the first fundamental frequency is changed, with respect to the case of zero hanging mass, by the factor:
\[
\frac{\omega^{2}}{\omega_{0}^{2}}=\frac{1}{\left(1+\frac{m}{3 M}\right)}=\frac{1}{\left(1+\frac{\alpha}{3}\right)}
\]

In general if one measures the oscillation period one will always find the period of the lowest harmonics.
The comparison of the approximate formula (41.11.01) with the exact result for a few values of the ratio \(\alpha \equiv m / M\) follows. We compare the approximate result for \(\theta, \widetilde{\theta}\), with the exact result.
For \(\alpha=1.0\) one finds \(\tilde{\theta}=0.82\) and \(\theta=0.86\).
For \(\alpha=0.5\) one finds \(\tilde{\theta}=0.645\) and \(\theta=0.653\).
For \(\alpha=0.1\) one finds \(\tilde{\theta}=0.3109\) and \(\theta=0.3110\).
For \(\alpha=0.05\) one finds \(\tilde{\theta}=0.22174\) and \(\theta=0.22176\).

\subsection*{41.11.07 Seismic Waves}

Seismic waves allows a tomography of the Earth.
See figures 41.1, 41.2, 41.3 .

\subsection*{41.11.08 Tsunamis}

Tsunamis cannot, strictly speaking, be described by the classical d'Alembert wave equation, but a more complex nonlinear wave-equation is required. A very simplified and very approximate qualitative description can be given as if a one-dimensional classical d'Alembert wave were involved.
Tsunamis are born from small amplitude and long wavelength waves in deep-water, generated by Earthquakes. The region where tsunamis are generated is usually large (hundreds of km ) with respect to the average sea depth (about four km ) and so is the wavelength.
A rapid transient results in gravitational waves with \(\lambda \approx 100 \mathrm{~km}\) (long waves).
Water waves are in general strongly dispersive, read \(\S 40.03 .09 .05\) - General Properties of Waves.
Tsunamis result in shallow-water waves non dispersive gravity waves. Tsunamis periods results range between \(10^{2} \div 10^{4} \mathrm{~s}\). Tsunamis amplitudes rarely exceed tens of cm in open seas so they are not noticeable.
The analogy with the longitudinal mechanical waves on a bar must consider a bar whose physical properties are changing along the direction of propagation: in case of water waves the change of depth is a change of the physical properties, changing the phase-velocity, and the wave impedance.
When these waves come close to the shore, where the depth of the sea is \(h\), the phase-velocity is approximated by \(v \sim \sqrt{g h}\). The frequency must stay constant at any distance along the propagation direction: see the discussion on kinematic relations leading to Snell laws, § 44 - Reflection and Refraction of Waves). Assume an idealized steady situation: the intensity/power must stay constant at any distance along the propagation direction.
As the phase-velocity tends to zero, while getting closer and closer to the shore one can deduce from the equations in § 41.08.02.01 - Mechanical Waves that the wave amplitude increases. Moreover, as \(\lambda=v / \nu\), the wavelength tends to zero.

\section*{Example}

Near the shore: \(h=0.5 \mathrm{~m}\) gives \(v=2.2 \mathrm{~m} / \mathrm{s}\).
In the Pacific Ocean, where a typical water depth is about \(h=4 k m\), a tsunami travels at about \(v=200 \mathrm{~m} / \mathrm{s}\) (long wavelength with respect to sea-depth).

This § is referenced at pages:
[2106, 2106]
©|Lim Yung-Kuo, Problems And Solutions On Mechanics, 1994, World Scientific, ...Ed., ....|1251||

Consider an emitter-receiver of sound waves who emits a signal and detects the echo of the signal it emitted. The frequency of the acoustic signal received by a stationary device as a function of the emitted frequency \(\nu_{0}\), in terms of the velocity of the object with respect to the air, \(V\), and the speed of sound, \(c\), is given by (one-dimensional problem)
\[
\nu=\nu_{0} \frac{c-V}{c+V} .
\]

In fact the object receives and re-emits, as a moving source, a frequency \(\nu=\nu_{0}(1-V / c)\).
Typically a piezo-electric emitter/receiver is used.

\section*{41-002 Velocity of Acoustic Waves}

This § is referenced at pages:
[Never referenced.]
Show that the velocity of longitudinal mechanical waves can be written as:
\[
\begin{equation*}
c_{\mathrm{L}}^{2}=\left.\frac{\partial p}{\partial \rho}\right|_{0}=\frac{B}{\rho_{0}} \tag{41.12.01}
\end{equation*}
\]

\section*{SOLUTION}
\[
\begin{aligned}
& 0=\mathrm{d} m=\rho \mathrm{d} V+V \mathrm{~d} \rho, \\
& \frac{1}{B}=-\frac{1}{V} \frac{\partial V}{\partial p}=\frac{1}{\rho} \frac{\partial \rho}{\partial p}
\end{aligned}
\]

41-003 Velocity of Acoustic Waves in Elastic Solids
This § is referenced at pages:
[2001, 2001, 2001, 2001]
Show that for an elastic solid medium the velocity of longitudinal waves propagating along the \(z\) axis, in absence of any displacement perpendicular to the \(z\) axis, can be written as:
\[
\begin{equation*}
c_{\mathrm{L}}^{2}=\left.\frac{\partial p}{\partial \rho}\right|_{0}=\frac{B}{\rho_{0}} \longrightarrow \frac{Y}{\rho_{0}} \tag{41.12.02}
\end{equation*}
\]

Note that the derivation in \(\S 25.07 .05\) - Introduction to Mechanics of Elastic Solids cannot be applied without changes, as in the present case it is assumed that the block deforms only in one direction. The fact that it can deform in one direction only implies that the relative change of volume is the same as the relative change of length, so that \(Y=B\).

\section*{SOLUTION}
\[
\rho \equiv \frac{\mathrm{d} m}{\mathrm{~d} V} \Longrightarrow \frac{\partial \rho}{\partial V}=-\frac{\rho}{V}
\]
\[
-\Delta p \equiv S_{z z} \equiv Y \frac{\Delta \xi_{z}}{\Delta z} \quad \text { by the convention on the signs of } p \text { and } S_{z z}
\]
\[
\begin{gathered}
\frac{\partial p}{\partial \rho}=\frac{\partial p}{\partial V} \frac{\partial V}{\partial \rho}=-\frac{\partial p}{\partial V} \frac{V}{\rho} \equiv \frac{B}{\rho} \\
\frac{\partial p}{\partial \rho}=-\frac{\partial p}{\partial V} \frac{V}{\rho} \sim-\frac{\Delta p}{\rho} \frac{z_{0}}{\Delta z}=\frac{Y}{\rho_{0}}
\end{gathered}
\]

Partial derivatives were used because one knows that the \(\rho=\rho[V, \ldots]\) function depends on other
thermodynamical variables also.
Beware that the pressure in Young law is actually a differential pressure, with respect to the equilibrium configuration.

\section*{41-004 Equation in Presence of Volume Forces}

This § is referenced at pages:
[1968, 1968, 2001, 2001]
Equation (41.02.05) refers to the case when there are no volume forces acting on the medium.
Generalize the derivation to the case when a given volume force is acting on the medium.

\section*{SOLUTION}

The eqaution is written in terms of the force per unit volume acting on the bulk of the material, \(f_{\mathrm{v}}\) :
\[
\begin{equation*}
\frac{\partial^{2} \xi}{\partial t^{2}}[z, t]-c^{2} \frac{\partial^{2} \xi}{\partial x^{2}}[z, t]=\frac{f_{\mathrm{v}}}{\rho_{0}} \tag{41.12.03}
\end{equation*}
\]

\section*{EM Waves in Vacuum Without Boundaries}

This § is referenced at pages:
[1961, 1961, 2038, 2038, 2041, 2041]
©|G.S.Smith, An Introduction To Classical Electromagnetic Radiation, 1997, CUP, ...Ed., .... 3.1|excellent and clear||
Vacuum means: no sources.
We start by studying EM waves in free vacuum space, that is, without matter and without boundaries. The effect of boundary conditions will be considered later (section § 44 - Reflection and Refraction of Waves) when introducing refraction and reflection of waves, and in § 43 - Waves in Bounded Regions. The effect of matter will be studied in detail in §50-ElectroMagnetic Waves in Matter.
For ElectroMagnetic waves in vacuum there is zero charge density and zero current density. Then, Maxwell Equations give the classical d'Alembert wave equation:
\[
\begin{align*}
& \nabla^{2} \mathbf{E}=\frac{1}{c^{2}} \frac{\partial^{2} \mathbf{E}}{\partial t^{2}} \\
& \boldsymbol{\nabla}^{2} \mathbf{B}=\frac{1}{c^{2}} \frac{\partial^{2} \mathbf{B}}{\partial t^{2}}  \tag{42.01.02}\\
& c^{2} \equiv\left(\varepsilon_{0} \mu_{0}\right)^{-1}
\end{align*},
\]
\[
(42.01 .01)
\]
\(\rightarrow\)
20322033 20362121
\(\rightarrow\)
20322033
2036

At this stage, \(c^{2}\) is just a shortcut for \(\left(\varepsilon_{0} \mu_{0}\right)^{-1}\). Note that, \(\varepsilon_{0}, \mu_{0}\) and \(c\) are exact constants, nowadays (read § B - International System of Units).
As often, one starts by studying MPW solutions, as a basis for description of any wave. In fact, the description in terms of MPW waves has its importance in that MPW allow to express any function via the Fourier Series|Integral.

Read \(\S 42.15\) - ElectroMagnetic Waves for an introduction to a realistic description of real EM waves, one which is not limited to MPW.

\subsection*{42.01.01 Maxwell Equations Versus d'Alembert Wave Equation}

This § is referenced at pages:
[2038, 2038, 2056, 2056]
Equations (42.01.01), (42.01.02) are deduced from Maxwell Equations by performing some derivatives and therefore they might admit more solutions than the original Maxwell Equations.

ElectroMagnetic fields must satisfy the wave equation, which follows from Maxwell Equations, but they must also satisfy Maxwell Equations themselves. Therefore one must investigate the constraints on the solution of the wave equation imposed by Maxwell Equations. The generic solution of the wave equation must then be replaced into Maxwell Equations to find the additional constraints, if any.

Note that it is rather obvious that there will be additional constraints from Maxwell Equations, because we know from Maxwell equations that the Electric|Magnetic fields are linked, while the wave equations (42.01.01), (42.01.02) decouple the two fields providing independent solutions but in non-static situations the Electric|Magnetic field cannot be separated.

\subsection*{42.01.02 EM MPW in Vacuum}

This § is referenced at pages:
[2035, 2035]
Read § 40.02.03.02 - General Properties of Waves.
The ElectroMagnetic wave equations (42.01.01), (42.01.02) admit MPW solutions, separately and independently for \(\mathbf{E}\) and \(\mathbf{B}\) :
\[
\begin{array}{|c}
\mathbf{E}[\mathbf{x}, t]=\mathbf{E}_{0} \cos \mathbf{k}_{\mathrm{E}} \cdot \mathbf{x}-\omega_{E} t-\phi_{E}  \tag{42.01.03}\\
\mathbf{B}[\mathbf{x}, t]=\mathbf{B}_{0} \cos \mathbf{k}_{\mathrm{B}} \cdot \mathbf{x}-\omega_{B} t-\phi_{B} \\
\hline
\end{array}
\]
where \(\mathbf{E}_{0}\) and \(\mathbf{B}_{0}\) are constant vectors, carrying the information on both the module, direction and orientation of the ElectroMagnetic fields.
For ElectroMagnetic waves in vacuum the (real) angular frequency \(\omega\) and the real wave-number, \(\mathbf{k}\), are connected, as a consequence of the wave equation, by the dispersion relation:
\[
\mathbf{k} \cdot \mathbf{k}=\frac{\omega^{2}}{c^{2}} \Longrightarrow \omega=|\mathbf{k}| c
\]

The ElectroMagnetic fields (42.01.03), (42.01.04) are solutions to the wave equation if and only if:
\[
\omega_{E}=\left|\mathbf{k}_{E}\right| c \quad \omega_{B}=\left|\mathbf{k}_{B}\right| c
\]

However, a priori, the wave-vector, \(\mathbf{k}\), frequency, \(\omega\), and phase, \(\phi\), might be different for the \(\mathbf{E}\) and \(\mathbf{B}\) fields. Nevertheless the ElectroMagnetic fields must also satisfy Maxwell Equations, from which the wave equation was derived, which might impose additional constraints. First of all note the following identities, which can be used to deduce the required results.
\[
\begin{aligned}
& \mathbf{V} \text { independent of } \mathbf{x} \Longrightarrow \operatorname{rot}(f \mathbf{V})=(\boldsymbol{\operatorname { g r a d }} f) \times \mathbf{V}, \\
& \mathbf{V} \text { independent of } \mathbf{x} \Longrightarrow \operatorname{div}(f \mathbf{V})=(\operatorname{grad} f) \cdot \mathbf{V} .
\end{aligned}
\]

By replacing the ElectroMagnetic fields (42.01.03), (42.01.04) into Maxwell Equations one finds the conditions to be satisfied by the fields in order to satisfy not only the wave equation but also Maxwell Equations. The two rotor Maxwell Equations, those which mix Electric|Magnetic fields, imply, first of all:
\[
\begin{equation*}
\omega \equiv \omega_{E}=\omega_{B} \quad \mathbf{k} \equiv \mathbf{k}_{E}=\mathbf{k}_{B} \quad \phi \equiv \phi_{E}=\phi_{B} \tag{42.01.05}
\end{equation*}
\]

In fact the identity between the two members of the Maxwell Equations with rotor, at any point and any time, can only be satisfied if frequency, wave-vector and phase are identical for the two fields, because Sinusoid|Cosinusoid functions with different coefficients are linearly independent.
Equation (42.01.05) implies, among other things, that the Electric|Magnetic fields are in phase, have the same angular frequency and wave-vector.
The two divergence equations do not mix the Electric|Magnetic fields and they provide the transversality conditions of the fields with respect to the wave-vector:
\[
\begin{array}{|c|}
\hline \mathbf{k} \cdot \mathbf{E}_{0}=0  \tag{42.01.06}\\
\hline \mathbf{k} \cdot \mathbf{B}_{0}=0 \\
\hline
\end{array}
\]
\(\rightarrow\)

That is, the Electric|Magnetic field in a MPW are transverse, that is orthogonal to the wave-vector.
On the contrary, the two rotor equations do mix the Electric|Magnetic fields, and give in terms of
\[
\mathbf{k} \equiv|\mathbf{k}| \hat{\boldsymbol{\kappa}} \equiv k \hat{\boldsymbol{\kappa}} \quad k=\omega / c \quad \text { where } \mathbf{k} \text { is a real vector here },
\]
the following set of equivalent equations:
\[
\begin{align*}
& \mathbf{B}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{E}_{0}\right)=+\frac{1}{c}\left(\hat{\boldsymbol{\kappa}} \times \mathbf{E}_{0}\right) \Longrightarrow E_{0}=c B_{0}  \tag{42.01.07}\\
& \mathbf{E}_{0}=-\frac{c^{2}}{\omega}\left(\mathbf{k} \times \mathbf{B}_{0}\right)=-c\left(\hat{\boldsymbol{\kappa}} \times \mathbf{B}_{0}\right) \Longrightarrow E_{0}=c B_{0} \tag{42.01.08}
\end{align*}
\]

Note that the two equations (42.01.07), (42.01.08) are actually equivalent, as it can be shown by vector multiplying any one of them by \(\mathbf{k}\) and using the transversality conditions. On the other hand the two equations (42.01.07), (42.01.08) imply the transversality conditions (42.01.06), (42.01.02). That is, for MPW the two divergence equations do not give any additional information with respect to the two rotor equations.
The two equations (42.01.07), (42.01.08) show that the three vectors \(\mathbf{E}_{0}, \mathbf{B}_{0}\) and \(\mathbf{k}\) form a orthogonal set of real vectors. In fact, combining the equations, one can obtain:
\[
\begin{equation*}
\mathbf{E}_{0} \times \mathbf{B}_{0}=\frac{\hat{\boldsymbol{\kappa}}}{c}\left|\mathbf{E}_{0}\right|^{2}=c \hat{\boldsymbol{\kappa}}\left|\mathbf{B}_{0}\right|^{2} \tag{42.01.09}
\end{equation*}
\]

Equations (42.01.17), (42.01.16) show that any of the two ElectroMagnetic fields is known when the other is given.
It is customary to treat EM MPW by describing the electric field only, while the magnetic field can be calculated from (42.01.16) once the electric field is known.

\subsection*{42.01.03 Longitudinal Components of the ElectroMagnetic Fields for a MPW in Vacuum}
© ©|J.E.Vitela |Am.J.Phys, , ..., ..., ...Ed., .... 72, 393 (2004)||
While for MPW only transverse ElectroMagnetic fields are allowed, thanks to the divergence equations, Maxwell Equations do not forbid a constant and uniform component of the ElectroMagnetic fields along the wave-vector, in general. However this uniform and constant field is normally not interesting when dealing with ElectroMagnetic waves. It is therefore normally ignored.

Consider any plane ElectroMagnetic wave, not necessarily a monochromatic one, propagating in vacuum along the \(\hat{\mathbf{e}}_{3}\) direction. The constant phase planes are normal to the \(z\) axis so that the fields only depend on \(z\) and time:
\[
\begin{aligned}
\mathbf{E}[\mathbf{r}, t] & =E_{x}[z, t] \hat{\mathbf{e}}_{1}+E_{y}[z, t] \hat{\mathbf{e}}_{2}+E_{z}[z, t] \hat{\mathbf{e}}_{3}, \\
\mathbf{B}[\mathbf{r}, t] & =B_{x}[z, t] \hat{\mathbf{e}}_{1}+B_{y}[z, t] \hat{\mathbf{e}}_{2}+B_{z}[z, t] \hat{\mathbf{e}}_{3}
\end{aligned} .
\]

Actually, one knows that the dependence is not on \(z\) and \(t\) independently, but on the single combination \(z \pm v t\)
\[
[z, t] \Longrightarrow[z \pm v t]
\]
but this is not relevant here, as we deal with Maxwell Equations only, not the wave equation.
Moreover, we also know (read § 42.02.03 - ElectroMagnetic Waves) that:
\[
E_{x}[z \pm v t] \propto B_{y}[z \pm v t] \quad E_{y}[z \pm v t] \propto B_{x}[z \pm v t]
\]
but this is not relevant here as well.
Then one has, for every component of the fields:
\[
\frac{\partial(\cdots)}{\partial x}=\frac{\partial(\cdots)}{\partial y}=0
\]

Therefore:
\[
\begin{array}{lll}
\operatorname{div} \mathrm{E}=0 & \Longrightarrow & \frac{\partial E_{z}}{\partial z}=0 \\
\operatorname{div} \mathrm{~B}=0 & \Longrightarrow \quad \frac{\partial B_{z}}{\partial z}=0
\end{array}
\]

Moreover:
\[
\begin{array}{lll}
\frac{1}{c^{2}} \partial_{t} \mathbf{E}=\operatorname{rot} \mathbf{B} & \Longrightarrow & \partial_{t} E_{z}=0 \\
-\partial_{t} \mathbf{B}=\operatorname{rot} \mathbf{E} & \Longrightarrow & \partial_{t} B_{z}=0
\end{array}
\]

Therefore if any component of the Electric|Magnetic field exist along the propagation direction it is both time and position independent.
In other words one can add to the MPW solutions (equation (42.01.03) or (42.01.04)) any constant and uniform term along the \(z\) axis, thus obtaining a valid solution to the Maxwell Equations.

\subsection*{42.01.04 Longitudinal Components for General ElectroMagnetic Waves in Vacuum}

Note however that if one does not consider plane ElectroMagnetic waves, but different waves, a longitudinal component of the ElectroMagnetic fields may be present. This is the case of so-called non TEM waves, that is non transverse-ElectroMagnetic waves.
For instance, in wave-guides, where ElectroMagnetic waves propagate in a bounded region, the longitudinal component of the MPW can be different from zero. Read § 43.03.03 - Waves in Bounded Regions.

\subsection*{42.01.05 Complex Electric|Magnetic Field Vector}

This § is referenced at pages:
[Never referenced.]
In order to describe a generic state of Polarization it is possible to use a complex field vector as well, which is capable to describe any Polarization state, as described in § 42.03.03 - ElectroMagnetic Waves.

\subsection*{42.01.06 EM MPW in Vacuum via the Complex Formalism}

This § is referenced at pages:
[2040, 2040]
In this section the same calculations done in section \(\S 42.01 .02\) - ElectroMagnetic Waves are done via the complex formalism.

The wave equation admits MPW solutions,
\[
\begin{equation*}
\mathbf{U}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi \tag{42.01.10}
\end{equation*}
\]
which can be written, in complex form, as:
\[
\begin{equation*}
\mathbf{U}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi \Longrightarrow \overline{\mathbf{U}}[\mathbf{x}, t]=\mathbf{U}_{0} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{x}-\omega t-\phi)] \equiv \overline{\mathbf{U}}_{0} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{x}-\omega t)] . \tag{42.01.11}
\end{equation*}
\]

As long as one considers ElectroMagnetic waves in vacuum the wave-vector \(\mathbf{k}\) is a real vector. However, the wave-vector \(\mathbf{k}\) can be generalized to a complex wave-vector \(\overline{\mathbf{k}}\) (read §42.06.02-ElectroMagnetic Waves).

In this section we still assume \(\mathbf{k}\) to be a real vector, as it is appropriate for vacuum and perfect media, read § 42.02.05 - ElectroMagnetic Waves. A truly real complex vector will be introduced in § 42.06 ElectroMagnetic Waves.

The constant \(\overline{\mathbf{U}}_{0}\) is a complex constant vector carrying the information on both the amplitude and phase of the wave.

The effect of space and time derivation on a complex MPW is the following:
\[
\begin{aligned}
\partial_{t}\left(\overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)]\right) & =-\beth \omega \overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)] \\
\frac{\partial}{\partial x^{i}}\left(\overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)]\right) & =+\beth k_{i} \overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)], \\
& \Longrightarrow \operatorname{div}\left(\overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)]\right)=+\beth\left(\mathbf{k} \cdot \overline{\mathbf{U}}_{0}\right) \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)] \\
& \Longrightarrow \operatorname{rot}\left(\overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)]\right)=+\beth\left(\mathbf{k} \times \overline{\mathbf{U}}_{0}\right) \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t)] \quad .
\end{aligned}
\]

Shortly:
\[
\begin{aligned}
& \operatorname{grad} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t-\phi)] \longrightarrow \beth \mathbf{k} \\
& \quad \partial_{t} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega t-\phi)] \longrightarrow-\beth \omega .
\end{aligned}
\]

Introduce a complex MPW solution in equations (42.01.01), (42.01.02), with the usual convention that the physical quantity is given by the real part of the complex number:
\[
\mathbf{U}[\mathbf{x}, t] \equiv \operatorname{Re}\left(\overline{\mathbf{U}}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{x}-\omega \mathrm{t})]\right)
\]

A priori the wave-vector, \(\mathbf{k}\), frequency, \(\omega\), and phase, \(\phi\), might be different for the \(\mathbf{E}\) and \(\mathbf{B}\) fields, except that for both fields the dispersion relation must be obeyed:
\[
\omega_{E}=\left|\mathbf{k}_{E}\right| c \quad \omega_{B}=\left|\mathbf{k}_{B}\right| c
\]

The expressions for the fields read:
\[
\begin{align*}
\overline{\mathbf{E}}[\mathbf{x}, t] & =\overline{\mathbf{E}}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathrm{E}} \cdot \mathbf{x}-\omega_{E} t\right)\right]=\mathbf{E}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathbf{E}} \cdot \mathbf{x}-\omega_{E} t-\phi_{E}\right)\right],  \tag{42.01.12}\\
\overline{\mathbf{B}}[\mathbf{x}, t] & =\overline{\mathbf{B}}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathrm{B}} \cdot \mathbf{x}-\omega_{B} t\right)\right]=\mathbf{B}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathrm{B}} \cdot \mathbf{x}-\omega_{B} t-\phi_{B}\right)\right], \tag{42.01.13}
\end{align*}
\]
where \(\overline{\mathbf{E}}_{0}\) and \(\overline{\mathbf{B}}_{0}\) are complex constant vectors carrying the information on the amplitude, direction and phase of the fields.
The four Maxwell Equations in vacuum, equations (33.07.06), (33.07.07), (33.07.08), (33.07.02), as described in section \(\S 33.07 .02\) - Basic Laws of ElectroMagnetism, give two transversality conditions, from the divergence equations, and the relations between the fields and the wave-vector.
The two divergence equations do not mix the Electric|Magnetic fields and they provide the transversality conditions of the fields with respect to the wave-vector:
\[
\begin{align*}
& \mathbf{k} \cdot \overline{\mathbf{E}}_{0}=0  \tag{42.01.14}\\
& \mathbf{k} \cdot \overline{\mathbf{B}}_{0}=0 \tag{42.01.15}
\end{align*}
\]

The Electric|Magnetic field in a MPW are transversal that is orthogonal to the wave-vector. Note that, as long as the wave-vector \(\mathbf{k}\) is real, the two complex equations (42.01.14), (42.01.15) are equivalent to the two real equations:
\[
\begin{aligned}
& \mathbf{k} \cdot \mathbf{E}_{0}=0 \\
& \mathbf{k} \cdot \mathbf{B}_{0}=0 .
\end{aligned}
\]

On the contrary, the two rotor equations do mix the Electric|Magnetic fields, and give the following set of equivalent equations:
\[
\begin{aligned}
& \operatorname{rot} \overline{\mathbf{E}}=+\beth\left(\mathbf{k}_{\mathbf{E}} \times \overline{\mathbf{E}}_{0}\right) \exp \left[\beth\left(\mathbf{k}_{\mathbf{E}} \cdot \mathbf{x}-\omega_{E} t\right)\right]=-\partial_{t} \overline{\mathbf{B}}=\beth \omega_{B} \overline{\mathbf{B}}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathbf{B}} \cdot \mathbf{x}-\omega_{B} t\right)\right], \\
& \operatorname{rot} \overline{\mathbf{B}}=+\beth\left(\mathbf{k}_{\mathrm{B}} \times \overline{\mathbf{B}}_{0}\right) \exp \left[\beth\left(\mathbf{k}_{\mathrm{B}} \cdot \mathbf{x}-\omega_{B} t\right)\right]=+\varepsilon_{0} \mu_{0} \partial_{t} \overline{\mathbf{E}}=-\beth \varepsilon_{0} \mu_{0} \omega_{E} \overline{\mathbf{E}}_{0} \exp \left[\beth\left(\mathbf{k}_{\mathbf{E}} \cdot \mathbf{x}-\omega_{E} t\right)\right] .
\end{aligned}
\]

It is obvious from the two previous equations that a necessary condition to satisfy Maxwell equations is that the wave-vectors and frequencies of the Electric|Magnetic fields are equal, because the equations must be satisfied at any point in space at any time, and this cannot happen unless the two exponentials are identical.

Therefore Maxwell Equations imply, first of all:
\[
\omega \equiv \omega_{E}=\omega_{B} \quad \mathbf{k} \equiv \mathbf{k}_{E}=\mathbf{k}_{B}
\]

Secondly, as long as \(\mathbf{k}\) is a real number, it follows that the two phases must be equal as well:
\[
\phi \equiv \phi_{E}=\phi_{B}
\]

In fact the identity between the two members of the Maxwell Equations with rotor can only be satisfied if frequency, wave-vector and phase are identical for the two fields. The latter equations shows that the Electric|Magnetic field must have the same frequency and wave-vector and, as long as \(\mathbf{k} \equiv k \hat{\boldsymbol{\kappa}}\) is a real number, they must be in phase. Therefore the dispersion relation is:
\[
\omega=c|\mathbf{k}| \text {. }
\]

Finally Maxwell Equations imply:
\[
\begin{align*}
& \overline{\mathbf{B}}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \overline{\mathbf{E}}_{0}\right)=+\frac{1}{c}\left(\boldsymbol{\kappa} \times \overline{\mathbf{E}}_{0}\right)  \tag{42.01.16}\\
& \overline{\mathbf{E}}_{0}=-\frac{c^{2}}{\omega}\left(\mathbf{k} \times \overline{\mathbf{B}}_{0}\right)=-c\left(\boldsymbol{\kappa} \times \overline{\mathbf{B}}_{0}\right) . \tag{42.01.17}
\end{align*}
\]

Note that the two equations (42.01.16), (42.01.17) are actually equivalent, as it can be shown by vector multiplying any one of them by \(\mathbf{k}\) and using the transversality conditions. Note that, as long as the wave-vector \(\mathbf{k}\) is real, the two complex equations (42.01.16), (42.01.17) are equivalent to the two real equations:
\[
\begin{aligned}
& \mathbf{B}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{E}_{0}\right)=+\frac{1}{c}\left(\boldsymbol{\kappa} \times \mathbf{E}_{0}\right) \\
& \mathbf{E}_{0}=-\frac{c^{2}}{\omega}\left(\mathbf{k} \times \mathbf{B}_{0}\right)=-c\left(\boldsymbol{\kappa} \times \mathbf{B}_{0}\right)
\end{aligned}
\]

The two equations (42.01.16), (42.01.17) show that the three vectors \(\overline{\mathbf{E}}_{0}, \overline{\mathbf{E}}_{0}\) and \(\mathbf{k}\) form a orthogonal set of complex vectors.

Equations (42.01.16), (42.01.17), imply, for real values of \(\mathbf{k}\) :
\[
\begin{array}{lll}
\mathbf{B}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{E}_{0}\right) & \Longrightarrow & B_{0}=\frac{k E_{0}}{\omega}=\frac{E_{0}}{c} \\
\mathbf{E}_{0}=-\frac{c^{2}}{\omega}\left(\mathbf{k} \times \mathbf{B}_{0}\right) & \Longrightarrow & E_{0}=\frac{c^{2} k B_{0}}{\omega}=c B_{0} \tag{42.01.19}
\end{array}
\]

Equations (42.01.16), (42.01.17), together with the transversality conditions (42.01.14), (42.01.15), imply, for real values of \(\mathbf{k}\) :
\[
\mathbf{k} \frac{c E_{0} B_{0}}{\omega}=\hat{\boldsymbol{\kappa}} E B=\mathbf{E}_{0} \times \mathbf{B}_{0}
\]
as one can show by vector multiplication of either equation (42.01.16) for \(\overline{\mathbf{E}}_{0}\) or equation (42.01.17) for \(\mathbf{B}_{0}\).

\section*{EM Waves in Perfect Media Without Boundaries}

This § is referenced at pages:
[1961, 1961]
The description of ElectroMagnetic fields inside matter in terms of \(\mathbf{E}\) and \(\mathbf{B}\) plus particles is always good under any circumstance: it is the microscopic description. However sometimes it is not necessary to go into the level of detail of the microscopic description. Then one may introduce the macroscopic description in terms of \(\mathbf{P}\) and \(\mathbf{M}\) which is always good, even in the realm of modern physics. In this case, however, it is sometimes necessary to make a model of matter.
The detailed treatment of the behavior of ElectroMagnetic waves in matter will be discussed in § \(50-\) ElectroMagnetic Waves in Matter.
For the present purposes it is enough to introduce the concept of perfect medium, that is an LHI medium such that the Electric-Permittivity | Magnetic-Permeability are just fixed (real) numbers independent of anything else than the nature of the material medium with \(\epsilon_{R} \geq 1\) and \(\mu_{R} \geq 0\), the conductivity is zero (so the free current density is zero) and the free charge density is zero:
\[
\begin{gathered}
\text { LHI medium }, \\
\begin{array}{c}
\epsilon_{\mathrm{R}} \geq 1 \quad \text { fixed } \\
\mu_{\mathrm{R}} \geq 0 \\
\text { fixed }, \\
\sigma=0 \Longrightarrow \mathbf{j}^{\mathrm{F}}=0 \\
\rho^{\mathrm{F}}=0
\end{array},
\end{gathered}
\]

Note that if any one of the latter hypotheses is not valid some of the basic relations deduced in this section may be violated.
A perfect medium does not absorb ElectroMagnetic energy from the ElectroMagnetic waves. The meaning of real (as opposed to complex) Electric-Permittivity | Magnetic-Permeability means that, for harmonic fields, there is no phase-shift between \(\mathbf{E} / \mathbf{P}\) and \(\mathbf{B} / \mathbf{M}\), as discussed in \(\S 50\) - ElectroMagnetic Waves in Matter.
In fact it will become clear that there is little difference between the behavior of ElectroMagnetic waves in vacuum with respect to a perfect medium.
A perfect medium is often a good approximation for describing ElectroMagnetic waves in matter, as long as the ElectroMagnetic wave is almost monochromatic and absorption is negligible.

\subsection*{42.02.01 EM MPW in Perfect Media}

The reasoning in § 42.01 - ElectroMagnetic Waves can be carried on in a similar way for a perfect LHI medium to find (Read also section \(\S 50\) - ElectroMagnetic Waves in Matter) the following relations:
\[
\begin{gathered}
\begin{array}{|}
\nabla^{2} \mathbf{E}=\frac{1}{v^{2}} \frac{\partial^{2} \mathbf{E}}{\partial t^{2}} \\
\nabla^{2} \mathbf{B}=\frac{1}{v^{2}} \frac{\partial^{2} \mathbf{B}}{\partial t^{2}} & , \\
\omega \equiv k v & c^{2} k^{2}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \omega^{2} & k=\frac{\omega}{c} \sqrt{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}} & \\
v \equiv \frac{1}{\sqrt{\mu_{\mathrm{R}} \epsilon_{\mathrm{R}}}} \frac{1}{\sqrt{\mu_{0} \varepsilon_{0}}}=\frac{c}{\sqrt{\mu_{\mathrm{R}} \epsilon_{\mathrm{R}}}} \quad \text { with } \quad c=2.998 \cdot 10^{8} \mathrm{~m} / \mathrm{s} .
\end{array} .
\end{gathered}
\]

Actually, the two equations are decoupled, but the Electric|Magnetic fields are only apparently decoupled. In fact, the equations have been obtained by derivation from Maxwell equations, which still rule, coupling the Electric|Magnetic fields. Therefore, additional constraints must be included on the solutions of d'Alembert equations. Read \(\S 42.01 .01\) - ElectroMagnetic Waves. The refractive index of the material is defined as:
\[
n \equiv \frac{c}{v}=\frac{c k}{\omega}=\sqrt{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}} .
\]

The same definition of the refractive index is extended to the more general case when the wave-vector is a complex vector:
\[
\begin{equation*}
\overline{\mathbf{n}} \equiv \frac{c}{\omega} \overline{\mathbf{k}} \tag{42.02.01}
\end{equation*}
\]

Maxwell Equations for MPW lead to the following relations:
\[
\begin{gathered}
\begin{array}{c}
\mathbf{k} \cdot \mathbf{D}_{0}=0 \Longrightarrow \mathbf{k} \cdot \mathbf{E}_{0}=0 \\
\mathbf{k} \cdot \mathbf{B}_{0}=0 \Longrightarrow \mathbf{k} \cdot \mathbf{H}_{0}=0 \\
\mathbf{B}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{E}_{0}\right) \Longrightarrow \mathbf{H}_{0}=+\frac{v^{2}}{\omega}\left(\mathbf{k} \times \mathbf{D}_{0}\right) \Longrightarrow B_{0}=\frac{k E_{0}}{\omega}=\frac{E_{0}}{v} \\
\mathbf{D}_{0}=-\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{H}_{0}\right) \Longrightarrow \mathbf{E}_{0}=-\frac{v^{2}}{\omega}\left(\mathbf{k} \times \mathbf{B}_{0}\right) \Longrightarrow D_{0}=\frac{k H_{0}}{\omega}=\frac{H_{0}}{v} \\
.
\end{array} .
\end{gathered}
\]

Note, in the above relations for the amplitudes, the inverted role of the Electric|Magnetic fields \(\mathbf{D}\) and \(\mathbf{H}\) with respect to \(\mathbf{E}\) and \(\mathbf{B}\).
\[
B_{0}=\frac{E_{0}}{v} \quad D_{0}=\frac{H_{0}}{v}
\]

Note that, on dimensional grounds, the role of electric and magnetic fields in the above equations are interchanged.

\subsection*{42.02.02 The Index of Refraction}

\section*{© - QUOTE}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|§ 31||
We have said before that light goes slower in water than in air, and slower, slightly, in air than in vacuum. This effect is described by the index of refraction. Now we would like to understand how such a slower velocity could come about. In particular, we should try to see what the relation is to some physical assumptions, or statements, we made earlier, which were the following:
- That the total electric field in any physical circumstance can always be represented by the sum of the fields from all the charges in the universe.
- That the field from a single charge is given by its acceleration evaluated with a retardation at the speed \(c\), always (for the radiation field).
But, for a piece of glass, you might think: "Oh, no, you should modify all this. You should say it is retarded at the speed \(c / n\)." That, however, is not right, and we have to understand why it is not.
It is approximately true that light or any electrical wave does appear to travel at the speed \(c / n\)
through a material whose index of refraction is \(n\), but the fields are still produced by the motions of all the charges-including the charges moving in the material - and with these basic contributions of the field travelling at the ultimate velocity \(c\). Our problem is to understand how the apparently slower velocity comes about.

\subsection*{42.02.03 General Plane Non-Monochromatic ElectroMagnetic MPW in Perfect Media}

This § is referenced at pages:
[2034, 2034]
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|1.4||
EM PW (non-monochromatic, in general) are described, in terms of the phase, \(\Phi\), by the fields:
\[
\begin{gathered}
\Phi \equiv \mathbf{k} \cdot \mathbf{r}-\omega t-\phi \\
\mathbf{E}[\mathbf{r}, t]=\mathbf{E}[\mathbf{k} \cdot \mathbf{r}-\omega t-\phi] \equiv \mathbf{E}[\Phi] \\
\mathbf{B}[\mathbf{r}, t]=\mathbf{B}[\mathbf{k} \cdot \mathbf{r}-\omega t-\phi] \equiv \mathbf{B}[\Phi]
\end{gathered}
\]

Let us introduce some short-hand notations:
\[
\mathbf{V}[\mathbf{r}, t] \equiv \mathbf{V}[\Phi] \equiv \mathbf{V}[\mathbf{k} \cdot \mathbf{r}-\omega t-\phi]
\]

It can be easily demonstrated that:
\[
\partial_{t} \mathbf{V}=-\omega \frac{\mathrm{d} \mathbf{V}}{\mathrm{~d} \Phi} \quad \frac{\partial \mathbf{V}}{\partial x^{s}}=k_{s} \frac{\mathrm{~d} \mathbf{V}}{\mathrm{~d} \Phi}=-\frac{k_{s}}{\omega} \partial_{t} \mathbf{V}
\]

One then finds from Maxwell Equations:
\[
\mathbf{k} \times \frac{\mathrm{d} \mathbf{E}}{\mathrm{~d} \Phi}=+\omega \frac{\mathrm{d} \mathbf{B}}{\mathrm{~d} \Phi} \quad \mathbf{k} \times \frac{\mathrm{d} \mathbf{H}}{\mathrm{~d} \Phi}=-\frac{\omega}{c^{2}} \frac{\mathrm{~d} \mathbf{D}}{\mathrm{~d} \Phi}
\]

By integrating the previous relations and neglecting possible integration constants, that is constant fields, one then finds:
\[
\mathbf{B}=+\frac{\mathbf{k} \times \mathbf{E}}{\omega} \quad \mathbf{D}=-c^{2} \frac{\mathbf{k} \times \mathbf{H}}{\omega}
\]

To complete the properties of ElectroMagnetic Waves it is necessary to describe the configuration of ElectroMagnetic fields in the plane perpendicular to the direction of the wave-vector.
© |R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|1.33||
EM waves are transverse waves. In the case of transverse waves different possible configurations are possible for the oscillating physical quantity in the plane perpendicular to the direction of propagation.
In this section the Polarization of ElectroMagnetic waves will be described, but it should be kept in mind that a parallel discussion might be carried on for any other transverse wave (for instance transverse elastic waves on a spring or in a solid medium).
It is interesting to note that the Polarization of ElectroMagnetic waves and its description is perhaps the simplest example of the description of states of a physical system in quantum physics.

\subsection*{42.03.01 Description of the Polarization of ElectroMagnetic Waves}

Maxwell Equations give a well-defined relation between the electric and magnetic field of an ElectroMagnetic MPW. However they impose no relation at all on the components of the Electric|Magnetic fields in the plane perpendicular to the wave-vector, \(\mathbf{k}\), that is on two components of the same field. The concept of Polarization deals with the different configurations of the Electric|Magnetic fields in the plane perpendicular to the wave-vector, \(\mathbf{k}\), for a MPW.
When dealing with Polarization of ElectroMagnetic waves one normally refers, just by convention, to the electric field vector, because it is the electric field vector which gives, normally, the most significant effects on matter. One knows that the general relations presented in section § 42.01 - ElectroMagnetic Waves allow to calculate the magnetic field of a MPW when the electric field is known. Therefore the ElectroMagnetic fields of ElectroMagnetic waves can be fully described from the knowledge of the electric field only.
Let the \(z\) axis be the propagation axis. Maxwell Equations do not imply any relation between the transverse components of the same field. We then choose two ElectroMagnetic MPW, one with electric fields along \(x\) and the other along \(y\), having the same frequency and wave-vector but arbitrary amplitudes and phase constants. The phase-velocity is assumed here to be fixed.
As Maxwell Equations are linear the resultant field is an admissible ElectroMagnetic field.
Let us consider the electric field at some fixed point, \(z=\bar{z}\), as a function of time:
\begin{tabular}{|ll|}
\hline\(E_{x}[t]=E_{x 0} \cos k \bar{z}-\omega t-\phi_{x}\) & with \(E_{x 0} \geq 0\) and \(0 \leq \phi_{x}<2 \pi\) \\
\hline\(E_{y}[t]=E_{y 0} \cos k \bar{z}-\omega t-\phi_{y}\) & with \(E_{y 0} \geq 0\) and \(0 \leq \phi_{y}<2 \pi\) \\
\hline
\end{tabular}.

Note that, provided one chooses the correct phase constant \(0 \leq \phi<2 \pi\), the amplitudes \(E_{x 0}\) and \(E_{y 0}\) can be taken as positive. This convention will be used here.
Different cases may arise, as discussed below, depending of the value of the difference of the phases of the two components. By convention it is defined as the phase constant of the \(y\) component minus the phase constant of the \(x\) component:
\[
\Delta \phi \equiv\left(\phi_{y}-\phi_{x}\right)
\]

We want to describe the behavior of the electric field vector in the \(x y\) plane as a function of time. From the point of view of geometry this means to pass from the parametric representation of \(E_{x}[t]\) and \(E_{y}[t]\) as a function of time (a parametric curve in the \(x y\) plane) to the Cartesian representation \(\mathcal{F}\left[E_{x}[t], E_{y}[t]\right]=0\) where time has been eliminated (a Cartesian curve in the \(x y\) plane).

\subsection*{42.03.01.01 Linear Polarization}

If \(\Delta \phi \equiv\left(\phi_{y}-\phi_{x}\right)=q \pi\), with \(q\) any integer number, the ElectroMagnetic wave is said to be linearly Polarized and the two components of the field are proportional and either in phase or out-of-phase by \(\pi\) :
\[
\left|E_{x}\right| E_{y 0}=\left|E_{y}\right| E_{x 0}
\]

At any fixed \(z\) position the electric field vector runs on a straight line segment, whose orientation depends on the values of \(E_{y 0}\) and \(E_{x 0}\).

A relation carrying more information, namely the relative sign between the two components, is easily deduced:
\[
\Delta \phi \equiv\left(\phi_{y}-\phi_{x}\right)=q \pi \Longrightarrow E_{x} E_{y 0}=(-1)^{q} E_{y} E_{x 0}
\]

The electric field of a linearly Polarized ElectroMagnetic wave has a fixed direction but its amplitude and orientation change with time.

\subsection*{42.03.01.02 Components in Quadrature and Circular Polarization}

If \(\Delta \phi \equiv\left(\phi_{y}-\phi_{x}\right)=\pi(q+1 / 2)\), with \(q\) any integer number, the ElectroMagnetic wave is said to be elliptically Polarized with axes parallel to \(x\) and \(y\) and the two components of the field are out-of-phase by plus/minus one-quarter cycle with the electric field going across an ellipse whose axes are the \(x\) and \(y\) axes:
\[
\left(\frac{E_{x}}{E_{x 0}}\right)^{2}+\left(\frac{E_{y}}{E_{y 0}}\right)^{2}=1
\]

In the special and most important case \(E_{x 0}=E_{y 0}\) the Polarization is circular and the electric field goes across a circumference.

The electric field of a circularly Polarized ElectroMagnetic wave has a fixed amplitude but its oriented direction changes with time.

The handedness of rotation can be calculated from the sign of the projection on the \(z\) axis of the vector \(\mathbf{E} \times \dot{\mathbf{E}}\), in a similar way to angular momentum, see section §42-018 - ElectroMagnetic Waves.

\subsection*{42.03.01.03 General Elliptic Polarization}

This § is referenced at pages:
[1068, 1068, 1223, 1223]
In the general case one obtains, with a generic \(\Delta \phi \equiv\left(\phi_{y}-\phi_{x}\right)\), a generic ellipse:
\[
\begin{equation*}
\left(\frac{E_{x}}{E_{x 0}}\right)^{2}+\left(\frac{E_{y}}{E_{y 0}}\right)^{2}-2\left(\frac{E_{x}}{E_{x 0}}\right)\left(\frac{E_{y}}{E_{y 0}}\right) \cos \Delta \phi=\sin ^{2} \Delta \phi \tag{42.03.01}
\end{equation*}
\]
\(\rightarrow\) 20422122
giving the so-called Lissajous figures for general elliptical Polarization.
Equation (42.03.01) actually includes all the possible cases of Polarization.
In fact, from the geometrical properties of the equation (42.03.01), one has that the ellipse has its axes parallel to the \(x\) and \(y\) axes if and only if \(\cos \Delta \phi=0\) and it degenerates into a straight line segment if and only if \(\sin \Delta \phi=0\).

Also in this general case, the handedness of rotation can be calculated from the sign of the projection on the \(z\) axis of the vector
\[
\mathbf{E} \times \dot{\mathbf{E}} \Longrightarrow \hat{\mathbf{e}}_{3} \cdot(\mathbf{E} \times \dot{\mathbf{E}})
\]
in a similar way to angular momentum, see section § 42-018 - ElectroMagnetic Waves.

\subsection*{42.03.01.04 Handedness and Helicity}
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|||
In general one might be interested to know the sense of rotation of the electric field. This is either described in terms of handedness or helicity. By convention one describes the sense of rotation of the electric field as it is seen by an observer looking at the incoming MPW, that is the MPW is going towards the observer.
The conventional nomenclature is the following one:
\begin{tabular}{||c||c|c|c||}
\hline \hline as seen by the observer & \begin{tabular}{c} 
traditional (optics) name \\
handedness
\end{tabular} & \begin{tabular}{c} 
particle physics name \\
helicity
\end{tabular} & \(\Delta \phi\) \\
\hline clockwise & \begin{tabular}{c} 
right-handed (R) \\
counter-clockwise
\end{tabular} & \begin{tabular}{c} 
negative helicity \\
positive helicity
\end{tabular} & \begin{tabular}{c}
\(\sin \Delta \phi>0\) \\
\(\sin \Delta \phi<0\)
\end{tabular} \\
\hline \hline
\end{tabular}

Note that the traditional (optics) name is just opposite to what one would use by applying the right-hand/left-hand rule along the direction of propagation, as if the observer would look at the back of the MPW.

\subsection*{42.03.02 Combinations of Different Polarization States}

Consider ElectroMagnetic MPW traveling along the positive \(z\) direction. Polarization is described in the \(x y\) plane.
It is particularly simple to describe Polarization states via the complex formalism.
Note: be careful to get correct the amplitude of the resulting ElectroMagnetic wave as a function of the amplitudes of the constituent waves.
Read §42.15.01 - ElectroMagnetic Waves before for the operative definition of Polarization states. In fact, the Quantum nature of the Polarization of ElectroMagnetic waves requires careful operative definitions, to match with formalism.

\subsection*{42.03.02.01 Circular Polarization From Linearly Polarized Waves}

Circular Polarization can be obtained by superposition of two waves linearly Polarized along two perpendicular axes and out-of-phase by \(\pm \pi / 2\) (plus/minus multiples of \(\pi\) ), with totally arbitrary phases \(\phi_{\mathrm{R}}\) and \(\phi_{\mathrm{L}}\), as follows:
\[
\begin{array}{lll}
\mathbf{E}_{\mathrm{R}}[z, t]=E_{0}\left(\cos k z-\omega t-\phi_{\mathrm{R}} \hat{\mathbf{e}}_{1}+\cos k z-\omega t-\left(\phi_{\mathrm{R}}+\pi / 2\right) \hat{\mathbf{e}}_{2}\right) & \Delta \phi=+\pi / 2 \\
\mathbf{E}_{\mathrm{L}}[z, t]=E_{0}\left(\cos k z-\omega t-\phi_{\mathrm{L}} \hat{\mathbf{e}}_{1}+\cos k z-\omega t-\left(\phi_{\mathrm{L}}-\pi / 2\right) \hat{\mathbf{e}}_{2}\right) & \Delta \phi=-\pi / 2 .
\end{array}
\]

The two above circularly Polarized ElectroMagnetic MPW traveling along the \(z\) direction can also described by the complex relations:
\(\mathbf{E}_{\mathrm{R}}=\operatorname{Re}\left(\sqrt{2} \mathrm{E}_{0} \exp [\beth(\mathrm{kz}-\omega \mathrm{t})]\left(\frac{\hat{\mathbf{e}}_{1}-\beth \hat{e}_{2}}{\sqrt{2}}\right)\right)=\operatorname{Re}\left(\sqrt{2} \mathrm{E}_{0} \exp [\beth(\mathrm{kz}-\omega \mathrm{t})] \mathbf{e}_{\mathrm{R}}\right) \quad E_{0} \equiv E_{0} \exp \left[-\beth \phi_{R}\right] \quad\),
\(\mathbf{E}_{\mathrm{L}}=\operatorname{Re}\left(\sqrt{2} \mathrm{E}_{0} \exp [\beth(\mathrm{kz}-\omega \mathrm{t})]\left(\frac{\hat{\mathbf{e}}_{1}+\beth \hat{e}_{2}}{\sqrt{2}}\right)\right)=\operatorname{Re}\left(\sqrt{2} \mathrm{E}_{0} \exp [\beth(\mathrm{kz}-\omega \mathrm{t})] \mathbf{e}_{\mathrm{L}}\right) \quad E_{0} \equiv E_{0} \exp \left[-\beth \phi_{L}\right]\).
Superposition of two ElectroMagnetic MPW traveling along the \(z\) direction with orthogonal Polarization and \(\pm \pi / 2\) phase difference leads to a circularly Polarized wave with the same amplitude as the amplitude of the two original ElectroMagnetic waves.

\subsection*{42.03.02.02 Linear Polarization From Circularly Polarized Waves}

Linear Polarization can be obtained by superposition of two waves with opposite circular Polarization:
\[
\mathbf{E}[z, t]=\mathbf{E}_{\mathrm{R}}[z, t]+\mathbf{E}_{\mathrm{L}}[z, t]=2 E_{0} \cos k z-\omega t-\frac{\phi_{\mathrm{R}}+\phi_{\mathrm{L}}}{2}\left(\cos \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \hat{\mathbf{e}}_{1}+\sin \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \hat{\mathbf{e}}_{2}\right) \bigcirc(42.03 .02) \rightarrow \rightarrow
\]

It is clear from the above relation that the resulting Polarization ia a linear one, because both components have the same phase factor, with a common phase constant: \(\frac{\phi_{\mathrm{R}}+\phi_{\mathrm{L}}}{2}\).

The characteristics of the resulting linearly Polarized wave is fully determined by the two arbitrary phases \(\phi_{\mathrm{R}}\) and \(\phi_{\mathrm{L}}\). Note that the factor:
\[
\left(\cos \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \hat{\mathbf{e}}_{1}+\sin \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \hat{\mathbf{e}}_{2}\right)
\]
is in fact a unit vector, whose direction gives the direction of the resulting field.
It then follows that the resulting ElectroMagnetic wave is always linearly Polarized in a direction which depends on the difference between the two phases \(\phi_{\mathrm{R}}\) and \(\phi_{\mathrm{L}}\). Note that the resulting amplitude is twice the amplitude of the two component EM waves.

The \(x\) and \(y\) components of the resulting field are:
\[
\begin{aligned}
& E_{x}=2 E_{0} \cos \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \cos k z-\omega t-\frac{\phi_{\mathrm{R}}+\phi_{\mathrm{L}}}{2} \\
& E_{y}=2 E_{0} \sin \frac{\phi_{\mathrm{L}}-\phi_{\mathrm{R}}}{2} \cos k z-\omega t-\frac{\phi_{\mathrm{R}}+\phi_{\mathrm{L}}}{2}
\end{aligned}
\]

\subsection*{42.03.03 Generic Polarization States}

This § is referenced at pages:
[2035, 2035, 2265, 2265]
The Polarization state of ElectroMagnetic MPW, as described by the complex amplitude in expressions like equation (42.01.11), form a complex vector space with Hermitian scalar product.

In fact, the addition of two MPW along the same direction provides a MPW along the same direction with the same frequency which is described by the algebraic sum of the two Polarization vectors, as from § 17.03.02-Linear Systems.

Moreover, multiplication of MPW by a complex scalar provides a MPW along the same direction with the same frequency, and different amplitude and phase, which is described by the algebraic algebraic product of the complex scalar with the Polarization vector, as from § 17.03.02-Linear Systems.

In fact, all the requirements for a complex vector space are satisfied.

\subsection*{42.03.03.01 Bases and Orthogonal Polarization States}
©|E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|8.13||

Read § 42.15.01 - ElectroMagnetic Waves.
- Standard Base for linear Polarization:
\[
\left\{\hat{\mathbf{e}}_{1}, \hat{\mathbf{e}}_{2}\right\} .
\]
- Other Bases for linear Polarization: any orthonormal base, \(\left\{\hat{\mathbf{e}}_{1}^{\prime}, \hat{\mathbf{e}}_{2}^{\prime}\right\}\), coming from any rotation in the \(x y\) plane starting from \(\left\{\hat{\mathbf{e}}_{1}, \hat{\mathbf{e}}_{2}\right\}\) :
\[
\left\{\hat{\mathbf{e}}_{1}^{\prime}, \hat{\mathbf{e}}_{2}^{\prime}\right\}=\operatorname{Re}\left(\left\{\hat{\mathbf{e}}_{1}, \hat{\mathbf{e}}_{2}\right\}\right)
\]
- Standard Base for circular Polarization:
\[
\left.\left\{\mathbf{e}_{\mathrm{R}}, \mathbf{e}_{\mathrm{L}}\right\} \equiv\left\{\frac{\hat{\mathbf{e}}_{1}-\beth \hat{\mathbf{e}}_{2}}{\sqrt{2}}, \frac{\hat{\mathbf{e}}_{2}+\beth \hat{\mathbf{e}}_{2}}{\sqrt{2}}\right\} \quad \mathbf{e}_{\mathrm{R}} \cdot \mathbf{e}_{\mathrm{R}}^{\star}=1 \quad \mathbf{e}_{\mathrm{L}} \cdot \mathbf{e}_{\mathrm{L}}^{\star}=1 \quad \mathbf{e}_{\mathrm{R}} \cdot \mathbf{e}_{\mathrm{L}}^{\star}=0 \quad \mathbf{e}_{\mathrm{L}} \cdot \mathbf{e}_{\mathrm{R}}^{\star}=0\right\}
\]
- Other Bases for circular Polarization: any base obtained from \(\left\{\mathbf{e}_{R}, \mathbf{e}_{L}\right\}\) as the standard bases for linear Polarization are obtained from \(\left\{\hat{\mathbf{e}}_{1}, \hat{\mathbf{e}}_{2}\right\}\) :
\[
\left\{\mathbf{e}_{\mathrm{R}}^{\prime}, \mathbf{e}_{\mathrm{L}}^{\prime}\right\}=\operatorname{Re}\left(\left\{\mathbf{e}_{\mathrm{R}}, \mathbf{e}_{\mathrm{L}}\right\}\right)
\]

In general:
\[
\hat{\mathbf{e}}_{\mathrm{k}} \cdot \hat{\mathbf{e}}_{\mathrm{j}}^{\star}=\delta_{k j}^{\because}
\]

It can be shown that in general two Polarization states are orthogonal if and only if their complex vectors are orthogonal, as for base states above:
\[
\mathbf{E}_{1} \cdot \mathbf{E}_{2}^{\star}=0 \quad \text { if and only if } \mathbf{E}_{1} \text { and } \mathbf{E}_{2} \text { are orthogonal }
\]

Any Polarization state can be described by a linear combination of the base vectors of any orthonormal base.

\subsection*{42.03.03.02 Pure States}

The generic complex field of a MPW propagating along the \(z\) axis can be written as:
\[
\mathbf{E}=\mathbf{E}_{\mathrm{R}}+\boldsymbol{\beth} \mathbf{E}_{\mathrm{I}}
\]
with the usual convention that the physical field is the real part of the complex field.
It can be also written, terms of the real positive amplitudes, \(E_{0 x}\) and \(E_{0 y}\), and the two real phases \(\phi_{x}\) and \(\phi_{y}\), as:
\[
\begin{aligned}
\mathbf{E}[\mathbf{r}, t] & =\hat{\mathbf{e}}_{1} E_{0 x} \exp \left[-\beth \phi_{x}\right] \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t)]+\hat{\mathbf{e}}_{2} E_{0 y} \exp \left[-\beth \phi_{y}\right] \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t)], \\
& =\left(\hat{\mathbf{e}}_{1} E_{0 x} \exp \left[-\beth \phi_{x}\right]+\hat{\mathbf{e}}_{2} E_{0 y} \exp \left[-\beth \phi_{y}\right]\right) \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t)]
\end{aligned}
\]

The latter relation shows that a generic complex vector, \(\mathbf{E}_{0}\), multiplying the MPW factor can describe a generic MPW with any given state of Polarization as:
\[
\mathbf{E}[\mathbf{r}, t]=\mathbf{E}_{0} \exp [\beth(\mathbf{k} \cdot \mathbf{r}-\omega t)]
\]

Two MPW propagating along the same direction and characterized by the vectors \(\mathbf{E}_{0 \mid 1}\) and \(\mathbf{E}_{0 \mid 2}\) are orthogonal if and only if:
\[
\left\langle\mathbf{E}_{0 \mid 1} \cdot \mathbf{E}_{0 \mid 2}\right\rangle=\mathbf{E}_{0 \mid 1}^{\star} \cdot \mathbf{E}_{0 \mid 2}=0=\mathbf{E}_{0 \mid 1} \cdot \mathbf{E}_{0 \mid 2}^{\star}=\left\langle\mathbf{E}_{0 \mid 2} \cdot \mathbf{E}_{0 \mid 1}\right\rangle
\]

This can be checked by direct calculation, motivating the use of complex base vectors in a complex vector space with hermitian scalar product.
In the complex formalism any Polarization state can be described as a superposition of a pair of complex base vectors in a complex vector space with hermitian scalar product satisfying the complex orthonormality condition:
\[
\mathbf{e}_{i} \cdot \mathbf{e}_{j}^{\star}=\delta_{i j}^{\because} \quad i, j=1,2
\]

Any Polarization state can be written in terms of the base vectors as:
\[
\mathbf{E}=E_{1} \mathbf{e}_{1}+E_{2} \mathbf{e}_{2}
\]

This is the basis of the so-called Jones-calculus capable to deal in a compact way with pure Polarization states and instruments changing the Polarization states.

Note that the description of Polarization states is in terms of a complex vector space, as it is appropriate for a two-states quantum system. This shall not be confused with the algebra of complex vectors of § 17.05 - Linear Systems.

\subsection*{42.03.03.03 Stokes Parameters}

Stokes parameters are used to describe the Polarization state of a MPW.
Three independent parameters are required to characterize the Polarization ellipse such as the two amplitudes and the phase \(\phi\). It is often convenient to use a different set of parameters, having the same physical dimensions.
The Stokes parameters of a MPW are defined as:
\[
\begin{aligned}
& s_{0}=E_{0 x}^{2}+E_{0 y}^{2}, \\
& s_{1}=E_{0 x}^{2}-E_{0 y}^{2}, \\
& s_{2}=2 E_{0 x} E_{0 y} \cos \Delta \phi, \\
& s_{3}=2 E_{0 x} E_{0 y} \sin \Delta \phi .
\end{aligned}
\]

Only three of the Stokes parameters are independent as they are related by:
\[
s_{0}^{2}=s_{1}^{2}+s_{2}^{2}+s_{3}^{2} .
\]

The parameter \(s_{0}\) is clearly proportional to the intensity of the wave. This allows to express the three parameters \(s_{1}, s_{2}\) and \(s_{3}\) as:
\[
\begin{aligned}
& s_{1}=s_{0} \cos 2 \chi \cos 2 \psi, \\
& s_{2}=s_{0} \cos 2 \chi \sin 2 \psi, \\
& s_{3}=s_{0} \sin 2 \chi,
\end{aligned}
\]

These relations point to a simple geometrical interpretation: the three parameters \(s_{1}, s_{2}\) and \(s_{3}\) can be interpreted as the three orthonormal Cartesian Coordinates Coordinate System of a point on the surface of a sphere of radius \(s_{0}\) such that the angle \(2 \chi\) may be regarded as the polar angle while \(2 \psi\) may be regarded as the azimuth angle.
Thus to any given Polarization state of a MPW of intensity \(s_{0}\) can be associated a point at the surface of the sphere, called the Poincaré sphere.
The following properties can be demonstrated.
- Define the auxiliary quantity:
\[
\tan \alpha \equiv \frac{E_{0 y}}{E_{0 x}} \quad 0 \leq \alpha \leq \pi / 2
\]
- The half azimuth angle \(\psi(0 \leq \psi \leq \pi)\) characterizes the orientation of the ellipse:
\[
\tan 2 \psi=\frac{2 E_{0 x} E_{0 y}}{E_{0 x}^{2}-E_{0 y}^{2}} \cos \Delta \phi=\tan 2 \alpha \cos \Delta \phi
\]
- Let \(a\) and \(b\) be the major and minor axes of the ellipse. Define the auxiliary quantity:
\[
\tan \chi \equiv \pm \frac{b}{a}
\]
where the sign in the definition may be used to distinguish the two senses in which the ellipse may be described.
- The half polar angle \(\chi(-\pi / 4 \leq \chi \leq+\pi / 4)\) characterizes the eccentricity of the ellipse and the sense in which the ellipse is being described.
\[
|\tan \chi|=\frac{b}{a} \leq 1
\]

\section*{Absorption Scattering Extinction of ElectroMagnetic Waves}

This § is referenced at pages:
[2273, 2273]

EM waves are absorbed and scattered; phenomenological introduction.

\subsection*{42.04.01 Phenomenological Introduction to the Beer-Lambert Law}

This § is referenced at pages:
[2282, 2282]
In this section a phenomenological introduction to absorption scattering and extinction of ElectroMagnetic waves (such as light) is presented.

A phenomenological approach is such that phenomena are just described without any attempt to explain, interpret nor model the phenomena themselves.

The term extinction is used to indicate the complex of absorption and scattering, that is light removal from the beam. Absorption implies transfer of energy into matter. Scattering implies removal of energy from the beam and re-direction of ElectroMagnetic waves and energy into a direction different from the original one.

Both scattering and absorption remove ElectroMagnetic waves and energy from a beam traversing a medium, so that the beam is attenuated and this attenuation is called extinction. Extinction is seen when looking directly at the light source. The Sun, for instance, is fainter and redder at sunset than at noon due to extinction along the air path. Extinction is strong in all colors, but it is stronger in blue light than in red light. Whether scattering or absorption is mainly responsible for this extinction cannot be judged from this observation alone. However when looking sideways at the air through which the Sun shines one can see that actually blue light is scattered more strongly. Measurements show that all light taken away from the original beam reappears sideways as scattered light. Therefore in this case it is scattering and not absorption causing the extinction.

Consider a cylindrical light beam across matter. The amount of light undergoing absorption/scattering is normally proportional to the actual beam intensity.

This follows easily from the corpuscular interpretation of ElectroMagnetic radiation in terms of photons and from the fact that the number of photons absorbed/scattered is proportional to the number of photons present in the beam, for truly independent absorption/scattering events and in absence of any coherence/correlation effect among different scattering centers.

Moreover, the number of photons absorbed/scattered is proportional to the thickness of the matter traversed, at least for infinitesimally thin layers of matter. The fact that the number of photons absorbed/scattered is proportional to the thickness of the infinitesimal layer of matter but this is not true for a finite piece of matter can be understood as follows. If a certain intensity enters a disk of certain thickness the extinction will be proportional to the original intensity. If another identical disk of matter follows the extinction will be again proportional to the entering intensity, which is the extincted intensity from the first disk, that is smaller than the original intensity. Therefore the extinction caused by the second disk will be smaller than the one caused by the first disk and the total extinction caused by the two disks less that twice the extinction caused by each single disk on the original intensity.

The proportionality to the intensity and infinitesimal disk thickness gives the Beer-Lambert law in optics, for the intensity of a beam as a function of the position \(z\) inside an homogeneous and isotropic
absorbing medium, in terms of the quantity \(\lambda\), the attenuation length (or extinction length or mean free path), Read also section \(\S\) 28.06.01 - Introduction to Many-Particles Systems.

The Beer-Lambert law is easily derived by assuming that the intensity change is proportional to the intensity itself as well as to the (infinitesimal) length of the path traversed as follows:
\[
\frac{\mathrm{d} I[z]}{\mathrm{d} z}=-\frac{I[z]}{\lambda} \quad \Longrightarrow \quad I[z]=I_{0} \exp \left[-\frac{z}{\lambda}\right]
\]

The mean free path provides the length over which the beam is attenuated. It can be expressed in terms of the cross-section for the interaction (either absorption or scattering) and the number density of targets, \(\eta_{\mathrm{N}}\), as (compare with equation (28.06.04)):
\[
\frac{1}{\lambda} \equiv \eta_{\mathrm{N}} \sigma
\]
in case of fixed targets.
Read § 28.06-Introduction to Many-Particles Systems for further details and developments.

\section*{Energy Linear Momentum Angular Momentum of ElectroMagnetic Waves}

This § is referenced at pages:
[1965, 1965, 2049, 2049, 2110, 2110]

After discussing polarization, the description of ElectroMagnetic MPW is complete and the dynamic quantities associated to ElectroMagnetic MPW can be introduced.
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|||

When an ElectroMagnetic wave is impinging onto a piece of matter it can give energy to the matter and it can also give linear momentum along its propagation direction and angular momentum around its propagation direction.

\subsection*{42.05.01 Intensity of ElectroMagnetic MPW}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|Vol. 2, § \(27.2|\mid\)
©|K.T.McDonald|WEB - URL|Extensive Recent Review - for instance see about Feynman, Stratton, Bossavit.|
The time-averaged value of the Poynting vector across any surface is usually called the intensity of the radiation across the surface. It is a measure of the energy flux across any surface, that is energy per unit time per unit area:
\[
I \equiv|\langle\mathbf{S}\rangle|
\]

Note that, even if the Poynting vector can be safely used only when integrated on a closed surface to describe the total power, in the present case the following arguments can be given in favor of interpreting it as the local energy flux, point by point.
- Experimentally the local energy flux via ElectroMagnetic waves described by the Poynting vector is consistent with measurements.
- In general many alternatives have been proposed to the Poynting vector, normally more complex than the Poynting vector itself, but none of them has been shown to be a better alternative to it, nor it has been able to replace the Poynting vector.
- A microscopic model of the energy given to a piece of matter, even if with the possible limits of any model, confirms, within the model, the use of the Poynting vector (read § 42.05 - ElectroMagnetic Waves).
In fact the energy flux involves some subtleties: see the references.

\subsection*{42.05.01.01 Intensity of ElectroMagnetic MPW in Vacuum}

This § is referenced at pages:
[2010, 2010]
Note that all the expressions in this section are only valid for \(\mathbf{E}\) and \(\mathbf{B}\) in-phase; all quantities are real quantities.

Consider a ElectroMagnetic MPW in vacuum:
\[
\begin{gathered}
\omega=|\mathbf{k}| c, \\
\mathbf{k} \equiv k \hat{\boldsymbol{\kappa}}, \\
\mathbf{E}[\mathbf{x}, t]=\mathbf{E}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi, \\
\mathbf{B}[\mathbf{x}, t]=\mathbf{B}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi, \\
\mathbf{k} \cdot \mathbf{E}_{0}=0, \\
\mathbf{k} \cdot \mathbf{B}_{0}=0, \\
\mathbf{B}_{0}^{\prime} \equiv c \mathbf{B}_{0}, \\
\mathbf{B}_{0}=+\frac{1}{\omega}\left(\mathbf{k} \times \mathbf{E}_{0}\right) \Longrightarrow \mathbf{B}_{0}^{\prime}=+\left(\hat{\boldsymbol{\kappa}} \times \mathbf{E}_{0}\right) \\
\mathbf{E}_{0}=-\frac{c^{2}}{\omega}\left(\mathbf{k} \times \mathbf{B}_{0}\right) \Longrightarrow \mathbf{E}_{0}=-\left(\hat{\boldsymbol{\kappa}} \times \mathbf{B}_{0}^{\prime}\right)
\end{gathered},
\]

The time-averaged energy density is:
\[
\begin{equation*}
\left.\left.\left\langle\frac{\mathrm{d} U}{\mathrm{~d} V}\right\rangle \equiv\langle u\rangle=\left.\frac{\varepsilon_{0}}{2}\langle | \mathbf{E}\right|^{2}\right\rangle+\left.\frac{1}{2 \mu_{0}}\langle | \mathbf{B}\right|^{2}\right\rangle=2\left\langle u_{E}\right\rangle=2\left\langle u_{B}\right\rangle=\frac{\varepsilon_{0}}{2}\left|\mathbf{E}_{0}\right|^{2}=\frac{1}{2 \mu_{0}}\left|\mathbf{B}_{0}\right|^{2} \tag{42.05.01}
\end{equation*}
\]

The time-averaged energy flux is (using equation (42.01.09)):
\[
\begin{equation*}
\left.\left.\langle\mathbf{S}\rangle \equiv \frac{1}{\mu_{0}}\langle\mathbf{E} \times \mathbf{B}\rangle=\frac{1}{\mu_{0}} \hat{\boldsymbol{\kappa}}\langle | \mathbf{E}| | \mathbf{B}| \rangle=\left.\frac{1}{\mu_{0}} \frac{\hat{\boldsymbol{\kappa}}}{c}\langle | \mathbf{E}\right|^{2}\right\rangle=\left.\frac{1}{\mu_{0}} c \hat{\boldsymbol{\kappa}}\langle | \mathbf{B}\right|^{2}\right\rangle=\frac{\varepsilon_{0} c}{2} \hat{\boldsymbol{\kappa}}\left|\mathbf{E}_{0}\right|^{2}=\frac{c}{2 \mu_{0}} \hat{\boldsymbol{\kappa}}\left|\mathbf{B}_{0}\right|^{2} \tag{42.05.02}
\end{equation*}
\]

Finally:
\[
\begin{equation*}
|\langle\mathbf{S}\rangle| \equiv \frac{1}{\mu_{0}}|\langle\mathbf{E} \times \mathbf{B}\rangle|=\frac{\varepsilon_{0} c}{2}\left|\mathbf{E}_{0}\right|^{2}=\frac{c}{2 \mu_{0}}\left|\mathbf{B}_{0}\right|^{2}=c\langle u\rangle \tag{42.05.03}
\end{equation*}
\]
which shows that, for ElectroMagnetic MPW in vacuum, the intensity is proportional to the volume energy density via the phase-velocity \(c(\operatorname{read} \S 40.04 .03\) - General Properties of Waves for the general discussion). Read \(\S\) 41.08.01.01 - Mechanical Waves for the similar relation for mechanical waves.

Note the suggestive relation (42.05.03) lining the energy flux with the energy density via the phase velocity is valid in this special case with no dispersion, that is with fixed phase velocity. In presence of dispersion the velocity might be not the phase velocity, see section \(\S 43.03 .03\) - Waves in Bounded Regions.

\subsection*{42.05.01.02 Intensity of ElectroMagnetic MPW in Perfect Media}

Note that all the expressions in this section are only valid for \(\mathbf{E}\) and \(\mathbf{B}\) in-phase; all quantities are real quantities.
The above relations (42.05.01), (42.05.02), (42.05.03) can be translated for a perfect medium by replacing:
\[
\begin{array}{r}
\varepsilon_{0} \longrightarrow \varepsilon_{0} \epsilon_{\mathrm{R}} \\
\mu_{0} \longrightarrow \mu_{0} \mu_{\mathrm{R}} \\
\hline
\end{array}
\]
\[
c \longrightarrow v
\]

Read § 42.06.03 - ElectroMagnetic Waves for the more general case.

\subsection*{42.05.02 Linear Momentum and Relation to the Energy Flux}

This § is referenced at pages:
[2452, 2452]
This is one of the rare cases when the effects of magnetic fields of ElectroMagnetic waves are noticeable. It is in fact the magnetic part of the Lorentz force which provokes the pressure. In fact for an ElectroMagnetic wave the ratio of the magnetic to electric force is:
\[
\frac{f_{\mathrm{mag}}}{f_{\mathrm{ele}}} \approx \frac{v B}{E}=\frac{v}{c}
\]

So that the effects of magnetic fields are often negligible, for non relativistic speeds of particles. However, under some circumstances, they are important, as in the case of radiation pressure.

\subsection*{42.05.02.01 An Approach Based on the Particle Nature at Normal Incidence}

For every amount of energy \(\epsilon\) in a traveling ElectroMagnetic MPW there is an amount of linear momentum p such that (read § 34.03 - Electric|Magnetic Properties of Matter):
\[
\begin{equation*}
\epsilon=c|\mathbf{p}| \equiv c p \tag{42.05.04}
\end{equation*}
\]

Let \(p_{0}\) be the module of the momentum of the incoming bit of wave. Let \(P\) be the module of the total final momentum. Assume the wave is fully absorbed: if the amount of energy given is \(\epsilon\), the linear momentum given along the propagation direction is \(\epsilon / c\) (from linear momentum conservation and \(\epsilon=p c\) ):
\[
p_{0}+0=P \Longrightarrow P=\epsilon / c
\]

Assume the wave is fully reflected, elastically, and let \(p^{\prime}\) be the module of the momentum of the bit of reflected wave: if the amount of energy given is \(\epsilon\), the linear momentum given along the propagation direction is \(2 \epsilon / c\) (from linear momentum conservation and \(\epsilon=p c\) ):
\[
p_{0}+0=-p^{\prime}+P \quad p^{\prime}=p_{0} \Longrightarrow P=2 \epsilon / c .
\]

Nevertheless the result can be demonstrated via classical arguments only, at least in a simplified configuration, with the advantage that the demonstration makes clear the physical processes leading to radiation pressure. Actually the fact that ElectroMagnetic waves are quantised has nothing to do with equation (42.05.04).

\subsection*{42.05.02.02 A Simplified Microscopic Argument for Total Absorbtion at Normal Incidence}

Interaction between light and matter is a complex phenomenon, where the incident and re-radiated radiation enter. The interference between incoming an re-radiated field to give rise to the refractive index, see \({ }^{1}\).
We want to compare the average force along the \(z\) direction, that is the linear momentum transferred by the wave to the matter per unit time, with the energy transferred by the wave to the matter per unit time. Total absorption of the ElectroMagnetic wave in matter is assumed. Consider the following simplified argument.

Consider an ElectroMagnetic wave whose propagation direction is along the \(z\) axis and the Polarization is along the \(x\) axis:
\[
\begin{aligned}
& E_{x}=E_{x 0} \cos k \bar{z}-\omega t, \\
& B_{y}=B_{y 0} \cos k \bar{z}-\omega t .
\end{aligned}
\]

Note that Polarization state was chosen arbitrarily as it has no effect.
The two fields are in-phase, as it must be, in vacuum.
The ElectroMagnetic MPW is impinging perpendicularly on a flat piece of material, with no free charges and no free currents. Assume that a very thin and rigid sheet of matter is present at a fixed \(z=\bar{z}\), kept there by some external force. Strictly speaking the above are the ElectroMagnetic fields outside matter: they are the same inside matter because of the conservation of tangential components for no free currents (also there are no free charges but this does not matter here). Actually we use here the real Electric|Magnetic fields plus charges/currents. The charges inside the sheet of matter cannot move in the \(z\) direction ( \(v_{z}=0\) ), because the thin sheet is constrained to stay there by the external forces.
The average force on any charge is:
\[
\langle\mathbf{F}\rangle=q \hat{\mathbf{e}}_{1}\left(\left\langle E_{x}\right\rangle-\left\langle v_{z} B_{y}\right\rangle\right)+q\left\langle v_{x} B_{y}\right\rangle \hat{\mathbf{e}}_{3} .
\]

In view of the fact that, by hypothesis, the particle cannot move in the \(z\) direction the term \(v_{z} B_{y}\) vanishes. Moreover, \(\left\langle E_{x}\right\rangle\) vanishes as well. The ElectroMagnetic fields are the ElectroMagnetic fields of the incoming wave, in vacuum. Actually if the particles in matter re-radiate the total ElectroMagnetic fields will be the sum of the incoming plus the radiated field.
It follows that:
\[
\left\langle F_{z}\right\rangle \equiv\left\langle F_{z}\right\rangle_{\mathrm{EM} \longrightarrow \mathrm{MATTER}} \simeq q\left\langle v_{x} B_{y}\right\rangle
\]

It is assumed that the ElectroMagnetic waves is totally absorbed by the sheet of matter. Therefore the rate at which work is done on the charge by the traveling wave is exactly:
\[
\langle\Pi\rangle \equiv\langle\Pi\rangle_{\mathrm{EM} \longrightarrow \text { MATTER }}=\langle\mathbf{v} \cdot \mathbf{F}\rangle=q\langle\mathbf{v} \cdot \mathbf{E}\rangle=q\left\langle v_{x} E_{x}\right\rangle .
\]

Therefore:
\[
\left\langle F_{z}\right\rangle=q\left\langle v_{x} B_{y}\right\rangle=q \frac{\left\langle v_{x} E_{x}\right\rangle}{c}=\frac{\langle\Pi\rangle}{c} .
\]

Finally:
\[
\left\langle F_{z}\right\rangle=\frac{\langle\Pi\rangle}{c} \quad \Leftrightarrow \quad p_{F} \equiv \frac{\left\langle F_{z}\right\rangle}{A}=\frac{\langle\Pi\rangle}{A c} \equiv \frac{I}{c} .
\]

\footnotetext{

}

\subsection*{42.05.02.03 Radiation Force-Pressure at Normal Incidence}

Let us keep in mind that the layer of matter has no recoil.
The general expression for the radiation force-pressure (that is force per unit area) at normal incidence is easily found, via the particle-like interpretation, in terms of the absorbed plus reflected intensity (as it is obvious that the transmitted energy gives no contribution):
\[
\begin{equation*}
p_{F} \equiv \frac{\mathrm{~d}^{2} F_{z}}{\mathrm{~d} A_{z} \mathrm{~d} t}=\frac{I_{\mathrm{A}}}{c}+2 \frac{I_{\mathrm{R}}}{c} \tag{42.05.05}
\end{equation*}
\]
\(\rightarrow\)
2053

While the expression (42.05.05) can be easily deduced via the corpuscular interpretation of ElectroMagnetic radiation (linear momentum conservation), it is more difficult to justify the factor 2 via the simplified in the classical model presented above, because in case of reflection one should account for the energy re-radiated back as ElectroMagnetic radiation by the charges in the sheet of matter.
In terms of the corpuscular interpretation of ElectroMagnetic waves one would write:
\[
\epsilon=|\mathbf{p}| c,
\]
and therefore:
\[
\begin{equation*}
\Delta P=\frac{E_{\mathrm{A}}}{c}+2 \frac{E_{\mathrm{R}}}{c} . \tag{42.05.06}
\end{equation*}
\]

Read also § 37.01.03 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum.

\subsection*{42.05.02.04 Force-Pressure From Linear Momentum Transport}

Use equation (37.01.08).

\subsection*{42.05.03 Angular Momentum and Relation to the Energy Flux}

©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|3.7||
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|P-7.19, P-7.20, P-7.21||
Circularly Polarized ElectroMagnetic waves carry angular momentum along the propagation direction. Right-handed circularly Polarized ElectroMagnetic waves have negative helicity and therefore carry angular momentum anti-parallel to the propagation direction.
Left-handed circularly Polarized ElectroMagnetic waves have positive helicity and therefore carry angular momentum parallel to the propagation direction.
In fact the angular momentum carried by MPW involves many subtleties: see the references.
A similar reasoning to the one carried on for the radiation force-pressure can be carried on for the angular momentum transfer.

\subsection*{42.05.03.01 An Approach Based on the Particle Nature of ElectroMagnetic Waves}

Assume that a ElectroMagnetic MPW is impinging at normal incidence on the surface of separation between two media. Assume that the wave is fully absorbed: if the amount of energy given is \(E\), the angular momentum given along the propagation direction by a circularly Polarized ElectroMagnetic wave is \(E / \omega\).
This is self-evident from the concept of photons, read § 34.03 - Electric|Magnetic Properties of Matter. In fact every amount of energy \(\epsilon\) in a traveling monochromatic ElectroMagnetic PW has a (quantised) amount of angular momentum around the propagation direction \(|\mathbf{J}|=\hbar\) such that:
\[
\begin{equation*}
\epsilon=|\mathbf{j}| \omega=\hbar \omega \tag{42.05.07}
\end{equation*}
\]
42.05.03.02 A Simplified Microscopic Argument for Total Absorbtion at Normal Incidence
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....||Clear derivation © |G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....||Clear derivation
42.05.03.03 Radiation Torque-Pressure at Normal Incidence

The boundary condition, as discussed in § 44.03 - Reflection and Refraction of Waves, implies what follows.

Assume the wave is fully reflected: it can be easily shown that the circular Polarization state is inverted by the reflection and therefore the helicity changes its sign so that the reflected wave carries the same angular momentum along \(z\) as the incoming wave. In fact the boundary conditions at the interface impose conditions on the tangential components of the ElectroMagnetic fields, that is the transverse ElectroMagnetic fields of the EM wave. The ElectroMagnetic fields of circularly Polarized waves at the interface describe a circumference, for both the incoming and reflected wave. Any continuity condition will require, to be satisfied, that the ElectroMagnetic fields of the incoming and reflected waves run along their circumference in the same way. This immediately implies that the incident and reflected waves have opposite handedness (and helicity) as they travel in opposite directions. Note that this is true also in the case when the reflected field is opposed to the incoming field.

In general: any continuity relation among incident, reflected and transmitted waves is such that all three waves rotate the same way, that is with the same angular momentum component along the direction of motions. This is to be contrasted to the case of the linear momentum component, which has the same sign for the transmitted wave but opposite sign for the reflected wave, both with respect to the incoming wave.

The general expression for the radiation torque-pressure (that is torque per unit area) at normal incidence from an elliptically (circularly) Polarized ElectroMagnetic wave is given in terms of the absorbed intensity.
\[
\begin{equation*}
p_{\Gamma} \equiv \frac{\mathrm{d}^{2} J}{\mathrm{~d} A \mathrm{~d} t}=\frac{I_{\mathrm{A}}}{\omega} \tag{42.05.08}
\end{equation*}
\]

The reflected intensity does not contribute as the reflected wave will carry the same angular momentum as the incoming wave.

In terms of the corpuscular interpretation of ElectroMagnetic waves one would write:
\[
\epsilon=|\mathbf{j}| \omega=\hbar \omega
\]
and therefore:
\[
\begin{equation*}
\Delta J=\frac{E_{\mathrm{A}}}{\omega} \tag{42.05.09}
\end{equation*}
\]

Use equation (37.01.15).

\section*{EM Waves in Ohmic LHI Media Without Boundaries}

This § is referenced at pages:
[1963, 1963, 1982, 1982, 2035, 2035, 2276, 2276, 2280, 2280]

After vacuum and prefect media, Ohmic media. Absorption appears.
After describing ElectroMagnetic waves in vacuum and perfect media, which feature no energy absorption, and having introduced absorption phenomenologically, it is possible to discuss absorptive media. Only dissipative media are discussed here, while also media amplificating energy, in principle, do exist (active/gain media).

Moreover, after having discussed Polarization of ElectroMagnetic waves it is possible to discuss the full complex representation of MPW.

Ohmic LHI media include plasmas, liquid metals as well as solid metals in most cases. In fact solid metals may be microscopically non isotropic but they are normally built of different small crystals with random orientation. As long as these crystals are small with respect to the wavelength of the ElectroMagnetic waves, the metal is macroscopically isotropic.

\subsection*{42.06.01 Equations for ElectroMagnetic MPW in Ohmic LHI Media}

Consider an Ohmic LHI medium. It should be kept in mind that the linearity is normally only justified for small enough fields.

Moreover, an Ohmic perfect LHI medium can be often be considered as a perfect medium (fixed \(\sigma>0\), fixed \(\epsilon_{\mathrm{R}} \geq 1\), fixed \(\mu_{\mathrm{R}} \geq 0\) ), but only in a limited range of frequencies of the ElectroMagnetic waves.

If the conductivity is different from zero any free charge will decay to zero at any point inside the medium in a finite time and will accumulate either at the boundary of the medium or at infinity. The time-scale of the free charge decay depends on the conductivity. A large number of cases is covered by assuming \(\rho^{\mathrm{F}}=0\), that is conductivity large enough that free charges decay fast enough with respect to the rate of change of the ElectroMagnetic fields. The hypothesis of good enough conductor will be assumed, unless specified otherwise.

The free current density, \(\mathbf{j}^{\mathrm{F}}\), is linked to the electric field (by definition for any Ohmic LHI medium):
\[
\mathbf{j}^{\mathrm{F}}=\sigma \mathbf{E}
\]

Moreover, (by definition for any Ohmic LHI medium) one has:
\[
\mathbf{D}=\epsilon_{\mathrm{R}} \varepsilon_{0} \mathbf{E} \quad \mathbf{B}=\mu_{\mathrm{R}} \mu_{0} \mathbf{H}
\]

The ElectroMagnetic fields in matter will then move the charges and the motion of charges will transfer energy to matter. Therefore, in general, energy will be transferred by ElectroMagnetic fields to matter, that is ElectroMagnetic energy is dissipated into internal energy of matter and the ElectroMagnetic fields attenuate.

Maxwell Equations in a in Ohmic LHI medium, in the absence of free charges, read:
\[
\begin{gathered}
\operatorname{div} \mathbf{E}=0 \\
\operatorname{div} \mathbf{B}=0 \\
\operatorname{rot} \mathbf{E}=-\partial_{t} \mathbf{B}, \\
\operatorname{rot} \mathbf{B}=+\sigma \mu_{\mathrm{R}} \mu_{0} \mathbf{E}+\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \partial_{t} \mathbf{E},
\end{gathered}
\]
where the free charge density has been set to zero as it is appropriate for any good enough conductor.

One derives, from Maxwell Equations, the following two decoupled modified d'Alembert Wave equations:
\[
\frac{\nabla^{\mathbf{2}} \mathbf{E}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{E}-\epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{\mathrm{R}} \mu_{0} \frac{\partial^{2} \mathbf{E}}{\partial t^{2}}=0}{\nabla^{\mathbf{2}} \mathbf{B}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{B}-\epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{\mathrm{R}} \mu_{0} \frac{\partial^{2} \mathbf{B}}{\partial t^{2}}=0}
\]
\(\rightarrow\)
2060
(42.06.02) \(\rightarrow\)

2060

Exactly the same equations are found for \(\mathbf{D}\) and \(\mathbf{H}\).
Actually, the two equations are decoupled, but the Electric|Magnetic fields are only apparently decoupled. In fact, the equations have been obtained by derivation from Maxwell equations, which still rule, coupling the Electric|Magnetic fields. Therefore, additional constraints must be included on the solutions of the wave equations. Read \(\S 42.01 .01\) - ElectroMagnetic Waves.
Therefore all ElectroMagnetic fields satisfy a modified d'Alembert wave equation (the dissipative d'Alembert Classical Non-Dispersive Wave equation) with the addition of a term linear in the first timederivative which has deep consequences on the behavior, as discussed in section §50-ElectroMagnetic Waves in Matter.
It should be noted that the present case of Ohmic LHI media includes, as special cases, the cases of vacuum and perfect media.

\subsection*{42.06.02 EM MPW in Ohmic LHI Media With the Complex Formalism}

This § is referenced at pages:
[2035, 2035]
© ©|D.R.Jackson|| Department of Electrical and Computer Engineering University of Houston Houston, TX 77204-4793|

Another step forward for studying ElectroMagnetic waves is done by considering the possibility of a complex solution to Maxwell Equations, with a complex wave-vector.

In general the wave-equation might admit MPW solutions with complex wave-vector:
\[
\begin{equation*}
\overline{\mathbf{U}}[\mathbf{r}, t]=\overline{\mathbf{U}}_{0} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)] \tag{42.06.03}
\end{equation*}
\]
where \(\overline{\mathbf{U}}_{0}\) is a complex constant vector carrying the information on both the amplitude and phase of the wave and the complex wave-vector, is written in terms of the two real vectors \(\mathbf{k}_{\mathrm{R}}\) and \(\mathbf{k}_{\mathrm{I}}\), as:
\[
\overline{\mathbf{k}}=\mathbf{k}_{\mathrm{R}}+\beth \mathbf{k}_{\mathrm{I}}
\]

The use of a complex wave-vector is motivated by the following physical considerations. We know that absorption of ElectroMagnetic waves in matter exists and therefore ElectroMagnetic waves may be attenuated under certain circumstances, amplified under other circumstances. Therefore a simple sinusoidal/cosinusoidal time dependence is not general enough to describe cases when absorption/amplification exists. Therefore, one possible generalization is to think of an exponentially damped harmonic field with a complex wave-vector and the formalism of complex fields.

Read § 17.04 - Linear Systems, § 17.04 - Linear Systems for the algebra of complex scalars and vectors. Use the convention that real fields are described via the real part of a complex field:
\[
\mathbf{U}[\mathbf{x}, t] \equiv \operatorname{Re}(\overline{\mathbf{U}}[\mathbf{x}, \mathrm{t}])
\]
also exploiting Euler formula.
As long as we perform linear operations, which keep the real and imaginary parts of complex numbers separated, we can use the formalism of complex numbers without troubles, remembering that the true physical quantity is the real part of the complex number.

The complex number in itself has no physical meaning; it is only a way to pack two real numbers, into one single complex number.

It is clear that the complex exponential dependence for the fields leads to a particularly simple form of the Maxwell Equations.
42.06.02.01 Absorption and dispersion
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|§ 7.10||
It is clear that the real part of the wave-vector, \(\mathbf{k}_{\mathrm{R}}\), is linked to the phase-velocity and the imaginary part of the wave-vector, \(\mathrm{k}_{\mathrm{I}}\), is linked to the extinction.
Absorption and dispersion are both phenomena described by the complex wave-vector and they are therefore linked. The link is given by the so-called Kramers-Krönig relations (actually the Hilbert transform). In fact the knowledge of one of the two quantities allows to recover the other one, thanks to the analiticity of the functions involved and the causality requirement. So, it turns out the real and imaginary parts of both \(\epsilon_{\mathrm{R}}[\omega]\) and \(\mid\) or \(\mu_{\mathrm{R}}[\omega]\), analytic response functions for a causal system, are connected and each part can be derived from the other.
Causality means that Polarization and Magnetization cannot precede the electric and magnetic fields, respectively. This is described by the Kramers-Krönig relations.

\subsection*{42.06.02.02 Operations with the complex formalism}

It is useful to determine the effects of common vector operations on the expression (42.06.03), in Cartesian Coordinates:
\[
\begin{gather*}
\operatorname{grad} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)]=(\beth \overline{\mathbf{k}}) \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)],  \tag{42.00.04}\\
\nabla^{2} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)]=\operatorname{div} \operatorname{grad} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)]=-\overline{\mathbf{k}} \cdot \overline{\mathbf{k}} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)] \quad,  \tag{42.06.05}\\
\nabla^{2} \overline{\mathbf{U}}_{0} \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)]=-\overline{\mathbf{U}}_{0}(\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}) \exp [\beth(\overline{\mathbf{k}} \cdot \mathbf{r}-\omega t)] \quad \text { Cartesian Coordinates only }, \tag{42.06.06}
\end{gather*}
\]
where the latter is obtained by observing that in Cartesian Coordinates the vector Laplacian is just the scalar Laplacian applied to the three components, as from equation (14.08.09)

\subsection*{42.06.02.03 Complex Direction Angles}

It is often useful to introduce direction angles to define the direction of the wave-vector \(\mathbf{k}\). When the wave-vector is complex, direction angles are complex as well.
Read § 17.05.01 - Linear Systems.

\subsection*{42.06.02.04 Homogeneous MPW}

One first case is the case when the wave-vector is complex and the real and imaginary parts of the complex wave-vector are two real vectors parallel to each other. In this case one can write:
\[
\overline{\mathbf{k}}=\mathbf{k}_{\mathrm{R}}+\beth \mathbf{k}_{\mathrm{I}}=\bar{k} \hat{\boldsymbol{\kappa}} \quad \text { with } \hat{\boldsymbol{\kappa}} \text { a real unit vector } \quad \hat{\boldsymbol{\kappa}} \cdot \hat{\boldsymbol{\kappa}}=1 \quad \text { as } \quad \mathbf{k}_{\mathrm{R}} \| \mathbf{k}_{\mathrm{I}} .
\]

The MPW is called homogeneous because the constant amplitude planes are parallel to the constant phase planes.
For homogeneous MPW the direction angles are real. This is in fact a point in favor of defining them in terms of \(k \equiv \sqrt{\mathbf{k} \cdot \mathbf{k}}\) and not \(|\mathbf{k}|\). In fact,
\[
\mathbf{k} \equiv k \hat{\boldsymbol{\kappa}} \quad \hat{\boldsymbol{\kappa}} \cdot \hat{\boldsymbol{\kappa}}=1 \quad k \in \mathbb{C} \quad \hat{\boldsymbol{\kappa}} \in \mathbb{R}^{3},
\]
implies that the direction angles are the direction cosines of the real unit vector \(\hat{\boldsymbol{\kappa}}\) :
\[
\begin{gather*}
\mathbf{k} \equiv k \hat{\boldsymbol{\kappa}}=\rho_{k} e^{\beth \theta_{k}} \hat{\boldsymbol{\kappa}}  \tag{42.06.07}\\
\mathbf{k} \cdot \mathbf{k}=\rho_{k}^{2} e^{2 \beth \theta_{k}}  \tag{42.06.08}\\
k=\sqrt{\mathbf{k} \cdot \mathbf{k}}=\rho_{k} e^{\beth \theta_{k}}  \tag{42.06.09}\\
\mathbf{k} \equiv k \hat{\boldsymbol{\kappa}} . \tag{42.06.10}
\end{gather*}
\]

Therefore, the direction angles are the real direction cosines of the real unit vector \(\hat{\boldsymbol{\kappa}}\).

The unit vector \(\hat{\boldsymbol{\kappa}}\) gives the direction of the time-averaged energy flow. Moreover, it points in the direction of the phase and attenuation vectors: all three vectors point in the same direction for a homogeneous monochromatic PW. This direction is, unambiguously, the direction of propagation of the MPW. The planes of constant phase are also the planes of constant amplitude, and all of them are perpendicular to \(\hat{\kappa}\). That is, the MPW has a uniform amplitude and phase across the plane perpendicular to the direction of propagation.

\subsection*{42.06.02.05 Non-Homogeneous MPW}

One second case general case is the case when the wave-vector is complex and the real and imaginary parts of the complex wave-vector are two real vectors not parallel to each other. In this case one can write:
\[
\begin{array}{|lll}
\hline \overline{\mathrm{k}}=\mathbf{k}_{\mathrm{R}}+\beth \mathrm{k}_{\mathrm{I}} & \text { with } \quad \mathbf{k}_{\mathrm{R}} \times \mathrm{k}_{\mathrm{I}} \neq 0 . \\
.
\end{array}
\]

The MPW is called non-homogeneous because the constant amplitude planes and the constant phase planes are not parallel to each other.
Constant-phase planes are orthogonal to the real part of the wave-vector: \(\mathrm{k}_{\mathrm{R}}\). Constant-amplitude planes are orthogonal to the imaginary part of the wave-vector: \(\mathbf{k}_{\mathrm{I}}\). Constant-phase planes and constantamplitude planes are not, in general, orthogonal between each other. MPW whose planes of constant amplitude are not coincident with the planes of constant phase are called non-homogeneous or non-uniform MPW.
If the MPW is not homogeneous, corresponding to complex direction angles, then the physical interpretation of the direction angles is not so clear.

\subsection*{42.06.02.06 ElectroMagnetic Waves in Vacuum}

For ElectroMagnetic waves in vacuum the (real) angular frequency \(\omega\) and the complex wave-vector, \(\overline{\mathbf{k}}\), are connected, as a consequence of the wave equation, by the relation:
\[
\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}=\frac{\omega^{2}}{c^{2}} \Longrightarrow \omega=k c \quad k \equiv \sqrt{\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}} .
\]

This implies \(\overline{\mathbf{k}}_{\mathrm{R}} \cdot \overline{\mathbf{k}}_{\mathrm{I}}=0\), that is the two real vectors, \(\mathbf{k}_{\mathrm{R}}\) and \(\mathbf{k}_{\mathrm{I}}\), are orthogonal and possibly \(\mathbf{k}_{\mathrm{I}}=0\).

\subsection*{42.06.02.07 ElectroMagnetic Waves in Perfect Media}

For ElectroMagnetic waves in prefect media the (real) angular frequency \(\omega\) and the complex wave-vector, \(\overline{\mathbf{k}}\), are connected, as a consequence of the wave equation, by the relation:
\[
\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}=\frac{\omega^{2}}{c^{2}} \epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \quad k \equiv \sqrt{\mathbf{k} \cdot \overline{\mathbf{k}}}
\]

This implies \(\overline{\mathbf{k}}_{\mathrm{R}} \cdot \overline{\mathbf{k}}_{\mathrm{I}}=0\), that is the two real vectors, \(\mathbf{k}_{\mathrm{R}}\) and \(\mathbf{k}_{\mathrm{I}}\), are orthogonal. An example is given by evanescent waves (read § 44.03.06-Reflection and Refraction of Waves).

\subsection*{42.06.03 Consequences From the Dissipative d'Alembert Wave Equation}

This § is referenced at pages:
[2051, 2051]
From this section on, complex quantities will not explicitly indicated any more in systematic way, in order to simplify the notations, unless it is necessary to avoid misunderstandings. It is implicit that wave-vectors and vector fields are in general complex quantities.
One of the main interests is in determining the energy flow which is given by the Poynting vector expressed in terms of \(\mathbf{H}\). Therefore in this section \(\mathbf{H}\) will be mostly used instead of \(\mathbf{B}\).
Consider a ElectroMagnetic MPW with complex wave-vector: \(\overline{\mathbf{k}} \equiv \mathbf{k}_{\mathrm{R}}+\beth \mathrm{k}_{\mathrm{I}}\).
The most general case of arbitrary \(\mathbf{k}_{\mathrm{R}}\) and \(\mathbf{k}_{\mathrm{I}}\) (non-homogeneous MPW) gives a rather cumbersome treatment and it is more general than what is needed in most cases. Therefore we will limit to the particular case, sufficient in most practical cases, of parallel \(\mathbf{k}_{\mathrm{R}}\) and \(\mathbf{k}_{\mathrm{I}}\) :
\[
\overline{\mathbf{k}} \equiv \mathbf{k}_{\mathrm{R}}+\beth \mathrm{k}_{\mathrm{I}} \quad \mathbf{k}_{\mathrm{R}} \| \mathrm{k}_{\mathrm{I}}
\]

In this case one can write:
\[
\overline{\mathbf{k}} \equiv \mathbf{k}_{\mathrm{R}}+\beth \mathbf{k}_{\mathrm{I}}=\bar{k} \hat{\boldsymbol{\kappa}} \quad \text { with } \hat{\boldsymbol{\kappa}} \text { a real unit vector } .
\]

The real and imaginary parts of the wave-vector, \(\mathbf{k}\), define the phase vector, \(\mathbf{k}_{\mathrm{R}}\), and an attenuation vector \(\mathbf{k}_{\mathrm{I}}\).
The phase vector has units of radians/meter and gives the direction of most rapid phase change.
The attenuation vector has units of nepers/meter and gives the direction of most rapid attenuation of amplitude.
The magnitude of the phase vector gives the phase change per unit length along the direction of the phase vector, while the magnitude of the attenuation vector determines the rate of attenuation along the direction of the attenuation vector.
Consider ElectroMagnetic MPW, implicitly suppressing the common time phase factor \(\exp [-\beth \omega t]\), expressed in the form:
\begin{tabular}{rl}
\hline \(\mathbf{E}[\mathbf{r}, t]=\mathbf{E}_{0} \exp [\beth \mathbf{k} \cdot \mathbf{r}] \equiv \mathbf{E}_{0} \Phi[\mathbf{r}]\) \\
\hline \(\mathbf{D}[\mathbf{r}, t]=\mathbf{D}_{0} \exp [\beth \mathbf{k} \cdot \mathbf{r}] \equiv \mathbf{D}_{0} \Phi[\mathbf{r}]\) \\
\hline \(\mathbf{B}[\mathbf{r}, t]=\mathbf{B}_{0} \exp [\beth \mathbf{k} \cdot \mathbf{r}] \equiv \mathbf{B}_{0} \Phi[\mathbf{r}]\) \\
\hline \(\mathbf{H}[\mathbf{r}, t]=\mathbf{H}_{0} \exp [\beth \mathbf{k} \cdot \mathbf{r}] \equiv \mathbf{H}_{0} \Phi[\mathbf{r}]\) \\
,
\end{tabular},

The complex vectors \(\mathbf{E}_{0}, \mathbf{B}_{0}, \mathbf{D}_{0}, \mathbf{H}_{0}\) define the Polarization of the wave.
As we are dealing with a Ohmic LHI medium, we have the constitutive equations:
\[
\begin{array}{|l|l|}
\hline \mathbf{j}^{\mathrm{F}}[\omega]=\sigma[\omega] \mathbf{E}[\omega] & \mathbf{D}[\omega]=\varepsilon_{0} \epsilon_{\mathrm{R}}[\omega] \mathbf{E}[\omega] \tag{42.06.11}
\end{array} \quad \mathbf{B}[\omega]=\mu_{0} \mu_{\mathrm{R}}[\omega] \mathbf{H}[\omega]
\]
in Fourier space, including, in the more general case, also time dispersion.
Actually, if also space dispersion in accounted for:
\[
\mathbf{j}^{\mathrm{F}}[\mathbf{k}, \omega]=\sigma[\mathbf{k}, \omega] \mathbf{E}[\mathbf{k}, \omega] \quad \mathbf{D}[\mathbf{k}, \omega]=\varepsilon_{0} \epsilon_{\mathrm{R}}[\mathbf{k}, \omega] \mathbf{E}[\mathbf{k}, \omega] \quad \quad \mathbf{B}[\mathbf{k}, \omega]=\mu_{0} \mu_{\mathrm{R}}[\mathbf{k}, \omega] \mathbf{H}[\mathbf{k}, \omega] .
\]

Read § 19.03 - Some Miscellaneous Topics.
Replacing the ElectroMagnetic MPW for the \(\mathbf{E} / \mathbf{B} / \mathbf{D} / \mathbf{H}\) fields into the dissipative d'Alembert wave equation, equations (42.06.01) (42.06.02) and the similar for the auxiliary fields, one finds that is satisfied only if the complex wave-vector satisfies:
\[
\begin{equation*}
|\mathbf{k}|^{2} \neq \mathbf{k} \cdot \mathbf{k}=k^{2}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}+\beth \omega \mu_{\mathrm{R}} \mu_{0} \sigma \equiv \quad k \equiv \operatorname{Re}(\mathrm{k})+\beth \operatorname{Im}(\mathrm{k}) \quad \operatorname{Im}(\mathrm{k})>0 \tag{42.06.13}
\end{equation*}
\]
that is the dispersion relation for these waves.
Ohm law, \(\mathbf{j}^{\mathbf{F}}=\sigma \mathbf{E}\), can be also accounted for inside the complex Electric-Permittivity, \(\bar{\epsilon}_{\mathrm{R}}\), and often is a way to simplify, as show in equation (42.06.14). In fact, the conductivity can be included in the Electric-Permittivity, as described in detail in § 50.02 - ElectroMagnetic Waves in Matter, by replacing the Electric-Permittivity, \(\epsilon_{\mathrm{R}}\), which does not include the effects of free charges, with the Electric-Permittivity, \(\bar{\epsilon}_{\mathrm{R}}\), which also includes the effect of free charges, according to equation (49.01.10).
\(|\mathbf{k}|^{2} \neq \mathbf{k} \cdot \mathbf{k}=k^{2}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}+\beth \omega \mu_{\mathrm{R}} \mu_{0} \sigma \equiv \bar{\epsilon}_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2} \Longrightarrow k=\frac{\omega}{c} \sqrt{\bar{\epsilon}_{\mathrm{R}} \mu_{\mathrm{R}}} \equiv \operatorname{Re}(\mathrm{k})+\beth \operatorname{Im}(\mathrm{k}) \quad \operatorname{Im}(\mathrm{k})>0\),
(42.06.14) \(\rightarrow\)
\[
\bar{\epsilon}_{\mathrm{R}}=\epsilon_{\mathrm{R}}+\beth \frac{\sigma}{\omega \varepsilon_{0}}
\]

It is important to be careful with the signs of \(\operatorname{Re}(\mathrm{k})\) and \(\operatorname{Im}(\mathrm{k})\), due to different conventions in the literature. Some authors, in fact, use a convention such that:
\[
\overline{k \equiv \operatorname{Re}(\mathrm{k})<\operatorname{Im}(\mathrm{k})} \quad k \equiv \operatorname{Re}(\mathrm{k})+\beth \operatorname{Im}(\mathrm{k}) .
\]

Starting from the convention for the complex notation, equations (42.01.10), (42.01.10), an attenuating wave requires a positive \(\operatorname{Im}(\mathrm{k})\).
A further extension is implicit from the constitutive relations (42.06.11), where all parameters
\[
\begin{array}{|lll}
\hline \sigma[\omega] \longrightarrow \bar{\sigma}[\omega] & \epsilon_{\mathrm{R}}[\omega] \longrightarrow \overline{\epsilon_{\mathrm{R}}}[\omega] & \mu_{\mathrm{R}}[\omega] \longrightarrow \overline{\mu_{\mathrm{R}}}[\omega]  \tag{42.06.15}\\
\hline
\end{array}
\]
are, a priori, complex functions of the frequency, as motivated by equation (42.06.11), by moving from the time-domain to the frequency domain with the Fourier transform.

\subsection*{42.06.04 Consequences From Maxwell Equations}

This § is referenced at pages:
[Never referenced.]
\begin{tabular}{|c|}
\hline \(\mathbf{E}[\mathbf{x}, t]=\mathbf{E}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi\) \\
\hline \(\mathbf{H}[\mathbf{x}, t]=\mathbf{H}_{0} \cos \mathbf{k} \cdot \mathbf{x}-\omega t-\phi\) \\
\hline
\end{tabular}

By replacing the field expressions in Maxwell Equations one finds that are still valid, also for complex \(\mathbf{k}\), the following equations, even if there are products: in fact, they come from Maxwell Equations by direct algebraic calculation:

The above equations can then be cast in the more suitable and symmetrical form:
\begin{tabular}{c}
\(\mathbf{k} \cdot \mathbf{E}_{0}=0\) \\
\hline \(\mathbf{k} \cdot \mathbf{H}_{0}=0\) \\
\hline \(\mathbf{k} \times \mathbf{E}_{0}=+\omega \mu_{0} \mu_{\mathrm{R}} \mathbf{H}_{0}\) \\
\hline \(\mathbf{k} \times \mathbf{H}_{0}=-\omega \varepsilon_{0} \bar{\epsilon}_{\mathrm{R}} \mathbf{E}_{0}\) \\
\hline
\end{tabular},
\begin{tabular}{|c|c|}
\hline (42.06.16) & \(\rightarrow\) \\
\hline & 20612062 \\
\hline (42.06.17) & 2061206 \\
\hline (42.06.18) & \(\xrightarrow{2061} 2062\) \\
\hline & 20612062 \\
\hline (42.06.19) & \(\rightarrow\) \\
\hline
\end{tabular}

The real and imaginary parts of the wave-vector are real vectors, not necessarily orthogonal, at variance from vacuum and perfect media.

\subsection*{42.06.05 Complex Wave Impedance and Wave Admittance}

This § is referenced at pages:
[Never referenced.]
The above equations (42.06.16), (42.06.17), (42.06.18), (42.06.19), imply that \(\mathbf{E}_{0}, \mathbf{H}_{0}\) and \(\mathbf{k}\) form an orthogonal set of complex vectors.
By scalar multiplying (42.06.18) by \(\mathbf{H}_{0}\), scalar multiplying (42.06.19) by \(\mathbf{E}_{0}\) and comparing the results, the definitions of the complex wave impedance \(\bar{Z}\) and complex wave admittance \(\bar{Y}\) is possible:
\[
\begin{align*}
& \mathbf{E}_{0} \cdot \mathbf{E}_{0} \equiv \bar{Z}^{2} \mathbf{H}_{0} \cdot \mathbf{H}_{0} \quad \bar{Z} \equiv \sqrt{\frac{\mu_{0} \mu_{\mathrm{R}}}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}} \quad \text { all complex, } \bar{Z} \text { chosen so that } \operatorname{Re}(\overline{\mathrm{Z}}) \geq 0 \quad, \quad \text { (42.06.20) } \\
& \mathbf{H}_{0} \cdot \mathbf{H}_{0} \equiv \bar{Y}^{2} \mathbf{E}_{0} \cdot \mathbf{E}_{0} \quad \bar{Y} \equiv \sqrt{\frac{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}{\mu_{0} \mu_{\mathrm{R}}}} \quad \text { all complex, } \bar{Y} \text { chosen so that } \operatorname{Re}(\overline{\mathrm{Y}}) \geq 0 \tag{42.06.21}
\end{align*}
\]

Equation (42.06.20) implies:
\[
E_{0}^{2} \equiv \mathbf{E}_{0} \cdot \mathbf{E}_{0}=\bar{Z}^{2} \mathbf{H}_{0} \cdot \mathbf{H}_{0} \equiv \bar{Z}^{2} H_{0}^{2} \Longrightarrow E_{0}=\bar{Z} H_{0} \quad \text { with } E_{0}, H_{0} \text { and } \bar{Z} \text { complex numbers }
\]

The wave impedance is thus defined as:
\[
\begin{equation*}
\bar{Z} \equiv \frac{E_{0}}{H_{0}} \tag{42.06.22}
\end{equation*}
\]

Equation (42.06.21) implies:
\[
H_{0}^{2} \equiv \mathbf{H}_{0} \cdot \mathbf{H}_{0}=\bar{Y}^{2} \mathbf{E}_{0} \cdot \mathbf{E}_{0} \equiv \bar{Y}^{2} E_{0}^{2} \Longrightarrow H_{0}=\bar{Y} E_{0} \quad \text { with } H_{0}, E_{0} \text { and } \bar{Y} \text { complex numbers }
\]

The wave admittance is thus defined as:
\[
\begin{equation*}
\bar{Y} \equiv \frac{H_{0}}{E_{0}} \tag{42.06.23}
\end{equation*}
\]

For homogeneous MPW only, equations (42.06.16), (42.06.17), (42.06.18), (42.06.19), imply that:
\[
\begin{equation*}
\left|\mathbf{E}_{0}\right|=|\bar{Z}|\left|\mathbf{H}_{0}\right| \quad\left|\mathbf{H}_{0}\right|=|\bar{Y}|\left|\mathbf{E}_{0}\right| . \tag{42.06.24}
\end{equation*}
\]

Read § 42-032 - ElectroMagnetic Waves. All MPW obey equations (42.06.20), (42.06.21), which is not in general the same as equation (42.06.24) because for a complex vector, in general,
\[
\begin{array}{cl}
|\mathbf{V}| & \begin{array}{l}
\text { is a real number }, \\
\sqrt{\mathbf{V} \cdot \mathbf{V}} \\
\text { is a complex number }
\end{array} \\
\sqrt{\mathbf{V} \cdot \mathbf{V}^{\star}} \equiv|\mathbf{V}| \neq \sqrt{\mathbf{V} \cdot \mathbf{V}}=\sqrt{\mathbf{V}^{\star} \cdot \mathbf{V}^{\star}}
\end{array} .
\]

Any homogeneous MPW can be decomposed into a sum of two PW, with electric field vectors Polarized perpendicular to each other, and with electric field vectors that are real, to within a multiplicative complex
constant. This follows from a simple rotation of coordinates: calling \(x\) and \(y\) the direction of the two electric field vectors one has, for a wave propagating in the positive \(z\) direction:
\[
\frac{E_{x}}{H_{y}}=-\frac{E_{y}}{H_{x}}=\bar{Z} \quad \frac{H_{y}}{E_{x}}=-\frac{H_{x}}{E_{y}}=\bar{Y}
\]

EM homogeneous MPW have real direction angles and obey
\[
\begin{equation*}
|\mathbf{E}|=|\bar{Z}||\mathbf{H}| \tag{42.06.26}
\end{equation*}
\]
which is more than equation (42.06.20), (42.06.21) obeyed by any ElectroMagnetic MPW.

\subsection*{42.06.06 Energy Flow}

The average energy flux for a MPW is given by any of the two equivalent equations:
\[
\begin{align*}
& \langle\mathbf{S}\rangle=\left\langle\operatorname{Re}\left(\mathbf{E} \times \mathbf{H}^{\star}\right)\right\rangle=\frac{1}{2} \operatorname{Re}\left(\mathbf{E}_{0} \times \mathbf{H}_{0}^{\star}\right)  \tag{42.06.27}\\
& \langle\mathbf{S}\rangle=\left\langle\operatorname{Re}\left(\mathbf{E}^{\star} \times \mathbf{H}\right)\right\rangle=\frac{1}{2} \operatorname{Re}\left(\mathbf{E}_{0}^{\star} \times \mathbf{H}_{0}\right) \tag{42.06.28}
\end{align*}
\]

\subsection*{42.06.06.01 Energy Flow in Terms of the Electric Field}

In the most common case when either \(\mathbf{k}\) or \(\mathbf{E}_{0}\) are proportional to a real vector (that is all the components of the complex vector have the same phase), one has:
\[
\mathbf{k}^{\star} \cdot \mathbf{E}_{0}=0 \quad \Leftrightarrow \quad \mathbf{k} \cdot \mathbf{E}_{0}^{\star}=0
\]
so that equations (42.06.16), (42.06.17), (42.06.18), (42.06.19), by developing the triple vector product, allows to write (42.06.27) as:
\[
\langle\mathbf{S}\rangle=\frac{1}{2} \operatorname{Re}\left(\mathbf{E}_{0} \times \mathbf{H}_{0}^{\star}\right)=\frac{1}{2 \omega} \operatorname{Re}\left(\frac{1}{\mu_{0} \mu_{\mathrm{R}}{ }^{\star}}\left|\mathbf{E}_{0}\right|^{2} \mathbf{k}^{\star}\right)=\frac{1}{2 \omega} \operatorname{Re}\left(\frac{1}{\mu_{0} \mu_{\mathrm{R}}}\left|\mathbf{E}_{0}\right|^{2} \mathbf{k}\right),
\]
where the last passage follows from the fact the real part of a complex number and the real part of its complex conjugate are identical.
It can be also rewritten as:
\(\langle\mathbf{S}\rangle=\frac{1}{2 \omega} \operatorname{He}\left(\frac{1}{\mu_{0} \mu_{\mathrm{R}}}\left|\mathbf{E}_{0}\right|^{2} \mathbf{k}\right)=\frac{1}{2 \omega}\left|\mathbf{E}_{0}\right|^{2} \operatorname{Re}\left(\frac{\mathrm{k}}{\mu_{0} \mu_{\mathrm{R}}}\right) \hat{\boldsymbol{\kappa}}=\frac{1}{2 \omega}\left|\mathbf{E}_{0}\right|^{2} \mathfrak{H e}\left(\frac{\omega \sqrt{\varepsilon_{0} \mu_{0} \bar{\epsilon}_{\mathrm{R}} \mu_{\mathrm{R}}}}{\mu_{0} \mu_{\mathrm{R}}}\right) \hat{\boldsymbol{\kappa}}=\frac{1}{2}\left|\mathbf{E}_{0}\right|^{2} \operatorname{He}(\mathrm{Y}) \hat{\boldsymbol{\kappa}}\)

\subsection*{42.06.06.02 Energy Flow in Terms of the Magnetic Field}

In the most common case when either \(\mathbf{k}\) or \(\mathbf{H}_{0}\) are proportional to a real vector (that is all the components of the complex vector have the same phase), one has:
\[
\mathbf{k}^{\star} \cdot \mathbf{H}_{0}=0 \quad \Leftrightarrow \quad \mathbf{k} \cdot \mathbf{H}_{0}^{\star}=0
\]
so that equations (42.06.16), (42.06.17), (42.06.18), (42.06.19), by developing the triple vector product, allows to write (42.06.28) as:
\[
\langle\mathbf{S}\rangle=\frac{1}{2} \operatorname{Re}\left(\mathbf{H}_{0} \times \mathbf{E}_{0}^{\star}\right)=\frac{1}{2 \omega} \operatorname{Re}\left(\frac{1}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}^{\star}}\left|\mathbf{H}_{0}\right|^{2} \mathbf{k}^{\star}\right)=\frac{1}{2 \omega} \operatorname{Re}\left(\frac{1}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}\left|\mathbf{H}_{0}\right|^{2} \mathbf{k}\right),
\]
where the last passage follows from the fact the real part of a complex number and the real part of its complex conjugate are identical.
It can be also rewritten as:
\(\langle\mathbf{S}\rangle=\frac{1}{2 \omega} \mathfrak{R e}\left(\frac{1}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}\left|\mathbf{H}_{0}\right|^{2} \mathbf{k}\right)=\frac{1}{2 \omega}\left|\mathbf{H}_{0}\right|^{2} \mathfrak{H e}\left(\frac{\mathrm{k}}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}\right) \hat{\boldsymbol{\kappa}}=\frac{1}{2 \omega}\left|\mathbf{H}_{0}\right|^{2} \mathfrak{H e}\left(\frac{\omega \sqrt{\varepsilon_{0} \mu_{0} \bar{\epsilon}_{\mathrm{R}} \mu_{\mathrm{R}}}}{\varepsilon_{0} \bar{\epsilon}_{\mathrm{R}}}\right) \hat{\boldsymbol{\kappa}}=\frac{1}{2}\left|\mathbf{H}_{0}\right|^{2} \mathfrak{R e}(\mathrm{Z}) \hat{\boldsymbol{\kappa}}\)

\title{
PLANE WAVE PROPAGATION AND REFLECTION
}

\author{

}

\begin{abstract}
The basic properties of plane waves propagating in a homogeneous isotropic region are reviewed, for both lossy and lossless media. These basic properties include the nature of the electric and magnetic fields, the properties of the wavenumber vector, and the power flow of the plane wave. Special attention is given to the specific case of a homogenous (uniform) plane wave, i.e., one having real direction angles, since this case is most often met in practice (for example, in the far-field of an antenna). Properties such as wavelength, phase and group velocity, penetration depth, and polarization are discussed for these plane waves.
\end{abstract}

The theory of reflection of plane waves from layered media is then discussed in a unified manner, using a transmission line model called the transverse equivalent network. This method decomposes the incident plane wave into TM and TE parts, and models each separately using a transmission line equivalent circuit. Basic reflection phenomena such as the law of reflection, Snell's law and the Brewster angle effect come directly from this model. More involved reflection problems are also easily treated using this approach. As an example, the reflected and transmitted fields due to a circular-polarized wave incident on the surface of the ocean are calculated.

\section*{1. INTRODUCTION}

Planes waves are the simplest solution of Maxwell's equations in a homogeneous region of space, such as free-space (vacuum). In spite of their simplicity, plane waves have played an important role throughout the development of electromagnetics, starting from the time of the earliest radio transmissions through the development of modern communications systems. Plane waves are important for several reasons. First, the far-field radiation from any transmitting antenna has the characteristics of a plane wave sufficiently far from the antenna. The incoming wavefield impinging on a receiving antenna can therefore usually be approximated as a plane wave. Second, the exact field radiated by any source in a region of space can be constructed in terms of a continuous spectrum of plane waves via the Fourier transform. Understanding the nature of plane waves is thus important for understanding both the far-field and the exact radiation from sources.

The theory of plane wave reflection from layered media is also a well-developed area, and relatively simple expressions suffice for understanding reflection and transmission effects when layers are present. Problems involving reflections from the earth or sea, for example, are easily treated using plane-wave theory. Even when the incident wavefront is actually spherical is shape, as from a transmitting antenna, plane-wave theory may often be approximately used with accurate results.

Throughout this article, it will be assumed that the regions of interest are homogeneous (the material properties are constant) and isotropic, which covers most cases of practical interest.

\section*{2. BASIC PROPERTIES OF A PLANE WAVE}

\section*{Definition of a plane wave}

The most general definition of a plane wave is an electromagnetic field having the form
\[
\begin{align*}
& \boldsymbol{E}=\boldsymbol{E}_{\boldsymbol{0}} \psi(x, y, z)  \tag{1}\\
& \boldsymbol{H}=\boldsymbol{H}_{\boldsymbol{0}} \psi(x, y, z) \tag{2}
\end{align*}
\]
where \(\boldsymbol{E}_{\boldsymbol{0}}\) and \(\boldsymbol{H}_{\boldsymbol{0}}\) are constant vectors, and the wavefunction \(\psi\) is defined as
\[
\begin{align*}
\psi(x, y, z) & =e^{-j\left(k_{x} x+k_{y} y+k_{z} z\right)} \\
& =e^{-j \boldsymbol{k} \cdot \boldsymbol{r}} \tag{3}
\end{align*}
\]
where
\[
\begin{align*}
& \boldsymbol{k}=\hat{\boldsymbol{x}} k_{x}+\hat{\boldsymbol{y}} k_{y}+\hat{\boldsymbol{z}} k_{z}=\boldsymbol{\beta}-j \boldsymbol{\alpha}  \tag{4}\\
& \boldsymbol{r}=\hat{\boldsymbol{x}} x+\hat{\boldsymbol{y}} y+\hat{\boldsymbol{z}} z \tag{5}
\end{align*}
\]
with \(k_{x}, k_{y}\), and \(k_{z}\) being complex constants that define a wavenumber vector \(\boldsymbol{k}\). (A time-harmonic dependence of \(e^{j \omega t}\) is assumed and suppressed.) The vector \(\boldsymbol{E}_{\boldsymbol{0}}\) defines the polarization of the plane wave. The real and imaginary parts of the wavenumber vector \(\boldsymbol{k}\) define the phase vector \(\boldsymbol{\beta}\) and an attenuation vector \(\boldsymbol{\alpha}\). The phase vector has units of radians/meter and gives the direction of most rapid phase change, while the attenuation vector has units of nepers/meter and gives the direction of most rapid attenuation. The magnitude of the phase vector gives the phase change per unit length along the direction of the phase vector, while the magnitude of the attenuation vector determines the rate of attenuation along the direction of the attenuation vector.

\section*{Basic properties}

In a homogeneous lossless space a plane wave must satisfy Maxwell's equations, which in the time-harmonic form are [1]
\[
\begin{align*}
& \nabla \times \boldsymbol{H}=j \omega \varepsilon \boldsymbol{E}  \tag{6}\\
& \nabla \times \boldsymbol{E}=-j \omega \mu \boldsymbol{H}  \tag{7}\\
& \nabla \cdot \boldsymbol{E}=0  \tag{8}\\
& \nabla \cdot \boldsymbol{H}=\boldsymbol{0} \tag{9}
\end{align*}
\]
where \(\varepsilon\) and \(\mu\) are the permittivity and permeability of the space. For free space, \(\varepsilon=\varepsilon_{0}\) and \(\mu\) \(=\mu_{0}\), where \(\mu_{0}\) is defined to be \(4 \pi \times 10^{-7}\) Henry/meter and \(\varepsilon_{0}\) is determined from the defined velocity of light (or any plane wave) in vacuum [2], \(c=2.99792458 \times 10^{8}\) meters/second, since \(c=1 / \sqrt{\varepsilon_{0} \mu_{0}}\). This gives the approximate value \(\varepsilon_{0}=8.85418781762039 \times 10^{-12}\) Farads \(/\) meter. A lossy medium can be modeled using a complex effective permittivity, accounting for conduction loss and/or polarization loss [1]. The complex effective permittivity is expressed as
\[
\begin{equation*}
\varepsilon=\hat{\varepsilon}-j\left(\frac{\sigma}{\omega}\right) . \tag{10}
\end{equation*}
\]

In this equation \(\hat{\mathcal{E}}\) is the complex permittivity of the material, accounting for polarization loss (if any), and \(\sigma\) is the conductivity of the medium.

Taking the curl of Eq. (7) and then substituting in Eq. (6) gives the vector wave equation
\[
\begin{equation*}
\nabla \times(\nabla \times \boldsymbol{E})-k^{2} \boldsymbol{E}=\boldsymbol{0}, \tag{11}
\end{equation*}
\]
where \(k\) is the (possibly complex) wavenumber defined by
\[
\begin{equation*}
k=k^{\prime}-j k^{\prime \prime}=\omega \sqrt{\mu \varepsilon}, \tag{12}
\end{equation*}
\]
with the square root chosen so that \(k\) lies in the fourth quadrant on the complex plane. Using the definition of the vector Laplacian,
\[
\begin{equation*}
\nabla^{2} \boldsymbol{E} \equiv \nabla(\nabla \cdot \boldsymbol{E})-\nabla \times(\nabla \times \boldsymbol{E}), \tag{13}
\end{equation*}
\]
and the fact that the divergence of the electric field is zero for a time-harmonic field in a homogeneous region [1], results in the vector Helmholtz equation
\[
\begin{equation*}
\nabla^{2} \boldsymbol{E}+k^{2} \boldsymbol{E}=\mathbf{0} \tag{14}
\end{equation*}
\]

In rectangular coordinates, the vector Laplacian is expressed as
\[
\begin{equation*}
\nabla^{2} \boldsymbol{E}=\hat{\boldsymbol{x}} \nabla^{2} E_{x}+\hat{\boldsymbol{y}} \nabla^{2} E_{y}+\hat{\boldsymbol{z}} \nabla^{2} E_{z} . \tag{15}
\end{equation*}
\]

Hence, all three rectangular components of the electric field satisfy the scalar Helmholtz equation
\[
\begin{equation*}
\nabla^{2} \Psi+k^{2} \Psi=0 \tag{16}
\end{equation*}
\]
in a homogeneous region.

Substituting Eq. (3) into Eq. (16) gives the result
\[
k_{x}^{2}+k_{y}^{2}+k_{z}^{2}=k^{2}
\]
or
\[
\begin{equation*}
\boldsymbol{k} \cdot \boldsymbol{k}=k^{2} \tag{17}
\end{equation*}
\]

This is the "separation equation" that relates the components of the wavenumber vector \(\boldsymbol{k}\) defined in Eq. (4). Note that the term on the left side of Eq. (17) is not in general equal to \(|\boldsymbol{k}|^{2}\), since \(\boldsymbol{k}\) may be complex.

Other fundamental relations for a plane wave may be found by substituting Eq. (1) and (2) into Maxwell's equations (6)-(9). Noting that \(\nabla \rightarrow-j \boldsymbol{k}\) for a plane wave, Maxwell's equations reduce to
\[
\begin{align*}
& \boldsymbol{k} \times \boldsymbol{H}=-\omega \varepsilon \boldsymbol{E}  \tag{18}\\
& \boldsymbol{k} \times \boldsymbol{E}=\omega \mu \boldsymbol{H}  \tag{19}\\
& \boldsymbol{k} \cdot \boldsymbol{E}=0  \tag{20}\\
& \boldsymbol{k} \cdot \boldsymbol{H}=0 \tag{21}
\end{align*}
\]

Equations (18) and (19) each imply that \(\boldsymbol{E} \cdot \boldsymbol{H}=0\), and together they also imply that \(\boldsymbol{k} \cdot \boldsymbol{E}=0\) and \(\boldsymbol{k} \cdot \boldsymbol{H}=0\). That is, all three vectors \(\boldsymbol{k}, \boldsymbol{E}\), and \(\boldsymbol{H}\) are mutually orthogonal. Another interesting property that is true for any plane wave, which may be derived directly from Eq. (18) or (19), is that
\[
\begin{equation*}
\boldsymbol{E} \cdot \boldsymbol{E}=\eta^{2} \boldsymbol{H} \cdot \boldsymbol{H}, \tag{22}
\end{equation*}
\]
where \(\eta\) is the intrinsic impedance of the space (possibly complex), defined from
\[
\begin{equation*}
\eta=\sqrt{\frac{\mu}{\varepsilon}} \tag{23}
\end{equation*}
\]
(the principle branch of the square root is chosen so that the real part of \(\eta\) is nonnegative). For vacuum, the intrinsic impedance is often denoted as \(\eta_{0}\), and has a value of approximately \(376.7303 \Omega\).

\section*{Power flow}

The complex Poynting vector for a plane wave, giving the complex power flow, is (assuming peak notation for phasors)
\[
\begin{equation*}
\boldsymbol{S}=\frac{1}{2} \boldsymbol{E} \times \boldsymbol{H}^{*} \tag{24}
\end{equation*}
\]

Using Eq. (19), the Poynting vector for a plane wave can be written as
\[
\begin{equation*}
\boldsymbol{S}=\frac{1}{2 \omega \mu^{*}}|\psi|^{2} \boldsymbol{E}_{0} \times\left(\boldsymbol{k}^{*} \times \boldsymbol{E}_{0}^{*}\right) \tag{25}
\end{equation*}
\]

Using the triple product rule \(\boldsymbol{A} \times(\boldsymbol{B} \times \boldsymbol{C})=(\boldsymbol{A} \cdot \boldsymbol{C}) \boldsymbol{B}-(\boldsymbol{A} \cdot \boldsymbol{B}) \boldsymbol{C}\), this can be rewritten as
\[
\begin{equation*}
\boldsymbol{S}=\frac{1}{2 \omega \mu^{*}}|\psi|^{2}\left|\boldsymbol{E}_{\boldsymbol{0}}\right|^{2} \boldsymbol{k}^{*}-\frac{1}{2 \omega \mu^{*}}|\psi|^{2}\left(\boldsymbol{E}_{\boldsymbol{0}} \cdot \boldsymbol{k}^{*}\right) \boldsymbol{E}_{\boldsymbol{0}}^{*} \tag{26}
\end{equation*}
\]

The second term in the above equation is not always zero for an arbitrary plane wave, even though \(\boldsymbol{E}_{\boldsymbol{0}} \cdot \boldsymbol{k}=0\), since \(\boldsymbol{k}\) may be complex in the most general case. If either \(\boldsymbol{k}\) or \(\boldsymbol{E}_{\boldsymbol{0}}\) is proportional to a real vector (i.e., all of the components of the vector have the same phase angle), then it is easily demonstrated that the second term vanishes. In this case the Poynting vector becomes
\[
\begin{equation*}
\boldsymbol{S}=\frac{1}{2 \omega \mu^{*}}|\psi|^{2}\left|\boldsymbol{E}_{\boldsymbol{0}}\right|^{2} \boldsymbol{k}^{*} \tag{27}
\end{equation*}
\]

If the medium is also lossless ( \(\mu\) is real), the time-average power flow (coming from the real part of the complex Poynting vector) is in the direction of the phase vector \(\boldsymbol{\beta}\). A similar derivation, casting the Poynting vector in terms of the \(\boldsymbol{H}_{\boldsymbol{0}}\) vector, yields
\[
\begin{equation*}
\boldsymbol{S}=\frac{1}{2 \omega \varepsilon}|\psi|^{2}\left|\boldsymbol{H}_{\boldsymbol{0}}\right|^{2} \boldsymbol{k} \tag{28}
\end{equation*}
\]
provided either \(\boldsymbol{k}\) or \(\boldsymbol{H}_{\boldsymbol{0}}\) is proportional to a real vector. If the region is lossless ( \(\varepsilon\) is real), the time-average power flow is then in the direction of the phase vector. Hence, for a lossless region, the time-average power flow is in the direction of the phase vector \(\boldsymbol{\beta}\) if any of the three vectors
\(\boldsymbol{k}, \boldsymbol{E}_{\boldsymbol{0}}\), or \(\boldsymbol{H}_{\boldsymbol{0}}\) is proportional to a real vector. In many practical cases of interest, one of the three vectors will be proportional to a real vector, and hence the conclusion will be valid. However, it is always possible to find exceptions, even for free space. One such example is the plane wave defined by the vectors \(\boldsymbol{k}=(1, j, 1), \quad \boldsymbol{E}_{\boldsymbol{0}}=(2,1,-2-j), \quad\) and \(\boldsymbol{H}_{\boldsymbol{0}}=(1 /(\omega \mu))(-2 j, 4+j, 1-2 j)\), at a frequency \(\omega=c \quad\left(k_{0}=1\right)\). This plane wave satisfies Maxwell's equations (18)-(21). However for this plane wave the vectors \(\boldsymbol{\beta}, \boldsymbol{\alpha}\), and \(\boldsymbol{p}=\operatorname{Re}(\boldsymbol{S})\) are all in different directions, since the power flow is in the direction of the vector \((5,0,4)\) One must then be careful to define what is meant by the "direction of propagation" for such a plane wave.

\section*{Direction angles}

One way to characterize a plane wave is through direction angles \((\theta, \phi)\) in spherical coordinates. The direction angles (which are in general complex) are defined from the relations
\[
\begin{align*}
& k_{x}=k \sin \theta \cos \phi  \tag{29}\\
& k_{y}=k \sin \theta \sin \phi  \tag{30}\\
& k_{z}=k \cos \theta \tag{31}
\end{align*}
\]

\section*{Homogeneous (uniform) plane wave}

One important class of plane waves is the class of homogeneous or uniform plane waves. A homogeneous plane wave is one for which the direction angles are, by definition, real. A
homogeneous plane wave enjoys certain special properties that are not true in general for all plane waves. For such a plane wave the wavenumber vector can be written as
\[
\begin{equation*}
\boldsymbol{k}=k \hat{\boldsymbol{R}}=\hat{\boldsymbol{R}}\left(k^{\prime}-j k^{\prime \prime}\right) \tag{32}
\end{equation*}
\]
where \(\hat{\boldsymbol{R}}\) is a real unit vector defined from
\[
\begin{equation*}
\hat{\boldsymbol{R}}=\hat{\boldsymbol{x}} \sin \theta \cos \phi+\hat{\boldsymbol{y}} \sin \theta \sin \phi+\hat{\boldsymbol{z}} \cos \theta . \tag{33}
\end{equation*}
\]

In this case the \(\boldsymbol{k}\) vector is proportional to the real vector \(\hat{\boldsymbol{R}}\), so the result of Eq. (27) applies. The unit vector \(\hat{\boldsymbol{R}}\) then gives the direction of time-average power flow, and also points in the direction of the phase and attenuation vectors. That is, all three vectors point in the same direction for a homogeneous plane wave. This direction is, unambiguously, the direction of propagation of the plane wave. The planes of constant phase are also then the planes of constant amplitude, being the planes perpendicular to the \(\hat{\boldsymbol{R}}\) vector. That is, the plane wave has a uniform amplitude across the plane perpendicular to the direction of propagation. If the plane wave is not homogeneous, corresponding to complex direction angles, then the physical interpretation of the direction angles is not clear.

From Eq. (18) or (19) it may be easily proven that the fields of a homogeneous plane wave obey the relation
\[
\begin{equation*}
|\boldsymbol{E}|=|\eta||\boldsymbol{H}| . \tag{34}
\end{equation*}
\]
(Recall that all plane waves obey Eq. (22), which is not in general the same as the above equation.)

Any homogeneous plane wave can be decomposed into a sum of two plane waves, with electric field vectors polarized perpendicular to each other, and with electric field vectors that are real, to within a multiplicative complex constant. This follows from a simple rotation of coordinates (the direction of propagation is then \(z^{\prime}\), with electric field vectors in the \(x^{\prime}\) and \(y^{\prime}\) directions. the two plane wave then have the fields \(\left(E_{x}, H_{y}\right)\) and \(\left(E_{y}, H_{x}\right)\), with \(E_{x} / H_{y}=-E_{y} / H_{x}=\eta\). This decomposition is used later in the discussion of polarization.

\section*{Lossless media}

Another important special case is when the medium is lossless, so that \(k^{\prime \prime}=0\). If Eq. (4) is substituted into the separation equation (17), the imaginary part of this equation immediately yields the relation
\[
\begin{equation*}
\boldsymbol{\beta} \cdot \boldsymbol{\alpha}=0 . \tag{35}
\end{equation*}
\]

Hence, for a lossless region, the phase and attenuation vectors are always perpendicular. In some applications (e.g., a Fourier transform solution of radiation from an aperture in a ground plane at \(z=0\), or from a planar current source at \(z=0\) [3]), a plane wave propagating in a lossless region has the characteristic that two of the wavenumbers, e.g., \(k_{x}\) and \(k_{y}\), are real (corresponding to the transform variables). In this case the third wavenumber \(k_{z}\) will be real if \(k_{x}^{2}+k_{y}^{2}<k^{2}\) and will be imaginary if \(k_{x}^{2}+k_{y}^{2}>k^{2}\). That is, all transverse wavenumbers \(\left(k_{x}, k_{y}\right)\) that lie within a circle of radius \(k\) in the wavenumber plane will be propagating, while all wavenumber outside the circle will be evanescent. In the first case the power flow is in the direction of the (real) \(\boldsymbol{k}\) vector \(\left(k_{x}, k_{y}, k_{z}\right)\), so that power leaves the aperture from this plane wave. In the second case
the power flow is in the direction of the transverse wavenumber vector \(\left(k_{x}, k_{y}, 0\right)\), so that no power leaves the aperture for this plane wave component. If the medium is complex, there is no sharp distinction between propagating and evanescent plane waves. In this case all plane waves carry power, in the direction of the vector \(\left(k_{x}, k_{y}, \operatorname{Im} k_{z}\right)\).

Finally, it can be noted that if a homogeneous plane wave is propagating in a lossless region, then the attenuation vector \(\boldsymbol{\alpha}\) must be zero, and all wavenumber components \(k_{x}, k_{y}\), and \(k_{z}\) are real.

\section*{Summary of Basic Properties}

A summary of the basic properties of a plane wave, discussed in the previous sections, is given in Table 1.

Table 1. Summary of the basic properties of a plane wave.
\begin{tabular}{|l|c|c|c|c|}
\hline & \multicolumn{2}{|c|}{ INHOMOGENEOUS } & \multicolumn{2}{c|}{ HOMOGENEOUS } \\
\hline \multicolumn{1}{|c|}{ PROPERTY } & Lossy & Lossless & Lossy & Lossless \\
\hline \hline Direction angles & complex & complex & real & real \\
\hline \begin{tabular}{l} 
Relation between \\
phase and \\
attenuation vectors
\end{tabular} & \(\boldsymbol{\beta} \cdot \boldsymbol{\alpha}=k^{\prime} k^{\prime \prime}\) & \(\boldsymbol{\beta} \cdot \boldsymbol{\alpha}=0\) & \(\boldsymbol{\beta} \| \boldsymbol{\alpha}\) & \(\boldsymbol{\alpha}=\boldsymbol{0}\) \\
\hline Impedance relations & \(\boldsymbol{E} \cdot \boldsymbol{E}=\eta^{2} \boldsymbol{H} \cdot \boldsymbol{H}\) & \(\boldsymbol{E} \cdot \boldsymbol{E}=\eta^{2} \boldsymbol{H} \cdot \boldsymbol{H}\) & \(\boldsymbol{E} \cdot \boldsymbol{E}=\eta^{2} \boldsymbol{H} \cdot \boldsymbol{H} \mid\) & \(\boldsymbol{E} \cdot \boldsymbol{E}=\eta^{2} \boldsymbol{H} \cdot \boldsymbol{H}\) \\
\hline
\end{tabular}

\section*{3. PROPAGATION OF A HOMOGENEOUS PLANE WAVE}

The case of a homogeneous plane wave is important enough to warrant further attention. Far away from a transmitting antenna, the radiation field always has behaves as a homogeneous plane wave (if the spherical wavefront is approximated as planar). As mentioned, a homogeneous plane wave is one propagating with real direction angles in space, with a direction of propagation described by a real unit vector. By a suitable rotation of coordinate axis, the direction of propagation may be assumed to be along the \(z\) axis. Furthermore, the plane way can always be represented as a sum of two separate plane waves, one with the electric field polarized
in the \(x\) direction, and the other polarized in the \(y\) direction. Considering the wave polarized in the \(x\) direction, the fields are
\[
\begin{align*}
& E_{x}=E_{0} e^{-j k z}  \tag{36}\\
& H_{y}=\frac{E_{0}}{\eta} e^{-j k z} . \tag{37}
\end{align*}
\]

The wavenumber \(k\) and the intrinsic impedance \(\eta\) of the space are given by Eqs. (12) and (23), respectively.

\section*{Wavelength, phase velocity, and group velocity}

The wavelength \(\lambda\) is defined at the distance required for the plane wave to change phase by \(2 \pi\) radians, and is given by
\[
\begin{equation*}
\lambda=\frac{2 \pi}{k^{\prime}} . \tag{38}
\end{equation*}
\]

The phase velocity of the plane wave is defined as the velocity at which a point of constant phase travels (such as the crest of the wave, where the electric field is the maximum). The phase velocity is given by
\[
\begin{equation*}
v_{p}=\frac{\omega}{k^{\prime}}=\frac{\omega}{\operatorname{Re}(\omega \sqrt{\mu \varepsilon})} . \tag{39}
\end{equation*}
\]

If the permittivity \(\varepsilon\) is not a function of frequency (true for vacuum, and often approximately true for nonconducting media, over a certain frequency range), then the phase velocity is constant with frequency (the plane wave propagates without dispersion). For vacuum the phase velocity is
\(c=2.99792458 \times 10^{8}\) meters/second. The group velocity (velocity of energy flow, and often a good approximation to the velocity of signal propagation [4], is given by
\[
\begin{equation*}
v_{g}=\frac{d \omega}{d k^{\prime}}=\frac{1}{\frac{d}{d \omega} \operatorname{Re}(\omega \sqrt{\mu \varepsilon})} . \tag{40}
\end{equation*}
\]

For a nondispersive lossless media (constant real-valued permittivity) the group velocity is equal to the phase velocity, and both are equal to
\[
\begin{equation*}
v_{p}=v_{g}=\frac{1}{\sqrt{\mu \varepsilon}} . \tag{41}
\end{equation*}
\]

\section*{Depth of penetration (skin depth)}

For a lossy medium, the plane wave decays as it propagates, since \(k^{\prime \prime}>0\). The depth of penetration \(d_{p}\) is defined as the distance required to reduce the field level by a factor of \(e \approx 2.71828\), so that the field is \(36.788 \%\) of the starting value (the power is reduced by a factor of \(e^{2}\), or is at a level of \(13.534 \%\) of the starting value). The depth of penetration is given as
\[
\begin{equation*}
d_{p}=\frac{1}{k^{\prime \prime}}=\frac{-1}{\operatorname{Im}(\omega \sqrt{\mu \varepsilon})} \tag{42}
\end{equation*}
\]

The permittivity is complex for a lossy media, and is represented by Eq. (10). Special cases are of particular interest. For a low loss medium, \(\varepsilon^{\prime \prime} \ll \varepsilon^{\prime}\), a simple binomial approximation of the square root in Eq. (42) gives
\[
\begin{equation*}
d_{p}=\frac{1}{k^{\prime \prime}} \approx \frac{1}{0.5 k^{\prime} \tan \delta} \tag{43}
\end{equation*}
\]
where
\[
\begin{equation*}
k^{\prime} \approx \omega \sqrt{\mu \varepsilon^{\prime}} \tag{44}
\end{equation*}
\]
and the loss tangent is defined as
\[
\begin{equation*}
\tan \delta=\frac{\varepsilon^{\prime \prime}}{\varepsilon^{\prime}} \tag{45}
\end{equation*}
\]

If the loss is due purely to medium conductivity (no polarization loss, so that \(\hat{\varepsilon}=\mathcal{\varepsilon}^{\prime}\) is a real number), the penetration depth formula (43) for the low-loss case becomes
\[
\begin{equation*}
d_{p} \approx \frac{2}{\sigma} \sqrt{\frac{\varepsilon^{\prime}}{\mu}} \tag{46}
\end{equation*}
\]

For a highly lossy medium, \(\varepsilon^{\prime} \ll \varepsilon^{\prime \prime}\), in which case we have
\[
\begin{equation*}
k^{\prime} \approx k^{\prime \prime} \approx \omega \sqrt{\frac{\mu \varepsilon^{\prime \prime}}{2}} . \tag{47}
\end{equation*}
\]

For a good conductor the conductivity is very large, so that \(\varepsilon^{\prime \prime} \approx \sigma / \omega\) from Eq. (10). In this case the penetration depth is more commonly referred to as the "skin depth" \(\delta\), since the value may be very small. (There is no relation to the \(\delta\) symbol appearing in the loss tangent symbol.) For a good conductor,
\[
\begin{equation*}
\delta=d_{p} \approx \sqrt{\frac{2}{\omega \mu \sigma}} \tag{48}
\end{equation*}
\]

For pure copper \(\left(\sigma=5.8 \times 10^{7} \mathrm{~S} / \mathrm{m}, \mu \approx \mu_{0}\right)\) at \(2.45 \mathrm{GHz}, \delta=1.335 \mu \mathrm{~m}\).

Whether a particular material falls into the "low loss" or "highly lossy" categories may depend on frequency. For example, consider typical seawater, which has roughly \(\hat{\varepsilon}_{r}=78\)
(ignoring polarization losses) and \(\sigma=4.0 \mathrm{~S} / \mathrm{m}\). Table 2 shows the loss tangent versus frequency. It is seen that the loss tangent is on the order of unity at microwave frequencies. For much lower frequencies the seawater is "highly lossy", and for much higher frequencies it is a "low loss" media. Note that the depth of penetration continues to decrease as the frequency is raised, even though the medium becomes more of a "low loss" material at higher frequencies, according to the definition used (a low loss tangent). At low frequencies the penetration depth is increasing inversely as the square root of frequency, according to Eq. (48). At high frequencies the penetration depth approaches a constant, according to Eq. (46).

Table 2. Loss tangent and penetration depth for typical seawater, versus frequency.

\section*{Summary of Homogeneous Plane Wave Properties}

A summary of the properties relating to wavelength, velocity, and depth of penetration for a homogeneous plane wave is given in Table 3.

Table 3. Propagation Properties of a homogeneous plane wave.
\begin{tabular}{|l|c|c|c|c|}
\hline & General & Highly Conducting & Low Loss & Lossless \\
\hline \hline wavelength & \(\frac{2 \pi}{k^{\prime}}\) & \(2 \pi \sqrt{\frac{2}{\omega \mu \sigma}}\) & \(\frac{2 \pi}{\omega \sqrt{\mu \varepsilon^{\prime}}}\) & \(\frac{2 \pi}{\omega \sqrt{\mu \varepsilon}}\) \\
\hline phase velocity & \(\frac{\omega}{k^{\prime}}\) & \(\sqrt{\frac{2 \omega}{\mu \sigma}}\) & \(\frac{1}{\sqrt{\mu \varepsilon^{\prime}}}\) & \(\frac{1}{\sqrt{\mu \varepsilon}}\) \\
\hline group velocity & \(\frac{d \omega}{d k^{\prime}}\) & \(2 \sqrt{\frac{2 \omega}{\mu \sigma}}\) & \(\frac{1}{\sqrt{\mu \varepsilon^{\prime}}}\) & \(\frac{1}{\sqrt{\mu \varepsilon}}\) \\
\hline \begin{tabular}{l} 
depth of \\
penetration
\end{tabular} & \(1 / k^{\prime \prime}\) & \(\sqrt{\frac{2}{\omega \mu \sigma}}\) & \(\frac{2}{\sigma} \sqrt{\frac{\varepsilon^{\prime}}{\mu}}\) & \(\infty\) \\
\hline \hline
\end{tabular}

\section*{Polarization}

The above discussion has assumed a homogeneous plane wave propagating in the \(z\) direction, polarized with the electric field in the \(x\) direction. The most general polarization of a wave propagating in the \(z\) direction is one having both \(x\) and \(y\) components of the field,
\[
\begin{equation*}
\boldsymbol{E}=\left(\hat{\boldsymbol{x}} E_{x 0}+\hat{\boldsymbol{y}} E_{y 0}\right) e^{-j(k z)} . \tag{49}
\end{equation*}
\]

The field components are represented in polar form as
\[
\begin{align*}
& E_{x 0}=\left|E_{x 0}\right| e^{j \phi_{x}},  \tag{50}\\
& E_{y 0}=\left|E_{y 0}\right| e^{j \phi_{y}} . \tag{51}
\end{align*}
\]

The phase difference between the two components is defined as
\[
\begin{equation*}
\phi=\phi_{y}-\phi_{x} \tag{52}
\end{equation*}
\]

Without any real loss of generality, \(\phi_{x}\) may be chosen as zero, so that \(\phi=\phi_{y}\). In the time domain, the field components are then
\[
\begin{align*}
& \varepsilon_{x}=\left|E_{x 0}\right| \cos (\omega t)  \tag{53}\\
& \varepsilon_{y}=\left|E_{y 0}\right| \cos (\omega t+\phi) \tag{54}
\end{align*}
\]

Using trigonometric identities, Eq. (54) may be expanded into a sum of \(\sin (\omega t)\) and \(\cos (\omega t)\) functions, and then Eq. (53) may be used to put both \(\cos (\omega t)\) and \(\sin (\omega t)\) in terms of \(\varepsilon_{x}\) (using \(\left.\sin ^{2}=1-\cos ^{2}\right)\). After simplification, the result is
\[
\begin{equation*}
A \boldsymbol{\varepsilon}_{x}^{2}+B \boldsymbol{\varepsilon}_{x} \varepsilon_{y}+C \boldsymbol{\varepsilon}_{y}^{2}=D \tag{55}
\end{equation*}
\]
where
\[
\begin{align*}
& A=\left|\frac{E_{y 0}}{E_{x 0}}\right|^{2}  \tag{56}\\
& B=-2\left|\frac{E_{y 0}}{E_{x 0}}\right| \cos \phi  \tag{57}\\
& C=1  \tag{58}\\
& D=\left|E_{y 0}\right|^{2} \sin ^{2} \phi . \tag{59}
\end{align*}
\]

After simplification, the discriminant of this quadratic curve is
\[
\begin{equation*}
\Delta=B^{2}-4 A C=-4\left|\frac{E_{y 0}}{E_{x 0}}\right|^{2} \sin ^{2} \phi \tag{60}
\end{equation*}
\]
which is always negative. This curve thus always represents an ellipse. The general form of the ellipse is shown in Fig. 1. The tilt angle of the ellipse is \(\tau\), and the axial ratio AR is defined as the ratio of the major axis of the ellipse to the minor axis ( \(\mathrm{AR} \geq 1\) ). In the time domain the electric field vector rotates with the tip of the vector lying on the ellipse. Right-handed elliptical polarization, or RHEP, corresponds to counterclockwise rotation (the thumb of the right hand aligns with the direction of propagation, the fingers of the right hand align with the direction of rotation in time). (This is the IEEE definition, opposite to the usual optics convention.) LHEP corresponds to rotation in the opposite direction.

Figure 1. Geometry of the polarization ellipse.

A convenient way to represent the polarization state is with the Poincaré sphere [5]. Using spherical trigonometric relations, the following results may be derived for the tilt angle of the ellipse and the axial ratio.
\[
\begin{align*}
& \tan 2 \tau=\tan 2 \gamma \cos \phi  \tag{61}\\
& \sin 2 \xi=\sin 2 \gamma \sin \phi, \tag{62}
\end{align*}
\]
where the parameter \(\xi\) is related to the axial ratio as
\[
\begin{align*}
\xi & =\cot ^{-1}(\mp A R), \quad-45^{0} \leq \xi \leq+45^{0} \\
& + \text { for LHEP }  \tag{63}\\
& - \text { for RHEP. }
\end{align*}
\]

The phase angle \(\phi\) is defined in Eq. (52). The parameter \(\gamma\) characterizes the ratio of the fields along the \(x\) and \(y\) axes, and is defined from
\[
\begin{equation*}
\gamma=\tan ^{-1}\left|\frac{E_{y 0}}{E_{x 0}}\right|, \quad 0 \leq \gamma \leq 90^{\circ} . \tag{64}
\end{equation*}
\]

There is no ambiguity in Eq. (62) for \(\xi\), since \(-90^{\circ} \leq 2 \xi \leq+90^{\circ}\). However, Eq. (61) gives an ambiguity for \(\tau\), since adding multiples of \(180^{\circ}\) does not change the tangent. To resolve this ambiguity, Table 4 may be used to determine the appropriate quadrant (1, 2, 3 or 4 ) that the angle \(2 \tau\) is in, based on the Poincaré sphere [5].

Table 4. Quadrant that the angle \(2 \tau\) is in.
\begin{tabular}{|c|c|c|}
\hline & \(\cos \phi>0\) & \(\cos \phi<0\) \\
\hline \(\cos 2 \gamma>0\) & 1 & 4 \\
\hline \(\cos 2 \gamma<0\) & 2 & 3 \\
\hline
\end{tabular}

The following special cases are important.
1) Linear polarization: \(\phi=0\) or \(180^{\circ}\), or either \(E_{x 0}\) or \(E_{y 0}\) is zero.

In this case \(\mathrm{AR}=\infty\) (the ellipse degenerates to a straight line).
2) Circular polarization: \(E_{y 0}=E_{x 0}\) and \(\phi= \pm 90^{\circ}\) (to within any multiple of \(180^{\circ}\) ).

In this case the ellipse becomes a circle (either RHCP or LHCP), and AR \(=1\).

It can also be noted that a wave of arbitrary polarization can be represented as a sum of RHCP and a LHCP waves, by noting that the arbitrarily polarized wave in Eq. (49) can be written as
\[
\begin{equation*}
\boldsymbol{E}=\hat{\boldsymbol{r}}\left[\frac{1}{\sqrt{2}}\left(E_{x 0}+j E_{y 0}\right)\right]+\hat{\boldsymbol{l}}\left[\frac{1}{\sqrt{2}}\left(E_{x 0}-j E_{y 0}\right)\right] \tag{65}
\end{equation*}
\]
where the unit-amplitude RHCP and LHCP waves are
\[
\begin{align*}
& \hat{\boldsymbol{r}}=\frac{1}{\sqrt{2}}(\hat{\boldsymbol{x}}-j \hat{\boldsymbol{y}}) e^{-j k z}  \tag{66}\\
& \hat{\boldsymbol{l}}=\frac{1}{\sqrt{2}}(\hat{\boldsymbol{x}}+j \hat{\boldsymbol{y}}) e^{-j k z} . \tag{67}
\end{align*}
\]

\section*{5. PLANE WAVE REFLECTION AND TRANSMISSION}

A general plane wave reflection/transmission problem consists of an incident plane wave impinging on a multilayer structure, as shown in Fig. 2. An important special case is the tworegion problem shown in Fig. 3. The incident plane wave may be either homogeneous or inhomogeneous, and any of the regions may have an arbitrary amount of loss. The vector
representing the direction of propagation for the incident wave in Figs. 2 and 3 is a real vector (as shown) if the incident wave is homogeneous, but the analysis is valid for the general case.

Figure 2. A plane wave reflecting from a multilayer stack of different materials. Each layer has a uniform (constant) set of material parameters. On the right side the equivalent transmission-line model (transverse equivalent network) is shown.

Figure 3. Reflection and transmission from a single interface between two different media. The transmission-line model (transverse equivalent network) for the two-region reflection problem is shown on the right.

The key to obtaining a simple solution to such reflection and transmission problems is the use of a transmission line model of the layered structured, which is based on TE-TM decomposition of the plane waves, discussed next.

\section*{TE-TM Decomposition}

According to a basic electromagnetic theorem [1], the fields in a source-free homogeneous region can be represented as the sum of two types of fields, a field that is transverse magnetic to \(z\left(\mathrm{TM}_{\mathrm{z}}\right)\) and a field that is transverse electric to \(z\left(\mathrm{TE}_{\mathrm{z}}\right)\). The \(\mathrm{TM}_{\mathrm{z}}\) field is defined as one that has \(H_{z}=0\), while the \(\mathrm{TE}_{\mathrm{z}}\) field by definition has \(\mathrm{E}_{\mathrm{z}}=0\). A general plane wave field may therefore be written as the sum of a \(\mathrm{TM}_{\mathrm{z}}\) plane wave and a \(\mathrm{TE}_{\mathrm{z}}\) plane wave. In free space, the direction \(z\) is rather arbitrary. When a layered media is present, the preferred direction \(z\) is perpendicular to the layers, because this allows for the \(\mathrm{TM}_{\mathrm{z}}\) and \(\mathrm{TE}_{\mathrm{z}}\) plane waves in each region to be modeled as waves on a transmission line. Standard transmission-line theory may then be conveniently used to solve plane-wave reflection and transmission problems in a relatively simple manner, without having to solve the electromagnetic boundary-value problem of matching fields at the interfaces. The \(\mathrm{TM}_{\mathrm{z}}\) plane wave is commonly referred to as one that is polarized with the electric field "in the place of incidence", while the \(\mathrm{TE}_{\mathrm{z}}\) place wave is polarized with the electric field "perpendicular to the plane of incidence". (The plane of incidence is the \(y-z\) plane.) For a homogeneous plane wave with an incident wave vector in the \(y-z\) plane, the polarizations are shown in Fig. 4.

Figure 4. Polarizations of incident \(\mathrm{TM}_{\mathrm{z}}\) and \(\mathrm{TE}_{\mathrm{z}}\) plane waves.

The field components may be found by using Maxwell's equations to write the transverse ( \(x\) and \(y\) ) field components in terms of the longitudinal components \(E_{z}\) and \(H_{z}\). The nonzero longitudinal component is assumed to be proportional to the wavefunction
\[
\begin{equation*}
\psi=\exp \left(-j\left(k_{x} x+k_{y} y \pm k_{z} z\right)\right) \tag{68}
\end{equation*}
\]

The plus sign in this equation is chosen for plane waves propagating or decaying in the positive \(z\) direction, while the negative sign is for propagation or decay in the minus \(z\) direction. This representation is convenient for plane-wave reflection problems, since the characteristic impedance of a transmission line that models a particular region will then have a positive characteristic impedance for both upward and downward propagating plane waves, in agreement with the usual transmission line convention.

For the \(\mathrm{TM}_{\mathrm{z}}\) plane wave, the normalized field components may then be written as
\[
\begin{array}{ll}
E_{x}=\mp k_{x} k_{z} \Psi(x, y, z) & H_{x}=\omega \varepsilon k_{y} \Psi(x, y, z) \\
E_{y}=\mp k_{y} k_{z} \Psi(x, y, z) & H_{y}=-\omega \varepsilon k_{x} \Psi(x, y, z)  \tag{69}\\
E_{z}=\left(k^{2}-k_{z}^{2}\right) \Psi(x, y, z) & H_{z}=0 .
\end{array}
\]

For a \(\mathrm{TE}_{\mathrm{z}}\) plane wave the corresponding results are
\[
\begin{array}{ll}
E_{x}=-\omega \mu k_{y} \Psi(x, y, z) & H_{x}=\mp k_{x} k_{z} \Psi(x, y, z) \\
E_{y}=\omega \mu k_{x} \Psi(x, y, z) & H_{y}=\mp k_{y} k_{z} \Psi(x, y, z)  \tag{70}\\
E_{z}=0 & H_{z}=\left(k^{2}-k_{z}^{2}\right) \Psi(x, y, z) .
\end{array}
\]

Note that a plane wave propagating in the \(z\) direction \(\left(k_{z}=k\right)\) has both longitudinal field components that are zero. Such a plane wave is TEM (transverse electric and magnetic) to the \(z\) direction)

It may be seen from the above equations that the transverse fields obey the relations
\[
\begin{align*}
\boldsymbol{E}_{t}^{T M} & =\mp Z_{0}^{T M}\left(\hat{\boldsymbol{z}} \times \boldsymbol{H}_{t}^{T M}\right)  \tag{71}\\
\boldsymbol{E}_{t}^{T E} & =\mp Z_{0}^{T E}\left(\hat{\boldsymbol{z}} \times \boldsymbol{H}_{t}^{T E}\right) \tag{72}
\end{align*}
\]
where
\[
\begin{align*}
& Z_{0}^{T M}=\frac{k_{z}}{\omega \varepsilon}  \tag{73}\\
& Z_{0}^{T E}=\frac{\omega \mu}{k_{z}} . \tag{74}
\end{align*}
\]

\section*{Transverse Equivalent Network}

From the above relations (71) and (72), the transverse (perpendicular to \(z\) ) field components behave as voltages and currents on a transmission line model - called the transverse equivalent network. In particular, the correspondence is given through the relations ( \(i=\mathrm{TM}\) or TE )
\[
\begin{align*}
& \boldsymbol{E}_{t}^{i}=\hat{\boldsymbol{e}} \psi_{t}(x, y) V^{i}(z)  \tag{75}\\
& \boldsymbol{H}_{t}^{i}=\hat{\boldsymbol{h}} \psi_{t}(x, y) I^{i}(z) \tag{76}
\end{align*}
\]
where the unit vectors are chosen so that
\[
\begin{equation*}
\hat{\boldsymbol{e}} \times \hat{\boldsymbol{h}}= \pm \hat{\boldsymbol{z}} \tag{77}
\end{equation*}
\]
for a plane wave propagating in the \(\pm \hat{z}\) direction. The transverse wavefunction
\[
\begin{equation*}
\psi_{t}(x, y)=e^{-j\left(k_{x} x+k_{y} y\right)} \tag{78}
\end{equation*}
\]
is a common transverse phase term that must be the same for all regions (if the transverse wavenumbers \(k_{x}\) or \(k_{y}\) were different between two regions, a matching of transverse fields at the boundary would not be possible). The fact that the transverse wavenumbers are the same in all regions leads to the "law of reflection", which states that the direction angle \(\theta\) for a reflected plane wave must equal that for the incident plane wave. It also leads to Snell's law, which states that the direction angles \(\theta\) inside each of the regions are related to each other, through
\[
\begin{equation*}
n_{i} \sin \theta_{i}=n_{1} \sin \theta_{1}, \quad i=1,2, \ldots N, \tag{79}
\end{equation*}
\]
where \(n_{i}\) is the index of refraction (possibly complex) of region \(i\), defined as \(n_{i}=k_{i} / k_{0}=\sqrt{\varepsilon_{r i} \mu_{r i}}\). It is often convenient to express the characteristic impedance for region \(i\) from Eqs. (73) and (74) in terms of the medium intrinsic impedance \(\eta_{i}\) as
\[
\begin{align*}
& Z_{0}^{T M}=\eta_{i} \cos \theta_{i}  \tag{80}\\
& Z_{0}^{T E}=\eta_{i} \sec \theta_{i} \tag{81}
\end{align*}
\]

Using Snell's law, the impedances then become
\[
\begin{align*}
& Z_{0}^{T M}=\eta_{i} \sqrt{1-\left(\frac{n_{1}}{n_{i}}\right)^{2} \sin ^{2} \theta_{1}}  \tag{82}\\
& Z_{0}^{T E}=\frac{\eta_{i}}{\sqrt{1-\left(\frac{n_{1}}{n_{i}}\right)^{2} \sin ^{2} \theta_{1}}} \tag{83}
\end{align*}
\]

The above expressions remain valid for lossy media. The square roots are chosen so that the real part of the characteristic impedances are positive.

The functions \(V(z)\) and \(I(z)\) behave as voltage and current on a transmission line, with characteristic impedance \(Z_{0}^{T M}\) or \(Z_{0}^{T E}\), depending on the case. Hence any plane-wave reflection and transmission problem reduces to a transmission line problem, giving the exact solution that satisfies all boundary conditions. One consequence of this is that \(\mathrm{TM}_{\mathrm{z}}\) and \(\mathrm{TE}_{\mathrm{z}}\) plane waves do not couple at a boundary. If the incident plane wave is \(\mathrm{TM}_{\mathrm{z}}\), for example, the waves in all regions will remain \(\mathrm{TM}_{\mathrm{z}}\) plane waves. Hence, the motivation for the \(\mathrm{TM}_{\mathrm{z}}-\mathrm{TE}_{\mathrm{z}}\) decomposition. The transverse equivalent network for the multilayer and two-region problems are shown on the right sides of Figs. 2 and 3, respectively. The network model is the same for either \(\mathrm{TM}_{\mathrm{z}}\) or \(\mathrm{TE}_{\mathrm{z}}\) polarization, except that the characteristic impedances are different. If an incident plane wave is a combination of both \(\mathrm{TM}_{\mathrm{z}}\) and \(\mathrm{TE}_{\mathrm{z}}\) waves, the two parts are solved separately and then summed to get the total reflected or transmitted field.

\section*{Special Case: Two-Region Problem}

For the simple two-region problem of Fig. 3, the reflected and transmitted voltages (modeling the transverse electric fields) are represented as
\[
\begin{align*}
& V^{\mathrm{ref}}(z)=\Gamma V^{\mathrm{inc}}(0) e^{+j k_{z}^{(1)} z}  \tag{84}\\
& V^{\mathrm{trans}}(z)=T V^{\mathrm{inc}}(0) e^{-j k_{z}^{(2)} z} \tag{85}
\end{align*}
\]
where the reflection and transmission coefficients are given by the standard transmission line equations
\[
\begin{align*}
\Gamma & =\frac{Z_{0}^{(2)}-Z_{0}^{(1)}}{Z_{0}^{(2)}+Z_{0}^{(1)}}  \tag{86}\\
T & =1+\Gamma . \tag{87}
\end{align*}
\]

Note that a plus sign is used in the exponent of Eq. (84) to account for upward propagation of the reflected wave.

\section*{A. Critical angle}

If regions 1 and 2 are lossless, and region 1 is more dense than region \(2\left(n_{1}>n_{2}\right)\), an incident angle \(\theta_{1}=\theta_{c}\) will exist for which \(k_{z}^{(2)}=0\). From Snell's law, the angle is
\[
\begin{equation*}
\theta_{c}=\sin ^{-1}\left(\frac{n_{2}}{n_{1}}\right) \tag{88}
\end{equation*}
\]

When \(\theta_{1}>\theta_{c}\), the wavenumber \(k_{z}^{(2)}\) will be purely imaginary, of the form \(k_{z}^{(2)}=-j \alpha_{z}^{(2)}\). In this case there is no power flow into the second region, since the phase vector in region 2 has no \(z\) component. In this case \(100 \%\) of the incident power is reflected back from the interface. There
are, however, still fields present in the second region, decaying exponentially with distance \(z\). In the second region the power flow is in the horizontal direction only.

\section*{B. Brewster angle}

For lossless layers, it is possible to have \(100 \%\) of the incident power transmitted into the second region, with no reflection. This corresponds to a matched transmission line circuit, with
\[
\begin{equation*}
Z_{0}^{(1)}=Z_{0}^{(2)} \tag{89}
\end{equation*}
\]

For nonmagnetic layers, it may be easily shown that this matching equation can only be satisfied in the \(\mathrm{TM}_{\mathrm{z}}\) case (there is always a nonzero reflection coefficient in the \(\mathrm{TE}_{\mathrm{z}}\) case, unless the trivial case of identical medium is considered). The angle \(\theta_{b}\) at which no reflection occurs is called the Brewster angle. For the \(\mathrm{TM}_{z}\) case, a simple algebraic manipulation of Eq. (89) yields the result
\[
\begin{equation*}
\tan \theta_{b}=\sqrt{\frac{\varepsilon_{2}}{\varepsilon_{1}}} . \tag{90}
\end{equation*}
\]

\section*{Orthogonality}

When treating reflection problems, there is more than one plane wave in at least one of the regions, a wave traveling in the positive \(z\) direction (focusing on the \(z\) variation) and a wave traveling in the negative \(z\) direction. Often, it is desired to calculate power flow in such a region. For a single plane wave, the complex power density in the \(z\) direction (the \(z\) component of the complex Poynting vector) is equal to the complex power flowing on the corresponding transmission line of the transverse equivalent network. When both an incident and a reflected wave are present, or both \(\mathrm{TM}_{\mathrm{z}}\) and \(\mathrm{TE}_{\mathrm{z}}\) waves are present the following orthogonality results are
useful. These theorems related to power flow in the \(z\) direction may be proven by direct calculation using the field components in rectangular coordinates.
1. An orthogonality exists between a homogeneous \(\mathrm{TM}_{\mathrm{z}}\) plane wave and a homogeneous \(\mathrm{TE}_{\mathrm{z}}\) plane wave propagating in the same direction, in the sense that the complex power density in the \(z\) direction, \(S_{z}\), is the sum of the two complex power densities \(S_{1 z}\) and \(S_{2 z}\). This is true for a lossy or lossless media.
2. An orthogonality exists between an incident wave and a reflected wave in a lossless media (both are either \(\mathrm{TE}_{\mathrm{z}}\) or \(\mathrm{TM}_{\mathrm{z}}\) ), provided the wavenumber component \(k_{z}\) of the two waves is real. The two waves are orthogonal in the sense that the time-average power density in the \(z\) direction, \(\operatorname{Re} S_{z}\), is the sum of the two time-average power densities \(\operatorname{Re} S_{1 z}\) and \(\operatorname{Re} S_{2 z}\).

To illustrate property 2 , consider an incident plane wave traveling in a glass region, impinging on an air gap that separates the glass region from another identical glass region, as shown in Fig.
5.

Figure 5. An incident wave traveling in a semi-infinite region of lossless glass impinges on an air gap separating the glass region from an identical region below. Incident, reflected and transmitted plane waves are shown.

If the incident plane wave is beyond the critical angle, the plane waves in the air region will be evanescent, with an imaginary vertical wavenumber \(k_{z}\). Each of the two plane waves in the air region (upward and downward) that constitute a standing-wave field do not, individually, have a time-average power flow in the \(z\) direction, since \(k_{z}\) is imaginary. However, there is an overall power flow in the \(z\) direction inside the air region, since there is a transmitted field in the lower region. The total power flow in the \(z\) direction is thus not the sum of the two individual power flows. The two waves in the air region are not orthogonal, and property 2 does not apply since the wavenumber \(k_{z}\) is not real.

\section*{VI. EXAMPLE}

A RHCP plane wave at a frequency of 1.0 GHz is incident on the surface of the ocean at an angle of \(\theta=30^{\circ}\). Determine the percentage of power that is reflected from the ocean, and characterize the polarization of the reflected wave (axial ratio, tilt angle, and handedness). Also, determine the field of the inhomogeneous transmitted plane wave. The parameters of the ocean water are assumed to be \(\hat{\varepsilon}=78\) and \(\sigma=4 \mathrm{~S} / \mathrm{m}\).

\section*{Solution}

The geometry of the incident and reflected waves is shown in Fig. 6. The incident plane wave is represented as
\(\boldsymbol{E}^{\mathrm{inc}}=E_{0}[\hat{\boldsymbol{x}}+\hat{\boldsymbol{u}}(-j)] e^{-j\left(k_{y} y+k_{z 1} z\right)}\)
where
\(k_{y}=k_{0} \sin \theta=\frac{1}{2} k_{0}\)
\(k_{z 1}=k_{0} \cos \theta=\frac{\sqrt{3}}{2} k_{0}\)
\(\hat{\boldsymbol{u}}=\hat{\boldsymbol{y}} \cos \theta-\hat{\boldsymbol{z}} \sin \theta\).
The reflected wave is represented as
\(\boldsymbol{E}^{\mathrm{ref}}=E_{0}[A \hat{\boldsymbol{x}}+B \hat{\boldsymbol{v}}] e^{-j\left(k_{y} y-k_{z 0} z\right)}\)
where
\(\hat{\boldsymbol{v}}=-\hat{\boldsymbol{y}} \cos \theta-\hat{\boldsymbol{z}} \sin \theta\).

Figure 6. Geometry that defines the coordinate system for the example of a plane wave reflecting from the surface of the ocean.

The \(x\) component of the incident and reflected waves corresponds to \(\mathrm{TE}_{z}\) waves, while the \(u\) and \(v\) components correspond to \(\mathrm{TM}_{\mathrm{z}}\) waves. (The \(u\) and \(v\) directions substitute for the \(y\) direction in the previous discussion on polarization.) The transverse equivalent network is shown in Fig. 3.

From Eqs. (82) and (83), the impedances are \(Z_{1}^{T M}=326.258 \Omega, \quad Z_{1}^{T E}=435.011 \Omega\),
\(Z_{2}^{T M}=34.051+j(13.269) \Omega, Z_{2}^{T E}=34.089+j(13.346) \Omega\). The reflection coefficients are then \(\Gamma^{T M}=-0.808535+j(0.066600)\) and \(\Gamma^{T E}=-0.853161+j(0.052724)\).

The coefficient \(A\) in Eq. (94) is determined directly from
\[
\begin{equation*}
A=\Gamma^{T E}=-0.853161+j(0.052724) . \tag{97}
\end{equation*}
\]

To determine the coefficient \(B\), recall that the voltages in the transverse equivalent network model only the transverse (horizontal) component of the electric field (the \(y\) component in the TM case). Hence,
\[
\begin{equation*}
-B E_{0} \cos \theta^{\mathrm{ref}}=\Gamma^{T M} E_{0}(-j) \cos \theta^{\mathrm{inc}} \tag{98}
\end{equation*}
\]

Since \(\theta^{\text {inc }}=\theta^{\text {ref }}=\theta, B\) is determined directly as
\[
\begin{equation*}
B=\Gamma^{T M}(j)=\Gamma^{T M}=-0.066600-j(0.808535) . \tag{99}
\end{equation*}
\]

The percent power reflected is calculated from
\[
\begin{equation*}
P_{\%}^{\mathrm{ref}}=100\left(\frac{\frac{1}{2}\left[\frac{|A|^{2}}{Z_{1}^{T E}}+\frac{|B \cos \theta|^{2}}{Z_{1}^{T M}}\right]}{\frac{1}{2}\left[\frac{1}{Z_{1}^{T E}}+\frac{|-j \cos \theta|^{2}}{Z_{1}^{T M}}\right]}\right) \tag{100}
\end{equation*}
\]
which yields
\[
\begin{equation*}
P_{\%}^{\mathrm{ref}}=69.441 . \tag{101}
\end{equation*}
\]

Hence \(30.559 \%\) of the incident power is transmitted into the ocean.
The phase angle between the \(v\) and \(x\) components of the reflected field is
\[
\begin{equation*}
\phi=\angle B-\angle A=88.827^{\circ} \tag{102}
\end{equation*}
\]

Hence, the reflected wave is a left-handed elliptically polarized wave.

The parameter \(\gamma\) is determined from the ratio of the magnitudes of the \(v\) and \(x\) components of the reflected field as
\[
\begin{equation*}
\gamma=\tan ^{-1}\left(\frac{|B|}{|A|}\right)=43.504^{\circ} . \tag{103}
\end{equation*}
\]

From the formulas in the Polarization section, the tilt angle \(\tau\) of the polarization ellipse from the \(x\) axis (towards the positive \(v\) axis) is then
\[
\begin{equation*}
\tau=10.690^{\circ} \tag{104}
\end{equation*}
\]
and the polarization parameter \(\xi\) is
\[
\begin{equation*}
\xi=43.393^{\circ} . \tag{105}
\end{equation*}
\]

The axial ratio of the reflected wave is then
\[
\begin{equation*}
A R=+\cot \xi=1.058 \tag{106}
\end{equation*}
\]

The reflected wave is nearly CP, since the ocean is highly reflecting (if the ocean were replaced by a perfect conductor, the reflected wave would be LHCP).

The transmitted field in the ocean is represented as
\[
\begin{equation*}
\boldsymbol{E}^{\mathrm{trans}}=E_{0}[\hat{\boldsymbol{x}} C+\hat{\boldsymbol{y}} D+\hat{\boldsymbol{z}} E] e^{-j\left(k_{y} y-k_{z z} z\right)} \tag{107}
\end{equation*}
\]
where \(k_{z 2}\) is the vertical wavenumber in the ocean, found from Eq. (31) as
\[
\begin{equation*}
k_{z 2}=k_{2} \cos \theta_{t}=k_{0} n_{2} \sqrt{1-\left(\frac{1}{n_{2}}\right)^{2} \sin ^{2} \theta}=k_{0}(9.582527-j 3.751642) . \tag{108}
\end{equation*}
\]

From the transverse equivalent network,
\[
\begin{equation*}
C=T^{T E}=1+\Gamma^{T E}=0.146839+j(0.052724) \tag{109}
\end{equation*}
\]
and
\[
\begin{equation*}
D=T^{T M}(-j \cos \theta)=\left(1+\Gamma^{T M}\right)(-j \cos \theta)=0.057678-j(0.165813) \tag{110}
\end{equation*}
\]

The \(z\) component of the transmitted field can be determined from the electric Gauss law (20), which gives
\[
\begin{equation*}
E=-\frac{1}{k_{z 2}}\left(k_{y} D\right) . \tag{111}
\end{equation*}
\]

Hence,
\[
\begin{equation*}
E=-0.0055466+j(0.00648030) . \tag{112}
\end{equation*}
\]

From the wavenumbers \(k_{y}\) and \(k_{z 2}\) the direction angles of the transmitted wave may be determined from Eqs. (29) - (31). The results are
\[
\begin{align*}
& \phi=90^{\circ}  \tag{113}\\
& \theta_{t}=0.045227+j(0.017679) \text { radians . } \tag{114}
\end{align*}
\]

The transmitted plane wave is inhomogeneous, since the angle \(\theta_{t}\) is complex.

\subsection*{42.06.07 Generic Solution for ElectroMagnetic MPW in Ohmic LHI Media}

Here a different way to solve for ElectroMagnetic MPW is presented.
Look for MPW solutions, that is solutions that only depends on time and on the coordinate measured along some fixed arbitrary direction, \(\xi\), along the unit vector \(\hat{\mathbf{n}}\). This means that at any time the vectors \(\mathbf{E}\) and \(\mathbf{B}\) are constant over planes normal to \(\hat{\mathbf{n}}\). These planes are defined by the relation:
\[
\mathbf{x} \cdot \mathbf{n}=\text { constant }
\]

The fields assume therefore the following form:
\[
\mathbf{E}=\mathbf{E}[\xi, t] \quad \mathbf{B}=\mathbf{B}[\xi, t]
\]

One also has the following relations, for any vector field, \(\mathbf{V}\) :
\[
\begin{aligned}
\boldsymbol{\nabla} \mathbf{V} & =\hat{\mathbf{n}} \frac{\partial \mathbf{V}}{\partial \xi} \\
\operatorname{rot} \mathbf{V} & =\frac{\partial}{\partial \xi}(\mathbf{n} \times \mathbf{V}) \\
\operatorname{div} \mathbf{V} & =\frac{\partial}{\partial \xi}(\mathbf{n} \cdot \mathbf{V})
\end{aligned}
\]

One then finds:
\[
\begin{array}{r}
\frac{\partial^{2} \mathbf{E}}{\partial \xi^{2}}-\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \frac{\partial^{2} \mathbf{E}}{\partial t^{2}}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{E}=\mathbf{0}  \tag{42.06.29}\\
\frac{\partial^{2} \mathbf{B}}{\partial \xi^{2}}-\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \frac{\partial^{2} \mathbf{B}}{\partial t^{2}}-\sigma \mu_{\mathrm{R}} \mu_{0} \partial_{t} \mathbf{B}=\mathbf{0}
\end{array}
\]

From the 3rd Maxwell Equation and 4th Maxwell Equation it follows that:
\[
\hat{\mathbf{n}} \cdot\left(\epsilon_{\mathbf{R}} \varepsilon_{0} \partial_{t} \mathbf{E}+\sigma \mathbf{E}\right)=0 \quad \hat{\mathbf{n}} \cdot \partial_{t} \mathbf{B}=0
\]
while the first and second Maxwell Equation imply:
\[
\hat{\mathbf{n}} \cdot \frac{\partial \mathbf{E}}{\partial \xi}=0 \quad \hat{\mathbf{n}} \cdot \frac{\partial \mathbf{B}}{\partial \xi}=0 .
\]

Therefore
\[
\begin{equation*}
\hat{\mathbf{n}} \cdot\left(\mathrm{d} \mathbf{E}+\frac{\sigma}{\epsilon_{\mathrm{R}} \varepsilon_{0}} \mathbf{E} \mathrm{~d} t\right)=0 \quad \hat{\mathbf{n}} \cdot \mathrm{~d} \mathbf{B}=0 \tag{42.06.30}
\end{equation*}
\]

Equations (42.06.30) prove that:
- transversality of the ElectroMagnetic waves;
- the \(\xi\)-component of the magnetic field cannot vary in time nor along \(\hat{\mathbf{n}}\), as a consequence of the fact that the fields are assumed to be constant over planes perpendicular to the \(\hat{\mathbf{n}}\) axis at any time;
- the \(\xi\)-component of the electric field satisfies the equation
\[
\frac{\mathrm{d} E_{\xi}}{\mathrm{d} t}+\frac{\sigma}{\epsilon_{\mathrm{R}} \varepsilon_{0}} E_{\xi}=0
\]
- if the conductivity is non zero, the longitudinal component of the electric field decays exponentially with a decay time given by the relaxation constant;
- a static electric field cannot be maintained inside a conductor;
- inside a perfect Polarizable material medium (that is perfectly insulator) a longitudinal component may be present, but it does not depend on time.

© |JChenEtAI|ExpressionsOfStoredAndDissipatedElectroMagneticEnergyDensities - WEB - URL|Definitive!|
In generic material media the simple picture of mutually perpendicular electric and magnetic field, perpendicular to the direction of propagation, must be abandoned, in general.
In general the transversality property of ElectroMagnetic waves no longer holds when they propagate in dissipative media, including LHI dissipative media. In this respect dissipative media can be either conducting media and|or dielectric (that is insulator) media with an imaginary part of the ElectricPermittivity. Read §50-ElectroMagnetic Waves in Matter.
Both the Electric-Permittivity and the Magnetic-Permeability depend in general on the frequency, in addition to be complex:
\[
\begin{equation*}
\epsilon_{\mathrm{R}}[\omega] \equiv \operatorname{Re}\left(\epsilon_{\mathrm{R}}[\omega]\right)+\beth \operatorname{Im}\left(\epsilon_{\mathrm{R}}[\omega]\right) \quad \mu_{\mathrm{R}}[\omega] \equiv \operatorname{Re}\left(\mu_{\mathrm{R}}[\omega]\right)+\beth \operatorname{Im}\left(\mu_{\mathrm{R}}[\omega]\right) \tag{42.08.01}
\end{equation*}
\]

Therefore, also the refractive index and wave impedance are in general complex.
The real and imaginary parts of the Electric-Permittivity and the Magnetic-Permeability are not independent of each other. They are related by the Kramer-Krönig relations. Moreover, the imaginary part of the Electric-Permittivity is closely related to the current inside the material via the Ohm relation \(\mathbf{j}^{\mathrm{F}}=\sigma \mathbf{E}\).

For an ElectroMagnetic MPW the power loss per unit volume is:
\[
\begin{equation*}
\left.\left.\frac{\mathrm{d} \varepsilon}{\mathrm{~d} t \mathrm{~d} V}=\frac{\omega}{2}\left(\operatorname{Im}\left(\epsilon_{\mathrm{R}}[\omega]\right)|\mathbf{E}|^{2}+\operatorname{Im}\left(\mu_{\mathrm{R}}[\omega]\right)|\mathbf{H}|^{2}\right)=\omega\left(\left.\operatorname{Im}\left(\epsilon_{\mathrm{R}}[\omega]\right)\langle | \mathbf{E}\right|^{2}\right\rangle+\left.\operatorname{Im}\left(\mu_{\mathrm{R}}[\omega]\right)\langle | \mathbf{H}\right|^{2}\right\rangle\right) \tag{42.08.02}
\end{equation*}
\]
where \(\mathbf{E}\) and \(\mathbf{H}\) are the real fields, and the bar denotes an average with respect to time.
In general, the absorption (dissipation) of energy is determined by the imaginary parts of \(\epsilon_{\mathrm{R}}[\omega]\) and \(\mu_{\mathrm{R}}[\omega]\). The two terms in (42.08.02) are called the electric and magnetic losses.
In passive media, the sign of these losses is determinate: the energy is dissipated, therefore:
\[
\begin{equation*}
\operatorname{Im}\left(\epsilon_{\mathrm{R}}[\omega]\right) \geq 0 \quad \operatorname{Im}\left(\mu_{\mathrm{R}}[\omega]\right) \geq 0 \tag{42.08.03}
\end{equation*}
\]
for all substances and at all (positive) frequencies.
The signs of the real parts of \(\epsilon_{\mathrm{R}}[\omega]\) and \(\mu_{\mathrm{R}}[\omega]\) are subject to no physical restriction. The so-called lefthanded materials, have both the real part of the Electric-Permittivity and magnetic negative § 50.03 ElectroMagnetic Waves in Matter.
For passive materials the imaginary part of the refractive index has to be positive
\[
\begin{equation*}
\operatorname{Im}(\mathrm{n}[\omega]) \geq 0 \tag{42.08.04}
\end{equation*}
\]
which guarantees that the amplitude of the wave decreases in an absorbing material.

Any non-steady process in an actual body is to some extent thermodynamically irreversible. The electric and magnetic losses in a variable ElectroMagnetic field therefore always occur to some extent, however slight. That is, the functions \(\operatorname{Im}\left(\epsilon_{\mathrm{R}}[\omega]\right)\) and \(\operatorname{Im}\left(\mu_{\mathrm{R}}[\omega]\right)\) are not exactly zero for any frequency other than zero, although it does not exclude the possibility of only very small losses in certain frequency ranges. Such ranges, in which the imaginary parts of the Electric-Permittivity and Magnetic-Permeability are very small in comparison with the real parts, are called transparency ranges. It is possible to neglect the absorption in these ranges and to introduce the concept of the internal energy of the body in the ElectroMagnetic field, in the same sense as in a static field. To determine this quantity, it is not sufficient to consider a purely monochromatic field, since the strict periodicity results in no steady accumulation of ElectroMagnetic energy. Let us therefore consider a field whose components have frequencies in a narrow range about some mean value \(\omega_{0}\).

The steady rate of change of the energy in unit volume neglecting the imaginary parts of the ElectricPermittivity and Magnetic-Permeability is given by:
\[
\begin{equation*}
\left.\left.\frac{\mathrm{d} \mathcal{E}}{\mathrm{~d} V}=\frac{1}{2}\left(\left.\frac{\mathrm{~d}\left(\omega \operatorname{Re}\left(\epsilon_{\mathrm{R}}[\omega]\right)\right)}{\mathrm{d} \omega}\langle | \mathbf{E}\right|^{2}\right\rangle+\left.\frac{\mathrm{d}\left(\omega \operatorname{Re}\left(\mu_{\mathrm{R}}[\omega]\right)\right)}{\mathrm{d} \omega}\langle | \mathbf{H}\right|^{2}\right\rangle\right) \tag{42.08.05}
\end{equation*}
\]
where \(\mathbf{E}\) and \(\mathbf{H}\) are the real fields. This is the required result: the mean value of the ElectroMagnetic part of the internal energy per unit volume of a transparent medium. If there is no dispersion, ElectricPermittivity and Magnetic-Permeability are constants, and equation (42.08.05) becomes the mean value of the rate of change of ElectroMagnetic energy:
\[
\begin{equation*}
\left.\left.\frac{\mathrm{d} \varepsilon}{\mathrm{~d} V}=\frac{1}{2}\left(\left.\epsilon_{\mathrm{R}}[\omega] \varepsilon_{0}\langle | \mathbf{E}\right|^{2}\right\rangle+\left.\mu_{\mathrm{R}}[\omega] \mu_{0}\langle | \mathbf{H}\right|^{2}\right\rangle\right) \tag{42.08.06}
\end{equation*}
\]
as it should.

\section*{Maxwell Equations With a Generic Harmonic Time Dependence}

Consider the ElectroMagnetic fields with harmonic time-dependence:
\[
\overline{\mathbf{E}}[\mathbf{x}, t] \equiv \overline{\mathbf{E}}[\mathbf{x}] \exp [-\beth \omega t] \quad \overline{\mathbf{B}}[\mathbf{x}, t] \equiv \overline{\mathbf{B}}[\mathbf{x}] \exp [-\beth \omega t]
\]

Consider also the sources with harmonic time dependence:
\[
\bar{\rho}[\mathbf{x}, t] \equiv \bar{\rho}[\mathbf{x}] \exp [-\beth \omega t] \quad \overline{\mathbf{j}}[\mathbf{x}, t] \equiv \overline{\mathbf{j}}[\mathbf{x}] \exp [-\beth \omega t] .
\]

Note that, even if the same symbols are used to denote the general (time-harmonic) field/source and the space-dependent part of the harmonic field/source itself, this should cause no confusion because the first one depends on \([\mathbf{x}, t]\), while the second one only depends on time.
Maxwell Equations with harmonic time-dependence read:
\[
\begin{aligned}
\operatorname{div} \overline{\mathbf{E}}[\mathbf{x}] & =\bar{\rho}[\mathbf{x}] / \varepsilon_{0}, \\
\operatorname{div} \overline{\mathbf{B}}[\mathbf{x}] & =0, \\
\operatorname{rot} \overline{\mathbf{E}}[\mathbf{x}] & =+\beth \omega \overline{\mathbf{B}}[\mathbf{x}], \\
\operatorname{rot} \overline{\mathbf{B}}[\mathbf{x}] & =-\beth \varepsilon_{0} \mu_{0} \omega \overline{\mathbf{E}}[\mathbf{x}]+\mu_{0} \overline{\mathbf{j}}[\mathbf{x}] .
\end{aligned}
\]

These are sometimes called the time-independent Maxwell Equations, implicitly referring to a harmonic time dependence. The equations can be combined to give the vector Helmholtz equation for the Electric|Magnetic fields:
\[
\begin{aligned}
& \nabla^{2} \overline{\mathbf{E}}[\mathbf{x}]+\frac{\omega^{2}}{c^{2}} \overline{\mathbf{E}}[\mathbf{x}]=0, \\
& \nabla^{2} \overline{\mathbf{B}}[\mathbf{x}]+\frac{\omega^{2}}{c^{2}} \overline{\mathbf{B}}[\mathbf{x}]=0 .
\end{aligned}
\]

\section*{Doppler Effect for ElectroMagnetic Waves}

This § is referenced at pages:
[1987, 1987, 2016, 2016]
Let us only consider ElectroMagnetic waves in vacuum.
Only the relative motion between the generator and the observer is relevant for ElectroMagnetic waves. EM waves in vacuum have the same speed for any observer. This is one of bases of the special theory of relativity.
Read §54.02 - Relativistic Kinematics.
Compare with the Doppler effect for mechanical waves § 41.10-Mechanical Waves.

\section*{Radar}

The Doppler effect can be used by a radar to measure the velocity of detected moving objects.

\section*{Cherenkov and Transition Radiation for ElectroMagnetic Waves}

\subsection*{42.13.01 Cherenkov Radiation}

This § is referenced at pages:
[2178, 2178]
It appears when a charged particle moves in a medium with a speed, \(\mathbf{V}\), larger than the speed of ElectroMagnetic waves in the medium (refractive index of the medium: \(n\) ). It is in fact a kind of shockwave producing a kind of shock-wave with axial symmetry around the velocity of the particle at an angle from the velocity given by:
\[
\cos \theta_{c}=\frac{c}{n V}
\]

\subsection*{42.13.02 Transition Radiation}

This § is referenced at pages:
[2178, 2178]
It appears when a charged particle crosses the boundary between two media with different characteristics.

This § is referenced at pages:
[2114, 2114, 2114, 2114]
In this section the word light will be often use as a synonym of electromagnetic waves.
Many important effects depend on the Polarization status of ElectroMagnetic radiation.
ElectroMagnetic MPW will be typically considered.
It should be noted that the effects studied in this section require a material medium which fails to fulfill some of the assumptions commonly used so far: homogeneity, isotropy and linearity, zero conductivity, the constraint that the Electric-Permittivity | Magnetic-Permeability are fixed (real) numbers only dependent of the material.
The media considered here cannot be modeled as a perfect media. Therefore the phenomena discussed in this section, strictly speaking, fall outside the domain of validity of the theory developed so far. However thanks, basically, to the assumed linearity they may be understood, in the simple form presented here, by using in a appropriate way the theory developed so far.
It is clear that removing some of the properties of a perfect medium may lead to new effects as Polarization of light induces a preferential direction and|or a preferential handedness. In fact since linearly Polarized light itself is endowed with a preferred direction, it may interact in a different way with systems which are not isotropic in the plane perpendicular to the wave-vector. If that is the case light with different linear Polarization may have different absorption and|or phase speed, for instance. Moreover, since circularly Polarized light itself is endowed with a chiral character, it may interact in a different way with chiral molecules. If that is the case light with different circular Polarization may have different absorption and|or phase speed, for instance.

\subsection*{42.14.01 Non-Perfect Media: Dichroism (Selective Absorption)}

The absorption coefficient (see equation (42.04.01)) depends on the Polarization state of light, that is on the direction of the ElectroMagnetic fields (for linear Polarization) or on the handedness of the ElectroMagnetic fields (for circular Polarization).

\subsection*{42.14.01.01 Linear Dichroism}

Typically there exists a preferred direction such that light impinging on the material at right angles with respect to the preferred direction suffers little (minimum) attenuation, when it is linearly Polarized along the preferred direction, while suffers a large (maximum) attenuation while it is Polarized along an orthogonal direction to the preferred direction. It is actually a linear polariser. The transmission axis is defined as the direction of the electric field when light suffers the minimum absorption.
The existence of dichroism experimentally demonstrates that ElectroMagnetic waves are (at least partially) transverse waves, because for longitudinal waves one would not expect a dependence of the transmission on the angle of rotation of the transmission axis in a plane perpendicular to the propagation axis of the wave.

\section*{Examples}

Polaroid: preferred direction created by the manufacturing process. It is made of highly-dichroic crystals inside a plastic material.

Tourmaline: little efficiency.
Malus law
The transmitted intensity when light is linearly Polarized at an angle \(\theta\) with the transmission axis is given by:
\[
I[\theta]=I_{0} \cos ^{2} \theta,
\]
in terms of the incoming light intensity, \(I_{0}\).
In case of un-Polarized light the transmitted intensity is half of the incoming intensity, as it is clear by averaging the \(\cos ^{2} \theta\).

\section*{Examples and Applications}
- Two linear polarisers at \(\pi / 2\) each other: no ElectroMagnetic radiation is transmitted, whatever the Polarization of the incident beam.
- un-Polarized light going across two linear polarisers at \(\pi / 2\) each other; add another one in between, not parallel to any of the other two: some ElectroMagnetic radiation is now transmitted.
The intensity of the transmitted radiation is: \(I_{0} \cos ^{2} \alpha \sin ^{2} \alpha\) as a function of the angle \(\alpha\) between the direction of the intermediate polariser and the direction of one of the others two.
This is a quantum-like phenomenon.

\subsection*{42.14.01.02 Circular Dichroism}

Circular dichroism, is the differential absorption of left-handed and right-handed circularly Polarized light.

Circular dichroism makes a linearly polarized ElectroMagnetic wave to become elliptically polarized.
See section § 42-021 - ElectroMagnetic Waves.
See § ?? - ??.

\subsection*{42.14.02 Non-Perfect Media: Birefringence}

\subsection*{42.14.02.01 Linear Birefringence}

The phase-velocity of the wave depends on the linear Polarization state of the wave, that is on the direction of the ElectroMagnetic field.
The different phase-velocity can introduce a difference of the phases of the \(x\) and \(y\) axes components, so that, while passing the medium, the Polarization state changes.
The simplest type of linear birefringence is that of materials with so-called uni-axial anisotropy: the structure of the material is such that it has an axis of symmetry with all perpendicular directions optically equivalent. This axis is known as the optical axis of the material. The two different indices of refraction, along and perpendicular to the optical axis, are known as extraordinary and ordinary.

\section*{Quarter-Wave and Half-Wave Lamina}

With a suitable preparation (that is a suitable cutting) of the birefringent material one can build a slab such that two orthogonal axes there exist in the plane of the slab, (the fast and slow axis), such that ElectroMagnetic radiation linearly Polarized along one of the two axes impinging on the slab will be still linearly Polarized along the same direction at the exit of the slab, but the phase velocities are different along the two axes.
Assume a MPW, linearly Polarized, propagating along the \(z\) direction. At \(z=0\) it meets a planar lamina perpendicular to the \(z\) axis and ending at \(z=H\). Let the \(x\) axis be the fast axis and the \(y\) axis be the slow axis \(\left(n_{y}>n_{x}\right.\) and \(\left.v_{y}<v_{x}\right)\) and let \(\Delta n \equiv\left(n_{y}-n_{x}\right) \geq 0\). The phase of each wave is:
\[
\Phi=k z-\omega t-\phi=\frac{\omega}{v} z-\omega t-\phi=\frac{\omega}{c} n z-\omega t-\phi
\]

Assuming that the \(x\) and \(y\) components are in phase at \(z=0\), the difference in the phase of the two \(x\) and \(y\) components at the exit of the lamina, \(z=H\), at any time, is the time-independent quantity:
\[
\begin{equation*}
\Delta \Phi \equiv \Phi_{y}-\Phi_{x}=\frac{\omega}{c} n_{y} H-\frac{\omega}{c} n_{x} H=\frac{\omega}{c} H\left(n_{y}-n_{x}\right) \equiv \frac{\omega}{c} H \Delta n=k_{0} H \Delta n=\frac{2 \pi}{\lambda_{0}} H \Delta n . \tag{42.14.01}
\end{equation*}
\]

In the general case of phase constants \(\phi_{y}\) and \(\phi_{x}\) at \(z=0\) the above relation simply generalizes to:
\[
\begin{equation*}
\Delta \Phi \equiv \Phi_{y}-\Phi_{x}=k_{0} H \Delta n+\Delta \phi=\frac{2 \pi}{\lambda_{0}} H \Delta n+\Delta \phi \tag{42.14.02}
\end{equation*}
\]

In the most general case a lamina of birefringent material thus setup will change an elliptic Polarization into another elliptic Polarization with a different \(\Delta \phi\). Exchanging linear and circular Polarization are special cases, all cases being described by relation (42.14.02).
Note that the change of phase depends on the wavelength.

\section*{Quarter-Wave Lamina}

Consider a linearly Polarized MPW with Polarization at \(\theta=+\pi / 4\) or \(\theta=-3 \pi / 4(\theta=-\pi / 4\) or \(\theta=+3 \pi / 4)\) on the \(x y\) plane: the two components \(E_{x}\) and \(E_{y}\) have the same amplitude and same phase (opposite phase) at the entrance. A quarter-wave lamina is such that:
\[
|\Delta \Phi|=\pi / 2+q \pi \quad q \text { any natural number (non-negative integer number) . }
\]

In order to have the solution with minimum thickness one has to choose \(q=0\) and then:
\[
\begin{equation*}
\frac{\omega}{c} H \Delta n=\pi / 2 \Longrightarrow H=\frac{\lambda_{0}}{4 \Delta n}, \tag{42.14.03}
\end{equation*}
\]
where \(\lambda_{0}\) is the vacuum wavelength. Under the previous conditions the wave is circularly Polarized at the exit of the lamina. Different choices of the natural number \(q\) will give a lamina thicker than the minimum possible thickness given by equation (42.14.03).
In the general case when \(\theta\) is arbitrary the light exits elliptically Polarized, except for \(\theta= \pm \pi / 4\) and \(\theta= \pm 3 \pi / 4\) (circular Polarization) and \(\theta=q \pi / 2\) with \(q\) any integer (linear Polarization).
If a quarter-wave lamina is reached by a circularly Polarized MPW a linear Polarization is found at the exit.
Stacking two quarter-wave laminae one after the other one finds at the exit a linear Polarization perpendicular to the Polarization at the entrance. The device is known as a half-wave lamina.
A quarter-wave lamina which converts linear to circular Polarization (or vice-versa) receives an angular momentum from the ElectroMagnetic wave as described in section § 42.05-ElectroMagnetic Waves.

\section*{Half-Wave Lamina}

A half-wave lamina is such that:
\[
|\Delta \Phi|=(q+1) \pi \quad q \text { any natural number (non-negative integer number) }
\]

In order to have the solution with minimum thickness one has to choose \(q=0\) and then:
\[
\begin{equation*}
\frac{\omega}{c} H \Delta n=\pi \Longrightarrow H=\frac{\lambda_{0}}{2 \Delta n} \tag{42.14.04}
\end{equation*}
\]

A half-wave lamina will change a circularly Polarized MPW into a circularly Polarized MPW of opposite handedness.

\subsection*{42.14.02.02 Circular Birefringence}

This § is referenced at pages:
[1755, 1755]
The phase-velocity of the wave depends on the circular Polarization state of the wave, that is on the chirality of the ElectroMagnetic fields and molecules. See § ?? - ??.
The different phase-velocity can introduce a difference of the phases of the left/right components, so that, while passing the medium, the Polarization state changes.
Circular birefringence is often known as optical activity. It may exist in isotropic media as well.
Circular birefringence depends on the existence of a Quadrupole moment of the elementary microscopic charge distribution: therefore it cannot be described simply in terms of the Polarization and Magnetization of the matter, which only describe Dipole moments of the elementary microscopic charge distribution. It appears in materials such that the refractive index for right-handed circularly Polarized waves is different from the refractive index for left-handed circularly Polarized waves:
\[
n_{R} \neq n_{L}
\]

It is due to the handedness of elementary constituents of matter (for instance sugar molecules).
The effect is to rotate the direction of Polarization of linearly Polarized ElectroMagnetic waves. The rotation does not depend on the initial orientation of the linear Polarization. The effect is obvious from equation (42.03.02). It must not be confused with circular Polarization: in circular Polarization the electric field of the ElectroMagnetic wave at the same place rotates in the plane perpendicular to the direction of propagation while in circular birefringence the ElectroMagnetic wave is linearly Polarized at any point but the direction of Polarization changes at different points.
circular birefringence is often masked by linear birefringence.

\subsection*{42.14.03 Electro-Optics and Magneto-Optics Effects}

\subsection*{42.14.03.01 Linear Birefringence Induced by Electric Fields}

The Pockels and Kerr effects are the linear birefringence induced by an external electric field.
Certain materials exhibit a linear (Pockels) electro-optic effect, linear in the applied electric field. Many isotropic transparent materials and all crystals exhibit a quadratic (Kerr) electro-optic effect, quadratic in the applied field:
\[
\Delta n=K_{E} \lambda E^{2} .
\]

\subsection*{42.14.03.02 Linear Birefringence Induced by Magnetic Fields}

The Voigt and Cotton-Mouton effects are the birefringence induced by an external magnetic field.
Some materials exhibit a linear (Voigt) magneto-optic effect, linear in the applied magnetic field. Some materials exhibit a quadratic (Cotton-Mouton) magneto-optic effect, quadratic in the applied field:
\[
\Delta n=K_{B} \lambda B^{2}
\]

\subsection*{42.14.03.03 Linear Birefringence Induced by Mechanical Stresses}

Birefringence is also induced by mechanical stresses.

\subsection*{42.14.03.04 Induced Circular Birefringence}

The Faraday effect is circular birefringence induced by an external magnetic field.
The Verdet law apply:
\[
\Delta \alpha=V B \Delta z \cos \theta_{B}
\]
42.14.04 Polarization of ElectroMagnetic Waves in Nature and Technology

WEB - URL

This § is referenced at pages:
[2032, 2032]
© \(\mathbb{C}\). Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|||
As often, light is used as a synonym of ElectroMagnetic radiation.
An ordinary and natural light source typically consists of a huge number of atomic/molecular light emitters whose positions and orientations are random in space. Excited Atoms|Molecules typically radiate Polarized wave-trains for times of the order of \(\Delta \tau \approx 10^{-8} \mathrm{~s}\), the so-called coherence time of the source (read § 48.02 - Interference Diffraction Wave-Fields and Coherence).
Different Atoms|Molecules and|or the same atom/molecule can emit at different frequencies. All the emitted ElectroMagnetic waves with the same frequency combine to form a single resultant Polarized ElectroMagnetic wave, which persists for times as long as \(\approx \Delta \tau\).
Wave-trains are continuously emitted so that the overall Polarization changes in a completely unpredictable way.
If these changes take place so quickly that any single resultant Polarization state cannot be identified, the ElectroMagnetic wave is referred to as natural light or un-Polarized light. However the name unPolarized light is misleading, since the light is composed of a rapidly varying succession of the different Polarization states. Therefore the name randomly Polarized is another way to name it.

As a results natural light is made of finite-length wave-trains with different frequencies, random relative Polarization and phases.
All in all, naturally produce ElectroMagnetic waves have the following characteristics different from the simple Polarized MPW discussed so far and requiring a more complex analysis (Read also § 40.03.13General Properties of Waves):
- real ElectroMagnetic waves may be approximated by plane ElectroMagnetic waves only at large distances from the sources.
- ElectroMagnetic waves at different frequencies may be present and the principle of superposition apply, read § 16 - Some Elements of Fourier Analysis;
- at any given frequency, instead of monochromatic (that is infinite length perfect sinusoids) wavetrains there exist finite length wave-trains, that is sinusoids, lasting for times \(\Delta \tau\), read § 16 - Some Elements of Fourier Analysis;
- each wave-train has a random Polarization (see section § 42.15.01 - ElectroMagnetic Waves);

\subsection*{42.15.01 Polarizers States and Degree of Polarization}

This § is referenced at pages:
[1986, 1986, 2043, 2043, 2044, 2044, 2113, 2113]
Solutions to Maxwell Equations are always Polarized ElectroMagnetic waves. Any superposition of solutions with arbitrary Polarization is a solution thanks to the linearity. A superposition of Polarized solutions with arbitrary Polarization gives partially Polarized (or totally un-Polarized) light.
The formalism describing Polarization states is the same formalism describing states in Quantum Physics.
The Polarization of ElectroMagnetic waves is perhaps the simplest example of quantum two-states system. Its full understanding provides a strong bridge to Quantum Physics.

\subsection*{42.15.01.01 Polarizers}

The degree of Polarization of non-Polarized radiation can be measured by means of polarisers, instruments capable to select a specific well-defined Polarization state from a beam of arbitrary Polarization. A Polarizer only transmits one specific Polarization state while absorbs all the rest.

A Polarizer is an instrument such that there exist at least one beam which is fully transmitted and at least one beam which is fully absorbed; moreover if the same beam is passed in sequence through two identical Polarizers the same intensity is found after that first Polarizer and after the sequence of two Polarizers:
\[
\begin{array}{|c}
\hline \text { there exist at least one beam such that } \mathcal{P} I_{0}=I=I_{0} \\
\begin{array}{|ll}
\hline \text { there exist at least one beam such that } \mathcal{P} I_{0}=0 \\
\hline \text { for any beam } \quad \mathcal{P P} I_{0}=\mathcal{P} I_{0} \Longrightarrow \mathcal{P}^{2}=\mathcal{P} \\
\hline
\end{array}
\end{array}
\]

\subsection*{42.15.01.02 States of Polarization}

Two Polarizers are said to select two orthogonal Polarization states if there exists at least one beam such that the first Polarizer leaves the beam un-attenuated while the second one absorbs it completely and there exists at least another beam such that the second Polarizer leaves the beam un-attenuated while the first one absorbs it completely. Then the two beams are said to carry orthogonal Polarization states. Therefore, if \(\mathcal{P}_{A}\) and \(\mathcal{P}_{B}\) are two orthogonal Polarizers
\[
\mathcal{P}_{A}^{2}=\mathcal{P}_{A} \quad \mathcal{P}_{B}^{2}=\mathcal{P}_{B} \quad \mathcal{P}_{A} \mathcal{P}_{B}=\mathcal{P}_{B} \mathcal{P}_{A}=0
\]

One example of orthogonal Polarization states are two radiation beams linearly Polarized along any two orthogonal directions.

A second example of orthogonal Polarization states are two radiation beams one carrying left circular Polarization and the other one carrying right circular Polarization.

\subsection*{42.15.01.03 Degree of Polarization}

Assuming to have Polarizers (read \(\S 42.14\) - ElectroMagnetic Waves) the degree of Polarization can be measured, at lest in principle, by considering the minimum and maximum intensities transmitted by all possible Polarizers and defining:
\[
\mathcal{P} \equiv \frac{I_{\mathrm{MAX}}-I_{\mathrm{MIN}}}{I_{\mathrm{MAX}}+I_{\mathrm{MIN}}}
\]

Actually: \(I_{\mathrm{MIN}}=0 \Longrightarrow \mathcal{P}=1\) and for \(I_{\mathrm{MAX}}=I_{\mathrm{MIN}} \Longrightarrow \mathcal{P}=0\).

\subsection*{42.15.01.04 Real Polarizers}
©|WEB - URL|||

How to construct a Polarizer is suggested by the discussion of the phenomenology of the Polarization of light in § 42.14 - ElectroMagnetic Waves. It is worth remembering the result of problem § 42-022ElectroMagnetic Waves.
Linear Polarizers: a sheet of linearly dichroic material (Polaroid, for instance).
Circular homogeneous Polarizer: a sheet of linearly dichroic material (Polaroid, for instance) sandwiched between two quarter-wave laminas with axes rotated by \(\pm \pi / 2\) with respect to one another with the transmission axis of the linearly dichroic material at \(\pm \pi / 4\) with respect to the fast/slow axes of the quarter-wave lamina.

Polarization of real ElectroMagnetic waves
The degree of Polarization of a general ElectroMagnetic wave is defined as the fraction of intensity of Polarized light with respect to the total light intensity:
\[
\mathcal{P} \equiv \frac{I_{\mathrm{P}}}{I_{\mathrm{P}}+I_{\mathrm{NP}}}
\]

Polarization of non Polarized light (in general: change of the degree of Polarization) can happen (among others means) by:
- reflection;
- scattering;
- polarisers.

\section*{ElectroMagnetic Spectrum and the Speed of Light}
©|WEB - URL|||
©|WEB - URL|||
The observation of stellar phenomena allows to quantify to a high degree the fact that vacuum is non dispersive at optical wavelengths.

42.17.05 EM Waves Radiated by an Infinite Neutral Plane Current Sheet

This § is referenced at pages:
[2130, 2130]
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|34.5||
Show that an infinite neutral plane current sheet at \(z=0\) with surface current \(\mathbf{j}_{\mathbf{S}}[x, y, t]=\mathbf{j}_{\mathrm{s}_{0}} \cos \omega t\), where \(\mathbf{j}_{\mathbf{S} 0}\) is a fixed vector in the \(x y\) plane, produces ElectroMagnetic MPW propagating in the \(\pm z\) direction.
Show that the Polarization of these ElectroMagnetic MPW is along \(\mathbf{j}_{\mathbf{s} 0}\).

\section*{SOLUTION}

Choose the direction of \(\mathbf{j}_{\mathbf{S} 0}\) as the \(x\) direction.
There can be no dependence on \(x\) and \(y\) but only on \(z\) (measuring the signed distance from the infinite sheet of current), so that partial derivatives with respect to \(x\) and \(y\). As a consequence, from the two Maxwell rotor equations at \(z \neq 0\), any component of the Electric|Magnetic field along \(z\), if it exists, is uniform and constant.

In fact, using the two Maxwell rotor equations at \(z \neq 0\) :
\[
\begin{gathered}
\frac{\partial()}{\partial x}=\frac{\partial()}{\partial y}=0, \\
\frac{\partial E_{z}}{\partial y}-\frac{\partial E_{y}}{\partial z}=-\frac{\partial E_{y}}{\partial z}=-\partial_{t} B_{x}, \\
\frac{\partial E_{x}}{\partial z}-\frac{\partial E_{z}}{\partial x}=+\frac{\partial E_{x}}{\partial z}=-\partial_{t} B_{y}, \\
\frac{\partial E_{y}}{\partial x}-\frac{\partial E_{x}}{\partial y}=0=-\partial_{t} B_{z}, \\
\frac{\partial B_{z}}{\partial y}-\frac{\partial B_{y}}{\partial z}=-\frac{\partial B_{y}}{\partial z}=+\frac{1}{c^{2}} \partial_{t} E_{x}, \\
\frac{\partial B_{x}}{\partial z}-\frac{\partial B_{z}}{\partial x}=+\frac{\partial B_{x}}{\partial z}=+\frac{1}{c^{2}} \partial_{t} E_{y}, \\
\frac{\partial B_{y}}{\partial x}-\frac{\partial B_{x}}{\partial y}=0=-\partial_{t} E_{z},
\end{gathered}
\]

Assume MPW along \(\pm z\), as required by symmetry.
At \(z=0\) the appropriate boundary conditions (equation (33.08)) must be satisfied:
\[
\hat{\mathbf{n}} \times \Delta \mathbf{B}_{\|}=\hat{\mathbf{n}} \times \Delta \mathbf{B}=\mu_{0} \mathbf{j}_{\mathrm{S}}
\]
with all the other boundary conditions automatically satisfied by the present choice of the ElectroMagnetic fields.
Therefore, immediately near the current sheet, on the two sides, one has the same electric field vector, at any point and any time, opposite wave-vector and opposite magnetic field vector, at any point and any time.
The conditions on the discontinuity of the magnetic field implies that the magnetic field vector is perpendicular to the current \(\mathbf{j}_{\mathbf{s} 0}\), that is along \(y\). Moreover, its module must be:
\[
B_{0}=\mu_{0}\left|\mathbf{j}_{\mathbf{s}_{0}}\right| / 2
\]

Therefore one can assume \(E_{x} \neq 0\) and \(E_{y}=0\) :
\[
E_{x}=E_{x 0} \cos k z-\omega t-\phi \quad E_{y}=0 .
\]

The above Maxwell Equations imply \(B_{x}=\) constant and
\[
-\frac{\partial B_{y}}{\partial z}=+\frac{1}{c^{2}} \partial_{t} E_{x} \Longrightarrow B_{y}=\ldots
\]

\subsection*{42.17.06 Complex Formalism for Polarization}

Show that a ElectroMagnetic MPW is linearly Polarized if and only if:
\[
\mathbf{E} \times \mathbf{E}^{\star}=0
\]

Any real vector gives a linearly Polarized wave.
Show that a MPW is circularly Polarized if and only if:
\[
\mathbf{E} \cdot \mathbf{E}=0 .
\]

Note the for complex vectors this does not imply at all that the vector is zero but only that the real and imaginary parts are orthogonal each other.

\subsection*{42.17.07 Cellular Phones}

A cell phone handset transmits \(P=1 \mathrm{~W}\) of power. What is the average Electric|Magnetic field at a distance of \(d=0.1 \mathrm{~m}\) from the handset? Assume the ElectroMagnetic wave propagates in air, whose ElectroMagnetic properties are quite similar to vacuum.

\subsection*{42.17.08 Average Value of the Poynting Vector and ElectroMagnetic Fields Near a Bulb-Lamp}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|||
Consider 200 W lamp isotropically emitting a fraction \(\eta=0.5\) of power, \(\Pi=100 \mathrm{~W}\), in the visible. The light from the lamp is carried by ElectroMagnetic radiation (see section § 42 - ElectroMagnetic Waves) and the energy flux (energy per unit time per unit area) is thus given by the Poynting vector.
Calculate the average value of the Poynting vector at a distance \(d=5 \mathrm{~m}\) from the lamp.
EM waves in vacuum have ElectroMagnetic fields linked by \(E=c B\) and there is little difference in air: determine the time average of the square of the Electric|Magnetic fields.

\section*{SOLUTION}
\[
\begin{gathered}
I=\langle S\rangle=\frac{\Pi}{4 \pi d^{2}}=0.31 \mathrm{~W} / \mathrm{m}^{2}, \\
I=\langle S\rangle=\frac{\left\langle E^{2}\right\rangle}{\mu_{0} c}=\frac{c\left\langle B^{2}\right\rangle}{\mu_{0}} \Longrightarrow\left\langle E^{2}\right\rangle=\mu_{0} c I, \\
\left\langle B^{2}\right\rangle=\mu_{0} I / c, \\
\langle E\rangle \equiv \sqrt{\left\langle E^{2}\right\rangle}=1.1 \cdot 10^{1} \mathrm{~V} / \mathrm{m}, \\
\langle B\rangle \equiv \sqrt{\left\langle B^{2}\right\rangle}=3.6 \cdot 10^{-8} \mathrm{~T} .
\end{gathered}
\]

Some comments are required.
\(\langle E\rangle\) is an appreciable macroscopic field, easly detectable in a Laboratory.
\(\langle B\rangle\) is very small, from the point of view of a Laboratory, because it has to be compared with the Earth magnetic field of the order of 0.5 gauss \(=0.5 \cdot 10^{-4} \mathrm{~T}\).
In practice instruments usually measure the electric field rather than the magnetic field.
However the average energy stored by Electric|Magnetic fields in ElectroMagnetic waves are the same and \(\langle E\rangle=c\langle B\rangle\). One cannot say the electric field in ElectroMagnetic waves is stronger than the magnetic field. One can only say that, when compared to typical fields on the Earth electric fields of ElectroMagnetic waves are relatively bigger than magnetic fields of EM waves are.

\subsection*{42.17.09 Sun-Bath}

The intensity of the solar radiation on top of the atmosphere is about \(I=1.2 \mathrm{~kW} / \mathrm{m}^{2}\). Neglecting the atmospheric absorption the radiation pressure is thus: \(p_{F} \approx 3 \cdot 10^{-6} \mathrm{~Pa}\).

\subsection*{42.17.10 Tails of Comets}

Small dust speckles are subject to both the gravitational attraction of the comet nucleus and the Sun radiation pressure: they are thrown away if they are too small as the gravitational force goes like the cube of the size of the particle, while the radiation pressure force goes like the square of of the size of the particle.
Both the radiation pressure force and the gravitational force goes like the inverse square distance from the Sun: depending on the size of the dust speckle one wins over the other.

\subsection*{42.17.11 Superposition of Two Monochromatic ElectroMagnetic MPW Along the Same Direction}

Consider the superposition of two monochromatic ElectroMagnetic MPW along the same direction with the same frequency in vacuum.
The resulting ElectroMagnetic wave is the linear superposition of the ElectroMagnetic fields.
Note, however, that the energy density and the Poynting vector do not sum:
\[
\begin{gathered}
u \equiv \frac{\varepsilon_{0}}{2}\left(\mathbf{E}_{1}+\mathbf{E}_{2}\right)^{2}+\frac{1}{2 \mu_{0}}\left(\mathbf{B}_{1}+\mathbf{B}_{2}\right)^{2} \neq u_{1}+u_{2}, \\
\mathbf{S} \equiv \frac{1}{\mu_{0}}\left(\mathbf{E}_{1}+\mathbf{E}_{2}\right) \times\left(\mathbf{B}_{1}+\mathbf{B}_{2}\right) \neq \mathbf{S}_{1}+\mathbf{S}_{2} .
\end{gathered}
\]

\subsection*{42.17.12 One Wave-Guide}

Visible light: \(\lambda \in[300 \mathrm{~nm} ; 700 \mathrm{~nm}]\) with \(\nu=c / \lambda \approx 10^{15} \mathrm{~Hz}\).
Propagation in a wave-guide: \(\omega=500 \mathrm{MHz}\) and \(\omega \geq \omega_{c}=p c \pi / \ell\) giving \(\ell \geq 0.3 \mathrm{~m}\).

©|A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....|§ 8.11||
Sound waves travel horizontally from a source to a receiver. Assume that the source has a speed \(u\), that the receiver has a speed \(v\) and that a wind of speed w is blowing from the source toward the receiver; all velocities are along the same direction. Assume that the source emits sound of frequency \(\nu_{0}\), and the speed of sound in still air is \(V\).
Calculate the frequency recorded by the receiver.
Note that if the velocities of source and receiver are equal, the existence of the wind makes no difference to the observed frequency of the received signal.

\section*{42-014 Example of a Solution to d'Alembert Equation}

Consider a divergence-less electric field which satisfies equation (42.01.01) and add an electric field with non-zero divergence and zero rotor. The resulting field, clearly, does not satisfy Maxwell Equations.
Show that the resulting field it nevertheless satisfies equation (42.01.01).

\section*{42-015 Most General One-Dimensional ElectroMagnetic Wave}

Consider a plane ElectroMagnetic wave propagating, in vacuum, in the positive \(z\) direction, with \(\mathbf{E}\) along the \(x\) axis (that is ElectroMagnetic wave Polarized along \(x\) ). Show that the most general solution to this problem is:
\[
\begin{aligned}
\mathbf{E}[\mathbf{x}, t] & =\hat{\mathbf{e}}_{1} f[k z-\omega t] \\
c \mathbf{B}[\mathbf{x}, t] & =\hat{\mathbf{e}}_{2} f[k z-\omega t]
\end{aligned}
\]
with \(f\) an arbitrary function.

\section*{42-016 General Elliptic Polarization}

Demonstrate equation (42.03.01).

\section*{SOLUTION}

The electric field at some fixed point at \(z=\bar{z}\), as a function of time, is:
\[
\begin{aligned}
& E_{x}=E_{x 0} \cos k \bar{z}-\omega t-\phi_{x} \equiv E_{x 0} \cos \mathcal{Z} \\
& E_{y}=E_{y 0} \operatorname{cosk} \bar{z}-\omega t-\phi_{y} \equiv E_{y 0} \cos \mathcal{Z}+\Delta \phi=E_{y 0}(\cos \mathcal{z} \cos \Delta \phi-\sin \mathcal{z} \sin \Delta \phi)
\end{aligned}
\]
with \(z \equiv\left(k \bar{z}-\omega t-\phi_{x}\right)\) and \(\Delta \phi \equiv \phi_{y}-\phi_{x}\). Then
\[
\begin{aligned}
\frac{E_{x}}{E_{x 0}} & =\cos \mathcal{Z} \\
\frac{E_{y}}{E_{y 0}}-\cos z \cos \Delta \phi & =-\sin z \sin \Delta \phi
\end{aligned}
\]
and summing after squaring both equations one finds equation (42.03.01).

\section*{42-017 General Elliptic Polarization: Special Cases}

Start from the general equation for elliptic Polarization, equation (42.03.01), and demonstrate under which conditions the Polarization is linear and circular.

\section*{42-018 Left and Right Elliptic Polarization}

This § is referenced at pages:
[2042, 2042, 2042, 2042]
Consider a MPW propagating along the positive direction of the \(z\) axis. The electric field at some fixed point at \(z=\bar{z}\), as a function of time, is:
\[
\begin{aligned}
& E_{x}=E_{x 0} \cos k \bar{z}-\omega t-\phi_{x}, \\
& E_{y}=E_{y 0} \cos k \bar{z}-\omega t-\phi_{y} .
\end{aligned}
\]

Show that an observer looking the incoming wave, that is looking towards the negative \(z\) axis, sees the electric field (and therefore also the magnetic field) vector rotating clockwise (negative helicity, righthanded Polarization) if \(\sin \Delta \phi \equiv \sin \phi_{y}-\phi_{x}>0\) and counter-clockwise (positive helicity, left-handed Polarization) if \(\sin \Delta \phi \equiv \sin \phi_{y}-\phi_{x}<0\).

\section*{SOLUTION}

\section*{First Solution}

Consider the vector \(\mathbf{E}\) in the \(x y\) plane. In analogy to the position vector, whose sense of rotation is given by the component along \(z\) of the angular momentum, one can calculate the projection on the \(z\) axis of the vector \(\mathbf{E} \times \dot{\mathbf{E}}\). The result is:
\[
\hat{\mathbf{e}}_{3} \cdot(\mathbf{E} \times \dot{\mathbf{E}})=E_{x 0} E_{y 0} \omega \sin -\Delta \phi
\]

\section*{Second Solution}

Consider the time-derivative of the electric field at a time when \(k \bar{z}-\omega t-\phi_{x}=0\). Its \(x\) component, at the chosen time, is zero, while its \(y\) component is:
\[
\dot{E}_{y}=+\omega E_{y 0} \sin k \bar{z}-\omega t-\phi_{x}-\Delta \phi=+\omega E_{y 0} \sin -\Delta \phi
\]

At the chosen time the \(x\) component of the electric field is positive and it takes its maximum value and its time derivative is zero.
At the chosen time the \(y\) component of the electric field has a time derivative which is positive if \(\Delta \phi<0\) (the sense of rotation is therefore counter-clockwise), while it is negative if \(\Delta \phi>0\) (the sense of rotation is therefore clockwise).

\section*{42-021 Circular dichroism on a linearly polarized ElectroMagnetic wave}

This § is referenced at pages:
[2109, 2109]
Show that circular dichroism makes a linearly polarized ElectroMagnetic wave to become elliptically polarized..

\section*{42-022 Intensity of an ElectroMagnetic Wave in Vacuum With Arbitrary Polarization}

This § is referenced at pages:
[2114, 2114]
Consider a ElectroMagnetic MPW moving in vacuum along the positive \(z\) direction, with electric field having the \(x\) and \(y\) components \(E_{x}\) and \(E_{y}\) and generic Polarization. Show that the intensity of the ElectroMagnetic wave can be written as:
\[
I=\frac{c \varepsilon_{0}}{2}\left(E_{x 0}^{2}+E_{y 0}^{2}\right) \equiv I_{x}+I_{y}
\]
whatever the phase relation between the \(x\) and \(y\) components of the fields.

\section*{SOLUTION}

Use the real representation of the fields.
\[
I=\langle | \mathbf{S}| \rangle=c \varepsilon_{0}\langle\mathbf{E} \cdot \mathbf{E}\rangle=c \varepsilon_{0}\left(E_{x 0}^{2} \cos ^{2} \ldots+E_{y 0}^{2} \cos ^{2} \ldots\right)=\frac{c \varepsilon_{0}}{2}\left(E_{x 0}^{2}+E_{y 0}^{2}\right)=I_{x}+I_{y} .
\]

Note that any pair of orthogonal Polarization states will give the same decomposition so that:
\[
\mathbf{E}_{01} \cdot \mathbf{E}_{02}=0 \Longrightarrow I=I_{1}+I_{2} .
\]

\section*{42-023 Radiation Pressure From the Sun at the Earth During a Sun-Bath}

Calculate the average pressure on a person taking a Sun-bath if the Sunlight intensity is of the order of \(I \approx 10^{1} \mathrm{~kW} / \mathrm{m}^{2}\).

\section*{42-024 Pressure From a Laser Pointer}

Estimate the pressure from a typical Laser pointer.

\section*{42-025 A Laser Pointer and Sun Radiation}

Assume that the same intensity of sunlight at the top of atmosphere, \(1.4 \mathrm{~kW} / \mathrm{m}^{2}\), reaches the Earth surface.
If you could safely look directly the sun at noon, estimate the power entering your eye. Assume the eye pupil can become as small as one mm diameter.
Compare the power with a typical safe laser pointer of a few mW .

\section*{42-026 Radiation Pressure at Oblique Incidence}

Consider a beam of MPW (this is an approximate description) at incidence \(\theta\) absorbed by a plane surface. Show that the normal radiation pressure (force per unit area perpendicular to the surface of separation) is given, in terms of the pressure the wave would give at normal incidence, as:
\[
\begin{equation*}
p[\theta]=p_{0} \cos ^{2} \theta . \tag{42.18.01}
\end{equation*}
\]

\section*{42-027 Radiation Pressure From un-Polarized Isotropic ElectroMagnetic Radiation}

Consider un-Polarized isotropic ElectroMagnetic radiation, with intensity \(I\), either absorbed or reflected by a plane surface. Show that the normal radiation pressure (force per unit area perpendicular to the surface of separation) is given, in terms of the pressure the wave wopuld give at normal incidence, as:
\[
p=\frac{I}{3 c} \quad \text { total absorption } \quad p=\frac{2 I}{3 c} \quad \text { total reflection } .
\]

\section*{42-028 Standing ElectroMagnetic waves}

Consider the standing wave:
\[
\begin{aligned}
& E_{x}=E_{x 0} \sin \omega t \sin k z, \\
& B_{y}=B_{y 0} \cos \omega t \cos k z,
\end{aligned}
\]
- Show that satisfy Maxwell Equation in vacuum and determine the dispersion relation.
- Determine the energy flux as a function of position and time as well as the time-averaged energy flux.
Start from either the electric or the magnetic field expression above and derived the other field by direct integration of Maxwell Equations.

\subsection*{43.01}

\section*{Standing Waves}

Standing waves, as opposed to traveling waves, are waves existing in at least partially bounded regions of space with all the points in space oscillating with the same time dependence. The wave is standing wave along the directions such that the time-averaged energy flux is zero. Read § 43.03.03 - Waves in Bounded Regions for a wave-guide with standing waves in the directions perpendicular to the direction of propagation along the guide, along which direction the wave is a traveling wave: a mixed standingtraveling wave.
Waves such that the time and space dependence are factorized, as described in § 40.02.03.05 - General Properties of Waves, are standing waves:
\[
\xi[\mathbf{r}, t]=f[\mathbf{r}] g[t]
\]
as at every point in space the time dependence is identical.

Examples of ElectroMagnetic waves traveling in vacuum with boundaries made of perfect conductors are studied.
Note that if the conductor is not perfect the ElectroMagnetic wave will drop to zero in the skin-depth length as discussed in \(\S 50.02\) - ElectroMagnetic Waves in Matter.
Note that the behavior of ElectroMagnetic waves in vacuum is quite different from the behavior in a wave-guide or cavity. In fact, in bounded regions, the governing equation is not only the d'Alembert wave equation, Maxwell equation have to be satisfied as well, one has a system of PDE different from the one in vacuum. Therefore, the dispersion relation is different.

\subsection*{43.03.01 Standing ElectroMagnetic Waves in One Dimension}

This § is referenced at pages:
[2133, 2133, 2139, 2139]
In this section an example of one-dimensional standing ElectroMagnetic wave is built.
Consider a ElectroMagnetic MPW traveling along the positive \(z\) direction, in the \(z<0\) half-space, with Polarization along the \(x\) axis, impinging on a perfect conductor filling the half-space \(z \geq 0\). The ElectroMagnetic fields, neglecting a non-essential phase-constant, are:
\[
\begin{aligned}
& E_{x}=+E_{x 0} \cos +k z-\omega t, \\
& B_{y}=+B_{y 0} \cos +k z-\omega t .
\end{aligned}
\]

As the conductor is a perfect conductor the electric field inside must be zero.
Moreover, the tangential component of the electric field must be conserved at the boundary and the electric field of the ElectroMagnetic MPW is tangential to the boundary.
As the above incoming electric field is not necessarily zero at \(z=0\) another electric field must be generated such that the sum of the two electric fields is zero at \(z<0\) near \(z=0\) in order to satisfy the continuity of the tangential component of the electric field.
As a result one finds that in order to satisfy the continuity of the tangential component of the electric field a reflected wave must be generated, which is assumed to be a ElectroMagnetic MPW traveling along the negative \(z\) direction, in the \(z<0\) half-space. This is a second ElectroMagnetic wave traveling in the negative direction of the \(z\) axis in the \(z<0\) half-space which sums to the incoming ElectroMagnetic wave. In order to satisfy the boundary condition for \(\mathbf{E}\) the reflected wave must have an electric field equal and opposite to the incoming wave at \(z=0\) and therefore its Polarization must be along the \(x\) axis. As a consequence of the requirements on the electric field the magnetic field will be identical to the incoming magnetic field, at \(z=0\), because \(\mathbf{k}\) will be reversed too. Therefore:
\[
\begin{aligned}
& E_{x}^{R}=-E_{x 0} \cos -k z-\omega t, \\
& B_{y}^{R}=+B_{y 0} \cos -k z-\omega t .
\end{aligned}
\]

The reflection from the perfect conductor is exactly what happens when light is reflected at normal incidence from a mirror.
In the \(z<0\) half-space the electric field will be the sum of the incoming plus reflected wave:
\[
\begin{aligned}
& z \leq 0 \Longrightarrow E_{x}=E_{x 0} \cos +k z-\omega t-E_{x 0} \cos -k z-\omega t=2 E_{x 0} \sin \omega t \sin k z \\
& z \leq 0 \Longrightarrow B_{y}=B_{y 0} \cos +k z-\omega t+B_{y 0} \cos -k z-\omega t=2 B_{y 0} \cos \omega t \cos k z
\end{aligned}
\]

Note that the magnetic field inside the perfect conductor must be constant, that is zero in absence of other static magnetic fields.

At \(z=0\) the electric field is zero but the magnetic field, in general, it is not, except at times such that \(\cos \omega t=0\). As we are supposing that at \(z>0\) there is a perfect conductor a surface current will arise at \(z=0\) to fulfill the boundary condition for the tangential components of the magnetic field.

This plane infinite surface current sheet is the real generator of the reflected and part of the transmitted ElectroMagnetic wave. In fact, it generates a plane ElectroMagnetic wave in both directions, going towards positive \(z\left(\mathbf{E}^{g+} / \mathbf{B}^{g+}\right)\) and negative \(z\left(\mathbf{E}^{g-} \equiv \mathbf{E}^{R} / \mathbf{B}^{g-} \equiv \mathbf{B}^{R}\right)\), as shown in section § 42.17.05ElectroMagnetic Waves. Therefore, the reflected EM wave sums to the incident ElectroMagnetic wave; the ElectroMagnetic wave going in the direction of positive \(z\) also sums and perfectly cancels the incident wave in the \(z>0\) semi-space so that there is no transmitted ElectroMagnetic wave.

The electric field is always zero at points where \(\sin k z=0\) (for \(z<0\) ), while the magnetic field is always zero at points where \(\cos k z=0\) (for \(z<0\) ). The Electric|Magnetic fields, therefore, are not in phase in space: they are out of phase by \(\lambda / 4\). Moreover, also the time dependence is out of phase by \(T / 4\).

If one now imagines to put another perfectly conducting wall at any \(\bar{z}<0\) such that \(\sin k \bar{z}=0\) the ElectroMagnetic waves are trapped between \(-L \equiv \bar{z} \leq z \leq 0\). The system is now a very simple example of what is known as a one-dimensional ElectroMagnetic cavity. If the frequency of the wave is fixed and the length of the one-dimensional cavity is \(L\), steady solutions can exist if and only if:
\[
\begin{equation*}
k=q \frac{\pi}{L} \quad q \text { any integer, } k \text { is quantized; in this problem } q<0 \tag{43.03.01}
\end{equation*}
\]

Note the analogy with the problem of the vibrating string (read § 41.06 - Mechanical Waves, § 40.02.02.04 - General Properties of Waves): in fact the equation is the same. So the current problem is totally analogous to the transverse vibrations of a string with the two ends fixed, where the electric field is the analogous of the transverse displacement of the string.
As the real generator of the reflected ElectroMagnetic wave is the infinite plane surface current sheet at \(z=0\), excited by the incoming ElectroMagnetic wave, there will be also a ElectroMagnetic wave, at \(z>0\) going towards positive \(z\left(\mathbf{E}^{g+} / \mathbf{B}^{g+}\right)\), which exactly cancel the incoming ElectroMagnetic wave at \(z>0\), so that the transmitted wave is zero:
\[
\begin{aligned}
& E_{x}^{g+}=-E_{x 0} \cos +k z-\omega t \Longrightarrow E_{x}^{T}=0, \\
& B_{y}^{g+}=-B_{y 0} \cos +k z-\omega t \Longrightarrow B_{y}^{T}=0
\end{aligned}
\]

Al the combinations of sinus and cosinus are allowed for both Electric|Magnetic fields:
\[
E_{x} \sim \sin \omega t \sin k z \quad E_{x} \sim \sin \omega t \cos k z \quad E_{x} \sim \cos \omega t \sin k z \quad E_{x} \sim \cos \omega t \cos k z
\]
with different values of \(k\), quantised similarly to equation (43.03.01).
It can be shown by direct calculation that the above expressions solve Maxwell equations, as it is necessary to be qualified as ElectroMagnetic waves.
These kind of waves are known as standing waves, as opposed to traveling waves. The time-average of the energy flux at any point is zero, as it can be shown from the ElectroMagnetic fields expressions. That is, the energy flux is not zero but its time average is zero at any point.
Even if these standing waves have been built by superposing traveling MPW, they show a type of solutions to Maxwell equations which are very different from MPW.

\subsection*{43.03.02 A Coaxial-Cable Transmission Line}

This § is referenced at pages:

A transmission line is a pair of electrical conductors carrying electrical signals from one place to another. Consider a lossless homogeneous coaxial-cable transmission line, that is with zero resistance.

The voltage and current at a certain position \(z\) along the coaxial-cable satisfy the d'Alembert Classical Non-Dispersive Wave equation, in case of zero resistance.
The characteristic wave impedance is \(\sqrt{\frac{L}{C}}\), where \(L \mid C\) are the Inductance|Capacitance per unit length. Phase-velocity is \(\sqrt{\frac{1}{L C}}\), where \(L \mid C\) are the Inductance|Capacitance per unit length and is fixed in a lossless homogeneous coaxial-cable transmission line, that is therefore non-dispersive.
For lossy homogeneous coaxial-cable transmission lines, the resulting equation is the dissipative d'Alembert wave equation.

\subsection*{43.03.03 Mixed Standing-Traveling Waves in Rectangular Wave-Guides}

In this section an example of ElectroMagnetic waves in a wave-guide is presented. Ordinary electronic circuits fails at high frequencies because the effects of distributed capacitance and inductance become severe. In this case, wave-guides can be used.
While transmission line is a pair of electrical conductors carrying electrical signals from one place to another, a wave guide is a device that guides waves, with minimal loss of energy while restricting the transmission of energy into one direction. It may refer to any kind of wave.
This kind of ElectroMagnetic waves are standing waves in two dimensions, \(x\) and \(y\), and traveling waves in the third dimension. In other word this kind of wave is a mixed standing-traveling wave.
Wave-guides propagate ElectroMagnetic waves whose characteristics are very different and more complex from those of MPW in a perfect medium or vacuum. These characteristics are: dispersion, absorption, frequency cut-off, non pure transversality and complex wave-vector.

\subsection*{43.03.03.01 Modes TE(px,0) as Special Solutions}

Consider a rectangular wave-guide along \(z\) with its sides made of a perfect conductor and its section a rectangle with sides \(\ell_{x}\) and \(\ell_{y}\) and vacuum inside. Let us study ElectroMagnetic wave propagation along the \(z\) axis.
Boundary conditions must be satisfied at the perfect conductor, such that the tangential component of the electric field at the boundary is zero (as it is zero inside the conductor) and the normal component of the magnetic field at the boundary is zero (as it is zero inside the conductor).

\section*{EM Fields}

Let us try a simple solution with time-harmonic behavior: electric field along \(y\) and independent of \(y\), which is transverse to the direction of propagation as it happens for ElectroMagnetic MPW, for instance:
\[
\begin{gathered}
\mathbf{E}[\mathbf{r}, t]=E_{y} \hat{\mathbf{e}}_{2} \\
E_{y}[x, z, t]=E_{0 y} \sin k_{x} x \cos k_{z} z-\omega t \Longrightarrow E_{y}[x, z, t]=\operatorname{Re}\left(\mathrm{E}_{0 \mathrm{y}} \operatorname{sink}_{\mathrm{x}} \mathrm{x} \exp \left[\beth\left(\mathrm{k}_{\mathrm{z}} \mathrm{z}-\omega \mathrm{t}\right)\right]\right)
\end{gathered}
\]
whose divergence is zero everywhere, as demanded by Maxwell Equations. The replacement of the above tentative solution for the electric field into d'Alembert wave equation gives the following condition:
\[
E_{y}\left(-k_{x}^{2}-k_{z}^{2}+\frac{\omega^{2}}{c^{2}}\right)=0 \Longrightarrow k_{z}= \pm \sqrt{\frac{\omega^{2}}{c^{2}}-k_{x}^{2}}
\]

However also all the boundary conditions must be satisfied. The Sinusoidal|Cosinusoidal term allows to satisfy at any point the boundary condition for the tangential component of the electric field provided:
\[
k_{x}=\frac{p_{x} \pi}{\ell_{x}} \quad p_{x} \in \mathbb{Z} \quad k_{x} \text { is quantized; in this problem } p_{x}>0
\]
that is a quantization condition on \(k_{x}\), similar to those for the vibrating string with fixed ends (read § 41.06 - Mechanical Waves, § 40.02.02.04 - General Properties of Waves) or the one-dimensional ElectroMagnetic cavity described in \(\S 43.03 .01\) - Waves in Bounded Regions.

The quantization condition on \(k_{x}\) translates into a quantization condition for \(k_{z}\) :
\[
-k_{x}^{2}-k_{z}^{2}+\frac{\omega^{2}}{c^{2}}=0 \Longrightarrow k_{z}= \pm \sqrt{\frac{\omega^{2}}{c^{2}}-k_{x}^{2}}= \pm \frac{1}{c} \sqrt{\omega^{2}-\omega_{c}^{2}}
\]
where the critical|cut-off frequency, \(\omega_{c}\), has been introduced:
\[
\omega_{c}=p_{x} \frac{\pi c}{\ell_{x}}
\]
whose meaning will become clear shortly.
The magnetic field can be calculated from the electric field and from the third Maxwell equation:
\[
\begin{gathered}
\partial_{t} \mathbf{B}=-\operatorname{rot} \mathbf{E}=+\hat{\mathbf{e}}_{1} \beth E_{y} k_{z}-\hat{\mathbf{e}}_{3} E_{0 y} k_{x} \cos k_{x} x \exp \left[\beth\left(k_{z} z-\omega t\right)\right] \\
\quad \text { with the complex notation: } \partial_{t}\{\ldots\} \quad \Leftrightarrow \quad-\beth \omega\{\ldots\},
\end{gathered}
\]
\[
B_{x}=-\frac{E_{y} k_{z}}{\omega} \Longrightarrow B_{x}[x, y, z, t]=-\frac{E_{0 y} k_{z}}{\omega} \sin k_{x} x \cos k_{z} z-\omega t
\]
\(B_{z}[x, y, z, t]=-\beth \frac{E_{0 y} k_{x}}{\omega} \cos k_{x} x \exp \left[\beth\left(k_{z} z-\omega t\right)\right] \Longrightarrow B_{z}[x, y, z, t]=+\frac{E_{0 y} k_{x}}{\omega} \cos k_{x} x \sin k_{z} z-\omega t\)
which is divergenceless, by direct calculation. The magnetic field has two components, even if the electric field has only one. A longitudinal component of the magnetic field exists, \(B_{z}\), which is not constant and not uniform. Therefore, even if the starting point was a purely transverse electric field, it turned out that the magnetic field has also a longitudinal component.

The components \(E_{y}\) and \(B_{x}\) are in phase between each other but they are both out-of-phase by \(\pi / 2\) both in time and space with respect to \(B_{z}\).

\section*{Some Properties of the Solutions}

The wavelength corresponding to vacuum is:
\[
\lambda_{0}=\frac{2 \pi c}{\omega}
\]

The phase-velocity depends on the frequency of the wave so that there is dispersion:
\[
v=\frac{\omega}{k_{z}}= \pm \frac{\omega}{\sqrt{\frac{\omega^{2}}{c^{2}}-k_{x}^{2}}}= \pm \frac{c}{\sqrt{1-\frac{\omega_{c}^{2}}{\omega^{2}}}} \quad \text { with }|v| \geq c
\]

The phase-velocity is larger than the speed of light in vacuum, but this is no problem as phase-velocity is not the speed of signal, information or energy transport. Therefore, in a wave-guide, monochromatic traveling waves with phase-velocity larger than the speed of light exists.

The wavelength is always larger than it would be in vacuum:
\[
\lambda=v T=\frac{\omega}{k_{z}} \frac{2 \pi}{\omega}=\frac{2 \pi}{k_{z}}=\frac{\lambda_{0}}{\sqrt{1-\frac{\omega_{c}^{2}}{\omega^{2}}}} \geq \lambda_{0}
\]

Let us discuss some limiting cases. Consider a wave-guide very large with respect to the wavelength:
- the critical frequency goes to zero:
\[
\ell_{x} \rightarrow \infty \Longrightarrow k_{z}= \pm \omega / c \quad \lambda=\lambda_{0} \quad v=c \quad \omega_{c}=0
\]
as it should;
- the quantization of \(k_{x}\) disappears, as the minimum absolute value of \(k_{x}\) is zero and the spacing between different allowed values of \(k_{x}\), tends to zero:
\[
\Delta k_{x}=\frac{\pi}{\ell_{x}} \Delta p_{x}
\]
as it should;
- the longitudinal component of the magnetic field goes to zero.

The MPW is thus recovered.
Consider high frequencies. If \(\omega\) increases then:
- \(k_{z}\) also increases and tends to \(k_{z}= \pm \omega / c\);
- \(\lambda_{0}\) and \(\lambda\) both decrease and tend to the same value \(\lambda_{0}\);
- the ratio between the amplitudes of the Electric|Magnetic fields tends to \(c\) as for plane ElectroMagnetic waves.
In fact for high-frequency waves with small wavelength the boundary have no effect. This is why light passes by long holes and pipes.
Consider high frequencies. If \(\omega\) decreases then:
- \(k_{z}\) also decreases, until it reaches zero, at the critical frequency;
- while \(\lambda_{0} \lambda\) both increase and \(\lambda\) tends to infinity at the critical frequency.

In fact, for low-frequency waves \(k_{z}\) becomes a pure imaginary number. The meaning of an imaginary wave-number can be understood as follows:
\[
\begin{aligned}
& k_{z}= \pm \beth k_{z}^{\prime} \quad \text { with } k_{z}^{\prime} \equiv \pm \frac{1}{c} \sqrt{\omega_{c}^{2}-\omega^{2}} \in \mathbb{R} \\
& E_{y}[x, z, t]=E_{0 y} \sin k_{x} x \exp \left[\mp k_{z}^{\prime} z\right] \exp [-\beth \omega t] .
\end{aligned}
\]

Therefore, below the critical frequency the wave equation is satisfied by a wave exponentially decreasing along \(z\) and with a time harmonic behavior and the phase-velocity is a pure imaginary number like \(k_{z}\).
It is worth remembering that, by definition, the frequency is always a real number, so that consistently with the relation \(\omega=k_{z} v\), the phase-velocity is a real number if and only if \(k_{z}\) is a real number.
The sign in front of \(k_{z}^{\prime}\) must be such that the wave amplitude decreases while going far away from the source, in any passive medium which cannot provide energy to the ElectroMagnetic wave \({ }^{1}\). In these conditions propagation is impossible and the ElectroMagnetic wave is just attenuated, and its intensity is decreased. This happens at and below the critical frequency. The ElectroMagnetic wave penetrates by a length \(L \approx 1 /\left|k_{z}^{\prime}\right|\). There is no energy propagation along \(z\). The energy must be necessarily reflected back.

\section*{Energy}

The energy flux above the critical frequency can be calculated as follows, from the direct general definitions for ElectroMagnetic fields. The Poynting vector has both the \(x\) and \(z\) components. However, when time-averaged, only the \(z\) component is non-zero with the present ElectroMagnetic fields. As the time-averaged \(z\) component of the Poynting vector depends on \(x\) and \(y\) it makes sense to average it on the cross-section of the wave-guide, using the following results:
\[
\ell \equiv \frac{q \pi}{k} \quad \int_{w=0}^{q \pi / k} \sin ^{2} k w \mathrm{~d} w=\int_{w=0}^{q \pi / k} \cos ^{2} k w \mathrm{~d} w=\frac{\pi q}{2 k}=\frac{\ell}{2} .
\]

\footnotetext{
\({ }^{1}\) A notable example of active medium is a Laser, which can amplify the ElectroMagnetic wave by taking energy from the medium.
}

The Poynting vector is:
\[
\begin{gathered}
\mathbf{S}=\frac{1}{\mu_{0}}\left(\hat{\mathbf{e}}_{1} E_{y} B_{z}-\hat{\mathbf{e}}_{3} E_{y} B_{x}\right) \\
\left\langle S_{x}\right\rangle=0 \\
\left\langle S_{z}\right\rangle=-\frac{1}{\mu_{0}}\left\langle E_{y} B_{x}\right\rangle=\frac{1}{2} \varepsilon_{0} c E_{0 y}^{2} \frac{c k_{z}}{\omega} \sin ^{2} k_{x} x \quad\left[\mathrm{~W} / \mathrm{m}^{2}\right] \\
\left\langle\Pi_{z}\right\rangle=\frac{1}{4} \varepsilon_{0} c \ell_{x} \ell_{y} E_{0 y}^{2} \frac{c k_{z}}{\omega} \quad[\mathrm{~W}]
\end{gathered}
\]

The energy density is made of the three terms corresponding to the three non zero components of the ElectroMagnetic fields: \(E_{y}, B_{x}\) and \(B_{z}\). We are interested in the time-averaged energy density. Moreover, we can integrate over \(x\) and \(y\) at fixed \(z\) to get the average energy density stored at a certain \(z\).
\[
\begin{gathered}
u=\frac{\varepsilon_{0}}{2} E_{y}^{2}+\frac{1}{2 \mu_{0}} B_{x}^{2}+\frac{1}{2 \mu_{0}} B_{z}^{2} \\
\langle u\rangle=\frac{\varepsilon_{0}}{4} E_{0 y}^{2} \sin ^{2} k_{x} x+\frac{1}{4 \mu_{0}} \frac{E_{0 y}^{2} k_{z}^{2}}{\omega^{2}} \sin ^{2} k_{x} x+\frac{1}{4 \mu_{0}} \frac{E_{0 y}^{2} k_{x}^{2}}{\omega^{2}} \cos ^{2} k_{x} x \\
\left\langle\frac{\Delta u}{\Delta z}\right\rangle \equiv \int_{x=0}^{\ell_{x}} \int_{y=0}^{\ell_{x}}\langle u\rangle \mathrm{d} x \mathrm{~d} y \\
\left\langle\frac{\Delta u}{\Delta z}\right\rangle=\frac{\varepsilon_{0}}{4} \ell_{x} \ell_{y} E_{0 y}^{2} \quad[\mathrm{~J} / \mathrm{m}]
\end{gathered}
\]

The relation between power and energy density follows:
\[
\begin{gathered}
\left\langle\Pi_{z}\right\rangle=\frac{c^{2} k_{z}}{\omega}\left\langle\frac{\Delta u}{\Delta z}\right\rangle \equiv v_{g}\left\langle\frac{\Delta u}{\Delta z}\right\rangle \\
v_{g}=\frac{c^{2} k_{z}}{\omega} \leq c
\end{gathered}
\]
where the group velocity, \(v_{g}\), has been introduced, showing that the energy transport has the speed given by the group velocity, in this problem. Read \(\S 40.03 .08\) - General Properties of Waves, \(\S 16.04 .05 .01\) Some Elements of Fourier Analysis.

\section*{Phase-Velocity and Group Velocity}

Read § 40.03.11 - General Properties of Waves, § 16.04.05.01 - Some Elements of Fourier Analysis, § 40.03.08 - General Properties of Waves.

The phase-velocity can be larger than \(c\) :
\[
v \equiv \frac{\omega}{k}
\]

It has been shown that the energy propagates along the guide with the group velocity which is smaller than the speed of light in vacuum:
\[
v_{g} \equiv \frac{\mathrm{~d} \omega}{\mathrm{~d} k}=\frac{c^{2} k_{z}}{\omega} \leq c
\]

Note, however, that in general it is possible for the group velocity to exceed the speed of light in vacuum. As for the phase velocity, in this case, this is not related to any sort of information transport and does not violate relativity.

The special solution found is a so-called TE, solution, that is transverse electric field, because the electric field is purely transverse and \(B_{z} \neq 0\).

\subsection*{43.03.03.02 TE Modes}

A solution such that the electric field is purely transverse is known as a TE solution, with \(B_{z} \neq 0\).

\subsection*{43.03.03.03 TM Modes}

A solution such that the magnetic field is purely transverse is known as a TM solution, with \(E_{z} \neq 0\).

\subsection*{43.03.03.04 Other Modes}

Many other solutions with different combinations of Electric|Magnetic fields exist.
The general solution with transverse electric field is known as the \(\mathrm{TE}\left(p_{x}, p_{y}\right)\) mode, where the first index is conventionally associated with the larger dimension of the rectangular wave-guide, so we assume \(\ell_{x}>\ell_{y}\) and at least one of the indices must be non-zero.
Similarly, the general solution with transverse magnetic field is known as the \(\operatorname{TM}\left(p_{x}, p_{y}\right)\) mode, where the first index is conventionally associated with the larger dimension of the rectangular wave-guide, so we assume \(\ell_{x}>\ell_{y}\) and at least one of the indices must be non-zero.
The mode with the lowest cutoff frequency is termed the dominant mode of the wave-guide. Often, one tries to choose the dimensions of the guide such that only this one mode can exist in the operating frequency band. No wave with frequency below it cutoff frequency can propagate (that is transport energy) in the wave-guide and the cutoff frequencies of all other modes are higher than the one for the dominant mode.
Note that in general the critical frequency depend on the mode, that is on the \(p_{x}\) and \(p_{y}\) integer values characterizing the solution.

\section*{Introduction}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|7|Good text.|
After having studied the properties of waves in spatially unlimited media one must study what happens when physical boundaries are present.
Let us always consider the problem locally, on a small part of the interface surface such that it can be considered a plane surface.
The propagation speed of waves depend on the physical properties of the medium. Therefore one expects some change to happen at the interfaces between media with different physical properties, as a consequence of the change of the propagation speed. Note that in the case of ElectroMagnetic waves also vacuum must be considered, in this respect, a medium, as the properties of ElectroMagnetic waves change passing from vacuum to another medium. Some kind of discontinuity in the wave property (such as in some derivative) may arise at these boundaries, as a consequence of the discontinuities of the physical properties of the media, even in the case when the waves are not material (that is mechanical) waves.
In general when waves reach a surface which separates two media with different physical properties there is both a reflected wave and a transmitted (also equivalently known as refracted) wave.
Reflection and refraction are phenomena characteristic of all the types of waves. The directional properties of reflected and refracted waves do not depend on the specific kind of wave. The amplitude relations do depend on the specific kind of wave.

We must therefore distinguish between:
- kinematic properties: relation between the directions of the incoming, reflected and refracted wavevectors, which are the same for every wave;
- dynamical properties: intensity of the incoming, reflected and refracted waves and changes in the states of Polarization, which may be different for different types of waves.

\subsection*{44.01.01 Some Examples}

When ElectroMagnetic waves from vacuum reach a piece of matter the charges are set into motion by the ElectroMagnetic fields of the wave and they re-radiate ElectroMagnetic waves, giving rise to reflected and transmitted ElectroMagnetic waves.
See the example in § 43.03.01 - Waves in Bounded Regions for one example with the precise mechanism for reflection.

\section*{Snell Laws for Reflection and Refraction of Waves}

This § is referenced at pages:
[2145, 2145, 2165, 2165]
The laws of reflection and refraction|transmission for waves, which will be derived in this section, are kinematic laws which do not depend on the specific type of wave.
Consider a MW moving in medium (1) where the phase-velocity is \(v_{1}\). The wave meets a surface separating the first medium from a second medium (2) where the phase-velocity is \(v_{2}\) and let's consider MW only.
Consider a small part of the surface such that it can be considered a plane surface. Consider a small part of the CPWF (which is well-defined as the wave is monochromatic) such that it can be considered locally plane.
Note that, in general, the two media might be dispersive media so that the phase-velocity may depend on the frequency of the wave, but this is not a problem as long as one considers MW.
Note that, at the boundary, the frequency of the waves cannot change because it is linked to the frequency of the source incoming wave which excites a force re-emission at the same frequency. This is clearly obvious, in steady conditions, for mechanical waves, as motion is produced by motion of pieces of matters, and also for ElectroMagnetic waves, as the incoming ElectroMagnetic fields excite motion of charges at the same frequency. That is, as long as in steady conditions the reflected and transmitted waves are monochromatic waves, their frequency must be the same as that of the incoming wave. Therefore the wavelength and phase velocity has both to change. However, this argument comes more from dynamical properties. A cleaner argument, only based on kinematic arguments and therefore a more general one, will bring to the same conclusion in equation (44.02.02).
The expression of the incident wave ( I , reflected wave \((\mathrm{R})\) and transmitted wave \((\mathrm{T})\) are:
\begin{tabular}{|llll}
\hline\(\psi_{\mathrm{I}}[\mathbf{r}, t]=\psi_{\mathrm{I} 0} \cos \left[\mathbf{k}_{\mathrm{I}} \cdot r-\omega_{\mathrm{I}} t-\phi_{\mathrm{I}}\right]\) & with & \(\nu_{\mathrm{I}} \lambda_{\mathrm{I}}=v_{\mathrm{I}}\) \\
\hline\(\psi_{\mathrm{R}}[\mathbf{r}, t]=\psi_{\mathrm{R} 0} \cos \left[\mathbf{k}_{\mathrm{R}} \cdot r-\omega_{\mathrm{R}} t-\phi_{\mathrm{R}}\right]\) & with & \(\nu_{\mathrm{R}} \lambda_{\mathrm{R}}=v_{\mathrm{R}}\) \\
\hline\(\psi_{\mathrm{T}}[\mathbf{r}, t]=\psi_{\mathrm{T} 0} \cos \left[\mathbf{k}_{\mathrm{T}} \cdot r-\omega_{\mathrm{T}} t-\phi_{\mathrm{T}}\right]\) & with & \(\nu_{\mathrm{T}} \lambda_{\mathrm{T}}=v_{\mathrm{T}}\) \\
\hline
\end{tabular},

The complex representation for the waves might be used, but it is not necessary here.
Note that the field \(\psi[\mathbf{r}, t]\) might be a scalar field or any component of a vector or tensor field. Moreover, its interpretation depends on the specific physical problem.
Let the interface between the two media be the plane \(z=0\) with medium 1 at \(z>0\) and medium 2 at \(z<0\). Therefore the incoming wave is traveling with \(k_{z}<0\).
Assume that it is legal to admit that the wave and/or its derivatives and/or some linear combination of them satisfy some condition of continuity across the boundary. Moreover, assumed that the superposition principle applies.
- This is certainly the case, usually, for mechanical waves.
- It is also the case for ElectroMagnetic waves when there is no free Charge|Current at the boundary, and for the always valid continuity conditions for the tangential component of the electric field and the normal component of the magnetic field.
The continuity condition at \(z=0\) reads something like:
\[
\begin{equation*}
\psi_{\mathrm{I}}[x, y, 0, t]+\psi_{\mathrm{R}}[x, y, 0, t]=\psi_{\mathrm{T}}[x, y, 0, t] \tag{44.02.01}
\end{equation*}
\]

For different linear combinations also with derivatives, the rest of the demonstration is equally valid. Note that the arbitrary constant term in the phases allow to account for any possible choice of the signs in equation (44.02.01).

In order to satisfy the continuity condition (44.02.01) at any point at \(z=0\) and at any time it is necessary, even if not sufficient in general, that the \(\mathbf{k} \cdot \mathbf{r}-\omega t\) part of the phases of the three components
at any point at \(z=0\) are identically equal. In fact, only if the space-dependent and time-dependent parts of the three phases are identical at any point at \(z=0\) at any time, there is some hope to satisfy the full continuity condition (44.02.01) at any point at \(z=0\) at any time; it is necessary, but not sufficient. Basically this necessity comes from the fact that Sinusoidal|Cosinusoidal functions with different wavenumber, and/or angular frequency, are linearly independent.
Note, on the contrary, that the constant term in the phase, as it is a constant term not dependent on space nor on time, is not constrained by this kind of argument on the phase, but maybe constrained by others arguments depending on the specific type of waves.
First of all the continuity condition (44.02.01) constrains the angular frequencies to be identical, in order to guarantee that, at any arbitrary point \(\mathbf{r}=\{x, y, 0\}\), the condition is satisfied at any time:
\[
\begin{equation*}
\omega_{\mathrm{I}}=\omega_{\mathrm{R}}=\omega_{\mathrm{T}} \equiv \omega \tag{44.02.02}
\end{equation*}
\]

Secondly the continuity condition (44.02.01) at \(z=0\) sets a constraint on the projection of the wavevector \(\mathbf{k}\) on the \(z=0\) plane:
\[
\begin{equation*}
\left[\mathbf{k}_{\mathrm{I}} \cdot \mathbf{r}\right]_{z=0}=\left[\mathbf{k}_{\mathrm{R}} \cdot \mathbf{r}\right]_{z=0}=\left[\mathbf{k}_{\mathrm{T}} \cdot \mathbf{r}\right]_{z=0} \tag{44.02.03}
\end{equation*}
\]

The two equations (44.02.02), (44.02.03) summarize the purely kinematic conditions at the interfaces for waves. Equation (44.02.03) has a number of consequences.
Due to the arbitrariness of the position vector \(\mathbf{r}\) in the \(z=0\) plane, the latter equations imply that the projection of the three wave-vectors on the \(z=0\) plane must be identical. Equation (44.02.03) can be written in explicit form in the \(x y\) plane for any of the wave-vectors (with \(\mathbf{r}=\{x, y, z\}\) ):
\[
x k_{\mathrm{I} x}+y k_{\mathrm{I} y}=x k_{\mathrm{R} x}+y k_{\mathrm{R} y}=x k_{\mathrm{T} x}+y k_{\mathrm{T} y}
\]

In fact equation (44.02.03) is just the equality of the three scalar products on the \(x y\) plane, that is the equality of the three scalar products is valid after projecting all the vectors on the \(x y\) plane, and not valid for the original vectors with three components. The equality of the projection on the \(z=0\) plane of the scalar products implies that the three wave-vectors all lye in a plane:
\[
\begin{equation*}
\mathbf{k}_{\mathrm{I}}, \mathbf{k}_{\mathrm{R}}, \mathbf{k}_{\mathrm{T}} \quad \text { are all coplanar } . \tag{44.02.04}
\end{equation*}
\]

Define the incidence plane as the plane containing the incident wave-vector and the normal to the surface at the point of incidence, \(\hat{\mathbf{N}}\), oriented along the positive direction of the \(z\) axis. The plane of incidence is thus the plane normal to the unit vector:
\[
\begin{equation*}
\hat{\mathbf{p}} \equiv \frac{\hat{\mathbf{N}} \times \mathbf{k}_{\mathrm{I}}}{\left|\hat{\mathbf{N}} \times \mathbf{k}_{\mathrm{I}}\right|} \tag{44.02.05}
\end{equation*}
\]

The co-planarity condition can be expressed as:
\[
\begin{equation*}
\hat{\mathbf{p}} \equiv \frac{\hat{\mathbf{N}} \times \mathbf{k}_{\mathrm{I}}}{\left|\hat{\mathbf{N}} \times \mathbf{k}_{\mathrm{I}}\right|} \quad \hat{\mathbf{p}} \cdot \mathbf{k}_{\mathrm{I}}=\hat{\mathbf{p}} \cdot \mathbf{k}_{\mathrm{R}}=\hat{\mathbf{p}} \cdot \mathbf{k}_{\mathrm{T}}=0 \tag{44.02.06}
\end{equation*}
\]

Finally one finds Snell laws:
\begin{tabular}{|c|c|c|c|c|}
\hline & \(\sin \theta_{\mathrm{R}}\) & Snell law of reflection (first Snell law) & (44.02.07) & \(\rightarrow\) \\
\hline \(\frac{\sin \theta_{\mathrm{I}}}{v_{\mathrm{I}}}=\frac{\sin \theta_{\mathrm{T}}}{v_{\mathrm{T}}}\) & Snell & transmission/refraction (second Snell law) & (44.02.08) & \(\xrightarrow{3142}\) \\
\hline
\end{tabular}
from (44.02.03).
The laws (44.02.07), (44.02.08), (44.02.06) have been deduced by just using arguments of continuity of the phase of the wave. Therefore they are valid for any wave, as long as some continuity condition at the interface can be assumed, as it is usually the case.
Note that while the law of refraction (44.02.08) involves the properties of both media, the law of reflection (44.02.07) does not involve any properties of the two media as it concerns properties of the waves in the same medium.
In case of a MPW incident on a plane, the reflected and refracted waves are still MPW, because the reflected and refracted rays are parallel. In case of incidence on a non-plane surface, the shape of the CPWF, in general, is not conserved.
If the continuity conditions apply on the derivatives, one still finds Sinusoid|Cosinusoids and therefore Snell laws, as necessary conditions, apply as well.
Snell laws, in general are not sufficient to fully determine the properties of the reflected and refracted wave, as dynamical conditions apply as well.
Note that a possible absorption inside the two media will not affect the Snell laws because the boundary conditions are to be applied at the boundary, while absorption will affect the waves in the bulk of the medium.

\subsection*{44.02.01 Mechanical Waves}

The case of purely longitudinal waves will be only considered, that is a purely uni-dimensional waves.
The general case of mechanical waves is complex and upon reflection/refraction transverse and longitudinal waves may interchange.
Read § 44.04 - Reflection and Refraction of Waves.

\subsection*{44.02.02 EM Waves}

In the case of ElectroMagnetic waves the second Snell law is usually re-written in terms of the refractive indexes of the two media:
\[
\mathrm{n}[\omega]_{\mathrm{I}} \sin \theta_{\mathrm{I}}=\mathrm{n}[\omega]_{\mathrm{T}} \sin \theta_{\mathrm{T}}
\]

\subsection*{44.02.03 Total Internal Reflection}

Snell law for refraction can be written as:
\[
\sin \theta_{\mathrm{T}}=\frac{v_{\mathrm{T}}}{v_{\mathrm{I}}} \sin \theta_{\mathrm{I}}
\]

In the case \(v_{\mathrm{I}}>v_{\mathrm{T}}\) the wave-vector of the transmitted wave gets closer to the normal.
In the case \(v_{\mathrm{I}}<v_{\mathrm{T}}\) the wave-vector of the transmitted wave gets farther away from the normal. In this case it is possible that Snell law for refraction gives \(\sin \theta_{\mathrm{T}}>1\). If this occurs there is no transmission but only reflection, the so-called total internal reflection. The condition for total internal reflection is:
\[
\begin{equation*}
\frac{v_{\mathrm{I}}}{v_{\mathrm{T}}} \leq \sin \theta_{\mathrm{I}} \leq 1 \quad \text { that is } v_{\mathrm{I}}<v_{\mathrm{T}} \text { is required } \tag{44.02.09}
\end{equation*}
\]

\subsection*{44.02.03.01 Maximum Entrance Angle}

Conversely, if \(v_{\mathrm{I}}>v_{\mathrm{T}}\), waves can enter the second medium at a maximum angle given by:
\[
\sin \theta_{\mathrm{T}}=\frac{v_{\mathrm{T}}}{v_{\mathrm{I}}}<1 \quad \text { for } \theta_{\mathrm{I}}=\pi / 2
\]

\subsection*{44.02.04 Reflection and Refraction Laws From Fermat Principle}
© \(\mid\) E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., .... \(|4.5|\) Excellent \(\mid\)

The reflection and refraction Snell laws can be easily derived from kinematic considerations from Fermat principle, read §51.02-Geometrical|Ray Optics.

\subsection*{44.02.05 Reflection and Refraction Laws From Huygens-Fresnel Principle}

The reflection and refraction Snell laws can be easily derived from kinematic considerations from Huygens-Fresnel principle, read § 47.03-Diffraction.

\subsection*{44.02.06 Reflection of Waves From Rough Surfaces and Rayleigh Criterion}

In the general case when the wave is not a MPW and the interface is not a plane one it is possible to subdivide the CPWF and the interface surface in small parts such that both can be considered as plane. This works as long as the dimensions of the plane piece of CPWF and|or surface is large with respect to the wavelength. If this condition is not satisfied diffraction phenomena (section § 47 -Diffraction) might become relevant.
The condition to be satisfied in order to treat the piece of CPWF and|or surface as plane is that the radius of curvature of the CPWF/surface is very much larger than the dimensions of the piece of CPWF/surface considered
The reflection from rough surfaces is known as non-specular reflection. The reflection from any real surface is, in general, a combination of specular and diffuse (non-specular) reflections.
The relevant smoothness of surface depends on the wavelength and angle of incidence of the PW. The Rayleigh criterion is usually adopted as a rough guideline. The Rayleigh criterion is based on the fact that different parallel rays will have different paths when reflected from a non planar surface, even if they are reflected into parallel directions.
A simplified argument to estimate to what extent reflection will be specular/diffuse is the following one. Assume a step-like surface, with steps of random length and equal height \(d\). Two parallel rays from MPW, with angle of incidence \(\theta\), reflected one by the upper layer and the other one by the lower layer, will gain a path/phase difference (see the calculations as in section § 46.10.05 - Interference and equation (46-009) with \(\mathrm{n}[\omega]=1\) ):
\[
\Delta s=2 d \cos \theta \Longrightarrow \Delta \delta=\frac{4 \pi d \cos \theta}{\lambda}
\]

The geometrical derivation is the same as in section § 46.10.05 - Interference with the simplifying assumption, here with respect to section \(\S 46.10 .05\) - Interference, that the refractive indexes are the same, so that the difference in the optical paths is only a geometrical difference. Also note that the relation \(\Delta s=2 d \cos \theta\) is trivially deduced when one considers two parallel rays one reflected by the upper layer and the second one reflected by the lower layer with the two reflection points lying on the same perpendicular line to the two layers.
A surface is defined as planar if and only if:
\[
\Delta \delta \ll 2 \pi \Longrightarrow 2 d \cos \theta \ll \lambda
\]

A rough surface is defined as a surface such that:
\[
\Delta \delta>\frac{\pi}{2} \Longrightarrow d>\frac{\lambda}{8 \cos \theta}
\]

The Rayleigh criterion can only be a generic guide, as in general the angle of incidence will vary because surfaces are not, in general, parallel.

The result implies that the effect of roughness is less important for high-incidence angles than it is for low incidence angles, as it is turns out from the fact that at grazing incidence the difference of paths tends to zero (the two paths tends to become parallel paths) while at normal incidence it tends to \(\Delta s=2 d\).

At grazing incidence surface tend to behave as specular surfaces. This result is made stringer by the fact that at grazing incidence the amplitude reflection coefficients tend to one.

\section*{Reflection and Refraction of ElectroMagnetic Waves}

This § is referenced at pages:
[2054, 2054, 2155, 2155]

In this section the intensity of reflected and refracted waves will be studied for the case of ElectroMagnetic waves.

EM MPW will be assumed except when specified otherwise.
Both media are assumed to be LHI media; they might be dispersive media as one will consider MPW.
In terms of the refractive index Snell law of refraction can be written as:
\[
\mathrm{n}[\omega]_{\mathrm{I}} \sin \theta_{\mathrm{I}}=\mathrm{n}[\omega]_{\mathrm{T}} \sin \theta_{\mathrm{T}}
\]

Thanks to the superposition principle, for linear systems, one can split the problem by examining the two cases of Polarization in the incidence plane and Polarization normal to the incidence plane.

In addition to the conventions used in \(\S 44.02\) - Reflection and Refraction of Waves it is convenient to set the incidence plane as the \(y=0\) plane. The geometry can thus be reduced to the \(x z\) plane.

Let the complex amplitude of the Electric|Magnetic field of the MPW be \(\overline{\mathbf{V}}_{\mathrm{I}}\) (incident wave), \(\overline{\mathbf{V}}_{\mathrm{R}}\) (reflected wave) and \(\overline{\mathbf{V}}_{\mathrm{T}}\) (transmitted/refracted wave).

It will be assumed, as it is appropriate for most cases, that there are no free charges nor free currents at the interface.

The results will be presented in terms of complex quantities in order to be readily applicable to the case of MPW with complex wave-vector.

\subsection*{44.03.01 Impedance|Admittance of ElectroMagnetic MPW}

This § is referenced at pages:
[2011, 2011]
Read also \(\S 40.03 .12\) - General Properties of Waves for other comments on the wave impedance.
As it is useful to deal with the intensity of reflected and refracted waves and the intensity is written in terms of the Poynting vector it is useful to introduce the concept of EM-wave impedance as in equation (42.06.22). The impedance of the ElectroMagnetic MPW is defined as in equation (42.06.22). Note that the wave impedance is a property of the medium only.

Note that the definitions involve the modules, as Electric|Magnetic fields have different directions in an ElectroMagnetic wave.

For LHI media it becomes:
\[
\begin{equation*}
Z \equiv \frac{E}{H}=\mu_{0} \mu_{\mathrm{R}} \frac{E}{B}=\mu_{0} \mu_{\mathrm{R}} v=\sqrt{\frac{\mu_{0} \mu_{\mathrm{R}}}{\varepsilon_{0} \epsilon_{\mathrm{R}}}} \tag{44.03.01}
\end{equation*}
\]

The reason why the vector field \(\mathbf{H}\) appears instead of the magnetic field is that \(\mathbf{H}\) appears in the expression of the Poynting vector, not \(\mathbf{B}\).

Therefore the impedance allows one to express the intensity as a function of one of the ElectroMagnetic fields multiplied/divided by the impedance, see section § 41.08.01.05-Mechanical Waves and § 40.03.12 - General Properties of Waves.

\subsection*{44.03.01.01 Case of Vacuum}

In vacuum:
\[
Z_{0}=\sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}=\mu_{0} c=\frac{1}{\varepsilon_{0} c}=377 \Omega
\]

\subsection*{44.03.01.02 Case of a Perfect Medium}

The following relations are useful to interchange the pair of parameters \(\epsilon_{\mathrm{R}}\) and \(\mu_{\mathrm{R}}\) with the pair of parameters \(\mathrm{n}[\omega]\) and \(Z\) :
\[
\epsilon_{\mathrm{R}}=\frac{\mathrm{n}[\omega]}{Z} \sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}
\]
\[
\mu_{\mathrm{R}}=\mathrm{n}[\omega] Z \sqrt{\frac{\varepsilon_{0}}{\mu_{0}}}
\]

These relations come from the fact that both the refractive index and the wave impedance are expressed in terms of the Electric-Permittivity | Magnetic-Permeability. Therefore it is possible to invert the equations and express the Electric-Permittivity | Magnetic-Permeability in terms of the refractive index and the wave impedance.

It is also often useful to remind the relation between the modules of the various fields for MPW, useful when dealing with boundary conditions:
\[
\begin{array}{|c}
\hline B=E \frac{\mathrm{n}[\omega]}{c} \\
\hline D=\frac{\mathrm{n}[\omega]}{c Z} E \\
H=\frac{1}{Z} E \\
B=\frac{\mathrm{n}[\omega] Z}{c} H, \\
D=\frac{\mathrm{n}[\omega]}{c} H,
\end{array},
\]
\[
\rightarrow
\]

\section*{case of a non-magnetic perfect medium}

Note that for most materials \(\mu_{\mathrm{R}} \simeq 1\). In this case the wave impedance and refractive index are not independent quantities any longer and the following relation apply:
\[
\mathrm{n}[\omega] Z=\sqrt{\frac{\mu_{0}}{\varepsilon_{0}}} \quad Z=\frac{\sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}}{\mathrm{n}[\omega]} \equiv \frac{Z_{0}}{\mathrm{n}[\omega]}
\]

\subsection*{44.03.01.03 General Case of a Complex Quantities}

The same relations, equation (44.03.01.02), (44.03.01.02), can be extended to the general case to swap the pair \(\left\{\overline{\epsilon_{\mathrm{R}}}, \overline{\mu_{\mathrm{R}}}\right\}\) (more useful in ElectroMagnetism) with the pair \(\{\overline{\mathrm{n}[\omega]}, \bar{Z}\}\), (more useful when dealing with waves):
\[
\begin{gather*}
\begin{array}{|c|}
\left.\hline \frac{\epsilon_{\mathrm{R}}}{}, \overline{\mu_{\mathrm{R}}}\right\} \leftrightarrow\{\overline{\mathrm{n}[\omega]}, \bar{Z}\} \\
\overline{\epsilon_{\mathrm{R}}}=\frac{\overline{\mathrm{n}[\omega]}}{\bar{Z}} \sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}
\end{array}  \tag{44.03.02}\\
\overline{\overline{\mu_{\mathrm{R}}}}=\overline{\mathrm{n}[\omega]} \bar{Z} \sqrt{\frac{\varepsilon_{0}}{\mu_{0}}}
\end{gather*},
\]
\[
\rightarrow
\]
\[
2165
\]

See equation (44.04.02) for the similar two pairs of parameters for mechanical waves.

\subsection*{44.03.02 Polarization Parallel to the Incidence Plane}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|7|Good text.|
© \(\mid\) E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|4.6|Excellent \(\mid\)
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|||
Aka p-Polarization.
It is assumed that the media are sufficiently insulating so that the density of free charges and currents is negligible at the surface.
In this section we explicitly denote physical quantities which might be complex as complex numbers, while normally this is not done.
Consider an ElectroMagnetic MPW Polarized parallel to the incidence plane, that is with the three (incident, reflected and transmitted) electric field vectors in the incidence plane; the three electric field vectors are co-planar but non collinear. Assume, by convention, that the components of the three electric field vectors along the normal to the interface surface ( \(z\) axis, oriented from medium 2 towards medium 1) are all positive. That is, imagine to follow the incident wave-vector with its orthogonal triplet of vectors \(\{\mathbf{E}, \mathbf{B}, \mathbf{k}\}\) and after Reflection|Transmission: both orthogonal terns of Reflected|Transmitted vectors \(\{\mathbf{E}, \mathbf{B}, \mathbf{k}\}\) have the same orientation as the incident one, whose component on the \(z\) axis is positive. Equivalently any two vector fields in the incidence plane are in-phase if their \(z\)-components are parallel while they are out-of-phase if their \(z\)-components are anti-parallel. Obviously in case the Reflected|Transmitted components turn out to be negative than the real Reflected|Transmitted electric field vectors would be inverted.
Continuity of the tangential component of \(\mathbf{E}\) and the tangential component of \(\mathbf{H}\) give:
\[
\begin{gathered}
\bar{E}_{\mathrm{I}} \cos \theta_{\mathrm{I}}-\bar{E}_{\mathrm{R}} \cos \theta_{\mathrm{R}}=\bar{E}_{\mathrm{T}} \cos \theta_{\mathrm{T}} \\
\bar{H}_{\mathrm{I}}+\bar{H}_{\mathrm{R}}=\bar{H}_{\mathrm{T}} .
\end{gathered}
\]

Note that equation (44.03.02) can be obtained from equation (44.03.03) by exchanging \(\mathbf{H}\) with \(\mathbf{E}\).
Introducing the wave impedance \(\bar{Z}\) and the notations, limited to the wave impedance and angles, \(\mathrm{I} \longrightarrow 1, \mathrm{R} \longrightarrow 1\) and \(\mathrm{T} \longrightarrow 2\), and using explicitly first Snell law, one finds:
\[
\begin{gathered}
\bar{E}_{\mathrm{I}} \cos \theta_{1}-\bar{E}_{\mathrm{R}} \cos \theta_{1}=\bar{E}_{\mathrm{T}} \cos \theta_{2}, \\
\frac{\bar{E}_{\mathrm{I}}}{\overline{\bar{Z}_{1}}}+\frac{\bar{E}_{\mathrm{R}}}{\bar{Z}_{1}}=\frac{\bar{E}_{\mathrm{T}}}{\bar{Z}_{2}} .
\end{gathered}
\]

The solution for the amplitude reflection coefficient and amplitude transmission coefficient is given by Fresnel equations:
\[
\begin{equation*}
\bar{r}_{\|} \equiv \frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}=\left(\frac{\bar{Z}_{1} \cos \theta_{1}-\bar{Z}_{2} \cos \theta_{2}}{\bar{Z}_{1} \cos \theta_{1}+\bar{Z}_{2} \cos \theta_{2}}\right) \tag{44.03.03}
\end{equation*}
\]
\[
\bar{t}_{\|} \equiv \frac{\bar{E}_{\mathrm{T}}}{\bar{E}_{\mathrm{I}}}=\left(\frac{2 \bar{Z}_{2} \cos \theta_{1}}{\bar{Z}_{1} \cos \theta_{1}+\bar{Z}_{2} \cos \theta_{2}}\right)
\]
\(\rightarrow\)
21482150
2169

It must be kept in mind that in equation (44.03.03) the angles \(\theta_{1}\) and \(\theta_{2}\) are not independent but they are linked by Snell law.
Note that the amplitude transmission coefficient can be larger than one.
The reflectivity (also known as reflectance) and transmissivity (also known as transmittance) follow (Read also § 44.03.05 - Reflection and Refraction of Waves):
\[
\begin{equation*}
\mathcal{R}_{\|} \equiv\left|\bar{r}_{\|}\right|^{2} \equiv \bar{r}_{\|} \bar{r}_{\|}^{\star}=\left|\frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\left|\frac{\bar{Z}_{1} \cos \theta_{1}-\bar{Z}_{2} \cos \theta_{2}}{\bar{Z}_{1} \cos \theta_{1}+\bar{Z}_{2} \cos \theta_{2}}\right|^{2} \quad \mathcal{T}_{\|}=1-\mathcal{R}_{\|} \neq\left|\bar{t}_{\|}\right|^{2} . \tag{44.03.04}
\end{equation*}
\]

Note that continuity of the normal component of \(\mathbf{B}\) is meaningless in this case because it is identically zero.
The continuity of the normal component of \(\mathbf{D}\) gives:
\[
\bar{D}_{\mathrm{I}} \sin \theta_{\mathrm{I}}+\bar{D}_{\mathrm{R}} \sin \theta_{\mathrm{R}}=\bar{D}_{\mathrm{T}} \sin \theta_{\mathrm{T}}
\]

This is equivalent to the equation for the tangential component of \(\mathbf{H}\) by using the Snell law and the expression of \(\epsilon_{\mathrm{R}}\) in terms of \(\mathrm{n}[\omega]\) and \(Z\) (equation (44.03.01.02)).

The reflectivity and transmissivity at normal incidence are (Read also §44.03.05-Reflection and Refraction of Waves):
\[
\begin{equation*}
\mathcal{R}_{\|}=\left|\frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\left|\frac{\bar{Z}_{1}-\bar{Z}_{2}}{\bar{Z}_{1}+\bar{Z}_{2}}\right|^{2} \tag{44.03.05}
\end{equation*}
\]
\[
\mathcal{T}_{\|} \equiv 1-\mathcal{R}_{\|}
\]
\(\rightarrow\)
2152
The transmissivity at normal incidence can be re-written as follows
\[
\mathcal{T}_{\|}=1-\mathcal{R}_{\|}=\frac{4\left|\bar{Z}_{1} \bar{Z}_{2}\right|}{\left|\bar{Z}_{1}+\bar{Z}_{2}\right|^{2}} \quad \mathcal{T}_{\|}=\frac{\bar{Z}_{1}}{\bar{Z}_{2}}\left|\frac{\bar{E}_{\mathrm{T}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\frac{\bar{Z}_{1}}{\bar{Z}_{2}}\left|\frac{2 \bar{Z}_{2}}{\bar{Z}_{1}+\bar{Z}_{2}}\right|^{2}
\]
where the first equation above is from direct calculation from \(\mathcal{R}\) while the second one is the application of (44.03.19).

The transmitted part of the electric field never inverts its sign.
Assume: \(Z_{1}>Z_{2}\). With this conventions, at normal incidence and for real impedance, the reflected electric field does not change its sign for \(Z_{1}>Z_{2}\), which means that the electric field is inverted. Moreover, with this conventions, at grazing incidence \((\theta=\pi / 2)\) and for real impedance, the reflected electric field changes its sign for \(Z_{1}>Z_{2}\), which means that the electric field is inverted as well.

For a non-magnetic medium when the incident medium has a lower refractive index than the transmitting medium, the component of the electric field parallel to the incidence will be in-phase from normal incidence until the Brewster angle and out-of-phase by \(\pi\) radians thereafter. However the transition is not actually discontinuous, since the electric field goes to zero at the Brewster angle. In case the incident medium has a larger refractive index than the transmitting medium, the analysis is more complex and can be found in the references.

With this convention at normal incidence the convention for the components parallel and perpendicular to the incidence plane are inverted.

Never confuse the conventions about the sign of the component of the vector field with the real orientation of the vector field.

\subsection*{44.03.02.01 Definition of Components for P-Polarization}

The conventions used can be summarized as:
\[
\begin{equation*}
\overline{\mathbf{H}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \propto \overline{\mathbf{k}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \times \hat{\mathbf{N}} \quad \overline{\mathbf{E}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \propto \overline{\mathbf{H}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \times \overline{\mathbf{k}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \tag{44.03.06}
\end{equation*}
\]

\subsection*{44.03.03 Polarization Perpendicular to the Incidence Plane}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|7|Good text.|
© \(\mid\) E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|4.6|Excellent|

Aka s-Polarization.
It is assumed that the media are sufficiently insulating so that the density of free charges and currents is negligible at the surface.
In this section we explicitly denote physical quantities which might be complex as complex numbers, while normally this is not done.
Consider an ElectroMagnetic MPW Polarized perpendicular to the incidence plane, that is with the three (incident, reflected and transmitted) electric field vectors perpendicular to the incidence plane; the three electric field vectors are collinear. Assume, by convention, that the components of the three electric field vectors perpendicular to the incidence plane, are positive when they have the same orientation with respect to the incidence plane. Obviously in case the Reflected|Transmitted components turn out to be negative than the real Reflected|Transmitted electric field vectors would be inverted.
Continuity of the tangential component of \(\mathbf{E}\) and the tangential component of \(\mathbf{H}\) give:
\[
\begin{gathered}
\bar{E}_{\mathrm{I}}+\bar{E}_{\mathrm{R}}=\bar{E}_{\mathrm{T}} \\
\bar{H}_{\mathrm{I}} \cos \theta_{\mathrm{I}}-\bar{H}_{\mathrm{R}} \cos \theta_{\mathrm{R}}=\bar{H}_{\mathrm{T}} \cos \theta_{\mathrm{T}}
\end{gathered}
\]

Note that equation (44.03.03) can be obtained from equation (44.03.02) by exchanging \(\mathbf{E}\) with \(\mathbf{H}\).
Introducing the wave impedance \(\bar{Z}\) and the notations, limited to the wave impedance and angles, \(\mathrm{I} \longrightarrow 1\), \(\mathrm{R} \longrightarrow 1\) and \(\mathrm{T} \longrightarrow 2\), and using explicitly first Snell law, one finds:
\[
\begin{gathered}
\bar{E}_{\mathrm{I}}+\bar{E}_{\mathrm{R}}=\bar{E}_{\mathrm{T}} \\
\frac{\bar{E}_{\mathrm{I}} \cos \theta_{1}}{\bar{Z}_{1}}+\frac{\bar{E}_{\mathrm{R}} \cos \theta_{1}}{\bar{Z}_{1}}=\frac{\bar{E}_{\mathrm{T}} \cos \theta_{2}}{\bar{Z}_{2}}
\end{gathered}
\]

The solution for the amplitude reflection coefficient and amplitude transmission coefficient is given by Fresnel equations:
\[
\begin{equation*}
\bar{r}_{\perp} \equiv \frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}=\left(\frac{\bar{Z}_{2} \cos \theta_{1}-\bar{Z}_{1} \cos \theta_{2}}{\bar{Z}_{2} \cos \theta_{1}+\bar{Z}_{1} \cos \theta_{2}}\right) \tag{44.03.07}
\end{equation*}
\]
\[
\bar{t}_{\perp} \equiv \frac{\bar{E}_{\mathrm{T}}}{\bar{E}_{\mathrm{I}}}=\left(\frac{2 \bar{Z}_{2} \cos \theta_{1}}{\bar{Z}_{2} \cos \theta_{1}+\bar{Z}_{1} \cos \theta_{2}}\right) .
\]

It must be kept in mind that in equation (44.03.03) the angles \(\theta_{1}\) and \(\theta_{2}\) are not independent but they are linked by Snell law.
Note that the amplitude transmission coefficient can be larger than one.
The reflectivity (also known as reflectance) and transmissivity (also known as transmittance) follow (Read also § 44.03.05 - Reflection and Refraction of Waves):
\[
\begin{equation*}
\mathcal{R}_{\perp} \equiv\left|\bar{r}_{\perp}\right|^{2} \equiv \bar{r}_{\perp} \bar{r}_{\perp}^{\star}=\left|\frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\left|\frac{\bar{Z}_{2} \cos \theta_{1}-\bar{Z}_{1} \cos \theta_{2}}{\bar{Z}_{2} \cos \theta_{1}+\bar{Z}_{1} \cos \theta_{2}}\right|^{2} \quad \mathcal{T}_{\perp}=1-\mathcal{R}_{\perp} \neq\left|\bar{t}_{\perp}\right|^{2} . \tag{44.03.08}
\end{equation*}
\]

Note that continuity of the normal component of \(\mathbf{D}\) is meaningless in this case because it is identically zero.
The continuity of the normal component of \(\mathbf{B}\) gives:
\[
\bar{B}_{\mathrm{I}} \sin \theta_{\mathrm{I}}+\bar{B}_{\mathrm{R}} \sin \theta_{\mathrm{R}}=\bar{B}_{\mathrm{T}} \sin \theta_{\mathrm{T}}
\]

This is equivalent to the equation for the tangential component of \(\mathbf{E}\) by using the Snell law and the expression of \(B\) in terms of \(E, \mathrm{n}[\omega]\) and \(c\) (equation (44.03.01.02)).
The reflectivity and transmissivity at normal incidence are (Read also §44.03.05 - Reflection and Refraction of Waves):
\[
\begin{equation*}
\mathcal{R}_{\perp}=\left|\frac{\bar{E}_{\mathrm{R}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\left|\frac{\bar{Z}_{2}-\bar{Z}_{1}}{\bar{Z}_{1}+\bar{Z}_{2}}\right|^{2} \quad \mathcal{J}_{\perp} \equiv 1-\mathcal{R}_{\perp} \tag{44.03.09}
\end{equation*}
\]

The transmissivity at normal incidence can be re-written as follows
\[
\mathcal{T}_{\perp}=1-\mathcal{R}_{\perp}=\frac{2\left(\bar{Z}_{1} \bar{Z}_{2}^{\star}+\bar{Z}_{1}{ }^{\star} \bar{Z}_{2}\right)}{\left|\bar{Z}_{1}+\bar{Z}_{2}\right|^{2}} \quad \mathcal{T}_{\perp}=\frac{\bar{Z}_{1}}{\bar{Z}_{2}}\left|\frac{\bar{E}_{\mathrm{T}}}{\bar{E}_{\mathrm{I}}}\right|^{2}=\frac{\bar{Z}_{1}}{\bar{Z}_{2}}\left|\frac{2 \bar{Z}_{2}}{\bar{Z}_{1}+\bar{Z}_{2}}\right|^{2}
\]
where the first equation above is from direct calculation from \(\mathcal{R}\) while the second one is the application of (44.03.19).

The transmitted part of the electric field never inverts its sign.
Assume: \(Z_{1}>Z_{2}\). With this conventions, at normal incidence and for real impedance, the reflected electric field components changes its sign for \(Z_{1}>Z_{2}\), which means that the electric field is inverted. Moreover, with this conventions, at grazing incidence \((\theta=\pi / 2)\) and for real impedance, the reflected electric field changes its sign for \(Z_{1}>Z_{2}\), which means that the electric field is inverted as well.

For a non-magnetic medium when the incident medium has a lower refractive index than the transmitting medium, the component of the electric field normal to the incidence undergoes a phase shift of \(\pi\) radians upon reflection In case the incident medium has a larger refractive index than the transmitting medium, the analysis is more complex and can be found in the references.

On the other hand the transmitted part of the electric field never inverts its sign.
With this convention at normal incidence the convention for the components parallel and perpendicular to the incidence plane are inverted.

Never confuse the conventions about the sign of the component of the vector field with the real orientation of the vector field.

\subsection*{44.03.03.01 Definition of Components for S-Polarization}

The conventions used can be summarized as:
\[
\begin{equation*}
\overline{\mathbf{E}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \propto \overline{\mathbf{k}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \times \hat{\mathbf{N}} \quad \overline{\mathbf{H}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \propto \overline{\mathbf{k}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \times \overline{\mathbf{E}}_{\mathrm{I}|\mathrm{R}| \mathrm{T}} \tag{44.03.10}
\end{equation*}
\]

\subsection*{44.03.04 Properties of Reflected|Transmitted Waves}

\subsection*{44.03.04.01 Some Properties Derived From Fresnel Laws}

The amplitude reflection coefficient \(r_{\perp}\) never changes its sign.
The absolute values of \(r_{\|}\)and \(r_{\perp}\) are symmetrical in \(\theta_{1}\) and \(\theta_{2}\).
Reflection can produce totally Polarized light but refraction can only produce partially Polarized light.
It is always:
\[
\left|r_{\|}\right| \leq\left|r_{\perp}\right| \quad \text { the equality applies if and only if } \theta=0 \text { and } \theta=\pi / 2
\]
showing that the partial Polarization perpendicular to the incidence plane always increases. In particular, for incident un-Polarized light, the reflected light is always partially Polarized perpendicular to the incidence plane. This effect is exploited in Polaroid glasses to reduced the glaring effect of specular reflection.
On the other hand the refracted light will experience an increase of Polarization parallel to the incidence plane.
The coefficient \(r_{\perp}\) is such that \(\left|r_{\perp}\right|\) increases monotonically with increasing \(\theta_{1}\), starting from the value \(\frac{\mathrm{n}[\omega]_{1}-\mathrm{n}[\omega]_{2}}{\mathrm{n}[\omega]_{1}+\mathrm{n}[\omega]_{2}}\). On the other hand the coefficient \(r_{\|}\)is such that \(\left|r_{\|}\right|\)starts from the value \(\frac{\mathrm{n}[\omega]_{1}-\mathrm{n}[\omega]_{2}}{\mathrm{n}[\omega]_{1}+\mathrm{n}[\omega]_{2}}\), as \(\left|r_{\perp}\right|\), and decreases until the Brewster angle, then it rises monotonically. For the behavior at \(\theta=\pi / 2\) (specular reflection) two cases must be distinguished. In case the second medium is optically denser \(\left(\mathrm{n}[\omega]_{2}>\mathrm{n}[\omega]_{1}\right)\) both \(\left|r_{\|}\right|\)and \(\left|r_{\perp}\right|\) rises up to one at \(\theta=\pi / 2\). In case the first medium is optically denser \(\left(\mathrm{n}[\omega]_{1}>\mathrm{n}[\omega]_{2}\right)\) both \(\left|r_{\|}\right|\)and \(\left|r_{\perp}\right|\) become one at the angle of total internal reflection and \(\theta\) can never reach \(\theta=\pi / 2\).
Consider the component of the field in the incidence plane. In the case \(n[\omega]_{2}>n[\omega]_{1}\) the direction of the electric field is inverted both at \(\theta_{\mathrm{I}}=0\) and \(\theta_{\mathrm{I}}=\pi / 2\); in the case \(\mathrm{n}[\omega]_{1}>\mathrm{n}[\omega]_{2}\) the direction of the electric field is conserved both at \(\theta_{\mathrm{I}}=0\) and at \(\theta_{\mathrm{I}}=\pi / 2\).
Consider the component of the field perpendicular to the incidence plane. This component always changes sign for \(\mathrm{n}[\omega]_{2}>\mathrm{n}[\omega]_{1}\); it always keeps the same sign for \(\mathrm{n}[\omega]_{2}<\mathrm{n}[\omega]_{1}\).

The transmitted electric field, on the other hand, is always in phase with the incident electric field.
At grazing incidence, \(\theta_{\mathrm{I}}=\pi / 2\), the reflectance goes to unity in any case. This is well known from common experience where one observes strong reflection at \(\theta_{\mathrm{I}}=\pi / 2\).

\subsection*{44.03.04.02 Reflected|Transmitted Intensities at Normal Incidence}

This § is referenced at pages:
[2166, 2166]
At normal incidence one finds, from both equations (44.03.05), (44.03.09):
\[
\begin{equation*}
|r|=\left|\frac{\bar{Z}_{1}-\bar{Z}_{2}}{\bar{Z}_{1}+\bar{Z}_{2}}\right| \quad|t|=\left|\frac{2 \bar{Z}_{2}}{\bar{Z}_{1}+\bar{Z}_{2}}\right| . \tag{44.03.11}
\end{equation*}
\]

The different signs of \(r_{\|}\)and \(r_{\perp}\) at normal incidence is just an artifact of the conventions chosen.

\subsection*{44.03.04.03 Media With Real Impedance}

Assume that all the wave impedances are real: \(\bar{Z} \rightarrow Z\), for the rest of this section. The intensity for MPW is:
\[
I_{0}=\frac{1}{2} \frac{\left|\mathbf{E}_{0}\right|^{2}}{Z}=\frac{1}{2} Z\left|\mathbf{H}_{0}\right|^{2} \quad \text { for real } \bar{Z}
\]

Energy conservation reads:
\[
I_{\mathcal{R}}+I_{\mathcal{T}}=\frac{1}{2 Z_{1}}\left|\mathbf{E}_{\mathrm{R}}\right|^{2}+\frac{1}{2 Z_{2}}\left|\mathbf{E}_{\mathrm{T}}\right|^{2}=\frac{\left|\mathbf{E}_{\mathrm{I}}\right|^{2}}{2}\left(\frac{1}{Z_{1}}\left(\frac{Z_{1}-Z_{2}}{Z_{1}+Z_{2}}\right)^{2}+\frac{1}{Z_{2}}\left(\frac{2 Z_{2}}{Z_{1}+Z_{2}}\right)^{2}\right)=\frac{1}{2 Z_{1}}\left|\mathbf{E}_{\mathrm{I}}\right|^{2}=I_{0}
\]

At normal incidence one can notice that on entering an optically denser medium \(\left(Z_{1}>Z_{2}\right)\) the electric field inverts its orientation while the magnetic field keeps the same orientation. The reverse happens on exiting an optically denser medium \(\left(Z_{1}>Z_{2}\right)\).
Note that the amplitude transmission coefficient is different from the one for mechanical waves (read § 44.04 .01 - Reflection and Refraction of Waves). However, the reflected and transmitted intensities are, exactly as for mechanical waves:
\[
\begin{gathered}
\frac{I_{\mathrm{R}}}{I_{\mathrm{I}}}=\left(\frac{Z_{1}-Z_{2}}{Z_{1}+Z_{2}}\right)^{2} \\
\frac{I_{\mathrm{T}}}{I_{\mathrm{I}}}=\frac{4 Z_{1} Z_{2}}{\left(Z_{1}+Z_{2}\right)^{2}} .
\end{gathered}
\]

\subsection*{44.03.04.04 Brewster Angle}

In the case of ElectroMagnetic wave Polarized in the plane of incidence there is one angle, the so-called Brewster angle, \(\theta_{1} \equiv \theta_{B}\), such that reflection is zero:
\[
\begin{equation*}
\bar{Z}_{1} \cos \theta_{1}=\bar{Z}_{2} \cos \theta_{2} \Longrightarrow \tan \theta_{B}=\sqrt{\frac{1-\frac{Z_{1}^{2}}{Z_{2}^{2}}}{\frac{\mathrm{n}[\omega]_{1}^{2}}{\mathrm{n}[\omega]_{2}^{2}}-1}} . \tag{44.03.12}
\end{equation*}
\]

In fact:
\[
\begin{gather*}
\mathrm{n}[\omega]_{1}^{2} \sin ^{2} \theta_{1}=\mathrm{n}[\omega]_{2}^{2} \sin ^{2} \theta_{2}, \\
Z_{1}^{2} \cos ^{2} \theta_{1}=Z_{2}^{2} \cos ^{2} \theta_{2}, \\
1=\cos ^{2} \theta_{2}+\sin ^{2} \theta_{2}=\frac{Z_{1}^{2}}{Z_{2}^{2}} \cos ^{2} \theta_{1}+\frac{\mathrm{n}[\omega]_{1}^{2}}{\mathrm{n}[\omega]_{2}^{2}} \sin ^{2} \theta_{1}=\cos ^{2} \theta_{1}+\sin ^{2} \theta_{1}, \\
\left(\frac{Z_{1}^{2}}{Z_{2}^{2}}-1\right) \cos ^{2} \theta_{1}+\left(\frac{\mathrm{n}[\omega]_{1}^{2}}{\mathrm{n}[\omega]_{2}^{2}}-1\right) \sin ^{2} \theta_{1}=0 \tag{44.03.13}
\end{gather*}
\]

If, as it is usual, the two media have negligible magnetic properties equation (44.03.01.02) implies \(Z \propto \mathrm{n}[\omega]^{-1}\) and the above formula reduces to the usual expression:
\[
\begin{equation*}
\tan \theta_{B}=\frac{\mathrm{n}[\omega]_{2}}{\mathrm{n}[\omega]_{1}} \quad \text { if and only if } \mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2} \tag{44.03.14}
\end{equation*}
\]

Note that Brewster angle exists in both cases of \(n[\omega]_{1}>n[\omega]_{2}\) and \(n[\omega]_{1}<n[\omega]_{2}\).
It can be shown that Brewster angle never exists for the component of the electric field perpendicular to the incidence plane as the corresponding equation has no solution.

Brewster angle is such that:
\[
\theta_{\mathrm{R}}+\theta_{\mathrm{T}}=\pi / 2 .
\]

Light reflected at the Brewster angle is totally Polarized in the plane perpendicular to the incidence angle. This gives the chance to build a linear Polarizer: Brewster angle Polarizer.

\subsection*{44.03.04.05 Impedance Matching|Mismatch}

If the impedances are very different there is large reflection (impedance mismatch).
If the impedances are very similar there is large transmission (impedance matching). If \(Z_{1}=Z_{2}\) the reflected wave is zero and all the energy passes into the second medium. In this case the impedances of the two media are said to be matched. For a medium which is both Polarizable and Magnetizable, the matching condition is:
\[
\begin{equation*}
\frac{\epsilon_{\mathrm{R} 1}}{\mu_{\mathrm{R} 1}}=\frac{\epsilon_{\mathrm{R} 2}}{\mu_{\mathrm{R} 2}} \tag{44.03.15}
\end{equation*}
\]

Note that in this case, the condition is obtained without the need to insert a anti-reflection coating made of a third material, because both media are both Polarizable and Magnetizable. Read § 44.06.05Reflection and Refraction of Waves.
Note that a perfect conductor has zero impedance, as it can be considered a medium with infinite Electric-Permittivity. Therefore ElectroMagnetic waves are reflected from a perfect conductor as there is a huge impedance mismatch.

\subsection*{44.03.04.06 Reflection Matrix}

The change of the Polarization state on reflection is described by the Reflection Matrix.
\[
\binom{\left.\overline{\mathbf{E}}_{p}\right|_{\mathrm{R}}}{\left.\overline{\mathbf{E}}_{s}\right|_{\mathrm{R}}}=\left(\begin{array}{cc}
\bar{r}_{p p} & \bar{r}_{p s} \\
\bar{r}_{s p} & \bar{r}_{s s}
\end{array}\right)\binom{\left.\overline{\mathbf{E}}_{p}\right|_{\mathrm{I}}}{\left.\overline{\mathbf{E}}_{s}\right|_{\mathrm{I}}}
\]

Experimental technique: ellipsometry.

\subsection*{44.03.04.07 Fresnel Equations for Non-Magnetic Media}

This is by far the most common case for most materials. In this case:
\[
Z \propto \frac{1}{\mathrm{n}[\omega]}
\]

The amplitude reflection coefficient and the amplitude transmission coefficient in the case of Polarization parallel to the incidence plane become:
\[
\begin{equation*}
r_{\|}=+\frac{\tan \left[\theta_{1}-\theta_{2}\right]}{\tan \left[\theta_{1}+\theta_{2}\right]} \quad t_{\|}=\frac{2 \sin \theta_{2} \cos \theta_{1}}{\sin \left[\theta_{1}+\theta_{2}\right] \cos \left[\theta_{1}-\theta_{2}\right]} \tag{44.03.16}
\end{equation*}
\]

The amplitude reflection coefficient \(r_{\|}\)changes its sign at the Brewster angle, when \(\theta_{1}+\theta_{2}=\pi / 2\), where \(r_{\|}=0\), because the denominator changes its sign.
The amplitude reflection coefficient and the amplitude transmission coefficient in the case of Polarization perpendicular to the incidence plane become:
\[
\begin{equation*}
r_{\perp}=-\frac{\sin \left[\theta_{1}-\theta_{2}\right]}{\sin \left[\theta_{1}+\theta_{2}\right]} \quad t_{\perp}=\frac{2 \sin \theta_{2} \cos \theta_{1}}{\sin \left[\theta_{1}+\theta_{2}\right]} . \tag{44.03.17}
\end{equation*}
\]

When we have Fresnel equations for non magnetic media, the Magnetic-Permeability can be put back into any of the equations by making the replacement:
\[
\mathrm{n}[\omega] \rightarrow \mathrm{n}[\omega] / \mu_{\mathrm{R}}
\]

\subsection*{44.03.04.08 Non Perfect Media and Complex Reflection|Transmission Coefficients}

Fresnel formulas derived in §44.03 - Reflection and Refraction of Waves are still valid for non perfect media, whose wave impedance and refractive index may be complex numbers. In this case the amplitude reflection coefficient and amplitude transmission coefficients have a modulus given by the modulus of the coefficient and a change of phase given by the phase of the complex number.
44.03.04.09 Plots of Coefficients in Various Cases

Plots of the Ratio of the Amplitudes: Amplitude Reflection Coefficient
Non-magnetic media: \(\mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2}=1\) and \(Z \propto 1 / \mathrm{n}[\omega]\).

Figure 44.1: amplitude reflection coefficients: parallel to the incidence plane (red) and perpendicular to the incidence plane (blue); \(\mathrm{n}[\omega]_{1}=1.0\) and \(\mathrm{n}[\omega]_{2}=1.5\).

Figure 44.2: amplitude reflection coefficients: parallel to the incidence plane (red) and perpendicular to the incidence plane (blue); \(\mathrm{n}[\omega]_{1}=1.5\) and \(\mathrm{n}[\omega]_{2}=1.0\).

Plots of the Ratio of the Amplitudes: Amplitude Transmission Coefficient
Non-magnetic media: \(\mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2}=1\) and \(Z \propto 1 / \mathrm{n}[\omega]\).

Figure 44.3: Amplitude transmission coefficients: parallel to the incidence plane (red) and perpendicular to the incidence plane (blue) \(; \mathrm{n}[\omega]_{1}=1.0\) and \(\mathrm{n}[\omega]_{2}=1.5\).

Figure 44.4: Amplitude transmission coefficients: parallel to the incidence plane (red) and perpendicular to the incidence plane (blue); \(\mathrm{n}[\omega]_{1}=1.5\) and \(\mathrm{n}[\omega]_{2}=1.0\).

Plots for Incidence Onto a Medium With Larger Refractive Index (ratio close to one)
Non-magnetic media: \(\mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2}=1\) and \(Z \propto 1 / \mathrm{n}[\omega]\).

Figure 44.5: Amplitude reflection coefficient squared: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue); amplitude transmission coefficient squared: parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(\mathrm{n}[\omega]_{2} / \mathrm{n}[\omega]_{1}=1.5\).

Figure 44.6: Reflectivity: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue). Transmissivity coefficient parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(\mathrm{n}[\omega]_{2} / \mathrm{n}[\omega]_{1}=1.5\).

Plots for Incidence Onto a Medium With Larger Refractive Index (ratio much larger than one)
Non-magnetic media: \(\mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2}=1\) and \(Z \propto 1 / \mathrm{n}[\omega]\).

Figure 44.7: Amplitude reflection coefficient squared: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue); amplitude transmission coefficient squared: parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(\mathrm{n}[\omega]_{2} / \mathrm{n}[\omega]_{1}=10.0\).

Figure 44.8: Reflectivity coefficient: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue). Transmissivity coefficient parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(n[\omega]_{2} / \mathrm{n}[\omega]_{1}=10.0\).

Plots for Incidence Onto a Medium With Smaller Refractive Index
Non-magnetic media: \(\mu_{\mathrm{R} 1}=\mu_{\mathrm{R} 2}=1\) and \(Z \propto 1 / \mathrm{n}[\omega]\).

Figure 44.9: Amplitude reflection coefficient squared: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue); amplitude transmission coefficient squared: parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(\mathrm{n}[\omega]_{2} / \mathrm{n}[\omega]_{1}=0.67\).

Figure 44.10: Reflectivity: parallel to the incidence plane (dark red) and perpendicular to the incidence plane (light blue). Transmissivity coefficient parallel to the incidence plane (light red) and perpendicular to the incidence plane (dark blue); refractive indexes: \(\mathrm{n}[\omega]_{2} / \mathrm{n}[\omega]_{1}=0.67\).

\subsection*{44.03.05 Energy Balance}

This § is referenced at pages:
[2148, 2148, 2148, 2148, 2150, 2150, 2150, 2150, 2173, 2173]
The reflected energy flux can be determined by just comparing the square of the ratio of the reflected and incident amplitudes.
On the other hand the transmitted energy flux cannot be determined by simply comparing the square of the ratio of the transmitted and incident amplitudes. In fact in this case the direction of the incident and transmitted waves are different and therefore a geometrical factor must be introduced to account for the fact that energy is exchanged at a fixed area at the interface but the incident and transmitted beams have different cross-sectional areas because the waves have different directions. Moreover, the intensity depends on the wave impedance giving factors which do not cancel in the ratio of the transmitted to incident intensities as they do in the ratio of the reflected to incident intensities. This is also evident from the fact that:
\[
\left|r_{\|}\right|^{2}+\left|t_{\|}\right|^{2} \neq 1 \quad\left|r_{\perp}\right|^{2}+\left|t_{\perp}\right|^{2} \neq 1
\]

The correct way to proceed is to write the balance of the power at a piece of surface of area \(A\) of the interface. Let \(J\) be the energy per unit time per unit surface area of the interface (note: per unit surface area of the interface!): not the intensity. For any piece of surface of the interface, \(A_{0}\), and any beam with Incidence/Reflection|Transmission angle \(\theta\), one can write the expression of the energy incident, reflected or transmitted as:
\[
\frac{\Delta E}{\Delta t}=S A_{\perp}=S A_{0} \cos \theta \equiv A_{0} J \Longrightarrow J \equiv S \cos \theta
\]

The equality in terms of the energy per unit time per unit surface area of the interface, \(J\), for any given piece of the surface, can be translated into an expression involving the Poynting vector and the relevant angles:
\[
J_{\mathrm{I}}=J_{\mathrm{R}}+J_{\mathrm{T}} \Longrightarrow S_{\mathrm{I}} \cos \theta_{\mathrm{I}}=S_{\mathrm{R}} \cos \theta_{\mathrm{R}}+S_{\mathrm{T}} \cos \theta_{\mathrm{T}}
\]

The following results for the reflectivity and the transmissivity can be found, for any of the two states of Polarization parallel and perpendicular to the incidence plane:
\[
\begin{gather*}
\mathcal{R} \equiv \frac{J_{\mathrm{R}}}{J_{\mathrm{I}}}=|r|^{2}  \tag{44.03.18}\\
\mathcal{T} \equiv \frac{J_{\mathrm{T}}}{J_{\mathrm{I}}}=|t|^{2} \frac{\operatorname{Re}\left(\mathrm{Z}_{\mathrm{I}}\right)}{\operatorname{Re}\left(\mathrm{Z}_{\mathrm{T}}\right)} \frac{\cos \theta_{\mathrm{T}}}{\cos \theta_{\mathrm{I}}} \tag{44.03.19}
\end{gather*}
\]

Note that the absorption of energy inside the two media does not enter the previous energy balance, because Fresnel relations strictly refer to just the boundary between the two media. Therefore the absorbed energy inside the second medium will be taken from the energy transmitted at the interface, determined by Fresnel relations. Obviously if the first medium is absorbing one should use for the incoming energy the energy reaching the surface: the energy reaching the interface has been already subtracted of the energy absorbed in the first medium.

\subsection*{44.03.06 Total Internal Reflection}

This § is referenced at pages:
[2058, 2058, 2172, 2172]
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|||
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
The two media are two perfect media, that is the refractive indexes are real. In fact total internal reflection is a kinematical property, so it must be possible to describe it for ElectroMagnetic waves also in the simple case of perfect media.
The interface plane is the plane \(x y\).
The incidence plane is the plane \(y=0\), that is the \(x z\) plane. All the problem is in this plane.
The projected vectors on the \(x y\) plane, \(\widetilde{\mathbf{k}}_{\mathrm{I}}, \widetilde{\mathbf{k}}_{\mathrm{R}}, \widetilde{\mathbf{k}}_{\mathrm{T}}\) (all bi-dimensional vectors) are all parallel. Let \(\widetilde{\mathbf{r}}\) be the position vector projected on the \(x y\) plane.
The incident wave-vector \(\mathbf{k}_{\mathrm{I}}\), and therefore \(\widetilde{\mathbf{k}}_{\mathrm{I}}\), are real vectors, by hypothesis.
Snell law implies:
\[
\widetilde{\mathbf{k}_{\mathrm{I}}} \cdot \widetilde{\mathbf{r}}=\widetilde{\mathbf{k}_{\mathrm{R}}} \cdot \widetilde{\mathbf{r}}=\widetilde{\mathbf{k}_{\mathrm{T}}} \cdot \widetilde{\mathbf{r}} .
\]

Snell law, in particular, does not forbid an imaginary part of the \(z\) component of \(\mathbf{k}_{\mathrm{T}}\), as it disappears when projecting onto the incidence plane to get of \(\widetilde{\mathbf{k}}_{\mathrm{T}}\) and it does not change \(\mathbf{k}_{\mathrm{T}} \cdot \widetilde{\mathbf{r}}\).
The condition for total internal reflection is:
\[
\begin{equation*}
\frac{\mathrm{n}[\omega]_{\mathrm{T}}}{\mathrm{n}[\omega]_{\mathrm{I}}} \leq \sin \theta_{\mathrm{I}} \leq 1 \quad \frac{\mathrm{n}[\omega]_{\mathrm{T}}}{\mathrm{n}[\omega]_{\mathrm{I}}} \leq \sin \theta_{\mathrm{T}} \leq 1 \tag{44.03.20}
\end{equation*}
\]

Actually the ElectroMagnetic fields in the second medium may be not exactly zero: the wave-vector in the second medium is complex with its imaginary part perpendicular to the surface.
Let the boundary between the two media be the plane \(x y\) with medium 1 at \(z>0\) and medium 2 at \(z<0\). Let the incidence plane be the plane \(x z\). An ElectroMagnetic MPW is traveling with \(\mathbf{k}_{\mathrm{I}}=\left\{k_{\mathrm{Ix}}, 0, k_{\mathrm{Iz}}\right\}\), with the wave-vector \(\mathbf{k}_{\mathrm{I}}\) real. Assume that total internal reflection apply:
\[
\sin \theta_{\mathrm{I}}>\frac{\mathrm{n}[\omega]_{2}}{\mathrm{n}[\omega]_{1}} \equiv \mathrm{n}[\omega] \quad \mathrm{n}[\omega]_{1}>\mathrm{n}[\omega]_{2} \text { and } \mathrm{n}[\omega]<1 .
\]

The (complex) transmitted wave can be written in terms of the, a priori complex, transmitted wave-vector, \(\overline{\mathbf{k}_{\mathrm{T}}}=\left\{\bar{k}_{\mathrm{Tx}}, 0, \bar{k}_{\mathrm{Tz}}\right\}\) with \(\bar{k}_{\mathrm{Tx}}\) and \(\bar{k}_{\mathrm{Tz}}\) complex numbers, as:
\[
\begin{gathered}
\bar{\psi}_{\mathrm{T}}[\mathbf{r}, t]=\bar{\psi}_{\text {OT }} \exp \left[\beth\left(\overline{\mathbf{k}}_{\mathrm{T}} \cdot \mathbf{r}-\omega t\right)\right]=\bar{\psi}_{\text {OT }} \exp [-\beth \omega t] \exp \left[\beth\left(x \bar{k}_{\mathrm{Tx}}+z \bar{k}_{\mathrm{T} \mathrm{z}}\right)\right]=, \\
\bar{\psi}_{\text {OT }} \exp [-\beth \omega t] \exp \left[\beth \bar{k}_{\mathrm{T}}\left(x \sin \theta_{\mathrm{T}}-z \cos \theta_{\mathrm{T}}\right)\right] \\
\text { with } \quad \bar{k}_{\mathrm{T}} \equiv \sqrt{\overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathbf{k}}_{\mathrm{T}}}
\end{gathered}
\]
where the signs come from the geometry and definition of \(\theta_{\mathrm{I}}\) and \(\theta_{\mathrm{T}}\).
The value of the square of \(\overline{\mathbf{k}_{\mathrm{T}}}\) is given by the relation:
\[
\overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathbf{k}_{\mathrm{T}}}=\frac{\omega^{2}}{v_{2}^{2}}
\]
which shows that the square of \(\overline{\mathbf{k}_{\mathrm{T}}}\) is a real and positive number.
Up to now it is standard: the fact that \(\overline{\mathbf{k}_{\mathrm{T}}}\) is complex will enter from now on.
Note that, for any complex vector \(\overline{\mathbf{k}}\) :
\[
\bar{k} \equiv \sqrt{\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}} \neq \sqrt{\overline{\mathbf{k}} \cdot \overline{\mathbf{k}}^{\star}}=\sqrt{\overline{\mathbf{k}}^{\star} \cdot \overline{\mathbf{k}}} \equiv|\overline{\mathbf{k}}| .
\]

However, in the present problem, \(\overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathrm{k}_{\mathrm{T}}}\) is real and positive.

Therefore:
\[
\begin{aligned}
\sin \theta_{\mathrm{T}}=\frac{\mathrm{n}[\omega]_{1}}{\mathrm{n}[\omega]_{2}} \sin \theta_{\mathrm{I}} \equiv \frac{\sin \theta_{\mathrm{I}}}{\mathrm{n}[\omega]}>\sin \theta_{\mathrm{I}} \Longrightarrow & \sin \theta_{\mathrm{T}} \text { is real but larger than one } \\
& \cos \theta_{\mathrm{T}}= \pm \beth \sqrt{\frac{\sin ^{2} \theta_{\mathrm{I}}}{\mathrm{n}[\omega]^{2}}-1} \Longrightarrow \quad k_{\mathrm{T} \mathrm{I}} \text { is pure imaginary } \\
& \bar{\psi}_{\text {OT }} \exp [-\beth \omega t] \exp \left[\beth \bar{k}_{\mathrm{T}}\left(x \sin \theta_{\mathrm{T}} \mp z \beth \sqrt{\frac{\sin ^{2} \theta_{\mathrm{I}}}{\mathrm{n}[\omega]^{2}}-1}\right)\right]= \\
& \bar{\psi}_{\text {OT }} \exp [-\beth \omega t] \exp \left[\beth \bar{k}_{\mathrm{T}} x \sin \theta_{\mathrm{T}}\right] \exp \left[ \pm \bar{k}_{\mathrm{T}} z \sqrt{\frac{\sin ^{2} \theta_{\mathrm{I}}}{\mathrm{n}[\omega]^{2}}-1}\right]
\end{aligned}
\]

Snell laws also applies to complex wave-vectors, as no reality hypothesis was made in the derivation. In this case, as the incoming \(\mathbf{k}\) is real, it implies that the imaginary part of that the transmitted wave-vector must be perpendicular to the surface, as second Snell law deals with the projection of the wave-vectors on the plane, which must be real in this problem, as the incoming \(\mathbf{k}\) is real.

\subsection*{44.03.06.01 Evanescent Wave}

The resulting wave is exponentially damped along the negative \(z\) direction, when the plus sign is taken in the last expression, as it is appropriate for physical reasons. Therefore constant amplitude planes are perpendicular to the \(z\) axis, while constant phase planes are perpendicular to the \(x\) axis. The amplitude of the wave decreases along the negative \(z\) direction while the wave propagates along the \(x\) direction. The evanescent wave, therefore does not penetrate into the second medium, in fact, due the decreasing amplitude: it is a surface wave.
The attenuation length in the negative \(z\) direction, \(\Lambda\), is of the order of \(\lambda_{2}\), the wavelength of the harmonic oscillation in the second medium along \(x\), because:
\[
\frac{2 \pi}{\lambda_{2}}=\bar{k}_{\mathrm{T}} \sin \theta_{\mathrm{T}} \quad \Lambda^{-1} \equiv \bar{k}_{\mathrm{T}} \sqrt{\frac{\sin ^{2} \theta_{\mathrm{I}}}{\mathrm{n}[\omega]^{2}}-1}
\]

The application of Fresnel relations shows that \(\left|r_{\|}\right|=1\) and \(\left|r_{\perp}\right|=1\).
It can be shown that while the ElectroMagnetic fields in the second medium is not zero, there is no average energy flow in the second medium as the time-average of the \(z\) component of the Poynting vector is zero.
In short the appearance of an imaginary component perpendicular to the interface can be understood as follows. When passing into the second medium \(\bar{k} \cdot \bar{k}\) must decrease while its component parallel to the interface must be conserved. Therefore, at a certain point while increasing the incidence angle, the \(z\) component must decrease to zero; after that an imaginary component along \(z\) must appear, to allow the \(\bar{k} \cdot \bar{k}\) to become as short as required.

\subsection*{44.03.06.02 Some More Technical Details}

The value of the squares of \(\mathbf{k}_{\mathrm{I}}\) and \(\mathbf{k}_{\mathrm{T}}\) are given by the relations:
\[
\begin{aligned}
& \mathbf{k}_{\mathrm{I}} \cdot \mathbf{k}_{\mathrm{I}}=\frac{\omega^{2}}{v_{1}^{2}}, \quad \mathbf{k}_{\mathrm{I}} \quad \text { is real, by hypothesis } \\
& \overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathbf{k}_{\mathrm{T}}}=\frac{\omega^{2}}{v_{2}^{2}}, \\
& , \quad \overline{\mathbf{k}_{\mathrm{T}}} \quad \text { may be complex, a priori } .
\end{aligned}
\]

By hypothesis as the velocities are real and \(\mathbf{k}_{\mathrm{I}} \cdot \mathbf{k}_{\mathrm{I}}\) is real as well, it follows that \(\overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathrm{k}_{\mathrm{T}}}\) must be real. However \(\overline{\mathrm{k}_{\mathrm{T}}} \cdot \overline{\mathrm{k}_{\mathrm{T}}}\) can be real also, for instance, in case \(\bar{k}_{\mathrm{Tz}}\) is pure imaginary. This allows the quantity
\(\overline{\mathbf{k}_{\mathrm{T}}} \cdot \overline{\mathbf{k}_{\mathrm{T}}}\) to decrease with respect to \(\left(\bar{k}_{\mathrm{Tx}}\right)^{2}\) itself in order to satisfy:
\[
\frac{\left(\bar{k}_{\mathrm{Tx}}\right)^{2}+\left(\bar{k}_{\mathrm{Tz}}\right)^{2}}{\left(k_{\mathrm{Ix}}\right)^{2}+\left(k_{\mathrm{Iz}}\right)^{2}}=\frac{v_{1}^{2}}{v_{2}^{2}}
\]

Snell law implies, among other things:
\[
\bar{k}_{\mathrm{Tx}}=k_{\mathrm{Ix}}
\]

It follows:
\[
\begin{gathered}
\left(\bar{k}_{\mathrm{Tz}}\right)^{2}=\left(\bar{k}_{\mathrm{Ix}}\right)^{2}\left(\frac{v_{1}^{2}}{v_{2}^{2}}-1\right)+\left(\bar{k}_{\mathrm{Iz}}\right)^{2}\left(\frac{v_{1}^{2}}{v_{2}^{2}}\right)= \\
\left(\bar{k}_{\mathrm{Tz}}\right)^{2}=\left(\mathrm{n}[\omega]^{2}-1\right)\left(\bar{k}_{\mathrm{Ix}}\right)^{2}+\mathrm{n}[\omega]^{2}\left(\bar{k}_{\mathrm{Iz}}\right)^{2}
\end{gathered}
\]

\subsection*{44.03.06.03 Frustrated Total Internal Reflection}

This § is referenced at pages:
[2169]
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|Pag. 50||
Adding a third layer of material parallel, in and past medium 2, close to the first boundary, the boundary conditions dramatically change, and the ElectroMagnetic wave is revived in the third medium. In this case, some energy is transmitted.

As for the example \(\S 44.06 .02\) - Reflection and Refraction of Waves, this example very nicely shows the effects on ElectroMagnetic waves reflection|transmission when changing boundary conditions: it is, in fact, the standard total internal reflection stuff modified by addition of another parallel boundary which causes a qualitative change of behavior.

\subsection*{44.03.07 Non Monochromatic Radiation Spectral Analysis and Dispersion of Light}

Fresnel formulae were deduced for monochromatic radiation. However there is no change in the frequency at the interface and, moreover the frequency does not appear in the Fresnel formulae. Therefore they can be applied to non-monochromatic radiation without any change.

Note that Snell refraction law actually depends on the frequency.

\section*{Reflection and Refraction of Longitudinal Mechanical Waves}

This § is referenced at pages:
[2142, 2142]
The case of purely longitudinal mechanical waves along the \(z\) axis (that is one-dimensional waves) will be considered in this section. Read also § 41 - Mechanical Waves.

Let the volume mass density be \(\rho\), the Young modulus be \(Y\) and the cross-section of the system having area cross-sectional area \(S\). Let the displacement along the \(z\) direction be \(\xi[z, t]\).

Consider a MPW with wave-vector module \(k>0\), angular frequency \(\omega\) and amplitude \(\xi_{0}\) :
\[
\xi_{ \pm}[z, t]=\xi_{0} \cos [ \pm k z-\omega t] \quad \frac{\partial \xi_{ \pm}}{\partial z}=\mp k \xi_{0} \sin [ \pm k z-\omega t] \quad \omega=k v \quad v^{2}=\frac{Y}{\rho}
\]

The intensity of the reflected and refracted (transmitted) waves at \(z=0\) is calculated from the boundary conditions. The relevant boundary conditions for longitudinal mechanical waves are the continuity of the displacement and of the partial derivative with respect to \(z\) multiplied by the Young modulus, as the latter is the force per unit area.
\[
\begin{gathered}
\xi_{\mathrm{I}}[0, t]+\xi_{\mathrm{R}}[0, t]=\xi_{\mathrm{T}}[0, t] \Longrightarrow \xi_{\mathrm{I} 0}+\xi_{\mathrm{RO} 0}=\xi_{\mathrm{T} 0} \\
-Y_{1} \frac{\partial \xi_{\mathrm{I}}}{\partial z}[0, t]-Y_{1} \frac{\partial \xi_{\mathrm{R}}}{\partial z}[0, t]=-Y_{2} \frac{\partial \xi_{\mathrm{T}}}{\partial z}[0, t] \Longrightarrow k_{1} Y_{1} \xi_{\mathrm{IO}}-k_{1} Y_{1} \xi_{\mathrm{R} 0}=k_{2} Y_{2} \xi_{\mathrm{T} 0}
\end{gathered}
\]

The second boundary condition is the condition that the force per unit area must be a continuous function across the boundary. It can be derived by considering a small cylinder around the interface between the two media, writing the first cardinal equation for the enclosed piece of matter and letting the cylinder become infinitesimally small:
\[
-Y_{1} \frac{\partial \xi_{1}}{\partial z}[z=-\epsilon / 2, t]+Y_{2} \frac{\partial \xi_{2}}{\partial z}[z=+\epsilon / 2, t]=S \epsilon \rho \frac{\partial^{2} \xi[\widetilde{z}, t]}{\partial t^{2}} \longrightarrow-Y_{1} \frac{\partial \xi_{1}}{\partial z}[0, t]=-Y_{2} \frac{\partial \xi_{2}}{\partial z}[0, t]
\]

It follows:
\[
\begin{aligned}
& r \equiv \frac{\xi_{\mathrm{RO}}}{\xi_{\mathrm{IO}}}=\frac{k_{1} Y_{1}-k_{2} Y_{2}}{k_{1} Y_{1}+k_{2} Y_{2}} \\
& t \equiv \frac{\xi_{\mathrm{TO}}}{\xi_{\mathrm{IO}}}=\frac{2 k_{1} Y_{1}}{k_{1} Y_{1}+k_{2} Y_{2}}
\end{aligned}
\]

Moreover, the following relations apply:
\[
\begin{equation*}
v^{2}=\frac{Y}{\rho} \quad k=\frac{\omega}{v}=\omega \sqrt{\frac{\rho}{Y}} \quad k Y=\omega \sqrt{\rho Y} \quad Z \equiv S \sqrt{\rho Y} \tag{44.04.01}
\end{equation*}
\]

Here two pairs of parameters can be used to describe the wave:
\[
\begin{equation*}
\{\rho, Y\} \leftrightarrow\{v, Z\} \tag{44.04.02}
\end{equation*}
\]
as for ElectroMagnetic waves, see equation (44.03.02).
Note that the frequencies are not changed, as this is a kinematic boundary condition (read § 44.02 Reflection and Refraction of Waves).

Therefore:
\[
r \equiv \frac{\xi_{\mathrm{RO}}}{\xi_{\mathrm{IO}}}=\frac{\sqrt{\rho_{1} Y_{1}}-\sqrt{\rho_{2} Y_{2}}}{\sqrt{\rho_{1} Y_{1}}+\sqrt{\rho_{2} Y_{2}}}=\frac{Z_{1}-Z_{2}}{Z_{1}+Z_{2}} \quad t \equiv \frac{\xi_{\mathrm{TO}}}{\xi_{\mathrm{IO}}}=\frac{2 \sqrt{\rho_{1} Y_{1}}}{\sqrt{\rho_{1} Y_{1}}+\sqrt{\rho_{2} Y_{2}}}=\frac{2 Z_{1}}{Z_{1}+Z_{2}} \geq 0
\]

The points at the interface generates a wave going in both directions: the reflected and the transmitted waves. The wave in the first medium is the superposition of the incident and the reflected waves.

The transmitted wave is always in-phase with the incident wave. On the other hand the reflected wave is either in-phase or out-of-phase by \(\pi\) according to the relative magnitude of \(Z_{1}\) and \(Z_{2}\).

\subsection*{44.04.01 Reflected|Transmitted Intensities}

This § is referenced at pages:
[2153, 2153]
Note that the amplitude transmission coefficient is different from the one for ElectroMagnetic waves at normal incidence, (read \(\S 44.03 .04 .02\) - Reflection and Refraction of Waves).

The reflected and transmitted intensities are, exactly as for the ElectroMagnetic waves at normal incidence:
\[
\frac{\frac{I_{\mathrm{R}}}{I_{\mathrm{I}}}=\left(\frac{Z_{1}-Z_{2}}{Z_{1}+Z_{2}}\right)^{2}}{\frac{I_{\mathrm{T}}}{I_{\mathrm{I}}}=\frac{4 Z_{1} Z_{2}}{\left(Z_{1}+Z_{2}\right)^{2}}}
\]

\subsection*{44.04.02 Impedance Matching/Mismatch}

As a general result, from formulas (44.04.03):
- if the impedances are very different there is large reflection (impedance mismatch);
- if the impedances are very similar there is large transmission (impedance matching).

Consider now some limiting cases.
If \(\left(Z_{2} / Z_{1}\right) \rightarrow \infty\) (infinitely hard second medium) the transmitted wave is zero while the reflected wave has the same amplitude of the incident wave but opposite sign (it is out-of-phase by \(\pi\) ).

If \(\left(Z_{1} / Z_{2}\right) \rightarrow \infty\) (infinitely soft second medium) the transmitted wave is twice the incident wave while the reflected wave has the same amplitude of the incident wave and the same sign (it is in-phase).

If \(Z_{1}=Z_{2}\) the reflected wave is zero and all the energy passes into the second medium. In this case the impedances of the two media are said to be matched.

If \(Z_{2}>Z_{1}\) the reflected wave is out-of-phase by \(\pi\) with respect to the incident wave to partly cancel, in the boundary condition, the incident wave as the transmitted wave has a smaller amplitude than the incident wave in this case.

If \(Z_{1}>Z_{2}\) the reflected wave is in-phase with respect to the incident wave to add to the incident wave, in the boundary condition, as the transmitted wave has a larger amplitude than the incident wave in this case.

Note that in this problem it is not necessary to add a phase-shift between the incident wave and the Reflected|Transmitted waves because the parameters, in particular \(Z\), are real numbers. Therefore it turned out that we are able to solve the problem without an additional phase-shift between the incident wave and the Reflected|Transmitted wave and the only possible phase-shifts are either \(\Delta \phi=0\) or \(\Delta \phi= \pm \pi\) which can be simply described as a change of sign.

The case of purely transverse mechanical waves along the \(z\) axis (that is two-dimensional waves) will be considered in this section.
Let the linear mass density be \(\lambda\), the string tension be \(T\) and the cross-section of the system having area cross-sectional area \(S\). Let the displacement along the \(\{x, y\}\) direction be \(\xi[x, y, t]\).

The wave characteristics are the following ones:
\[
\begin{equation*}
v^{2}=\frac{T}{\lambda} \quad k=\frac{\omega}{v}=\omega \sqrt{\frac{\lambda}{T}} \quad k T=\omega \sqrt{\lambda T} \quad Z \equiv \sqrt{\lambda T} . \tag{44.05.01}
\end{equation*}
\]

\section*{Examples and Physical Applications}

\subsection*{44.06.01 Light}

\subsection*{44.06.01.01 Light Guides}

Built from, for instance, flexible glass fibres: optical fibres. Light trapped inside the light guide can run a long way with, ideally, no losses.
Applications: endoscopy, data-transmission.

\subsection*{44.06.01.02 Air-Glass Interface}

Interface air-glass. refractive index of glass \(\mathrm{n}[\omega] \simeq 1.5\). refractive index of air \(\mathrm{n}[\omega] \simeq 1.0\).
The amplitude reflection coefficient at normal incidence is about 0.04 . The tiny reflection from glass is the responsible of the reflected image which can be seen under low illumination when looking across a window.
The total internal reflection angle from glass to air is \(\simeq 42^{\circ}\).
The Brewster angle is \(\simeq 57^{\circ}\).

\subsection*{44.06.01.03 Dispersion of Light}

Many different phenomena, such as rainbows, show that refraction of light depends on the light color, that is wavelength. Therefore one is compelled to conclude that the refractive index depends on the wavelength. Read § 50 - ElectroMagnetic Waves in Matter.

\subsection*{44.06.01.04 Sun at Sunset}

Demonstrate, using Snell laws, that the image of Sun at sunset is shorter, in the vertical direction, than in the horizontal direction so that the image is not circular.
Use refraction into a medium with larger refractive index to show:
\[
\begin{gathered}
\Delta \theta_{2} \simeq \frac{\mathrm{n}[\omega]_{1}}{\mathrm{n}[\omega]_{2}} \frac{\cos \theta_{1}}{\cos \theta_{2}} \Delta \theta_{1} \\
\mathrm{n}[\omega]_{1}<\mathrm{n}[\omega]_{2} \Longrightarrow \\
\\
\Delta \theta_{1}>\theta_{2} \Longrightarrow \operatorname{tos} \theta_{1}<\cos \theta_{2}
\end{gathered}
\]

\subsection*{44.06.01.05 Mirage}

A mirage is a naturally occurring optical phenomenon in which light rays are bent to produce a displaced image of distant objects or the sky.
Inferior mirage: hot air near the Earth has a lower refractive index than cooler air above. The image of an object appears to come from below the Earth thanks to the curvature of the rays (a convex function).
Superior mirage: the other way round, caused by temperature inversion (including the so-called Fata Morgana).

Mirages also happen for sound waves.

\subsection*{44.06.02 Multiple Reflections Between Layers of Dielectrics (Anti-Reflection Coatings)}

This § is referenced at pages:
[2164, 2164]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
Consider three LHI materials separated by three plane surfaces at \(z=0\) and \(z=L\). A MPW, linearly Polarized, is traveling in the positive direction of the \(z\) axis inside medium 1 , and reaches medium 2 at \(z=0\). It is partially reflected and the transmitted part travels, inside medium 2 , until it reaches the interface with medium 3 at \(z=L\), where it is partially reflected and transmitted.

This example very nicely shows the effects on ElectroMagnetic waves reflection|transmission when changing boundary conditions: it is, in fact, the standard reflection|transmission stuff giving Fresnel equations (44.03.03), (44.03.07), modified by addition of another parallel boundary. Under this respect, it is similar to frustrated internal reflection in (44.03.06.03).
Let us use the convention that all the electric fields are conventionally oriented as the direction of the incoming electric field. Then the conventional orientation for the magnetic field of waves traveling in the positive direction is opposite to that of the magnetic field of waves traveling in the negative direction.
The Electric|Magnetic fields of the MPW are:
\[
\overline{\mathbf{E}}=\overline{\mathbf{E}}_{0} \exp [\beth( \pm k z-\omega t)] \quad \overline{\mathbf{H}}=\overline{\mathbf{H}}_{0} \exp [\beth( \pm k z-\omega t)] \quad \text { with } \overline{\mathbf{E}}=\overline{Z \mathbf{H}},
\]
where any phase is included in the complex constant vector.
The waves are defined from \(z=-\infty\) to \(z=+\infty\), but they are made of different pieces to be joined at the two interfaces.
The common \(\exp [-\beth \omega t]\) factor can be removed.
The explicit use of \(\ldots\) to denote complex quantities will be avoided here, because all quantities are considered a priori as complex quantities.
The continuity equations at the interfaces for the electric field and for \(\mathbf{H}\), are:
\[
\begin{gathered}
E_{\mathrm{I}}+E_{\mathrm{R}}=E_{2}^{+}+E_{2}^{-}, \\
\frac{E_{\mathrm{I}}}{Z_{1}}-\frac{E_{\mathrm{R}}}{Z_{1}}=\frac{E_{2}^{+}}{Z_{2}}-\frac{E_{2}^{-}}{Z_{2}}, \\
E_{2}^{+} \exp \left[+\beth k_{2} L\right]+E_{2}^{-} \exp \left[-\beth k_{2} L\right]=E_{\mathrm{T}} \exp \left[+\beth k_{3} L\right], \\
\frac{E_{2}^{+}}{Z_{2}} \exp \left[+\beth k_{2} L\right]-\frac{E_{2}^{-}}{Z_{2}} \exp \left[-\beth k_{2} L\right]=\frac{E_{\mathrm{T}}}{Z_{3}} \exp \left[+\beth k_{3} L\right] .
\end{gathered}
\]

Note that the phase of \(E_{\mathrm{T}} \exp \left[+\beth k_{3} L\right]\) might be just ignored by re-absorbing it into the definition of \(E_{\mathrm{T}}\).
The solution of the system of four equations in four unknown variables, \(E_{\mathrm{R}}, E_{2}^{+}, E_{2}^{-}\)and \(E_{\mathrm{T}}\), gives the complex amplitude reflection coefficient:
\[
r=\frac{E_{\mathrm{R}}}{E_{\mathrm{I}}}=\left(\frac{Z_{2}\left(Z_{3}-Z_{1}\right) \cos \left[k_{2} L\right]-\beth\left(Z_{2}^{2}-Z_{1} Z_{3}\right) \sin \left[k_{2} L\right]}{Z_{2}\left(Z_{3}+Z_{1}\right) \cos \left[k_{2} L\right]-\beth\left(Z_{2}^{2}+Z_{1} Z_{3}\right) \sin \left[k_{2} L\right]}\right) .
\]

This result shows that the Reflection|Transmission coefficients can be complex numbers, even for real wave impedance.
It can be verified that for either \(L=0\) or \(Z_{2}=Z_{3}\) or \(Z_{1}=Z_{2}\) one obtains the same results as the standard Fresnel formulas for two media.
The reflectivity is given by:
\[
\mathcal{R}=\left|\frac{E_{\mathrm{R}}}{E_{\mathrm{I}}}\right|^{2}=\left(\frac{Z_{2}^{2}\left(Z_{3}-Z_{1}\right)^{2} \cos ^{2}\left[k_{2} L\right]+\left(Z_{2}^{2}-Z_{1} Z_{3}\right)^{2} \sin ^{2}\left[k_{2} L\right]}{Z_{2}^{2}\left(Z_{3}+Z_{1}\right)^{2} \cos ^{2}\left[k_{2} L\right]+\left(Z_{2}^{2}+Z_{1} Z_{3}\right)^{2} \sin ^{2}\left[k_{2} L\right]}\right) .
\]

It can be shown that the reflectivity has extrema for:
\[
\begin{equation*}
k_{2} L=m \pi / 2 \Longrightarrow \frac{2 L}{\lambda_{2}}=m / 2 \Longrightarrow \lambda_{2}=\frac{2 L}{m / 2} \tag{44.06.01}
\end{equation*}
\]
but this is obvious, as it corresponds to an half-integer number of wavelengths inside the path of length \(2 L\), that is corresponds to a travel forward and backward inside medium 2. Under these conditions, a stationary wave is formed in medium 2 .
In the case \(Z_{1}<Z_{2}<Z_{3}\) :
- the points at \(k_{2} L=m \pi\) are maxima;
- the points at \(k_{2} L=\pi / 2+m \pi\) are minima.

In the case of minima, the reflectivity is identically zero for \(Z_{2}=\sqrt{Z_{1} Z_{3}}\). The reflectivity is thus zero (as the numerator of \(r\) is clearly zero) for:
\[
k_{2} L=(2 m+1) \frac{\pi}{2} \quad \text { and } \quad\left\{Z_{2}=\sqrt{Z_{1} Z_{3}} \quad \Leftrightarrow \quad\left\{\mathrm{n}[\omega]_{2}=\sqrt{\mathrm{n}[\omega]_{1} \mathrm{n}[\omega]_{3}} \quad \text { for non-magnetic media }\left(\mu_{\mathrm{R}}=1\right)\right\}\right\}
\]

The condition on the thickness of the layer correspond, for the minimum thickness \(m=0\), to a thickness of one quarter of wavelength.
The case when reflection is zero is the case of optical impedance matching between media 1 and 3 by using the adapter medium 2. In practical cases it might be impossible to obtain exact matching, that is zero reflection, but only a reduced reflection. Moreover, the condition depends on the frequency.

The reflected wave is canceled if and only if the wave reflected from the first surface combines to exactly cancel the wave first refracted/transmitted by the first surface and then reflected by the second surface and finally refracted/transmitted again by the first surface to go back in the first medium. Therefore the exact optical impedance matching is the case of destructive interference, in fact (read § 46 - Interference).

\section*{Examples and Applications}
- Multi-layers dielectric coatings.
- Multi-layers dielectric mirrors.

44-005 Refractive index and density
Explain why the refractive index increases with density of the material.

\section*{44-006 Radio-Telescopes and Optical Telescopes}

The surfaces of a radio-telescope, operating in radio-waves with wavelengths of the order of meters, do not need the geometrical precision of optical telescopes, operating with wavelengths of the order of hundreds of nanometers.

\section*{44-007 Typical Glasses}

Take a typical glass with \(\mathrm{n}[\omega]=1.5\). At normal incidence:
\[
\mathcal{R}_{\|}=\mathcal{R}_{\perp} \simeq 0.04
\]

Note: typical glasses show dispersion, that is dependence of the phase velocity (and therefore refractive index) on the frequency of the monochromatic PW.

Double image from the train window: double reflection, the second one with reduced intensity; better seen when outside it is dark.

44-008 reflectivity and transmissivity in TIR for ElectroMagnetic Waves
Verify that in presence of total internal reflection the reflectivity is one and and the transmissivity is zero usingFresnel equations for ElectroMagnetic waves.

\section*{44-009 Energy Flux in TIR for ElectroMagnetic Waves}

Verify that in presence of total internal reflection the average value of the Poynting vector in the second medium is zero using the results in §44.03.06-Reflection and Refraction of Waves.

44-010 Reflection of ElectroMagnetic Waves and ElectroMagnetic Fields in the First Medium
Study the total ElectroMagnetic field in the first medium, by superposing the incident and reflected ElectroMagnetic waves. In particular show that a standing wave is present in addition to a traveling wave and that the total field correponds to a non homogeneous plane ElectroMagnetic wave.

\section*{44-011 Reflected and Refracted Flux}

Consider ElectroMagnetic waves at normal incidence at the plane interface between two LHI media. Determine if a condition exists on the refractive indexes of the two materials such that the reflected energy is larger that the transmitted energy.

\section*{44-012 Reflection of Circularly Polarized Waves}
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|8.27||
Determine how the handedness of a circularly Polarized waves changes at normal reflection with two non-magnetic media with \(\chi_{M}^{*}=1\) in the two cases: \(n[\omega]_{2}>\mathrm{n}[\omega]_{1}\) and \(\mathrm{n}[\omega]_{1}>\mathrm{n}[\omega]_{2}\).

\section*{44-013 Curvature and trajectory of optical rays in Atmosphere}
©|WEB - URLII|
Study the problem of refraction/transmission of light rays in the atmosphere.
Assume first that the Earth is flat and let \(z\) be the height above the Earth. Consider a light ray going up the Earth atmosphere, starting at an height \(z_{0}\) where the light ray has a incidence angle, that is the angle with respect to the normal to the Earth, \(\theta_{0}\). Let the atmosphere refractive index be varying as a function of \(z, \mathrm{n}[\omega][z]\), such that: \(\mathrm{n}[\omega]\left[z=z_{0}\right]=\mathrm{n}[\omega]_{0}\) and \(\mathrm{n}[\omega]\left[z=z_{1}\right]=\mathrm{n}[\omega]_{1}\). Consider a large but finite number of layers, \(M\), of thickness \(\Delta z \equiv\left(z_{1}-z_{0}\right) / M\) and calculate the light reflected and transmitted at every layer. Finally, let the number of layers go to infinity and find the continuous limit.
Use now the results derived above to describe in a qualitative way for a spherical Earth the fact that astronomical bodies can be seen even when they are slightly below the horizon and, in general, the fact that the real position of astronomical bodies is slightly different from their apparent position.

\section*{44-014 Shift of Light Rays on Passing a Plane Transparent Lamina}

Light rays with incidence angle \(\theta_{0}\) on a transparent lamina of thickness \(D\) and refractive index \(n[\omega]\) pass across the lamina. Calculate the shift of the rays exiting the lamina with respect to the incident rays and its dependence on the thickness of the lamina and on the refractive index.

\section*{44-018 Magnesium-Fluoride Anti-Reflection Coating}

Magnesium-Difluoride \(\left(\mathrm{MgF}_{2}\right)\) has \(\mathrm{n}[\omega]_{2}=1.38\). Determine the amplitude reflection coefficient for a quarter-wave coating on glass ( \(\mathrm{n}[\omega]_{3}=1.5\) ).

\section*{44-019 Maximum Deviation Prism}

A prism is made of a material of refractive index \(n[\omega]\) and has the shape of a cylinder with a isosceles triangle as a basis. The apex angle, that is the angle opposite to the base of the isosceles triangle, is \(\alpha\).
Consider a light ray parallel the bases of the prism with incidence angle \(\theta_{0}\) on one of the two lateral faces corresponding to the two equal sides of the isosceles triangle.
Determine the angular deviation of the ray exiting from the opposite lateral face, that is the angle between the exiting and the entering ray.
Determine the incidence angle giving the minimum deviation angle.

\section*{44-020 Energy Balance at Reflection|Transmission for ElectroMagnetic Waves}
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|||
Consider the plane interface separating two LHI media. Show explicitly that the energy balance presented in §44.03.05-Reflection and Refraction of Waves is correct at arbitrary incidence by using the Fresnel relations.

\section*{44-021 Brewster Angle}

Consider a flat uniform lamina of thickness \(d\) and refractive index \(\mathrm{n}[\omega]_{2}\) inside a medium of refractive index \(n[\omega]_{1}\). Assume that light is directed towards the lamina at the Brewster angle relative to the passage from medium 1 to medium 2 . Show that the light transmitted inside the lamina and reaching the second face of the lamina will be at the Brewster angle relative to the passage from medium 2 to medium 1.

\section*{44-022 Cherenkov Light and TIR}

A plane transparent lamina with parallel faces is made of a material with refractive index \(n[\omega]\). Cherenkov light is emitted inside the lamina by a particle crossing the lamina perpendicularly at a speed close to the speed of light in vacuum.
Determine the minimum value of \(n[\omega]\) such that all Cherenkov light suffers TIR instead of exiting the lamina.

Radiation == Energy transported irreversibly out to infinity.
Because of the finite speed of light the radiate power is retarded:
\[
\begin{equation*}
W_{\mathrm{RAD}}\left[t_{0}\right]=\lim _{r^{\prime} \rightarrow \infty} W_{\mathrm{RAD}}\left[t_{0}+\frac{r^{\prime}}{c}\right] \equiv \lim _{r^{\prime} \rightarrow \infty} \oiiint_{r<r^{\prime} / c} \mathbf{S} \cdot \mathrm{~d} \mathbf{S} \tag{45.00.01}
\end{equation*}
\]

ElectroMagnetic radiation is produced by accelerated charges, with many examples/applications such as:
- the production of x-rays;
- the acceleration of charged particles to relativistic velocities in particle-accelerators;
- the radiation from antennas;
- the reception of ElectroMagnetic waves by antennas;
- heat and light from the Sun;
- light emitted by a bulb-lamp;

\section*{ElectroMagnetic Potentials for Time-Dependent Fields}

This § is referenced at pages:
[1716, 1716, 1720, 1720, 1961, 1961]

\subsection*{45.01.01 Lorenz Gauge}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|6.5||
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|2.1.2||
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
A most useful gauge choice is the Lorenz Gauge, defined in equation (33.11.03).
In fact the Lorenz Gauge gives rise to two uncoupled non-homogeneous wave equations:
\[
\begin{array}{|}
\nabla^{2} \Phi-\varepsilon_{0} \mu_{0} \frac{\partial^{2} \Phi}{\partial t^{2}}=-\rho / \varepsilon_{0} \\
\nabla^{2} \mathbf{A}-\varepsilon_{0} \mu_{0} \frac{\partial^{2} \mathbf{A}}{\partial t^{2}}=-\mu_{0} \mathbf{j} \tag{45.01.02}
\end{array}
\]

17192177
21782180
\(\xrightarrow{2210}\)
17192177
Therefore, one can find solutions for \(\Phi / \mathbf{A}\) independently from one another. However, the sources are non independent, as they must be linked by the charge continuity equation (62.05.01), which is in turn is consistent with the Lorenz gauge fixing condition (read § 45-011 - Radiation of ElectroMagnetic Waves).

Note that, in static conditions, the Lorenz Gauge reduces to:
\[
\operatorname{div} \mathbf{A}=0 \quad \text { in static conditions }
\]
while the wave equations (45.01.01), (45.01.02) reduce to the Poisson equation. Read § 45.03 - Radiation of ElectroMagnetic Waves for discussion of the solutions.

\subsection*{45.01.02 Coulomb Gauge or Radiation Gauge or Transverse Gauge}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|6.5||
Another useful gauge is the Coulomb gauge, or radiation gauge or transverse (Coulomb) gauge. It is defined as:
\[
\operatorname{div} \mathbf{A}=0
\]

This is especially useful in regions without charges and currents ( \(\rho[\mathbf{x}, t]=0\) and \(\mathbf{j}[\mathbf{x}, t]=0\) ), hence the name: radiation gauge. In fact in this case, the two equations (33.11.07), (33.11.07) become:
\[
\begin{gathered}
\boldsymbol{\nabla}^{2} \Phi=0 \\
\boldsymbol{\nabla}^{2} \mathbf{A}-\varepsilon_{0} \mu_{0} \frac{\partial^{2} \mathbf{A}}{\partial t^{2}}=0 \\
\hline
\end{gathered}
\]

The Laplace equation for the scalar potential has the particular solution, \(\Phi[\mathbf{x}, t]=0\), as \(\rho[\mathbf{x}, t]=0\). The wave equation for the vector potential is just an homogeneous wave equation. Both Electric|Magnetic fields can be calculated from the vector potential only:
\[
\begin{array}{|l|}
\hline \mathbf{E}=-\partial_{t} \mathbf{A} \\
\hline \mathbf{B}=+\boldsymbol{\operatorname { r o t }} \mathbf{A} \\
\hline
\end{array}
\]

It can be shown that in the transverse gauge there is no instantaneous propagation of signals, even if the equation for the scalar potential is a static one, that is based on the Laplace, time independent, operator.

© |D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|11||
Throughout this section it will be always assumed that the sources of ElectroMagnetic fields are localized near the origin of some Coordinate System. Moreover, Maxwell Equations in vacuum will be always used, to emphasize their fundamental meaning. Matter will be treated as a set of particles with some specific properties (mass, spin, charge, Electric|Magnetic Dipole moment, ...), the way it is. The macroscopic description of ElectroMagnetic fields in matter will never be used in this section.
When the full set of Maxwell Equation are solved one finds that, in the non-static case, solutions exist capable to carry energy to infinity, as they are made of ElectroMagnetic fields decreasing, at large distance from the sources, as \(r^{-1}\), as opposed to static fields, decreasing, at large distance from the sources, as \(r^{-2}\). ElectroMagnetic fields decreasing, at large distance from the sources, as \(r^{-1}\) are called radiation fields. The flux of the Poynting vector at large distances, in presence of radiation fields, does not go necessarily to zero, leaving room to energy transport to infinity. In this case, the radiated power is the power crossing a gigantic sphere surrounding the sources when the radius of the sphere goes to infinity.

\subsection*{45.02.01 Physical Origin of Radiation of ElectroMagnetic Fields}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
The non-homogeneous wave equations for the ElectroMagnetic potentials, equations (45.01.01) and (45.01.02), show that the vector potential is a linear function of the current density, \(\mathbf{j}\), as the wave equation is a linear equation. We also know that the electric field contains a term which is the time derivative of the vector potential. Therefore one expects that the electric field will contain a term depending on the acceleration of the charges. Similarly, the magnetic field will depend on the acceleration, as it can be shown from Jefimenko equations (45.03.05), (45.03.06).
Dimensional considerations imply that a term depending on the acceleration of the charges must go as \(r^{-1}\) at large distances. In fact, assuming that \(\mathbf{E}\) depends on \(q\) (linearly, as expected from Maxwell Equations), on a (linearly, as expected from the above considerations), and on \(\varepsilon_{0}, c, r\), it turns out that the dependence on the distance is proportional to \(r^{-1}\), for a term depending on the acceleration. At large enough distances from the generators of the ElectroMagnetic waves can be approximated by a MPW, so that the magnetic field must have the same \(r^{-1}\) dependence on the distance.
The study of ElectroMagnetic radiation involves therefore studying the terms of the electric and magnetic fields going as \(r^{-1}\) at large distances. The radiation field is therefore capable to carry ElectroMagnetic energy to infinity.
In order to have emission of ElectroMagnetic radiation in vacuum, therefore, the source charges must be accelerated. Important apparent exceptions to the requirement of acceleration of the source charges are given by Cherenkov radiation and transition radiation, (read § 42.13.01 - ElectroMagnetic Waves, \(\S 42.13 .02\) - ElectroMagnetic Waves), which, however, involve motion of charges inside some material medium. Actually this point shows how misleading the macroscopic description in terms of averaged Polarization \(\mid\) Magnetization and/or auxiliary vectors \(\mathbf{D} \mid \mathbf{H}\) can be. In fact, it hides that Cherenkov radiation
and transition radiation are due to time-varying Polarization, producing accelerated Polarization charges. Only apparently, it gives radiation production with non accelerated charges.
The fact that a charge moving at constant speed in vacuum does not emit ElectroMagnetic radiation is consistent with relativity, as there is a Reference Frame where the charge is stationary.
It can be shown that, in case the motion of the particle is periodic, the emitted radiation has a discrete energy spectrum with frequencies multiples of the fundamental frequency \({ }^{1}\).

\subsection*{45.02.02 Retarded Time}

Maxwell Equations in vacuum give a precise value, \(c\), for the speed of light in vacuum.
Therefore ElectroMagnetic fields move in vacuum at speed \(c\) and the time-delay between the event producing the ElectroMagnetic radiation at \(\mathbf{r}_{1}\) at \(t_{1}\) and the observation of the ElectroMagnetic radiation produced by that event at \(\mathbf{r}_{2}\) at \(t_{2}\) is:
\[
\begin{equation*}
\Delta t \equiv t_{2}-t_{1}=\frac{\left|\mathbf{r}_{2}-\mathbf{r}_{1}\right|}{c} \tag{45.02.01}
\end{equation*}
\]

This first introduces the concept of retarded time: what the observer sees now is what was emitted exactly a time ago equal to the propagation time from the emission point to the observation point.
The notation \([\ldots]_{\mathrm{R}}\) will denote that the expression must be calculated at the retarded time, \(t_{\mathrm{R}}\).

\subsection*{45.03.01 Retarded Potentials Solution}
© |D.Griffiths, M.Heald|Time-dependent generalizations of the Biot-Savart and Coulomb laws|Am.J.Phys,
.Ed., .... 59, 111 (1991)|
In case of localized Charge|Current, equations (45.01.01), (45.01.02) (the non-homogeneous wave equations for the ElectroMagnetic potentials in the Lorenz Gauge) have the following solutions (the retarded potentials solution):
\[
\begin{equation*}
\Phi[\mathbf{x}, t]=\frac{1}{4 \pi \varepsilon_{0}} \iiint \frac{\rho[\mathbf{y}, t-|\mathbf{x}-\mathbf{y}| / c]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y} \quad \mathbf{A}[\mathbf{x}, t]=\frac{\mu_{0}}{4 \pi} \iiint \frac{\mathbf{j}[\mathbf{y}, t-|\mathbf{x}-\mathbf{y}| / c]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y} \tag{45.03.01}
\end{equation*}
\]
the integration being carried throughout the whole space.
The solution equation (45.03.01) can be quickly found from the Green function \({ }^{2}\) of the 3D wave operator:
\[
G\left[\mathbf{y}, t, \mathbf{x}, t_{\mathrm{R}}\right]=\frac{\delta\left[t_{\mathrm{R}}-t+|\mathbf{x}-\mathbf{y}| / c\right]}{|\mathbf{x}-\mathbf{y}|}
\]

It can be verified, by a direct and cumbersome calculations, that equations (45.03.01) are the solutions of the inhomogeneous wave equation (45.01.01), (45.01.02), by substituting into equation (45.01.01), (45.01.01). One has to remember that the retarded time brings into a dependence on the position via the retarded time.
Equations (45.03.01) have a very simple physical interpretation as they just show that one may regard the potentials as arising from infinitesimal contributions from each infinitesimal volume element of space, each one time-retarded and contributing the amounts:
\[
\begin{equation*}
\frac{\rho[\mathbf{y}, t-|\mathbf{x}-\mathbf{y}| / c]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y} \quad \frac{\mathbf{j}[\mathbf{y}, t-|\mathbf{x}-\mathbf{y}| / c]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y} . \tag{45.03.02}
\end{equation*}
\]

The retarded potentials solution in equation (45.03.01) represent a particular solution to the nonhomogeneous wave equations (45.01.01), (45.01.02). Any solution of the homogeneous part of equations (45.01.01), (45.01.02), that is the wave equation, can be added to the retarded potentials solution, in order to satisfy the appropriate boundary conditions. The general solution to the equation is obtained by adding to the particular solution, given by the retarded potentials solution, the general solution of the homogeneous equation, in the Lorenz Gauge.
The retarded potentials solution in equation (45.03.01) can be justified by the heuristic argument given in \(\S 45.02\) - Radiation of ElectroMagnetic Waves, assuming the speed of propagation is \(c\). However this arguments must be taken with care. In fact if one were to apply the same argument (the retardation) to the electric or magnetic field one would find a totally wrong result. In fact the solution for the ElectroMagnetic fields is provided by Jefimenko equations (45.03.05), (45.03.06).

\section*{© - QUOTE}
D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....

Well, that all sounds reasonable - and surprisingly simple. But are we sure it's right? I didn't actually derive these formulas for \(\Phi\) and \(\mathbf{A}\); all I did was invoke a heuristic argument ("electromagnetic news travels at the speed of light") to make them seem plausible.

In case you think I'm being fussy, let me warn you that if you apply the same argument to the fields you'll get entirely the wrong answer. ...

In fact, d'Alembert equations for the potentials are the same d'Alembert equations as for the fields, so the question arise on why one does not get the retarded solution for the ElectroMagnetic fields? The answer is that, for fields, the d'Alembert equations need to be complemented with additional conditions from Maxwell equations and, in particular, one knows that Electric|Magnetic fields are not really independent. On the other hand, the two equations for potentials are independent, apart from Lorenz gauge condition which is, however, satisfied thanks to charge continuity equation. The two d'Alembert equations for the potentials, in the Lorenz gauge, do not need any additional constraint to be satisfied, while the solutions to the two d'Alembert equations for the fields need additionally to satisfy Maxwell equations. In fact, the wrong time-retarded Coulomb and Biot-Savart laws would imply a total decoupling of Electric|Magnetic fields, which is implicit in the d'Alembert equations for Electric|Magnetic fields, but not consistent with Maxwell equations.

Note that, in general,
\[
\text { total charge } \neq \iiint \rho[\mathbf{y}, t-|\mathbf{x}-\mathbf{y}| / c] \mathrm{d} \mathbf{y}
\]
due to the kinematics of the charges.

\subsection*{45.03.01.01 Retarded Time and Advanced Time}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|10||
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|16||

The name retarded potentials solution (retarded with respect to the timing of Charge|Current), comes from the fact that the effect of the Charge|Current configuration on the ElectroMagnetic fields at positiontime \(\{\mathbf{x}, t\}\), is due to the configuration of the Charge|Current at an anticipated time, \(t_{\mathrm{R}}\), (called the retarded-time), that is, it is retarded with respect to what happened at the source, by a retardation given by the travel-time of the ElectroMagnetic radiation:
\[
\begin{equation*}
t_{\mathrm{R}} \equiv t-|\mathbf{x}-\mathbf{y}| / c \tag{45.03.03}
\end{equation*}
\]
\(\rightarrow\)

The difference between the time and the retarded time is just the time that EM radiation takes to go from \(\mathbf{x}\) to \(\mathbf{y}\).

It is important to stress that the retarded time has nothing to do with changes of Reference Frame. Times and retarded times are always measured in the same Laboratory Frame and therefore no relativistic transformation of times is involved. In fact, in the definition of retarded-time, there is no reference to typical relativistic factors, such as \(\beta\) and \(\gamma\).

Similarly, it can be shown that there exist also the solution with the retarded time replaced by the advanced time:
\[
t_{\mathrm{A}} \equiv t+|\mathbf{x}-\mathbf{y}| / c
\]

However, even if this is a solution from the mathematical point of view, it has to be discarded on the basis of causality, because it represents the case of radiation being received before being emitted.

The concept of retarded time is well-known for instance, with respect to The Andromeda Galaxy, which is approximately 2.5 million light-years distant from Earth. We are seeing today how it was 2.5 million years ago, as we receive today the ElectroMagnetic fields generated by charges|currents there.

Similarly, the concept of advanced time would be the, clearly non-physical, possibility that we see today the Andromeda Galaxy as it would be in the future, 2.5 million years after now.

\subsection*{45.03.01.02 Information-Collecting Sphere}

The retarded potentials solution may be visualized as follows. Consider an observer located at \(\mathbf{x}\) in space. Let a sphere centered at \(\mathbf{x}\) contract with radial speed \(c\) such that it has collapsed into \(\mathbf{x}\) at the time of observation \(t\). The time \(t_{\mathrm{R}}\) at which this information-collecting sphere passes by the generators of ElectroMagnetic radiation at \(\mathbf{y}\) is then the time at which the source produced the effect which is felt at x at time \(t\).

\subsection*{45.03.01.03 Quasi-Static Approximation}
© |D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|10||
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|16||
The quasi-static approximation involves neglecting the propagation time of the ElectroMagnetic fields in the expressions (45.03.01) of the retarded potentials, such that there is little difference between time and retarded time, when compared to the characteristic time, \(T\), of change of the sources:
\[
\left|t_{\mathrm{R}}-t\right|=\frac{|\mathbf{x}-\mathbf{y}|}{c} \ll T \Longrightarrow \Phi[\mathbf{x}, t] \simeq \frac{1}{4 \pi \varepsilon_{0}} \iiint \frac{\rho[\mathbf{y}, t]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y} \quad \mathbf{A}[\mathbf{x}, t] \simeq \frac{\mu_{0}}{4 \pi} \iiint \frac{\mathbf{j}[\mathbf{y}, t]}{|\mathbf{x}-\mathbf{y}|} \mathrm{d} \mathbf{y}
\]
(45.03.04)

The condition \(\left|t_{\mathrm{R}}-t\right|=|\mathbf{x}-\mathbf{y}| / c \ll T\), in case of harmonic time dependence of the sources, expresses the fact that the distance between the points where the potentials are calculated and the sources is much shorter than the wavelength of the monochromatic components of the ElectroMagnetic fields:
\[
|\mathbf{x}-\mathbf{y}| \ll c T \equiv \lambda .
\]

\subsection*{45.03.02 Jefimenko Solution for ElectroMagnetic Fields}

This § is referenced at pages:
[Never referenced.]

©|D.Griffiths \& M.Heald|Time-dependent generalizations of the Biot-Savart and Coulomb laws|Am.J.Phys, , ..., ..., ...Ed., .... 59, 111 (1991)|
©|J.A.Heras||Am.J.Phys, , ..., ..., ...Ed., .... 62, 525 (1994) and Am.J.Phys, , ..., ..., ...Ed., .... 62, 1109 (1994)|
©|Tran-Cong Ton \(\mid\) On the time-dependent, generalized Coulomb and Biot-Savart laws|Am.J.Phys, , ..., ..., ...Ed., .... 59, 520 (1991); doi: 10.1119
Jefimenko equations express the ElectroMagnetic fields in terms of the Charge|Current densities directly. Jefimenko equations are derived by direct calculation from the retarded potentials solution:
\[
\mathbf{r} \equiv \mathbf{x}-\mathbf{y}
\]
\[
\begin{align*}
\mathbf{E}[\mathbf{x}, t]=\frac{1}{4 \pi \varepsilon_{0}} \iiint\left(\rho\left[\mathbf{y}, t_{\mathrm{R}}\right] \frac{\mathbf{r}}{r^{3}}+\frac{\partial \rho}{\partial t}\left[\mathbf{y}, t_{\mathrm{R}}\right] \frac{\mathbf{r}}{c^{2}}-\frac{1}{c^{2} r} \frac{\partial \mathbf{j}}{\partial t}\left[\mathbf{y}, t_{\mathrm{R}}\right]\right) \mathrm{d} \mathbf{y} \\
\mathbf{B}[\mathbf{x}, t]=\frac{\mu_{0}}{4 \pi} \iiint\left(\left(\frac{1}{r^{2}} \mathbf{j}\left[\mathbf{y}, t_{\mathrm{R}}\right]+\frac{1}{c r} \frac{\partial \mathbf{j}}{\partial t}\left[\mathbf{y}, t_{\mathrm{R}}\right]\right) \times \frac{\mathbf{r}}{r}\right) \mathrm{d} \mathbf{y}
\end{align*}, \quad \text { (45.03.05)} \underset{21782180}{\rightarrow}
\]

The equations contain retarded versions of the Coulomb and Biot-Savart laws as their leading terms. They show explicitly that the Coulomb and Biot-Savart laws fail for time-dependent sources.
In the quasi-static situation, developing a slowly varying current as
\[
\mathbf{j}\left[t_{\mathrm{R}}\right] \simeq \mathbf{j}[t]+\left(t_{\mathrm{R}}-t\right) \partial_{\mathrm{t}} \mathbf{j}[t],
\]
there is a fortuitous cancellation such that neglecting retardation and dropping the second term in the expression of the magnetic field gives the Biot-Savart law.

\section*{© - QUOTE}

\section*{[?]}
[Never referenced.]
Use a Taylor series to express the charge and current-density at the present (un-retarded) time in terms of the source and its derivatives at the retarded time.
...

The integrand of Jefimenko equation for magnetic field neatly embraces the first two terms of this series. That is, the static Biot-Savart formula, evaluated at present time, contains only a secondorder error due to retardation when applied to time-dependent currents. The same argument applies to the Jefimenko equation for electric field: the first-order retardation cancels out in the Coulomb portion of the electric field.
On the other hand, when the time variation is rapid, both fields are dominated by their all at terms, which represent accelerated charge and fall off with the inverse first power of distance. These are the terms that represent ElectroMagnetic radiation. These generalized formulas make clear that, fundamentally, it is charges and currents that produce electric and magnetic fields. Because the Maxwell rotor equations relate the rotor of one field to the time-derivative of the other, it is common to describe the phenomenon of Faraday induction, for instance, by saying that a time-varying magnetic field causes a (spatially varying) electric field. But this statement is open to challenge by the argument that in the relativistic formulation the two fields are elements of a single four-dimensional tensor. From this view neither field can cause the other (any more than one component of \(\mathbf{E} \mid \mathbf{B}\) can cause another component). Rather, both fields are caused by charges and currents. Because Maxwell's (differential) equations are local (they apply at a point), their time-derivative induction terms are, in effect, proxies for the charges and currents located elsewhere.

The generalized field formulas show an intriguing asymmetry. Using the electric field potential formula, we can trace the \(\dot{\mathbf{j}}\) term back to the \(\dot{\mathbf{B}}\) induction term in Faraday's law, while the \(\rho\) and \(\dot{\rho}\) terms are traceable to the Coulomb charge sources of Gauss' law. But the magnetic field potential formula, traces the entire integrand back to the Biot-Savart current sources in the original Ampere's law. There is no explicit manifestation here of Maxwell's \(\dot{\mathbf{E}}\) induction term; it is hidden in the retardation.

\subsection*{45.03.03 Heaviside-Feynman Solution for a Point Charge}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|1.28, 2.21||
©|S.Bobbio \& E.Gatti, Elettromagnetismo E Ottica, 1991, Bollati-Boringhieri, ...Ed., ....|||
© |G.S.Smith, An Introduction To Classical Electromagnetic Radiation, 1997, CUP, ...Ed., ....|||
The Heaviside-Feynman formula, is a special case of Jefimenko equations obtained when the source is a single point charge and generalizes Coulomb law for a moving point charge.

The Electric|Magnetic fields produced by a point charge \(q\) moving in a totally arbitrary way can be expressed by means of Heaviside-Feynman Formula:
\[
\mathbf{E}=\frac{q}{4 \pi \varepsilon_{0}}\left(\left[\frac{\hat{\mathbf{e}}[\mathbf{r}]}{r^{2}}\right]_{\mathrm{R}}+\left[\frac{r}{c}\right]_{\mathrm{R}} \frac{\mathrm{~d}}{\mathrm{~d} t}\left[\frac{\hat{\mathbf{e}}[\mathbf{r}]}{r^{2}}\right]_{\mathrm{R}}+\frac{1}{c^{2}} \frac{\mathrm{~d}^{2}}{\mathrm{~d} t^{2}}[\hat{\mathbf{e}}[\mathbf{r}]]_{\mathrm{R}}\right) \quad \mathbf{B}=\frac{1}{c} \mathbf{E} \times[\hat{\mathbf{e}}[\mathbf{r}]]_{\mathrm{R}} \quad . \quad \text { (45.03.07) } \quad \rightarrow
\]

It is often known as Heaviside-Feynman Formula. The expression is written in terms of the retarded position of the point charge, with respect to the observer, defined by the unit vector \(\hat{\mathbf{e}}[\mathbf{r}]\). That is, the unit vector \(\hat{\mathbf{e}}[\mathbf{r}]\) points to the observer starting form the retarded (that is apparent) position of the charge: the position the charge had at the time when the radiation now reaching the observer left the charge.

At variance from equation (45.03.01), here we must use the retarded position of the point charge also, because we have just a point radiating particle.

The radiation field, that is the asymptotic field at large distances, is given by just the last term, as the first two terms decrease at infinity more rapidly than the \(r^{-1}\) of the last term.

The derivation of equation (45.03.07) is mathematically cumbersome; see the references.

\section*{ElectroMagnetic Fields of a Point Charge Moving at Constant Velocity}

Figure 45.1: \(\mathcal{F J G U R E}\)
Consider a point charge moving at constant velocity, v.
The electric field at a fixed observation point located at \(\mathbf{r}\) relative to the instantaneous position of a point charge moving with constant velocity \(\mathbf{v}\) is directed along the line from the instantaneous position of the charge to the observation point. Its is given by:
\[
\begin{equation*}
\mathbf{E}[\mathbf{r}]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{2}} \frac{1-\beta^{2}}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\mathbf{r}}{r} \quad \text { with } \boldsymbol{\beta} \equiv \mathbf{v} / c \tag{45.04.01}
\end{equation*}
\]
where \(\theta\) is the angle between the direction of the velocity, \(\mathbf{v}\), and the direction from the instantaneous position of the charge to the fixed observation point. The corresponding magnetic field is:
\[
\begin{equation*}
\mathbf{B}=\frac{1}{c^{2}} \mathbf{v} \times \mathbf{E}=\frac{1}{c} \boldsymbol{\beta} \times \mathbf{E} \tag{45.04.02}
\end{equation*}
\]

According to special relativity the field is just the Lorentz transformed field of the field of a point charge standing still with respect the inertial Reference Frame moving with the charge.

Note that the charge is assumed to be in motion at constant velocity for an infinite time. Therefore the fact that the electric field points to the instantaneous position of the charge does not imply any instantaneous transmission of information. The charge, in fact, has been moving for a long time at constant speed before reaching the current instantaneous position and therefore it has been its position known along its path.

© |WEB - URL|| Visualization|

A simplified derivation of the ElectroMagnetic radiation emission will be presented in this section, for a very special case of a charge in accelerated motion for a very short time and moving at constant velocity before and after the short period of acceleration and with all speeds assumed to be non relativistic.

Even if this example is of limited generality, it is very useful to understand the physical mechanism of ElectroMagnetic radiation generation.

The formulas (45.04.01), (45.04.02) will be used together with the knowledge that ElectroMagnetic Perturbation|Disturbance|Signals move with the speed of light, \(c\). In fact ElectroMagnetic fields in vacuum satisfy the d'Alembert wave equation with speed \(c\), and we know that no signal can travel faster than \(c\), read \(\S 16.04 .05 .03\) - Some Elements of Fourier Analysis. That is: whatever the shape of the signal, nothing arrives at any point before light in vacuum:
\[
\begin{equation*}
\psi[\mathbf{x}, t]=0 \quad \text { for }|\mathbf{x}|>c t \text { if signal generated at } \mathbf{x}=0 \text { and } t=0 . \tag{45.05.01}
\end{equation*}
\]

Consider a point charge, \(q\), which is standing still at the origin of an Inertial Reference Frame from time \(t=-\infty\) until time \(t=0\). At \(t=0\) the charge starts to move in the positive direction of the \(z\) axis with constant acceleration \(a \equiv a\), for a short time \(\Delta t\). Afterwards it stops accelerating and continues to move at constant velocity \(v=a \Delta t\). The motion of the charge is always in the direction fo the \(z\) axis. The conditions are therefore:
\[
\begin{align*}
|\mathbf{v}| \ll c \quad & \Delta t \ll t \quad(1 / 2) a \Delta t^{2} \ll r \equiv c t \quad(1 / 2) a \Delta t^{2} \ll v t  \tag{45.05.02}\\
& \text { constant acceleration: }\{0, \Delta t\}(\text { duration: } \Delta t \ll t)  \tag{45.05.03}\\
& \text { constant speed: }\{\Delta t, t\} \text { (duration: } t-\Delta t \simeq t) \tag{45.05.04}
\end{align*}
\]

Note that as a consequence of the above assumptions the the charge stays in a limited region of space, that is it is a localized source.

At \(t<0\) the electric field is the electric field of a stationary point charge at the origin, as given by Coulomb law, while the magnetic field is zero:
\[
\begin{equation*}
\mathbf{E}[\mathbf{r}]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q \mathbf{r}}{r^{3}} \quad \mathbf{B}[\mathbf{r}]=0 \tag{45.05.05}
\end{equation*}
\]

The electric field lines are radially directed from the origin, isotropically distributed at \(t<0\).
Kinks in the electric field lines are created when the charge suddenly starts to accelerate at \(t=0\), and, moreover, the change of the electric field creates a magnetic field. The kinks of the electric field lines and the created magnetic field lines propagate outward at the speed of light: we know from Maxwell equations, in fact, that ElectroMagnetic fields propagate in vacuum at the speed of light.

Note that, due to the geometry, the kinks of the electric fields have a higher field line density, so that one expects that the electric field there is larger than outside.
As we are looking for the fields at large distance, the PW approximation will be adequate, unless we are going to correlate ElectroMagnetic fields at large distances between one another. Using the PW approximation we can simply calculate the magnetic field from the electric field as:
\[
\mathbf{B}=\frac{\mathbf{k} \times \mathbf{E}}{\omega} .
\]

Consider now a time \(t\) very much larger than \(\Delta t: t \gg \Delta t\). As the speed of the charge is always non relativistic one can consider that the charge remains confined into a negligibly small region near the origin of the Coordinate System when observing from a very large distance. Therefore one can assume that the information about the charge propagates as spherical waves centered at the origin.
At any time \(t\), at any location at distance \(r>c t\) from the origin the news that the charge has started to move (that is the kinks of the electric field lines and the newly created magnetic field) has not arrived yet. Therefore the electric field lines are the same as they were at \(t<0\) while the magnetic field is still zero.
At any time \(t\), at any location at distance \(r<c(t-\Delta t)\) from the origin the news that the charge has stopped accelerating has already arrived and the kinks of the electric field lines and the newly created magnetic field have already passed away. Therefore the electric field and magnetic fields are the ones due to the charge moving at constant speed \(v\). This is a radial electric field pointing away from the present position of the charge; the position is the present position of the charge, because the motion of the charge is non-relativistic.
According to equation (45.04.01), for non relativistic velocities, the electric field is thus:
\[
\begin{equation*}
\mathbf{E}^{\prime}\left[\mathbf{r}^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q \mathbf{r}^{\prime}}{r^{\prime 3}} . \tag{45.05.06}
\end{equation*}
\]

We are interested in the kinks of the electric field which propagate outward at the speed of light. We can use the first Maxwell Equation at a given instant to relate the fields just ahead of the kink (given by equation (45.05.05)) with the fields just behind the kinks (given by equation (45.05.06)) by conserving the flux of the electric field.

Consider a time \(t \gg \Delta t\). At this time the kink is very far away from the charge. We can neglect the distance that the charge traveled during the acceleration phase, \(a(\Delta t)^{2} / 2\), with respect to the much larger distance \(v t\) that it has traveled at constant velocity after stopping acceleration. In this way we can consider that the radiation was effectively produced at a point, the origin of the Coordinate System.
Consider an observation point \(\mathbf{r}\) whose position vector makes an angle \(\theta\) with the velocity \(\mathbf{v}\). Choose the time \(t\) such that the kink is starting to sweep past the observation point at time \(t: r=c t\). Consider now \(\mathbf{r}^{\prime}\) at the rear of the kink. Since \(v \ll c\) the charge has traveled a distance \(v t\) that is much shorter than \(r=c t\). Therefore the directions of \(\mathbf{r}\) and \(\mathbf{r}^{\prime}\) are essentially parallel to each other. Therefore:
\[
\mathbf{r} \| \mathbf{r}^{\prime} \quad r^{\prime}=r-v t \cos \theta-c \Delta t=c t-v t \cos \theta-c \Delta t=r\left(1-\frac{v}{c} \cos \theta-\frac{\Delta t}{t}\right) \approx r .
\]

In fact, the wave-front corresponding to the charge startup is described by the sphere \(r[t]=c t\), for \(t>0\); the wave-front corresponding to the charge stopping accelerating is described by the sphere: \(r[t]=c t-c \Delta t\), for \(t>\Delta t\).
The electric field lines come from the line integral of the electric field, by definition, therefore they have to be continuous functions. In fact, as long as the electric field is continuous or has only discontinuity of first kind, the field line is continuous.
Let us consider, for the time being, only the modules of the physical quantities, because all directions and orientations are anyway known.
Consider, in the region of the kink, the components of the electric field parallel and perpendicular to the radial direction: \(E_{\perp}\) and \(E_{\|}\). From geometrical considerations only one can deduce:
\[
\begin{equation*}
\frac{E_{\perp}}{E_{\|}}=\frac{v_{\perp} t}{c \Delta t}=\frac{\left(a_{\perp} \Delta t\right)(r / c)}{c \Delta t}=\frac{a_{\perp} r}{c^{2}} . \tag{45.05.07}
\end{equation*}
\]

We need the value of \(E_{\|}\). let us apply the first Maxwell Equation to a small cylinder box whose axis is parallel to \(\mathbf{r}\) while one of the bases is just outside the kink (region not yet reached by the kink, radial field \(E_{r}\) ) and the other one is inside the kink (radial component of the field \(E_{\|}\)). As there is no charge inside we conclude that:
\[
E_{\|}=E_{r}=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{2}}
\]

Note that we have applied, in fact, conservation of the normal component of the electric field across the two moving surfaces of discontinuity: \(r=c t\) and \(r=c(t-\Delta t)\). This is possible because conservation of the normal component of the electric field also apply at moving surfaces while the same is not true for the conservation of the tangential component of the electric field (which is not conserved, in fact, in this case), see section § 33.08.04 - Basic Laws of ElectroMagnetism.
If the same argument is applied to the rear of the kink one finds:
\[
E_{\|}=E_{r}^{\prime} \simeq E_{r} \quad \text { because } r \simeq r^{\prime}
\]

It should be kept in mind that one always has in mind, implicitly, taking the limit for \(\Delta t \rightarrow 0\) which implies an infinitesimally small cylinder such that the contribution of the lateral surface to the flux of the electric field is zero.
The radiation field is thus:
\[
E_{\perp}=\frac{a_{\perp} r}{c^{2}} E_{\|}=\frac{1}{4 \pi \varepsilon_{0}} \frac{q a_{\perp}}{r c^{2}}
\]

Let us re-introduce vector notation.
In order to calculate the direction of the electric field \(\mathbf{E}_{\perp}\) one should note that \(\mathbf{E}_{\perp}\) at the position \(\mathbf{r}\) and time \(t\) has the opposite direction of the acceleration. The acceleration relevant is the one at time \(t_{\mathrm{R}}=t-(r / c)\), due to retardation. Note that, while in general it is not possible to obtain the solution just by retarding the static solutions for the fields, it this case it was demonstrated the the solution is just the retarded one.
Assuming that, in a limited region of space, the ElectroMagnetic spherical wave can be treated as a plane wave, all the results for PW can be used and summarized in the radiation formula for a time-infinitesimal acceleration:
\(\mathbf{E}_{\mathrm{R}}[\mathbf{r}, t]=-\frac{1}{4 \pi \varepsilon_{0}} \frac{q \mathbf{a}_{\perp}\left[t_{\mathrm{R}}\right]}{r c^{2}} \quad \mathbf{B}_{\mathrm{R}}[\mathbf{r}, t]=\frac{\hat{\mathbf{e}}_{r} \times \mathbf{E}_{\mathrm{R}}[\mathbf{r}, t]}{c} \quad \hat{\mathbf{e}}_{r} \equiv \mathbf{r} / r \quad t_{\mathrm{R}}=t-(r / c)=\) propagation delay.
normally used under the condition specified in equation (45.05.10) for non time-infinitesimal motions. Note that, in the above formulas, there is time retardation between both \(\mathbf{a} \rightarrow \mathbf{E}\) and \(\mathbf{a} \rightarrow \mathbf{B}\), but no time retardation between \(\mathbf{E}\) and \(\mathbf{B}\).
Note the useful identity:
\[
\mathbf{a}_{\perp} \equiv \mathbf{n} \times(\mathbf{a} \times \mathbf{n}) \quad \mathbf{r} \equiv r \hat{\mathbf{n}} \quad \hat{\mathbf{n}}=\frac{\mathbf{k}}{k}
\]
where the component of the acceleration perpendicular to the line of sight has been introduced:
\[
\left|\mathbf{a}_{\perp}\right|=a \sin \theta
\]

Thus one can rewrite the above equations as:
\[
\begin{equation*}
\mathbf{E}_{\mathrm{R}}[\mathbf{r}, t]=\left.\frac{1}{4 \pi \varepsilon_{0}} q \frac{\mathbf{n} \times(\mathbf{n} \times \mathbf{a})}{r c^{2}}\right|_{t_{\mathrm{R}}=t-r / c} \quad \mathbf{B}_{\mathrm{R}}[\mathbf{r}, t]=\frac{\mathbf{k} \times \mathbf{E}_{\mathrm{R}}[\mathbf{r}, t]}{\omega} \quad t_{\mathrm{R}}=t-(r / c)<t \tag{45.05.09}
\end{equation*}
\]

The results of equation (45.05.08) show three basic features:
- The Electric|Magnetic fields must be evaluated using the distance and acceleration (actually \(\mathbf{a}_{\perp}\) ) of the charge at the so-called retarded position of the point charge (its apparent position), that is the position the charge had at the time \(t_{\mathrm{R}}\).
- The Electric|Magnetic fields decrease at large distances as \(r^{-1}\), at variance from the static fields.
- The electric field is anti-parallel to the component of the acceleration perpendicular to the line of sight, and the magnetic field is calculated from the electric field according to the PW approximation.
The radial component inside the kink is the same as the radial field ahead and behind the kink: therefore it carries no news, it is not radiation and it is not part of the traveling wave. A detector of ElectroMagnetic fields which could only detect the radial part of the field would not notice anything at the passage of the kink. That is why we will only include the transverse field into the radiation field. This result is to be expected, to some extent, because one knows that for PW the longitudinal component of the fields are constant both in space and in time, for a PW, and, therefore, they are not to be considered part of the time-varying ElectroMagnetic fields. Obviously only in a limited region of space the present ElectroMagnetic wave can be considered as a PW.
The electric field is in the plane determined by the acceleration and the radial position vector such that any charge moving produces EM radiation instantaneously polarized in the plane containing the instantaneous acceleration and radial position vectors. In particular, rectilinear motion produces linearly Polarized radiation.

\subsection*{45.05.02 Spatially Limited Source of Non-Relativistic Point Charges Seen From a Large Distance}

We shall assume that, in a limited region of space, at large distance from the origin, all the results for PW can be used.
Consider a charge moving in an arbitrary way at non-relativistic velocity. Assume it stays near the origin of the Coordinate System, such that the position vector from the charge to the observation point can be considered nearly constant. Assume the motion is harmonic in time with angular frequency \(\omega\).
Under these conditions there is a one-to-one correspondence between the radiation detected at time \(t\) and the transverse acceleration of the radiating charge at the single retarded time \(t_{\mathrm{R}}\).
It can be shown in a rigorous way that equation (45.05.08) can be used provided:
\[
\begin{equation*}
v \ll c \quad r \gg \lambda \equiv c 2 \pi / \omega \gg\{\text { dimension of the source }\} \tag{45.05.10}
\end{equation*}
\]
\(\rightarrow\)

\subsection*{45.05.02.01 Power Radiated by a Non-Relativistic Charge: Larmor Radiation Formula}
©|T.Padmanabhan, Theoretical Astrophysics, Vol. 1,2,3, 2000/2001/2002, CUP, ...Ed., ....|Vol 1, chapt 4||
From equation (45.05.08) the Poynting vector at distance \(\mathbf{r}\) and time \(t\) turns out to be:
\[
|\mathbf{S}[\mathbf{r}, t]|=\frac{q^{2} a^{2}\left[t_{\mathrm{R}}\right] \sin ^{2} \theta}{16 \pi^{2} r^{2} \varepsilon_{0} c^{3}}
\]
which depends on the acceleration at the retarded time \(t_{\mathrm{R}}\)
The total radiated power crossing a spherical surface of radius \(r\), centered on the charge, at time \(t\) can be obtained by integrating over the sphere at radius \(r\) ( \(r\) is arbitrary, fixed and not integrated):
\[
P[r, t]=r^{2} \iint|\mathbf{S}[\mathbf{r}, t]| \mathrm{d} \Omega
\]

The total instantaneous radiated power by a non-relativistic charge (Larmor Radiation Formula) is thus:
\[
\begin{equation*}
P[r, t]=\frac{q^{2} a^{2}\left[t_{\mathrm{R}}\right]}{6 \pi \varepsilon_{0} c^{3}}=\frac{q^{2} a^{2}[t-r / c]}{6 \pi \varepsilon_{0} c^{3}} \equiv \frac{2 e^{2} a^{2}\left[t_{\mathrm{R}}\right]}{3 c^{3}} \quad e^{2} \equiv \frac{q^{2}}{4 \pi \varepsilon_{0}} . \tag{45.05.11}
\end{equation*}
\]

The latter expression is written in terms of the charge, \(e\), in the Gauss system of units.
Note that the power in Larmor Radiation Formula, equation (45.05.11), is crossing the surface at distance \(r\) from the charge at time \(t\), but it comes from radiation actually emitted by the charge at time \(t_{\mathrm{R}} \equiv t-r / c\).

Note that if one further assumes a Sinusoidal|Cosinusoidal dependence of the acceleration (harmonic motion) one additional factor \(1 / 2\) will appear.

\subsection*{45.05.03 Near-Zone ElectroMagnetic Fields}

The exact solution for the ElectroMagnetic fields produced by a moving charge contain, in addition to radiation ElectroMagnetic fields varying as \(r^{-1}\), also ElectroMagnetic fields varying as \(r^{-2}\) and \(r^{-3}\). These ElectroMagnetic fields dominate at sufficiently small distances. In fact they are called near-zone ElectroMagnetic fields. They do not contribute any net outgoing energy flux at large distances but they are relevant at small distances.
Their calculation is much more difficult than the calculation of the large-distance ElectroMagnetic fields.

See the very important comment in § 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order Multipoles.
The ElectroMagnetic potentials for a point charge moving with arbitrary velocity is derived from the general expressions (45.03.01) once the Charge|Current velocity for a point charge is written in terms of the Dirac delta:
\[
\begin{gathered}
\rho[\mathbf{y}, t]=q \delta^{3}\left[\mathbf{y}-\mathbf{r}_{\mathrm{Q}}[t]\right] \quad \mathbf{j}[\mathbf{y}, t]=q \mathbf{v}[t] \delta^{3}\left[\mathbf{y}-\mathbf{r}_{\mathrm{Q}}[t]\right], \\
\Phi[\mathbf{x}, t]=\frac{1}{4 \pi \varepsilon_{0}}\left[\frac{q}{r-\boldsymbol{\beta} \cdot \mathbf{r}}\right]_{\mathrm{R}} \quad \mathbf{A}[\mathbf{x}, t]=\frac{\mu_{0}}{4 \pi}\left[\frac{q c \boldsymbol{\beta}}{r-\boldsymbol{\beta} \cdot \mathbf{r}}\right]_{\mathrm{R}} \quad[\boldsymbol{\beta}]_{\mathrm{R}} \mathbf{A}[\mathbf{x}, t]=c \Phi[\mathbf{x}, t]
\end{gathered}
\]

The fact that the expressions must be calculated at the retarded time, \(t_{\mathrm{R}}\), comes from the effect of the Dirac delta. In fact, it can be shown that at any time, \(t\), and any observation location, \(\mathbf{x}\), there is one and only one solution, for \(t_{R}\), to the equation of retarded time, equation (45.03.03), calculated at the position of the charge:
\[
\begin{equation*}
t_{\mathrm{R}} \equiv t-\frac{\left|\mathbf{x}-\mathbf{y}\left[t_{\mathrm{R}}\right]\right|}{c} \quad[\cdots]_{\mathrm{R}}:=t \rightarrow t_{\mathrm{R}} \tag{45.06.01}
\end{equation*}
\]
where the notation for calculating the expressions at the retarded time, \(t_{\mathrm{R}}\), instead of the current time, \(t\) has been emphasized.
In equation (45.06.01) the position of the charge, \(\mathbf{y}\), must be evaluated at the retarded time, \(t_{\mathrm{R}}\), because equation (45.06.01) expresses the time when the ElectroMagnetic radiation emitted by the charge at \(\mathbf{y}\) was emitted so that it reaches the observation point, \(\mathbf{x}\), at time \(t\).
The factor at the denominator can be seen as a purely geometrical factor, due to the particle moving closer/farther from the observer.

\subsection*{45.06.03 Lienard-Wieckert Fields for a Point Charge}

This § is referenced at pages:
[2209, 2209]
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|14||
The ElectroMagnetic fields derived from the potentials (45.06.02) are made of a part depending on the velocity of the charge (the velocity field) and a part depending on the acceleration of the charge (the acceleration field). Consider a point charge moving with position \(\mathbf{r}_{\mathrm{Q}}[t]\), velocity \(\mathbf{v} \equiv c \beta\) and acceleration a. The ElectroMagnetic fields are:
\[
\begin{gather*}
r \equiv\left|\mathbf{x}-\mathbf{r}_{\mathbf{Q}}\right| \\
\hat{\mathbf{n}} \equiv \frac{\mathbf{x}-\mathbf{r}_{\mathbf{Q}}}{\left|\mathbf{x}-\mathbf{r}_{\mathrm{Q}}\right|} \equiv \frac{\mathbf{x}-\mathbf{r}_{\mathbf{Q}}}{r}, \\
\hat{\mathbf{E}[\mathbf{x}, t]=\frac{q}{4 \pi \varepsilon_{0}}\left[\frac{\hat{\mathbf{n}}-\boldsymbol{\beta}}{\gamma^{2} r^{2}(1-\mathbf{n} \cdot \boldsymbol{\beta})^{3}}\right]_{\mathrm{R}}+\frac{q}{4 \pi \varepsilon_{0}}\left[\frac{\hat{\mathbf{n}} \times((\hat{\mathbf{n}}-\boldsymbol{\beta}) \times \mathbf{a})}{c^{2} r(1-\mathbf{n} \cdot \boldsymbol{\beta})^{3}}\right]_{\mathrm{R}}}  \tag{45.06.02}\\
\mathbf{B}[\mathbf{x}, t]=\frac{1}{c}[\mathbf{n} \times \mathbf{E}]_{\mathrm{R}} \tag{45.06.03}
\end{gather*},
\]

Note that the velocity field is apparently different from the field derived for a moving charge in § 56.09.06 - ElectroMagnetism and Relativity. However the difference is only apparent because in \(\S 56.09 .06\) - ElectroMagnetism and Relativity the ElectroMagnetic fields were referred to the current position of the charge while in this section they are refereed to the retarded position of the point charge.

\subsection*{45.06.03.01 Velocity Field}

It is the part of field depending on the velocity and as the inverse square distance, in equation (45.06.02). Therefore at large enough distance it goes to zero and does not affect radiation fields.

\subsection*{45.06.03.02 Acceleration (Or Radiation) Field}
©|W.K.H.Panoffsky \& M.Phillips, Classical Electricity And Magnetism, 1962, Addison-Wesley, 2ndEd., ....|20.2||
The acceleration field is also called the radiation field as it is the only part of the field surviving at large distances.
The acceleration fields, both \(\mathbf{E}\) and \(\mathbf{B}\), is an odd function for changing \(\mathbf{a} \rightarrow-\mathbf{a}\), at fixed \(\beta\). Therefore the Poynting vector is an even function for changing \(\mathbf{a} \rightarrow-\mathbf{a}\), at fixed \(\beta\). In particular, in the instantaneous Rest Frame of the particle the energy flux and linear momentum density are an even function for changing \(\mathbf{a} \rightarrow-\mathbf{a}\), as \(\beta=0\) and therefore the total linear momentum is zero.
The simple expression of the radiation field in the instantaneous Rest Frame is of special interest, as it often appears:
\[
\begin{aligned}
& r \equiv\left|\mathbf{x}-\mathbf{r}_{\mathbf{Q}}\right| \\
& \hat{\mathbf{n}} \equiv \frac{\mathbf{x}-\mathbf{r}_{\mathrm{Q}}}{\left|\mathbf{x}-\mathbf{r}_{\mathrm{Q}}\right|}=\frac{\mathbf{x}-\mathbf{r}_{\mathrm{Q}}}{r}, \\
& \mathbf{E}[\mathbf{x}, t]=\frac{q}{4 \pi \varepsilon_{0}}\left[\frac{\mathbf{n} \times(\mathbf{n} \times \mathbf{a})}{c^{2} r}\right]_{\mathrm{R}} \quad \text { when } \beta \simeq 0 \\
& \mathbf{B}[\mathbf{x}, t]=\frac{q}{4 \pi \varepsilon_{0}}\left[\frac{\mathbf{a} \times \mathbf{n}}{c^{3} r}\right]_{\mathrm{R}} \quad \text { when } \beta \simeq 0
\end{aligned}
\]
45.06.04 Radiation Reaction

\title{
Oscillating Ideal Electric|Magnetic Dipoles - Dipole Radiation
}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 11.1||
Oscillating ideal Electric|Magnetic Dipoles produce ElectroMagnetic radiation (Electric|Magnetic Dipole radiation). They represent a particularly significant example because real antennas as well as the emission of ElectroMagnetic radiation by atoms and molecules can often be represented as oscillating ideal Electric|Magnetic Dipoles.
The ElectroMagnetic Dipole radiation produced at large distance from the source is a non isotropic vector (transverse) spherical wave.
See \({ }^{3}\) for a different derivation of the dipole radiation, parallel between electric and magnetic cases, with a clean presentation of the different approximations.

\subsection*{45.07.01 Oscillating Ideal Electric Dipole (Electric Dipole Radiation)}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|9.2||
The Electric Dipole radiation comes from a globally neutral system of charges oscillating in such a way to produce an oscillating Electric Dipole. A very simple model is that of two equal and opposite charges harmonically oscillating back and forth along the \(z\) axis around the origin with a half-cycle de-phasing between each other.
The qualitative behavior of the radiation ElectroMagnetic fields can be easily found from the basic radiation fields relations (45.05.08). In fact we expect zero EM fields on the axis, because the projected acceleration is zero there. On the other hand we expect a maximum electric field, directed along \(z\), on the \(x y\) plane, because the projected acceleration is maximum there.
In order to apply the previous results of section § 45.05 - Radiation of ElectroMagnetic Waves the conditions (45.05.10) must be satisfied. In particular the Electric Dipole must be short, with respect to the wavelength.

\subsection*{45.07.01.01 Derivation From the Radiation Formula}

Consider a point charge undergoing an harmonic motion along the \(z\) axis with a component of the acceleration \(a_{z}\) :
\[
z[t]=z_{0} \cos [\omega t+\phi] \quad \dot{z}[t]=-z_{0} \omega \sin [\omega t+\phi] \quad \ddot{z}[t]=-z_{0} \omega^{2} \cos [\omega t+\phi] \equiv a_{z},
\]
where a phase constant is not relevant. One should note that, as the \(\hat{\mathbf{e}}_{\theta}\) unit vector is directed as the \(z\) axis at \(\theta=0\), we have:
\[
\begin{array}{lllll}
E_{\theta}>0 & \Leftrightarrow & a_{z}>0 & \Leftrightarrow & \mathbf{a}_{\perp} \cdot \hat{\mathbf{e}}_{\theta}<0 \\
E_{\theta}<0 & \Leftrightarrow & a_{z}<0 & \Leftrightarrow & \mathbf{a}_{\perp} \cdot \hat{\mathbf{e}}_{\theta}>0
\end{array} .
\]

In short one can simply notice that a positive \(a_{z}\) gives rise to a \(\mathbf{a}_{\perp}\) whose projection along \(\hat{\mathbf{e}}_{\theta}\) is negative. Therefore:
\(E_{\theta}[r, \theta, t]=-\frac{q}{4 \pi \varepsilon_{0} c^{2}}\left(\frac{-a_{z}\left[\mathrm{t}_{\mathrm{R}}\right] \sin \theta}{r}\right)=\frac{q}{4 \pi \varepsilon_{0} c^{2}}\left(\frac{a_{z}\left[t_{\mathrm{R}}\right] \sin \theta}{r}\right)=\frac{q}{4 \pi \varepsilon_{0} c^{2}}\left(\frac{-\omega^{2} z_{0} \cos [\omega(t-r / c)+\phi] \sin \theta}{r}\right)\),
where the time retardation has been introduced:
\[
t_{\mathrm{R}}=t-r / c
\]

Note that it is exactly the time retardation introduced into the acceleration that gives rise to the progressive outgoing wave factor: \(\cos [\omega(t-r / c)]\).

\footnotetext{
\({ }^{3}\) ©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 11.1||
}

If one also had another charge, with equal magnitude but opposite sign (that is \(q \rightarrow-q\) ) oscillating with opposite phase with respect to the first one (that is \(z[t] \rightarrow-z[t]\) and \(a[t] \rightarrow-a[t]\) ) then the radiation Electric|Magnetic fields would be the same. The two charges would make an oscillating Electric Dipole.
Therefore, in terms of the Electric Dipole moment,
\[
\mathrm{p}[t] \equiv \mathrm{p}_{0} \cos [\omega t+\phi] \equiv|q|\left(2 z_{0}\right) \cos [\omega t+\phi]
\]
the electric and magnetic fields, from equations (45.05.08), can be written as:
\[
\begin{gather*}
E_{\theta}[r, \theta, t]=-\frac{\omega^{2} \mathrm{p}_{0}}{4 \pi \varepsilon_{0} c^{2}} \frac{\cos [\omega t-k r]}{r} \sin \theta  \tag{45.07.01}\\
B_{\psi}[r, \theta, t]=-\frac{\omega^{2} \mathrm{p}_{0}}{4 \pi \varepsilon_{0} c^{3}} \frac{\cos [\omega t-k r]}{r} \sin \theta=\frac{E_{\theta}}{c}  \tag{45.07.02}\\
c B_{\psi}[r, \theta, t]=E_{\theta}[r, \theta, t]
\end{gather*},
\]

The ElectroMagnetic radiation fields of the oscillating Electric Dipole are non-isotropic spherical waves. These ElectroMagnetic fields are in phase, mutually perpendicular, and transverse to the direction of propagation; the ratio of their amplitudes is \(E / B=c\), as expected for ElectroMagnetic waves.
Note the geometry:
\[
\mathbf{k}\left\|\hat{\mathbf{e}}_{r} \quad \mathbf{E}\right\| \hat{\mathbf{e}}_{\theta} \quad \mathbf{B} \| \hat{\mathbf{e}}_{\psi} .
\]

When a Electric Dipole antenna is used as a receiving antenna it detects the electric field of the incoming ElectroMagnetic wave.

\subsection*{45.07.01.02 Direct Derivation From the Potentials}

Use the Lorenz Gauge. Consider a very small Electric Dipole at the origin, oscillating at fixed frequency:
\[
\mathrm{p}[t]=\mathrm{p}_{0} \exp [-\beth \omega t] \quad \mathrm{p}_{0} \| \hat{\mathbf{e}}_{3} .
\]

Assume the oscillating Dipole occupies a small cylindrical region, at the origin of the Coordinate System, of length \(L\) and base area \(S\) and that is it contained inside a sphere of diameter \(D\).
The current and current density at the origin are given by:
\[
I[t] \frac{\mathrm{d} \mathbf{L}}{\mathrm{~d} V}=I[t] \frac{\mathrm{d} \mathbf{L}}{\mathrm{~d} L \mathrm{~d} S}=\mathbf{j}[t] \Longrightarrow \frac{1}{L S} \frac{\mathrm{dp}}{\mathrm{~d} t}[t]=\frac{(-\beth \omega) \mathrm{p}_{0}}{L S} \exp [-\beth \omega t]
\]
while the current density anywhere else is zero.
Assume that the ElectroMagnetic wave is observed at a position \(\mathbf{r}\) at a distance, \(r \equiv|\mathbf{r}|\), very much larger than the wavelength, \(\lambda\), which is, in turn, very much larger than the dimensions of the source:
\[
\begin{equation*}
r \gg \lambda \equiv \frac{2 \pi c}{\omega} \equiv \frac{2 \pi}{k} \gg D / 2 \tag{45.07.03}
\end{equation*}
\]
\(\vec{~}\)
The latter condition ensures that the retardation is the same for all points of the source.
The retarded potentials solution, equation (45.03.01), gives, under the hierarchical approximation (45.07.03):
\[
\begin{aligned}
\mathbf{A}[\mathbf{x}, t]= & \frac{\mu_{0}}{4 \pi} \int \frac{I\left[t_{\mathrm{R}}\right]}{r} \mathrm{~d} \mathbf{L}=\frac{\mu_{0}}{4 \pi} \int \frac{I[t-r / c]}{r} \mathrm{~d} \mathbf{L}= \\
& =\frac{\mu_{0}}{4 \pi} L \frac{(-\beth \omega) \mathrm{p}_{0}}{L} \exp [-\beth \omega(t-r / c)] \frac{1}{r}=\frac{\mu_{0}}{4 \pi}(-\beth \omega) \mathrm{p}_{0} \frac{\exp [-\beth \omega(t-r / c)]}{r}= \\
& =\frac{\mu_{0}}{4 \pi}(-\beth \omega) \mathrm{p}_{0} \frac{\exp [\beth(k r-\omega t)]}{r} .
\end{aligned}
\]

The magnetic field at large distance is calculated by retaining only the largest terms at large distance, that is the radiation term going as \(r^{-1}\). It is:
\[
\begin{aligned}
& \mathbf{B}[\mathbf{x}, t]=\operatorname{rot} \mathbf{A}= \\
& \qquad \begin{array}{l}
=\frac{\mu_{0}}{4 \pi}(-\beth \omega) \operatorname{rot}\left(\mathrm{p}_{0} \frac{\exp [\beth(k r-\omega t)]}{r}\right)=\frac{\mu_{0}}{4 \pi}(\beth \omega) \mathrm{p}_{0} \times \frac{\exp [\beth(k r-\omega t)]}{r}= \\
\\
=\frac{\mu_{0}}{4 \pi} \omega^{2} \frac{\mathbf{r} \times \mathrm{p}_{0}}{c r^{2}} \exp [\beth(k r-\omega t)]
\end{array}
\end{aligned}
\]

As we are looking for the large distance fields, the ElectroMagnetic waves can be treated as PW. Therefore the electric field can be simply calculated from the well-known relations for MPW (equation (42.01.08)):
\[
\mathbf{E}=\frac{c^{2}}{\omega}(\mathbf{B} \times \mathbf{k})=c(\mathbf{B} \times \mathrm{n}[\omega])=\frac{\mu_{0}}{4 \pi} \omega^{2} \frac{\mathbf{r} \times\left(\mathrm{p}_{0} \times \mathbf{r}\right)}{r^{3}} \exp [\beth(k r-\omega t)] .
\]

The non-zero (real) components of the oscillating ideal electric dipole fields in spherical coordinates turn out to be the equations (45.07.01) and (45.07.02).

\subsection*{45.07.02 Oscillating Ideal Magnetic Dipole (Magnetic Dipole Radiation)}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|9.2||
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|||
The Magnetic Dipole radiation is very similar to the Electric Dipole radiation. It comes from an oscillating ideal Magnetic Dipole, that is a globally neutral current loop carrying an oscillating current. A very simple model is that of a plane circular loop with axis along the \(z\) direction and centered at the origin carrying an harmonic current.
In order to apply the previous results of section § 45.05 - Radiation of ElectroMagnetic Waves the conditions (45.05.10) must be satisfied. In particular the Magnetic Dipole must be short, with respect to the wavelength.
Some qualitative behavior of the radiation ElectroMagnetic fields can be easily found from the basic radiation fields relations (45.05.08). In fact we expect zero ElectroMagnetic fields on the axis, because the projected acceleration of all the charges of the current loop sum to zero there at any time. Note that the accelerations of the charges, as well as the current and velocities of the charges, is changing to produce a changing Magnetic Dipole, and includes both a centripetal and a tangential acceleration. In the \(x-y\) plane the contributions do not sum to zero because of the different distances from the observation point of the different current elements. We expect, on the \(x-y\) plane the electric field to be in the \(x-y\) plane and therefore the magnetic field perpendicular to it.

\subsection*{45.07.02.01 Derivation by Analogy With the Electric Dipole}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 7.64||
It can be derived from the duality transformation, under which Maxwell's equations with magnetic charge are invariant, read the reference.
Consider a small current loop (magnetic Dipole), small with respect to the wavelength.
It can be shown that the ElectroMagnetic fields far away from the location of the Dipole can be obtained from the Electric Dipole fields with the following replacements:
\[
\begin{array}{|lll}
\mathbf{E} \longrightarrow c \mathbf{B} & \mathbf{B} \longrightarrow-\mathbf{E} / c & \mathrm{p} \longrightarrow \mathrm{~m} / c \\
\hline
\end{array}
\]

When a Magnetic Dipole antenna is used as a receiving antenna it detects the magnetic field of the incoming ElectroMagnetic wave.

\subsection*{45.07.02.02 Direct Derivation From the Potentials}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 11.1.3||
Read the reference; there is not so much physics in the calculations.
The non-zero (real) components of the oscillating ideal magnetic dipole fields in spherical coordinates are:
\[
\begin{array}{|c|}
\hline E_{\psi}=+\frac{\mu_{0} \omega^{2} \mathrm{~m}_{0}}{4 \pi c} \frac{\cos [k r-\omega t]}{r} \sin \theta \\
B_{\theta}=-\frac{\mu_{0} \omega^{2} \mathrm{~m}_{0}}{4 \pi c^{2}} \frac{\cos [k r-\omega t]}{r} \sin \theta \tag{45.07.06}
\end{array},
\]

These ElectroMagnetic fields are in phase, mutually perpendicular, and transverse to the direction of propagation; the ratio of their amplitudes is \(E / B=c\), as expected for ElectroMagnetic waves.

\subsection*{45.07.03 EM Ideal Dipole Radiation: ElectroMagnetic Spherical Waves}

The expression of a generic monochromatic spherical wave is:
\[
\psi[r, \theta, \psi]=A[\theta, \psi] \frac{\cos [k r-\omega t-\phi]}{r}
\]

The ElectroMagnetic radiation fields produced by both an oscillating Electric Dipole and an oscillating Magnetic Dipole are non-isotropic spherical waves with no azimuthal dependence, that is:
\[
\psi[r, \theta]=A[\theta] \frac{\cos [k r-\omega t-\phi]}{r} .
\]
with a dependence from the polar angle, as it is clear from equations (45.07.01), (45.07.02) as well as from the correspondence relation (45.07.04) while there is no dependence on the azimuthal angle.
Note the strong frequency dependence of the emitted power.

\subsection*{45.07.04 Oscillating Ideal Dipoles: The Electric Versus the Magnetic Dipole}

\subsection*{45.07.05 Radiated Power by Electric Dipole Versus Magnetic Dipole}

This § is referenced at pages:
[2273, 2273, 2274, 2274]
Show that the ratio between radiated power from Electric|Magnetic Dipoles,
\[
\frac{P_{\mathrm{E}}}{P_{\mathrm{M}}}=\left(\frac{c \mathrm{p}_{0}}{\mathrm{~m}_{0}}\right)^{2}
\]
can be written:
1. for a dilute LHI medium with a given Electric|Magnetic susceptibilities is:
\[
\frac{P_{\mathrm{E}}}{P_{\mathrm{M}}} \approx\left(\frac{\chi_{\mathrm{E}}}{\chi_{\mathrm{M}}}\right)^{2} \gg 1
\]
which is typically much larger than one;
2. for an ideal Electric|Magnetic Dipole of size \(\approx d\) at frequency \(\omega\), as:
\[
\frac{P_{\mathrm{E}}}{P_{\mathrm{M}}} \approx\left(\frac{c}{d \omega}\right)^{2} \gg 1
\]
which is typically much larger than one.
Only systems carefully constrained to exclude any Electric Dipole radiation will exhibit Magnetic Dipole radiation.

\section*{SOLUTION}
1. In the first case, use equations (45.07.07), (45.07.08) and:
\[
\frac{P_{\mathrm{E}}}{P_{\mathrm{M}}}=\left(\frac{c \mathrm{p}_{0}}{\mathrm{~m}_{0}}\right)^{2} \quad \mathrm{p}_{0}=\left(\varepsilon_{0} \chi_{\mathrm{E}}\right) E_{0} \Delta V \quad \mathrm{~m}_{0}=\left(\chi_{\mathrm{M}} / \mu_{0}\right) B_{0} \Delta V
\]

Remember that ElectroMagnetic waves are radiated in vacuum, and therefore in this problem all relations are to be computed in vacuum and the electric over magnetic field module ratio is \(c\).
2. In the second case:
\[
\mathrm{p}_{0} \approx q d \Longrightarrow I_{0}=q \omega \quad \text { and } \quad \mathrm{m}_{0} \approx \pi d^{2}
\]
45.07.06 Radiated Power of Dipole Antennas

The instantaneous and time-averaged radiated energy per unit area and time is:
\[
\begin{gathered}
S[r, \theta, t] \propto \frac{\omega^{4} \sin ^{2} \theta}{r^{2}} \cos ^{2}[k r-\omega t-\phi] \\
\langle S[r, \theta, t]\rangle \propto \frac{\omega^{4} \sin ^{2} \theta}{r^{2}} \equiv S_{0} \frac{\sin ^{2} \theta}{r^{2}}
\end{gathered}
\]

\subsection*{45.07.06.01 Electric Dipole}

The total averaged radiated power is found by integrating on the solid angle:
\[
\begin{equation*}
P_{\mathrm{E}}=\frac{1}{4 \pi \varepsilon_{0}} \frac{\mathrm{p}_{0}^{2} \omega^{4}}{3 c^{3}}=\frac{\mathrm{p}_{0}^{2} \omega^{4}}{12 \pi \varepsilon_{0} c^{3}} \tag{45.07.07}
\end{equation*}
\]

Note that a factor \(1 / 2\) is introduced with respect to Larmor Radiation Formula due the time-averaging.
At fixed \(p_{0}\) the radiated power depends on the fourth power of the frequency.

\subsection*{45.07.06.02 Magnetic Dipole}

The total averaged radiated power is found by replacement from (45.07.04):
\[
\begin{equation*}
P_{\mathrm{M}}=\frac{\mu_{0}}{4 \pi} \frac{\mathrm{~m}_{0}^{2} \omega^{4}}{3 c^{3}}=\frac{\mu_{0} \mathrm{~m}_{0}^{2} \omega^{4}}{12 \pi c^{3}} \tag{45.07.08}
\end{equation*}
\]

Note that a factor \(1 / 2\) is introduced with respect to Larmor Radiation Formula due the time-averaging.
At fixed \(m_{0}\) the radiated power depends on the fourth power of the frequency.

\subsection*{45.07.06.03 Radiation Diagram for Dipole Radiation}

See figure 45.2.

\subsection*{45.07.07 EM Dipole Radiation: Current Elements}

Both Electric|Magnetic Dipole radiation expressions can be expressed in terms of the currents which power the real antenna.

\subsection*{45.07.07.01 Electric Dipole}

Consider the following simple model for an oscillating Electric Dipole: two small electrodes connected by a straight conductor with length \(L\) along the \(z\) axis. Assume that a harmonic current
\[
I[t]=I_{0} \cos [\omega t+\phi]=\frac{\mathrm{d} q}{\mathrm{~d} t}
\]
crosses any section of the straight conductor. The current is positive when it flows in the positive \(z\) direction.
Charge is input/output from the two electrodes: in the circuit language the antenna is a capacitor. The charge on the electrode at positive \(z\) is:
\[
q[t]=\frac{I_{0}}{\omega} \sin [\omega t+\phi]
\]

The Electric Dipole moment as a function of time is:
\[
\mathrm{p}[t]=L q[t]=L \frac{I_{0}}{\omega} \sin [\omega t+\phi] \equiv \mathrm{p}_{0} \sin [\omega t+\phi] \Longrightarrow \mathrm{p}_{0}=L \frac{I_{0}}{\omega} .
\]

The total radiated power is thus:
\[
\begin{equation*}
P_{\mathrm{E}}=\frac{L^{2} I_{0}^{2} \omega^{2}}{12 \pi \varepsilon_{0} c^{3}} \tag{45.07.09}
\end{equation*}
\]

It shows a dependence on the second power of the frequency (compare with (45.07.10)).

\subsection*{45.07.07.02 Magnetic Dipole}

Consider the following simple model for an oscillating Magnetic Dipole: a plane circular loop of area \(A\) where a current
\[
I[t]=I_{0} \cos [\omega t+\phi]
\]
flows.
The Magnetic Dipole moment as a function of time is:
\[
\mathrm{m}[t]=A I[t]=A I_{0} \cos [\omega t+\phi] \equiv \mathrm{m}_{0} \sin [\omega t+\phi] \Longrightarrow \mathrm{m}_{0}=A I_{0} .
\]

The total radiated power is thus:
\[
\begin{equation*}
P_{\mathrm{M}}=\frac{\mu_{0} A^{2} I_{0}^{2} \omega^{4}}{12 \pi c^{3}} . \tag{45.07.10}
\end{equation*}
\]

It shows a dependence on the fourth power of the frequency (compare with (45.07.09)).

Figure 45.2: \(\mathcal{F J G U R E}\)
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 11.1.4||
Electric charge is conserved and therefore the electric monopole does not radiate; in fact, the monopole term is proportional to the total charge, which cannot change. If charge were not conserved, we would get a monopole field proportional to \(1 / r\).
Note that an electrically charged spherical distribution whose radius oscillates (a monopole) would not radiate, as the field outside is exactly the same at any time. On the other hand, for acoustic waves, monopoles do radiate. In fact, in addition to being both waves, ElectroMagnetic waves and acoustic waves, there are differences due to physical equations describing ElectroMagnetic versus acoustic systems \({ }^{4}\).
If the electric dipole moment vanishes then there is no electric dipole radiation. The next term in the development is made of the magnetic dipole term and the electric quadrupole term.
If the magnetic dipole and electric quadrupole contributions vanish, the next term in the development is made of the magnetic quadrupole term and electric octupole term.

\footnotetext{
\({ }^{4}\) It can be shown that a spherically symmetric solution of Maxwell equations, for a system with a spherically symmetric charge and current distributions, is necessarily static in a region with no charges/currents (electromagnetic version of Birkhoff's theorem).
}

This § is referenced at pages:
[Never referenced.]
A system which converts charges/currents into radiated ElectroMagnetic waves is generically called an emitting antenna. Similarly, a system which converts ElectroMagnetic waves into charges/currents is generically called an receiving antenna.
It is not possible to create an antenna which emits radiation uniformly.
Consider a large sphere which surrounds the antenna at large distance. The radiation is propagating radially, so that that the electric|magnetic fields must lie tangent to the sphere and be uniform. Intuitively this is impossible and this is confirmed by a result in topology called the hairy ball theorem: there does not exist a nowhere vanishing vector field on a sphere, but any vector field must vanish at two or more points.

\subsection*{45.09.01 Radiation Resistance/Impedance of an Antenna}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ problem 11.3|Electric dipole antenna|
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ problem 11.6|Magnetic dipole antenna|
The radiation resistance, \(R\), (or radiation impedance, \(Z\) ) is defined in term of the radiated power and current as:
\[
P \equiv R \frac{I_{0}^{2}}{2}
\]

The radiation resistance of a small linear Electric Dipole antenna of length \(L\) is:
\[
\begin{equation*}
R_{\mathrm{E}}=80 \pi^{2}\left(\frac{L}{\lambda}\right)^{2} \simeq 790\left(\frac{L}{\lambda}\right)^{2} \Omega \propto \lambda^{-2} \quad L \ll \lambda \tag{45.09.01}
\end{equation*}
\]

The radiation resistance of a small circular Magnetic Dipole antenna of radius \(R\) is:
\[
\begin{equation*}
R_{\mathrm{M}}=\frac{8 \pi^{5}}{3} \mu_{0} c\left(\frac{R}{\lambda}\right)^{4} \simeq 307432\left(\frac{R}{\lambda}\right)^{4} \Omega \propto \lambda^{-4} \quad R \ll \lambda . \tag{45.09.02}
\end{equation*}
\]

Note that thanks to the smallness of the antennas the radiation resistance is very small.
Moreover, the radiation resistance of the magnetic dipole antenna is smaller than the electric dipole antenna, for comparable sizes, making it a less efficient antenna.

\subsection*{45.09.02 Mutual Coupling of Antennas}

Antennas located in close proximity one another interact in a complicated manner. This interaction is the so-called mutual coupling and the effect is to change the current on an antenna from the one that the antenna would have if it were isolated in free space. Therefore the current on an antenna not only depends on the voltage source of the antenna itself but also on the current on all nearby antennas.
45.09.03 Dipole Antennas in Practice

They include: Electric Dipole antennas and Magnetic Dipole antennas.
They are often used in arrays to exploit interference.

\subsection*{45.09.04 Directional Gain}

The directional gain of an antenna is defined as:
\[
G[\theta, \psi]=\frac{\langle S[r, \theta, \psi]\rangle}{P} 4 \pi r^{2} .
\]

EM waves in vacuum propagate out to infinity, carrying energy, linear momentum and angular momentum with them. Radiation carries a irreversible flow of energy away from the source. The source is normally assumed to be localized near the origin of a suitable Coordinate System of same Inertial Reference Frame .
If one imagines a large spherical shell of radius \(R\) containing all the sources, one can calculate the total power passing out through this surface, \(W[R]\), by integrating the Poynting vector. The radiated power is the limit of this quantity as the radius of the sphere goes to infinity:
\[
W_{\mathrm{RAD}} \equiv \lim _{R \rightarrow \infty} W[R]
\]

This is the energy per unit time that is transported out to infinity, and never comes back.
The power radiated by a charge is actually the amount of energy lost by the charge in a retarded time interval \(\mathrm{d} t_{\mathrm{R}}\) during the emission of the signal. There is a subtle reason why the rate at which energy per unit area passes through the sphere (at infinity), is not, in general, the same as the rate at which energy per unit area left the particle.
In fact, let \(\frac{d W}{d \Omega}\) be the energy per unit time per unit solid angle that passes through a large sphere of radius \(r\). The rate at which energy per unit solid angle left the charge is related to it, in general, by the relation:
\[
\begin{equation*}
\frac{\mathrm{d} W}{\mathrm{~d} t_{\mathrm{R}}}=\left(1-\frac{(\mathbf{r}-\mathbf{x}) \cdot \mathbf{u}}{|\mathbf{r}-\mathbf{x}| c}\right) \frac{\mathrm{d} W}{\mathrm{~d} t} \tag{45.10.01}
\end{equation*}
\]
with \(\mathbf{r}\) the location of the point on the sphere at a large distance \(r\) from the source of radiation and \(\mathbf{x}\) is the position of the source of radiation moving with velocity \(\mathbf{u}\).
The factor relating the two powers per unit solid angle is just a geometrical factor, the same which comes out in Doppler effect.

\subsection*{45.10.01 Relativistic Emitted Power}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 11.2||
The generalization of Larmor formula, equation (45.05.11) requires a clear distinction between the rate at which energy passes through the large sphere, the rate at which energy left the particle, according to equation (45.10.01).
45.10.02 Lorentz Transformation of the Power Angular Distribution
©|T.Padmanabhan, Theoretical Astrophysics, Vol. 1,2,3, 2000/2001/2002, CUP, ...Ed., ....|1.4.3||
Consider a set of charged particles moving as a whole with velocity u. In the Rest Frame the emitted ElectroMagnetic radiation will have some angular distribution, \(\frac{\mathrm{d}^{2} E^{\prime}}{\mathrm{d} t^{\prime} \mathrm{d} \Omega^{\prime}}\). One might be interested in the angular distribution in the Laboratory frame, \(\frac{\mathrm{d}^{2} E}{\mathrm{~d} t \mathrm{~d} \Omega}\). Consider the special Lorentz Transformation between the Laboratory frame, \(\mathcal{J}\), and the Rest Frame of the system, \(\mathcal{J}^{\prime}\), moving with velocity \(\mathbf{u}\) with respect to the Laboratory frame.
The relativistic aberration law gives:
\[
\cos \theta^{\prime}=\frac{\cos \theta-u}{1-u \cos \theta} \quad \psi^{\prime}=\psi .
\]

The transformation laws are:
\[
\begin{aligned}
\mathrm{d} \Omega^{\prime} & =\frac{1}{\gamma^{2}(1-u \cos \theta)^{2}} \mathrm{~d} \Omega \\
\mathrm{~d} E^{\prime} & =\gamma \mathrm{d} E(1-u \cos \theta) \\
\mathrm{d} t_{\mathrm{R}} & =\mathrm{d} t / \gamma
\end{aligned}
\]

It follows:
\[
\frac{\mathrm{d}^{2} E}{\mathrm{~d} t \mathrm{~d} \Omega}=\frac{1}{\gamma^{4}(1-u \cos \theta)^{3}} \frac{\mathrm{~d}^{2} E^{\prime}}{\mathrm{d} t_{\mathrm{R}} \mathrm{~d} \Omega^{\prime}}
\]

In Bohr theory of hydrogen, the electron in its ground state was supposed to travel in a circle of radius \(a_{0}=0.5 \cdot 10^{-10} \mathrm{~m}\), held in orbit by the Coulomb attraction of the proton. According to classical electrodynamics, this electron should radiate, and hence spiral into the nucleus.
1. Show that \(v \ll c\) for most of the trip.
2. Calculate the lifespan of Bohr atom using Larmor formula, assuming that each revolution is essentially circular.

\subsection*{45.11.02 Charged Point Particle in a Uniform and Constant Magnetic Field}

The motion of a charged point particle in a uniform and constant magnetic field is a uniform circular motion with axis parallel to the magnetic field. If the particle is losing energy the particle is actually spiraling inward. The motion has a constant velocity (possibly zero) along the direction of the magnetic field but this component of the motion has no acceleration and therefore does not contribute to ElectroMagnetic radiation and can be ignored in the following discussion. The motion in the plane perpendicular to the magnetic field is a uniform circular motion (if the energy is constant), with centripetal acceleration contributing to ElectroMagnetic radiation. Note that the charge in uniform circular motion has a Magnetic Dipole moment. However there is no emission of Magnetic Dipole radiation because the magnetic Dipole moment is a constant one.

\subsection*{45.11.02.01 Cyclotron Radiation}

Cyclotron radiation is the ElectroMagnetic radiation emitted by a particle moving, at non relativistic velocities, in a uniform circular motion. The name comes from cyclotrons, a kind of particle accelerator, where charged particles move at non relativistic velocities, in a uniform circular motion.
The emitted radiation is at any time a Electric Dipole radiation with axis along the radius from the center to the instantaneous position of the particle. Emission is maximum tangentially to the orbit and it is symmetrical with respect to the plane of the orbit.
Due to the features of Electric Dipole radiation an observer at large distances (with respect to the orbit radius) will see: circularly Polarized radiation, if the observer is along the axis of the orbit (along the magnetic field, when moving from the center of the orbit); linearly Polarized radiation, if the observer is in the plane of the orbit (perpendicularly to the magnetic field, when moving from the center of the orbit). The observer will see elliptic Polarization at any intermediate location.
The frequency of the emitted radiation, for this periodic motion, is the same cyclotron frequency of the motion of the particle. In fact the generator of ElectroMagnetic radiation is just equivalent to two Electric Dipoles locate at the center of the orbit and directed at \(\pi / 2 \mathrm{rad}\) on to the other, both lying in
the plane of the magnetic field and with frequency given by the cyclotron frequency which emit exactly at that frequency.

\subsection*{45.11.02.02 Synchrotron Radiation}

Synchrotron radiation is the ElectroMagnetic radiation emitted by a particle moving, at relativistic velocities, in a uniform circular motion. The name comes from the synchrotron, a kind of particle accelerator, where charged particles move at relativistic velocities, in a uniform circular motion.

At relativistic velocities the ElectroMagnetic radiation emission is directed along the velocity of the particle, in the forward direction, inside a cone of half-angle \(\Delta \theta \approx 1 / \gamma=\sqrt{1-\beta^{2}}\). That is the emission is concentrated near the velocity \(\mathbf{v}\) of the particle, only in the forward direction. An observer in the plane of the orbit will see periodically a bunch of synchrotron radiation, at periodic intervals given by the orbital period.
The concentration of the ElectroMagnetic radiation in the forward direction has significant effects on the energy spectrum. In fact the observed radiation is now an impulsive one. Therefore the radiation spectrum is enlarged to a large range of frequencies and it is not centered any more around the frequency of the circular motion. The spread of frequencies is roughly given by the inverse of the time duration of the pulse and it is roughly given by: \(\omega_{\mathrm{M}}=\omega_{c} \gamma^{2}\).

\subsection*{45.11.03 Bremsstrahlung}

It is the term denoting in general EM radiation emitted by a charged particle under acceleration. The word is a German word for braking radiation. It is in particular used referring to the ElectroMagnetic radiation caused by accelerations of charged particle when passing through the field of another particle, typically an atomic nucleus.
The energy emitted by an accelerated particle is, non relativistically, proportional to \(m^{-2}\), with \(m\) the mass of the particle. Bremsstrahlung therefore plays a particularly important role for light particles.
A typical example is X-ray bremsstrahlung from interaction between electrons and nuclei. In this case the classical calculation is easily done by computation of the electron trajectory in the Coulomb field of the nucleus.
Another example is the bremsstrahlung produced in the plasma of the solar corona from free electrons scattering off the free ions.

Other astrophysical examples exist.

\subsection*{45.11.04 Linear/Angular Momentum Radiated by a Non-Relativistic Point Charge}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 11.27||

The energy per unit time radiated by a non-relativistic point charge is given by the Larmor formula.
1. The linear momentum radiated per unit time is:
\[
\begin{equation*}
\frac{\mathrm{d} \mathbf{p}_{\mathrm{RAD}}}{\mathrm{~d} t}=\frac{\mu_{0} q^{2}}{6 \pi c^{3}} a^{2} \mathbf{v} \tag{45.11.01}
\end{equation*}
\]
2. The angular momentum radiated per unit time is:
\[
\begin{equation*}
\frac{\mathrm{d} \mathbf{j}_{\mathrm{RAD}}}{\mathrm{~d} t}=\frac{\mu_{0} q^{2}}{6 \pi c} \mathbf{v} \times \mathbf{a} \tag{45.11.02}
\end{equation*}
\]
45.11.05 Linear/Angular Momentum Radiated by a Moving Point Charge
©|R.Napolitano \& S.Ragusa|A simple calculation of the rate of emission of energy and of linear and angular momentum by a point charge in arbit
The energy per unit time radiated by a non-relativistic point charge is given by the Larmor formula.
1. The linear momentum radiated per unit proper-time is:
\[
\begin{equation*}
\frac{\mathrm{d} \mathbf{p}_{\mathrm{RAD}}}{\mathrm{~d} \tau}=\frac{\mu_{0} q^{2}}{6 \pi c^{3}} \frac{\mathbf{a}^{2}-(\mathbf{a} \times \boldsymbol{\beta})^{2}}{\left(1-\beta^{2}\right)^{3}} \boldsymbol{\beta} \tag{45.11.03}
\end{equation*}
\]
2. The angular momentum radiated per unit proper-time is:
\[
\begin{equation*}
\frac{\mathrm{d} \mathrm{j}_{\mathrm{RAD}}}{\mathrm{~d} \tau}=\frac{\mu_{0} q^{2}}{6 \pi c} \frac{\beta \times \mathbf{a}}{1-\beta^{2}} \tag{45.11.04}
\end{equation*}
\]

\section*{45-005 EM Energy Loss per Turn in a Synchrotron}

Consider a synchrotron with orbit radius equal to \(\rho\) where independent charged point particles are circulating with an orbital period \(T\). Calculate the energy loss per particle per turn.

\section*{SOLUTION}

Use Larmor Radiation Formula in equation (??), exploiting the fact that for a circular orbit \(\mathbf{v} \cdot \mathbf{a}=0\). Remind that the acceleration for a uniform circular motion is \(v^{2} / \rho\) in relativistic kinematics as well as in non-relativistic one. Note that the dynamics will not enter, as we are just interested to know the emitted power from a given kinematics, and we don't care about the force which is providing the kinematics. Therefore, omitting the retarded time:
\[
\begin{gathered}
-W_{q}\left[t_{\mathrm{R}}\right]=\frac{q^{2}}{6 \pi \varepsilon_{0} c^{3}}\left[\gamma^{4} \mathbf{a}^{2}\right]_{t_{\mathrm{R}}}, \\
-\Delta E_{q}^{\mathrm{turn}}=-W_{q} T=\frac{q^{2}}{6 \pi \varepsilon_{0} c^{3}} \gamma^{4} \mathbf{a}^{2} T=\frac{q^{2}}{6 \pi \varepsilon_{0} c^{3}} \gamma^{4} \frac{v^{4}}{\rho^{2}} \frac{2 \pi \rho}{v}=\frac{q^{2}}{3 \varepsilon_{0} c^{3}} \frac{v^{3} \gamma^{4}}{\rho} .
\end{gathered}
\]

[2246, 2246, 2246, 2246]
Interference demonstrates the wave-like character of a phenomenon.
It is specific of the wave-like character of wave-phenomena that the combined effect of two or more waves (sources) may produce no signal (no effect at all) in a region where one single wave (source) would have produced some signal (effect). Thus the spatial distribution of energy is changed by interference phenomena, which cause a rearranging/redistribution in space of the energy density/flux.
Interference is basically an effect derived from the linearity of the equations (superposition principle) and from the fact that energy density/flux is typically given by the square of the sum of the amplitudes. Thus interference comes from the fact that on squaring a sum of amplitudes cross-products appear.
Interference applies to any kind of wave phenomenon.
Quantum physics shows that interference phenomena also apply to particles.
Interference leads to a redistribution of energy in space, with respect to the location where energy would be with single sources.
Since now on we will consider cases when either two or more different waves have different phases at the source and|or they reach an observation point following, possibly, different paths: the problem, most often, is not just a one-dimensional problem. This introduces peculiar effects due to the different paths followed by the different waves from the source to the observation point.
Interference arises when the number of sources is finite or a countable infinite set: it is discussed in this section.
Diffraction arises when the number of sources is an infinite continuum: it is discussed in § 47 - Diffraction.
In this section, as in the forthcoming \(\S 47\) - Diffraction on diffraction, unless specified otherwise, the discussion will be limited to observations at very large distances from the sources, in such a way that: in the case of longitudinal waves, the interfering waves are just parallel waves and can be summed as longitudinal components; in the case of transverse waves, the fields lie in the plane perpendicular to the wave-vector and can be summed as components as long as they have the same Polarization, or must be summed as 2D vectors in the perpendicular plane, otherwise. Note that sum the Perturbation|Disturbance|Signals means to sum the components along any fixed direction.

The very large distances from the sources is implicit in the so-called Fraunhofer regime for interference/diffraction.
It is always assumed that different sources do not interact nor affect each other, so that they are truly independent sources. This might not be the case in practice but, in this case, no progress is possible without modeling the interactions among sources|fields.
The case of observations near the sources and|or superposition of waves traveling in different directions is considerably more complex from the computational point of view.
Our concerns are only with the classical limit, where many photons are present simultaneously and their associated ElectroMagnetic fields can be described by Maxwell equations.
While interference and diffraction are phenomena proper to any kind of waves, the discussion will be limited to ElectroMagnetic waves, due to their huge interest.
Until coherence is presented, in § 48 - Interference Diffraction Wave-Fields and Coherence, all sources are assumed to be strictly monochromatic point sources. Therefore, they appear as generators of spherical (possibly non isotropic) waves. At large enough distance, waves appear as MPW.

\subsection*{46.01.01 Some Interference Phenomena and Applications}

Some common phenomena and applications of interference are the following:
- the colored fringes produced by a thin film of oil floating on water and in soap bubbles are due to interference;
- the colored fringes when light is reflected by a CD/DVD;
- anti-reflection coatings on lenses and mirrors exploit interference;
- the classical experiment showing interference is Young experiment;
- radio jamming;
- coherent constructive interference occurs in reflection from a smooth surface when the angle of reflection equals the angle of incidence but it does not occur in reflection when the angle of reflection is different from the angle of incidence when, in fact, coherent destructive superposition is in action.
- ...

\subsection*{46.01.02 Some Toy Examples}

This § is referenced at pages:
[2215, 2215, 2223, 2223, 2223, 2223, 2224, 2224, 2225, 2225]
Interference, is in a nutshell, the fact that the intensity is typically proportional to the time-average of the square of the total field; the total field is the linear superposition of the different fields (for linear systems) and therefore the cross-products show up in the intensity formula.

\subsection*{46.01.02.01 Scalar MPW With the Same Frequencies in 1D}

Consider two different scalar-fields MPW propagating along the \(z\) direction, with the same frequency and phase-velocity:
\[
\begin{equation*}
\psi_{1}[z, t]=\psi_{1 \mid 0} \cos \left[k z-\omega t-\phi_{1}\right] \quad \psi_{2}[z, t]=\psi_{2 \mid 0} \cos \left[k z-\omega t-\phi_{2}\right] \tag{46.01.01}
\end{equation*}
\]

Let us calculate the intensity, to within a proportionality constant which is irrelevant in the forthcoming derivation. In fact all the results will be expressed in terms of the intensities and any proportionality constant might be included in the definition of the field (46.01.01)

The intensity, after averaging over an integer number of periods, is thus given, to within a proportionality constant, by:
\[
I=\left\langle\psi^{2}[z, t]\right\rangle \propto \frac{1}{2} \psi_{0}^{2} \quad \psi_{0} \propto \sqrt{2 I}
\]
that is independent of the position \(z\).
The superposition principle implies that, in the case of two independent sources which do not affect each other, the intensity is calculated by first summing the fields, squaring afterwards and finally taking the time-average, to obtain:
\[
\begin{aligned}
I & =\left\langle\left(\psi_{1}[z, t]+\psi_{2}[z, t]\right)^{2}\right\rangle, \\
& =I_{1}+I_{2}+2\left\langle\psi_{1}[z, t] \psi_{2}[z, t]\right\rangle, \\
& =I_{1}+I_{2}+4 \sqrt{I_{1}} \sqrt{I_{2}}\left\langle\left(\cos \left[k z-\omega t-\phi_{1}\right] \cos \left[k z-\omega t-\phi_{2}\right]\right)\right\rangle, \\
& =I_{1}+I_{2}+2 \sqrt{I_{1}} \sqrt{I_{2}}\left\langle\left(\cos \left[2 k z-2 \omega t-\left(\phi_{1}+\phi_{2}\right)\right]+\cos \left[\phi_{2}-\phi_{1}\right]\right)\right\rangle .
\end{aligned}
\]

The hypotheses imply:
\[
\left\langle\cos \left[2 k z-2 \omega t-\left(\phi_{1}+\phi_{2}\right)\right]\right\rangle=0
\]

Finally it follows:
\[
I=I_{1}+I_{2}+2 \sqrt{I_{1}} \sqrt{I_{2}}\left\langle\cos \left[\phi_{2}-\phi_{1}\right]\right\rangle \quad \text { time-averaged energy flux }
\]

The term
\[
2 \sqrt{I_{1}} \sqrt{I_{2}}\left\langle\cos \left[\phi_{2}-\phi_{1}\right]\right\rangle
\]
is called the interference term. Its presence might give rise to either increased or decreased total intensity, when compared to the sum of the intensities of the single sources, depending on the quantity
\[
\left\langle\cos \left[\phi_{2}-\phi_{1}\right]\right\rangle \equiv\langle\cos \Delta \phi\rangle \equiv\left\langle\cos \left[\phi_{1}-\phi_{2}\right]\right\rangle,
\]
which determines the interference characteristics of the phenomenon.
By definition we have interference if and only if:
\[
I \neq I_{1}+I_{2} \quad \Leftrightarrow \quad\langle\cos \Delta \phi\rangle \neq 0 .
\]

Interference just moves the distribution is space of the energy.
The limiting cases are the following:
\[
\langle\cos \Delta \phi\rangle=\left\{\begin{array}{l}
+1 \Longrightarrow I=I_{\mathrm{MAX}}=\left(\sqrt{I_{1}}+\sqrt{I_{2}}\right)^{2} \quad, \quad\left(=4 I_{0} \quad \text { for } I_{1}=I_{2} \equiv I_{0}\right) \\
0 \Longrightarrow I=I_{\mathrm{AVE}}=I_{1}+I_{2}, \quad\left(=2 I_{0} \quad \text { for } I_{1}=I_{2} \equiv I_{0}\right) \\
-1 \Longrightarrow I=I_{\mathrm{MIN}}=\left(\sqrt{I_{1}}-\sqrt{I_{2}}\right)^{2} \quad, \quad\left(=0 \quad \text { for } I_{1}=I_{2} \equiv I_{0}\right)
\end{array}\right.
\]

Consider, as an example, the simple case \(\psi_{1 \mid 0}=\psi_{1 \mid 0}=\psi_{0}\); one has:
\[
\left\{\begin{array}{l}
\Delta \phi=0 \Longrightarrow \psi_{1}[z, t]+\psi_{2}[z, t]=2 \psi_{1}=2 \psi_{2} \\
\Delta \phi= \pm \pi / 2 \Longrightarrow \text { cosinusoid of amplitude } \sqrt{2} \psi_{0} \\
\Delta \phi= \pm \pi \Longrightarrow \text { zero }
\end{array}\right.
\]

When the intensity is increased, with respect to the sum of the intensities of the individual sources, one speaks of constructive interference. When the intensity is decreased, with respect to the sum of the intensities of the individual sources, one speaks of destructive interference.
Two sources having a fixed interference factor, \(\langle\cos \Delta \phi\rangle\), are said to be mutually coherent sources (section § 48.02 - Interference Diffraction Wave-Fields and Coherence).
Two sources having an interference factor equal to zero, \(\left\langle\cos \left[\phi_{2}-\phi_{1}\right]\right\rangle \equiv\langle\cos \Delta \phi\rangle=0\), are said to be mutually incoherent sources (section § 48.02 - Interference Diffraction Wave-Fields and Coherence).

\subsection*{46.01.02.02 Scalar MPW at Different Frequencies in 1D}

Consider again the same tool example of § 46.01.02 - Interference of two different one-dimensional scalar-field MPW, with phase constants, \(\phi_{1}\) and \(\phi_{2}\) but assume now that the two waves have different frequencies. The wave-vectors will be, a priori, different. Therefore:
\[
\psi_{1}[z, t]=\psi_{1 \mid 0} \cos \left[k_{1} z-\omega_{1} t-\phi_{1}\right] \quad \psi_{2}[z, t]=\psi_{2 \mid 0} \cos \left[k_{2} z-\omega_{2} t-\phi_{2}\right] .
\]

Now the interference term in the intensity s:
\[
\propto\left\langle\cos \left[\left(k_{1}+k_{2}\right) z-\left(\omega_{1}+\omega_{2}\right) t-\left(\phi_{1}+\phi_{2}\right)\right]+\cos \left[\left(k_{1}-k_{2}\right) z-\left(\omega_{1}-\omega_{2}\right) t-\left(\phi_{1}-\phi_{2}\right)\right]\right\rangle=0,
\]
averaging to zero, because the time-averaging now is done on two co-sinusoids, while in the previous case the equality of the frequencies left one time-constant term: \(\left\langle\cos \left[\phi_{2}-\phi_{1}\right]\right\rangle \equiv\langle\cos \Delta \phi\rangle\).
Therefore, there is no interference among MW at difference frequencies: the intensity is just the sum of the two intensities at any location and time.

\subsection*{46.01.02.03 Scalar MPW With the Same Frequencies in 3D}

This § is referenced at pages:
[2222, 2222]
In a general 3D configuration, the phase difference at any point in space comes both from the intrinsic phase difference of the sources and the possible difference of phase gained by the two waves when traveling along different paths from the sources to the observation point. The latter might be both geometrical and|or due to different properties of the crossed media.

Consider two different scalar-fields MPW propagating in 3 D , with wave-vectors \(\mathbf{k}_{1}\) and \(\mathbf{k}_{2}\), with the same frequency and phase-velocity:
\[
\begin{equation*}
\psi_{1}[\mathbf{r}, t]=\psi_{1 \mid 0} \cos \left[\mathbf{k}_{1} \cdot \mathbf{r}-\omega t-\phi_{1}\right] \quad \psi_{2}[\mathbf{r}, t]=\psi_{2 \mid 0} \cos \left[\mathbf{k}_{2} \cdot \mathbf{r}-\omega t-\phi_{2}\right] \tag{46.01.02}
\end{equation*}
\]

One finds:
\[
I=I_{1}+I_{2}+2 \sqrt{I_{1}} \sqrt{I_{2}} \cos \left[\left(\mathbf{k}_{2}-\mathbf{k}_{1}\right) \cdot \mathbf{r}-\left(\phi_{2}-\phi_{1}\right)\right]
\]

Note that, for vector waves, the computations might be more complex, when accounting for the directions of the vectors, read § 46.04 - Interference.

The minima and maxima of intensity are located in parallel planes, perpendicular to the difference of the wave-vectors, \(\mathbf{k}_{\Delta} \equiv \mathbf{k}_{2}-\mathbf{k}_{1}\), and separated by the distance \(2 \pi /\left|\mathbf{k}_{2}-\mathbf{k}_{1}\right|\).

In case the minima and maxima of intensity are observed on an arbitrarily oriented observation plane, the fringes can be described in terms of a fringe vector \(\mathbf{k}_{f}\) that is the projection of \(\mathbf{k}_{\Delta}\) into the observation plane whose normal is \(\hat{\mathbf{n}}\) :
\[
\mathbf{k}_{f} \equiv \hat{\mathbf{n}} \times\left(\mathbf{k}_{\Delta} \times \hat{\mathbf{n}}\right)=\mathbf{k}_{\Delta}-\left(\mathbf{k}_{\Delta} \cdot \hat{\mathbf{n}}\right) \hat{\mathbf{n}} \equiv \frac{2 \pi}{\Lambda} \hat{\mathbf{k}}_{f} \quad \Lambda \equiv \frac{2 \pi}{\left|\mathbf{k}_{f}\right|} \quad \mathbf{k}_{\Delta} \equiv \mathbf{k}_{2}-\mathbf{k}_{1} \quad . \quad \text { (46.01.03) } \quad \rightarrow
\]

The modulated intensity bands are called interference fringes.
The fringe vector, \(\mathbf{k}_{f}\), describes both the direction of the fringes, and the fringe period \(\Lambda\)

\subsection*{46.01.03 Conditions for Interference to Occur}

This § is referenced at pages:
[Never referenced.]
© \(\mathbb{C}\) E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....|||

In order for interference to occur between two MPW the following conditions must apply as necessary, albeit not sufficient, conditions.
- The two MPW must have almost the same frequency. In fact, if two waves are to interfere producing a stable interference pattern, they must have very nearly the same frequency. Otherwise any significant frequency difference would produce a rapidly varying, time-dependent phase difference, which would cause the interference term in the intensity to average to zero during the observation. This is to be compared to the discussion about beats in \(\S 40.03 .11\) - General Properties of Waves, where it is shown that the closer the two frequencies, the slower are varying the intensity patterns.
- If both sources have a non-monochromatic spectrum the components at different frequencies will interfere with the waves of the same frequencies produced by the other source. As a consequence a great many of fairly similar and slightly displaced overlapping monochromatic interference patterns will tend to wash-out the interference pattern. The interference pattern will not be as sharp nor as extensive as an almost monochromatic interference pattern, but some observable interference may be present.
- The two MPW must have the same Polarization (if transverse waves are involved), or, to be more precise, have non orthogonal Polarization, to have some interference.
- The clearest interference pattern (that is the pattern with maximum contrast) exist when the interfering waves have equal or nearly equal amplitudes. In fact, in this case, the central regions of the dark|bright interference fringes correspond to almost complete destructive|constructive interference, respectively, thus yielding maximum contrast of the interference pattern.
- The two sources must be mutually coherent (read § 48.02 - Interference Diffraction Wave-Fields and Coherence). In fact, for an interference pattern to be observed, the two sources need to have a constant phase-difference. Actually interference patterns shifted in some way will occur whenever there is some phase difference between the sources, as long as it remains constant. Such sources are called coherent sources.
The previous conditions are necessary in order to obtain an intensity (irradiance) which is not the sum of the intensities (irradiance) of the two MPW.

Interference arises from two different origins:
- a different phase-constant of the involved sources;
- a difference of phases gained between the two sources due to different paths from the source to the observation point.
Note that, as far as interference is concerned, what is really important is the time-average of the interference factor.

In many cases one might actually have interference fringes which changes so quickly, and possibly randomly, such that one observes, in practice, a uniform illumination unless one has a detector capable to follow the fast changes.

In general, especially for non scalar fields and not far-away from the sources, the addition of the waves might be something more complex than the simple scalar sum envisaged in these tool examples.

This § is referenced at pages:
[2313, 2313]
Consider any monochromatic ElectroMagnetic wave. The optical path length (OPL) between two points in a isotropic linear medium is defined as proportional to the travel time:
\[
\begin{equation*}
\Lambda \equiv \int_{C} \mathrm{n}[\omega][\mathbf{x}] \mathrm{d} s=c^{2} \int_{C} \frac{\mathrm{~d} t}{v[\mathbf{x}]} \tag{46.02.01}
\end{equation*}
\]

It is the key quantity, determining the conditions for constructive|destructive interference. In the simplest case, the optical path length is just the change of phase of a MPW
See its use in § 51.02-Geometrical|Ray Optics.

\subsection*{46.03}

\section*{Localization and Visibility of the Interference Fringes}

We mostly limit the discussion to fringes forming at infinity (Fraunhofer regime) so that some kind of instrument is required to converge the rays into the same point in order for interference to occur.

\subsection*{46.03.00.01 Observation of Haidinger Fringes}

In all the cases presented, the superposition of the waves to provide interference takes place, strictly speaking, at infinity because the superposition is assumed to take place at large distance among waves produced by different sources running parallel to each other but, in general, along different straight lines.
An optical instrument capable to let parallel rays converge at a point without adding any relative phase shift (read §51-Geometrical|Ray Optics for light) is practically required to cause interference. In practical cases, for light, the human eye can do this, allowing to see interference fringes from the interference on the retina of incident parallel rays.
Technical details and realistic configurations, for light, are the subject of Geometrical|Ray Optics (read § 51 - Geometrical|Ray Optics). Here it will be just assumed that such a device exists and is being used. Typically, for light, a suitable lens works well: a lens which makes all parallel rays converge into the same point keeping the same optical path, that is to say without adding any phase-shift.

\subsection*{46.03.00.02 Contrast of the Interference Fringes}

It is important to emphasize that, when superposing two different waves, a phase difference at some point might arise from different distances/paths from the sources. Therefore the phase difference, \(\Delta \phi\), might be position dependent. This gives rise to the so-called interference fringes: different light intensity at different points in space.
The contrast between the interference fringes is measured by the visibility factor, \(\mathcal{\nu}\), (that is the contrast) which can be expressed via equation (46.01.02.01) as:
\[
\text { contrast } \equiv \mathcal{V} \equiv \frac{I_{\mathrm{MAX}}-I_{\mathrm{MIN}}}{I_{\mathrm{MAX}}+I_{\mathrm{MIN}}}=\frac{2 \sqrt{I_{1} I_{2}}}{I_{1}+I_{2}} \leq 1
\]

The maximum visibility factor, \(\mathcal{V}=1\), is obtained when \(I_{1}=I_{2}\).

\section*{Interference of ElectroMagnetic MPW}

This § is referenced at pages:
[2216, 2216]
Fresnel and Arago demonstrated that orthogonally Polarized ElectroMagnetic waves never interfere, confirming the transversal character of ElectroMagnetic waves.

\subsection*{46.04.01 EM MPW Propagating Along the Same Direction}

Consider an arbitrary number of different ElectroMagnetic MPW propagating along the \(z\) direction, with the same frequency and phase-velocity. That is: all the ElectroMagnetic MPW have the same wave-vector and frequency but arbitrary amplitudes and phases.

\subsection*{46.04.01.01 EM MPW in the Same Direction With the Real Formalism}

\section*{First Analysis}

The electric field components along the \(x\) and \(y\) directions will be the sum of the \(x\) and \(y\) components of all the ElectroMagnetic waves. These are all Sinusoidal|Cosinusoidal functions with the same frequency (but arbitrary amplitudes and phases) and therefore the sum is still a Sinusoidal|Cosinusoidal function with the same frequency, and a suitable amplitude and phase, according to section § 17.02 - Linear Systems. The electric field will be therefore the electric field of a general ElectroMagnetic MPW propagating in the \(z\) direction (read § 42.03 - ElectroMagnetic Waves). That is the electric field will have in general both \(x\) and \(y\) components, with arbitrary amplitudes and phases. The magnetic fields, along the \(x\) and \(y\) directions, will be given, thanks to Maxwell Equations, by:
\[
\mathbf{B}=\frac{\mathbf{k} \times \mathbf{E}}{\omega}
\]

Therefore the resulting ElectroMagnetic wave will be a generic ElectroMagnetic MPW propagating along the \(z\) direction, with generic (in general elliptic) Polarization (k may be complex).

\section*{Second Analysis}

The resulting Electric|Magnetic field is the sum of all the Electric|Magnetic fields.
The magnetic field of each component ElectroMagnetic MPW is given by
\[
\mathbf{B}_{j}=\frac{\mathbf{k} \times \mathbf{E}_{j}}{\omega}
\]
and the frequency and wave-vector of every ElectroMagnetic MPW are the same.
Therefore, as also the resulting magnetic field is the sum of all the magnetic fields, the total magnetic field can be written as:
\[
\mathbf{B}=\frac{\mathbf{k} \times \mathbf{E}}{\omega} .
\]

Therefore the resulting ElectroMagnetic wave will be a generic ElectroMagnetic MPW propagating along the \(z\) direction, with generic (in general elliptic) Polarization ( \(\mathbf{k}\) may be complex).

\subsection*{46.04.01.02 EM MPW in the Same Direction With the Complex Formalism}

A ElectroMagnetic MPW, with arbitrary Polarization, can be written with the complex formalism as:
\[
\begin{equation*}
\overline{\mathbf{E}}[z, t]=\overline{\mathbf{E}_{0}} \exp [\beth(k z-\omega t)] . \tag{46.04.01}
\end{equation*}
\]

The complex constant vector \(\overline{\mathbf{E}_{0}}\) contains all the information about amplitudes and phases of the \(x\) and \(y\) components, that is about the state of Polarization of the ElectroMagnetic wave. It fully describes a ElectroMagnetic MPW of a given frequency and wave-vector.
The superposition of many ElectroMagnetic MPW along the \(z\) direction can be done easily with the complex formalism and without any problem because it is a linear operation. The superposition of \(N\) waves is just obtained by summing the \(\mathbf{E}_{0}\) complex vectors of all the waves, because the exponential factors in equation (46.04.01) factorize:
\[
\overline{\mathbf{E}}[z, t]=\left(\overline{\mathbf{E}}_{0 \mid 1}+\overline{\mathbf{E}}_{0 \mid 2}+\ldots+\overline{\mathbf{E}}_{0 \mid N}\right) \exp [\beth(k z-\omega t)] .
\]

\subsection*{46.04.01.03 No Interference Between ElectroMagnetic Waves With Orthogonal Polarization}

This § is referenced at pages:
[Never referenced.]
The relation (46.04.02) shows that if one superimposes two ElectroMagnetic MPW with orthogonal Polarization the resulting intensity will be the sum of the two intensities: two ElectroMagnetic MPW with orthogonal Polarization do not interfere.
In fact two ElectroMagnetic MPW propagating in the same direction have orthogonal Polarization if and only if:
\[
\left(\overline{\mathbf{E}}_{1}\right) \cdot\left(\overline{\mathbf{E}}_{2}\right)^{\star}=\left(\overline{\mathbf{E}}_{1}\right)^{\star} \cdot\left(\overline{\mathbf{E}}_{2}\right)=0
\]

The fact that two EM MPW with orthogonal Polarization do not interfere can be also shown directly as follows.

\section*{Linear Polarization}

Consider two MPW propagating along the positive \(z\) direction, \(\mathbf{k}=k \hat{\mathbf{e}}_{3}\), linearly Polarized, respectively, along the \(x\) and \(y\) direction. The Electric|Magnetic fields are given by:
\[
\begin{aligned}
& \mathbf{E}_{1}=E_{0 \mid 1} \cos \left[\mathbf{k} \cdot \mathbf{r}-\omega t-\phi_{1}\right] \hat{\mathbf{e}}_{1}, \\
& \mathbf{E}_{2}=E_{0 \mid 2} \cos \left[\mathbf{k} \cdot \mathbf{r}-\omega t-\phi_{2}\right] \hat{\mathbf{e}}_{2}, \\
& \mathbf{H}_{1}=\frac{\hat{\mathbf{e}}_{3} \times \mathbf{E}_{1}}{Z} \propto \hat{\mathbf{e}}_{2}, \\
& \mathbf{H}_{2}=\frac{\hat{\mathbf{e}}_{3} \times \mathbf{E}_{2}}{Z} \propto \hat{\mathbf{e}}_{1} .
\end{aligned}
\]

Note that the arbitrary relative phases of the \(x\) and \(y\) components of the electric field imply that the resulting ElectroMagnetic wave has an arbitrary Polarization.
The resulting Poynting vector is:
\[
\mathbf{S}=\left(\mathbf{E}_{1}+\mathbf{E}_{2}\right) \times\left(\mathbf{H}_{1}+\mathbf{H}_{2}\right)=\mathbf{E}_{1} \times \mathbf{H}_{1}+\mathbf{E}_{2} \times \mathbf{H}_{2},
\]
where the last equality follows from the fact that, thanks to the orthogonality of the Polarization: \(\mathbf{E}_{1} \| \mathbf{H}_{2}\) and \(\mathbf{E}_{2} \| \mathbf{H}_{1}\). Therefore two waves linearly Polarized in orthogonal directions do not interfere as the intensity (that is the average value of the Poynting vector) sum.
Note that \(Z\) might be complex and in this case it would be better to use the complex notation. However in this problem only the directions of the vectors are relevant to the result.

Note that the result might have been obtained in a easier way noting that, thanks to the fact the the two waves have identical wave-vectors, one can write:
\[
\mathbf{H}_{1}+\mathbf{H}_{2}=\frac{\hat{\mathbf{e}}_{3} \times \mathbf{E}_{1}}{Z}+\frac{\hat{\mathbf{e}}_{3} \times \mathbf{E}_{2}}{Z}=\frac{\hat{\mathbf{e}}_{3} \times\left(\mathbf{E}_{1}+\mathbf{E}_{2}\right)}{Z} .
\]

This implies:
\[
I \propto\left(\mathbf{E}_{1}+\mathbf{E}_{2}\right)^{2}
\]
because everything goes as in the case of one single MPW with \(\mathbf{E}=\mathbf{E}_{1}+\mathbf{E}_{2}\).

\section*{Circular Polarization}

This § is referenced at pages:
[Never referenced.]
In the case the two Polarization states are given by left and right circularly Polarized waves one knows that the left and right circularly Polarized states can be expressed as a linear superposition of \(x\) and \(y\) linearly Polarized states. This fact provides an alternative route to the demonstration that left and right circularly Polarized waves do not interfere, alternative to the direct computation of the Poynting vector.

\subsection*{46.04.01.04 Intensity}

Consider a generic set of homogeneous ElectroMagnetic MPW with possibly complex wave-vector of type \(\overline{\mathbf{k}}=\mathbf{k}_{\mathrm{R}}+\beth \mathbf{k}_{\mathrm{I}}=\bar{k} \hat{\boldsymbol{\kappa}}\), with \(\hat{\boldsymbol{\kappa}}\) a real unit vector.

The reasoning of the previous sections allows the following conclusions.
The energy flux of ElectroMagnetic MPW will be given, in terms of either the total electric field, \(\overline{\mathbf{E}}\), or the total magnetic field, \(\overline{\mathbf{H}}\), by the complex Poynting vector:
\[
\begin{equation*}
\langle\mathbf{S}\rangle=\frac{\hat{\boldsymbol{\kappa}}}{2} \operatorname{He}\left(\frac{\overline{\mathbf{E}}_{0}^{\star} \cdot \overline{\mathbf{E}}_{0}}{\overline{\mathrm{Z}}}\right)=\frac{\hat{\boldsymbol{\kappa}}}{2} \operatorname{Re}\left(\overline{\mathrm{Z}} \overline{\mathbf{H}}_{0}^{\star} \cdot \overline{\mathbf{H}}_{0}\right), \tag{46.04.02}
\end{equation*}
\]
in terms of the total Electric|Magnetic fields, as for one single ElectroMagnetic wave.
In vacuum it becomes:
\[
I\left[\mathbf{x}_{\mathrm{P}}\right]=c \varepsilon_{0}\left\langle\overline{\mathbf{E}}\left[\mathbf{x}_{\mathrm{P}}, t\right] \cdot \overline{\mathbf{E}}^{\star}\left[\mathbf{x}_{\mathrm{P}}, t\right]\right\rangle=\frac{c \varepsilon_{0}}{2}\left|\overline{\mathbf{E}_{0}}\right|^{2}
\]

As we have demonstrated that any sum of ElectroMagnetic MPW with the same wave-vector can be reduced to a single ElectroMagnetic MPW with the same wave-vector we get the interference formula for superposition of two waves:
\[
I=I_{1}+I_{2}+\frac{\hat{\boldsymbol{\kappa}}}{2} \operatorname{Re}\left(\frac{\overline{\mathbf{E}}_{1}^{\star} \cdot \overline{\mathbf{E}}_{2}}{\overline{\mathrm{Z}}}\right)
\]

\subsection*{46.04.02 EM MPW Crossed Beams}

Study the interference between two ElectroMagnetic MPW with either electric or magnetic field in the same direction but different wave-vectors. Read § 46.01.02.03 - Interference.

\title{
Interference Among Monochromatic Point Sources of Spherical Waves
}

The discussion will be based on the ElectroMagnetic waves radiated by an oscillating ideal Electric|Magnetic Dipole, considered as a point source (antenna) emitting Dipole ElectroMagnetic radiation (read § 45 - Radiation of ElectroMagnetic Waves). The advantage of this approach is that the fields produced by the sources are perfectly known in the ideal case. In addition to that, real EM antennas are often exploiting interference.
It is assumed that the two antennas do not affect each other. For instance, there si a suitable ElectroMagnetic screen between them.
When one needs to be more specific, for the sake of clarity, we will assume the case of the oscillating ideal Electric Dipole, but it is obvious that a parallel discussion might be done for a oscillating ideal Magnetic Dipole. Moreover, it is obvious that the same reasoning would apply to any interference setup for light, like the one of the Young experiment, as long as one can consider the light sources as point sources. Similarly, the same reasoning also apply to sound sources.
In case the sources cannot be considered point sources one must take into account diffraction phenomena, as discussed in § 47 - Diffraction.
The treatment will be limited to distances from the sources very large with respect to the distances among the sources (the so-called Fraunhofer regime). In this regime the spherical waves can be considered MPW and all wave-vectors can be considered parallel among each other. For longitudinal waves this reduces the problem to exactly the simple tool example discussed in section § 46.01.02 - Interference. For ElectroMagnetic waves, that are transverse waves, one must take into account also the Polarization of the wave. Unless specified otherwise, it will be implicitly assumed that the interfering transverse waves have the same Polarization which, again, reduces the problem to exactly the simple tool example discussed in section § 46.01.02-Interference.

According to the previous discussion the following hypothesis will be assumed. The point sources are emitters of spherical waves (not necessarily isotropic waves):
\(\psi[\mathbf{r}, t]=\frac{A[\theta, \psi]}{r} \cos [k r-\omega t-\phi]=\mathfrak{H e}\left(\frac{\overline{\mathrm{A}}}{\mathrm{r}} \exp [\beth(\mathrm{kr}-\omega \mathrm{t})]\right) \quad \bar{A}=A \exp [-\beth \phi] A>0 \quad A=A[\theta, \psi]\),
(46.05.01)
where in general the amplitude might depend on the angle, \(A=A[\theta, \psi]\), and \(\psi[\mathbf{r}, t]\) must satisfy the appropriate wave equation as well as any other equation for the systems, if any. In the case of the oscillating ideal Electric|Magnetic Dipole fields, located at the origin of a spherical Coordinate System and oriented along the \(\theta=0\) direction, \(\psi[\mathbf{r}, t]\) is either the \(\theta\) or the \(\psi\) component of the Electric \(\mid\) Magnetic field. Note the for ideal oscillating (point) dipoles, the field (46.05.01) is exact.
The oscillating ideal Electric|Magnetic Dipole fields are taken for a quantitative example, based on known physics, read § 45 - Radiation of ElectroMagnetic Waves,

\subsection*{46.05.01 Two Identical Parallel Oscillating Ideal Electric Dipoles With Arbitrary Phases}

This § is referenced at pages:
[2226, 2226, 2251, 2251]
Different arrangements can be considered, as for instance:
1. two identical (harmonic) oscillating ideal Electric|Magnetic Dipoles, located on the \(z\) axis, at \(\{0,0,+d / 2\}\) and \(\{0,0,-d / 2\}\), and oriented along the positive \(z\) axis and with arbitrary phases;
2. two identical (harmonic) oscillating ideal Electric|Magnetic Dipoles, located on the \(x y\) plane, at \(\{0,+d / 2,0\}\) and \(\{0,-d / 2,0\}\), and oriented along the positive \(z\) axis with arbitrary phases.

In both cases, and in all other cases when the two dipoles are parallel, if \(\lambda \gg d\), the field at large distance is just the field of a single Dipole, given by the sum of the two identical dipoles, with a fixed phase depending on the phases of the two sources. Therefore, this case is not interesting for interference and we will consider \(\lambda \lesssim d\).
Note that the small-wavelength condition above is not in conflict with conditions (45.05.10), which are the basis of all our formulas, because the latter refers to the size of the single source. It is the real dipole antenna which has to be smaller than the wavelength.
Let us consider the case two identical ideal (harmonic) oscillating Electric Dipoles, located on the \(x y\) plane, at \(\{0,+d / 2,0\}\) and \(\{0,-d / 2,0\}\), and oriented along the positive \(z\) axis. Assume they emit ElectroMagnetic waves in vacuum, for simplicity. The results obtained in terms of relative intensities will be valid in any other case, for any LHI medium.
The oscillating ideal Electric Dipoles emit non-isotropic spherical waves, as in equation (45.07.01), (45.07.02), which will be described in terms of spherical coordinates \(\{r, \theta, \psi\}\) :
\[
\begin{array}{ll}
E_{\theta}=-\frac{\mu_{0}}{4 \pi} \frac{\omega^{2} \mathrm{p}_{0} \sin \theta}{r} \cos [k r-\omega t-\phi] \propto \frac{\sin \theta}{r} \cos [k r-\omega t-\phi] & E_{r}=E_{\psi}=0 \\
B_{\psi}=-\frac{\mu_{0}}{4 \pi} \frac{\omega^{2} p_{0} \sin \theta}{c r} \cos [k r-\omega t-\phi] \propto \frac{\sin \theta}{r} \cos [k r-\omega t-\phi] & B_{r}=B_{\theta}=0 \tag{46.05.03}
\end{array}
\]

The emission of the single sources in the \(x y\) plane, that is at \(\theta=\pi / 2\), is totally isotropic.
Assume that the two sources have a priori different relative phases, \(\phi_{1}\) and \(\phi_{2}\). In case of real ElectroMagnetic antennas this is easy controlled by the antenna circuitry.
Look at the fields produced on the \(x y\) plane, \(\theta=\pi / 2\), at large distance \(R \gg d\) from the two Dipoles. Thanks to the large distance, one can neglect the difference between the distances at the denominator in the expressions of the fields of the two Dipoles and one can assume that the ElectroMagnetic fields produced by the two Dipoles are parallel to each other. However, the difference of the two distances cannot be neglected inside the phase of the fields, because its product with \(k\) enters as the argument of a cosinus, so that the product can produce large changes of phases. This can be made rigorous by expanding the \(r^{-1}\) : the zero order term in \(r^{-1}\) is exactly the expression to be used here, as shown in equation (46.05.01).
In this case it is useful to sum the fields, first, and to square afterwards. The sum of the fields is made easy, in this case, by the fact that the amplitude of the two Sinusoidal|Cosinusoidal fields is the same. Compare with § 46.01.02 - Interference, where the fields are first squared, as it is easier in case the amplitudes are different.
\[
\begin{gathered}
\psi[r, \theta] \equiv\left\{E_{\theta} ; B_{\psi}\right\} \equiv \frac{A[\theta]}{r} \cos [k r-\omega t-\phi] \\
\psi_{1}\left[r_{1}, \theta\right]+\psi_{2}\left[r_{2}, \theta\right]=\frac{A[\theta]}{r_{1}} \cos \left[k r_{1}-\omega t-\phi\right]+\frac{A[\theta]}{r_{2}} \cos \left[k r_{2}-\omega t-\phi\right] \\
\psi_{1}\left[r_{1}, \theta\right]+\psi_{2}\left[r_{2}, \theta\right]=\frac{A[\theta]}{R+\Delta R_{2}} \cos \left[k r_{1}-\omega t-\phi\right]+\frac{A[\theta]}{R+\Delta R_{1}} \cos \left[k r_{2}-\omega t-\phi\right] \\
\psi_{1}\left[r_{1}, \theta\right]+\psi_{2}\left[r_{2}, \theta\right] \simeq \frac{A[\theta]}{R}\left(1-\frac{\Delta R_{1}}{R}\right) \cos \left[k r_{1}-\omega t-\phi\right]+\frac{A[\theta]}{R}\left(1-\frac{\Delta R_{2}}{R}\right) \cos \left[k r_{2}-\omega t-\phi\right]= \\
\simeq \frac{A[\theta]}{R} \cos \left[k r_{1}-\omega t-\phi\right]+\frac{A[\theta]}{R} \cos \left[k r_{2}-\omega t-\phi\right]-\frac{\Delta R_{1}}{R}(\ldots)-\frac{\Delta R_{2}}{R}(\ldots)= \\
\simeq \frac{A[\theta]}{R} \cos \left[k r_{1}-\omega t-\phi\right]+\frac{A[\theta]}{R} \cos \left[k r_{2}-\omega t-\phi\right]
\end{gathered}
\]

Let:
\[
R \equiv \frac{r_{1}+r_{2}}{2}
\]

Therefore, at \(\theta=\pi / 2\) :
\[
\begin{aligned}
\psi\left[r_{1}, r_{2}, \theta=\pi / 2\right] & \simeq \frac{1}{R}\left(\cos \left[k r_{1}-\omega t-\phi_{1}\right]+\cos \left[k r_{2}-\omega t-\phi_{2}\right]\right)= \\
& \simeq \frac{2}{R}\left(\cos \left[\frac{2 k R-\left(\phi_{1}+\phi_{2}\right)}{2}-\omega t\right] \cos \left[\frac{k\left(r_{1}-r_{2}\right)-\left(\phi_{1}-\phi_{2}\right)}{2}\right]\right)= \\
& \propto \frac{1}{R}\left(\cos \left[k R-\frac{\left(\phi_{1}+\phi_{2}\right)}{2}-\omega t\right] \cos \left[\frac{k d \sin \chi-\left(\phi_{1}-\phi_{2}\right)}{2}\right]\right) .
\end{aligned}
\]

The angle \(\chi\) has been introduced as the angle between the direction of observation and the median axis between the two sources in the \(x y\) plane, as it is customary when studying interference:
\[
\begin{equation*}
r_{1}-r_{2} \equiv d \sin \chi \tag{46.05.04}
\end{equation*}
\]

In this specific case, the median axis is the \(x\) axis. Beware: it has no relation at all with the polar angle in equations (46.05.02) and (46.05.03).
The result is spherical wave, as a function of \(R\), originating at the origin and modulated in amplitude by the factor:
\[
\cos \left[\frac{k d \sin \chi-\left(\phi_{1}-\phi_{2}\right)}{2}\right] .
\]

The emission has become non isotropic in the \(x y\) plane (that is at \(\theta=\pi / 2\) ). This factor is position dependent but time-independent.
The difference of the phases of the two sources is the significant quantity which will be called \(\delta\) :
\[
\delta \equiv \frac{k\left(r_{1}-r_{2}\right)-\left(\phi_{1}-\phi_{2}\right)}{2} \equiv \frac{k d \sin \chi+\left(\phi_{2}-\phi_{1}\right)}{2} \equiv \frac{k d \sin \chi+\Delta \phi}{2}
\]

Note that in this bi-dimensional problem the phase difference was born from different path lengths from the source to the observation point in addition to a possible phase difference between the sources, \(\Delta \phi\). This is markedly different from the one-dimensional toy-model described in section § 46.01.02 - Interference, because in that 1D case, the paths were identical (unless considering forth-back changes of direction).
Beware that the sign of \(\left(r_{1}-r_{2}\right)=k d \sin \chi\) depends on the sign convention for \(\chi\) and the definition of source one and two. The present convention is that \(\chi\) is positive in the counterclockwise direction and source 1 is the one at \(\{0,-d / 2,0\}\) and source 2 is the one at \(\{0,+d / 2,0\}\).
When time-averaging the electric field the cosinusoidal term will provide the usual \(1 / 2\) factor. The intensity for the two sources, as a function of the intensity of a single source in the same conditions, \(I_{0}\), is thus, in vacuum:
\[
\begin{equation*}
I=c \varepsilon_{0}\left\langle E^{2}\right\rangle=4 I_{0} \cos ^{2} \delta=I_{0}\left(\frac{\sin [2 \delta]}{\sin \delta}\right)^{2} . \tag{46.05.05}
\end{equation*}
\]

Note that an essential assumption is that the two antennas do not interact, that is do not affect, each other.

\section*{Discussion of the Results}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||

\section*{In-phase sources}

Consider the case of in-phase sources, \(\phi_{1}=\phi_{2}\). The result (46.05.05) shows that the intensity has equal height maxima at
\[
\frac{k d \sin \chi}{2}=m \pi \quad \Leftrightarrow \quad d \sin \chi=m \lambda
\]
that is the difference in the two paths from the source to the receiver, \(\left|r_{1}-r_{2}\right|\), is equal to a multiple of the wavelength. This is the constructive interference.
The result (46.05.05) shows that the intensity has zeros at
\[
\frac{k d \sin \chi}{2}=(2 m+1) \frac{\pi}{2} \quad \Leftrightarrow \quad d \sin \chi=(2 m+1) \frac{\lambda}{2},
\]
that is the difference in the two paths from the source to the receiver, \(\left|r_{1}-r_{2}\right|\), is equal to an odd multiple of half-wavelength. This is the destructive interference.

\section*{In-quadrature sources}

Study the case of in-quadrature sources, \(\left|\phi_{2}-\phi_{1}\right|=\pi / 2\).

\section*{Plots of the radiation diagram}

The radiation diagram for a set of antennas is a graphics, in spherical coordinates, plotting the function \(r[\theta \equiv \chi] \propto I[\chi]\), that is to say: in the direction \(\theta \equiv \chi\) plot a point at a distance proportional to the intensity emitted by the antennas in that direction.
Some results are plotted in figures 46.1, 46.2, 46.3, 46.4.

\subsection*{46.05.02 Linear Array of Identical Oscillating Electric Dipoles: In-Phase Sources}

This § is referenced at pages:
[2230, 2230, 2230, 2230, 2232, 2232, 2232, 2232, 2233, 2233, 2259, 2259]
Consider now the problem similar to the one in §46.05.01 - Interference but with a linear array of \(N\) Dipoles, instead of two, in row of length \(L\) centered at the origin.
Let \(d\) be the distance between neighboring the Dipoles, located one the \(y\) axis, symmetrically with respect to the origin. The positions are then
\[
\begin{array}{|llll|}
\hline L=(N-1) d & y_{i}=d(i-1)-L / 2 & x_{i}=z_{i}=0 & i=1, \ldots N  \tag{46.05.06}\\
\hline
\end{array}
\]

Assume that all the Dipoles are all in phase and then set \(\phi=0\). It is useful to use in this problem the complex representation. Therefore, putting into a single constant \(\bar{A}\) the constant terms but leaving explicitly expressed the distance \(R\), one finds:
\[
\begin{aligned}
\bar{\psi}\left[r_{1}, r_{2}, \ldots r_{N}, t\right] & =\frac{\bar{A}}{R}\left(\exp \left[\beth\left(k r_{1}-\omega t\right)\right]+\exp \left[\beth\left(k r_{2}-\omega t\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-\omega t\right)\right]\right), \\
& =\frac{\bar{A}}{\bar{R}} \exp \left[\beth\left(k r_{1}-\omega t\right)\right]\left(1+\exp \left[\beth\left(k r_{2}-k r_{1}\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-k r_{1}\right)\right]\right), \\
& =\frac{\bar{A}}{R} \exp \left[\beth\left(k r_{1}-\omega t\right)\right](1+\exp [-\beth k d \sin \chi]+\ldots+\exp [-\beth k(N-1) d \sin \chi]), \quad . \quad \\
& =\frac{\bar{A}}{R} \exp \left[\beth\left(k r_{1}-\omega t\right)\right] \sum_{j=0}^{N-1}(\exp [-\beth k d \sin \chi])^{j}, \\
& =\frac{\bar{A}}{R} \exp \left[\beth\left(k r_{1}-\omega t\right)\right] \exp [-\beth(N-1) \delta] \frac{\sin [N \delta]}{\sin \delta}
\end{aligned}
\]

(a) Parameters: \(d=\lambda / 2\) and \(\Delta \phi \equiv \phi_{2}-\phi_{1}=+\pi / 2\) (horizontal \(x\) axis, vertical \(y\) axis).

Figure 46.1: ..

(a) Parameters: \(d=\lambda / 2\) and \(\Delta \phi \equiv \phi_{2}-\phi_{1}=-\pi / 2\) (horizontal \(x\) axis, vertical \(y\) axis).

Figure 46.2: ...

(a) Parameters: \(d=\lambda / 4\) and \(\Delta \phi \equiv \phi_{2}-\phi_{1}=+\pi / 2\) (horizontal \(x\) axis, vertical \(y\) axis).

Figure 46.3: ..

(a) Parameters: \(d=\lambda / 4\) and \(\Delta \phi \equiv \phi_{2}-\phi_{1}=-\pi / 2\) (horizontal \(x\) axis, vertical \(y\) axis).

Figure 46.4: ...

The expression for the sum of the terms of a geometrical progression (12.04.02) was used.
Finally:
\[
|\psi|=\frac{|\bar{A}|}{R}\left|\frac{\sin [N \delta]}{\sin \delta}\right|
\]

The result is again a spherical wave whose amplitude is modulated by a position-dependent factor depending again on the quantity:
\[
\delta \equiv \frac{k d \sin \chi}{2}
\]

Beware that the sign of
\(\left(r_{N}-r_{1}\right)=-(N-1) d \sin \chi \quad\left(r_{i}-r_{1}\right)=-(i-1) d \sin \chi \quad\left(r_{i}-r_{j}\right)=-(i-j) d \sin \chi \quad i, j=1, \ldots N\),
(46.05.07)
depends on the sign convention for \(\chi\) and the definition of source number. The present convention is that \(\chi\) is positive in the counter-clockwise direction and source 1 is the one at negative \(y\) while source \(N\) is the one at positive \(y\), that is the numbering of sources increases with \(y\).
The intensity for the \(N\) sources, as a function of the intensity of a single source in the same conditions, \(I_{0}\), is thus:
\[
\begin{equation*}
I=I_{0}\left(\frac{\sin [N \delta]}{\sin \delta}\right)^{2} \tag{46.05.08}
\end{equation*}
\]

In practice the intensity decreases away from the center due to the effect of diffraction from the finite size sources.

\section*{Discussion of the Results}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||

The result (46.05.08) shows that the intensity is an even periodic function in \(\delta\) with period \(\pi\), thanks to the \(\sin ^{2} \delta\) functions, where the periodicity is given by the \(\sin ^{2} \delta\) at the denominator. As the function is an even function and periodic with period \(\pi\), it is symmetrical about any \(\delta=m \pi\).

As a function of \(\chi\) the intensity function is a even function, periodic with period \(\pi\), thanks to the \(\sin ^{2}[(\ldots) \sin \delta]\) functions.

\section*{Maxima and Minima of intensity}

The intensity has equal height absolute maxima at:
\[
\begin{equation*}
\delta=\frac{k d \sin \chi}{2}=m \pi \quad \Leftrightarrow \quad d \sin \chi=m \lambda \tag{46.05.09}
\end{equation*}
\]
where the denominator vanishes. In this case the difference in the two paths from the source to the receiver of any two adjacent sources is equal to a multiple of the wavelength. This is the constructive interference condition, with all the sources interfering constructively. In fact the maximum value cannot be anywhere else than the direction where all the waves interfere constructively. The value of the intensity at the absolute maxima is: \(I=N^{2} I_{0}\).

The result (46.05.08) shows that the intensity has zeros at
\[
\begin{equation*}
N \delta=N \frac{k d \sin \chi}{2}=m \pi \quad \Leftrightarrow \quad d \sin \chi=m \frac{\lambda}{N} . \tag{46.05.10}
\end{equation*}
\]

There are \(N-1\) zeros between any two absolute maxima. The zeros are missing at the position of the absolute maxima. It is rather clear that the above condition (46.05.10) gives destructive interference: in fact one is summing \(N\) sinusoids with a relative phase-shift of: \(0, \lambda / N, 2 \lambda / N, 3 \lambda / N, \ldots,(N-1) \lambda / N\). There are \(N-2\) relative maxima (of low amplitude) between any two absolute maxima.

It is important to stress that the geometry of the interference figure strongly depends on the wavelength of the waves. In particular the position of the maxima and minima depends on the wavelength

\section*{Angular Spread of the interference figure}

Equation (46.05.09) shows that for large \(\lambda / d\), the two secondary maxima adjacent to the primary maximum, those corresponding to \(m= \pm 1\), would have a large value, possibly greater than one. If \(\lambda / d>1\), there is no secondary maxima. However, in practice, in most realistic situations, it is reasonable to doubt that, unless \(\lambda / d \ll 11\), some of the approximations fail.

Therefore, it is normally assumed that the angles with respect to the direction of the primary maximum, the one such that all paths have the same length, are small, so that \(\sin \chi \simeq \chi\).

See § 46.09 - Interference.

\section*{Width of the peak}

The width of the peak is conventionally measured as the distance between the first two zeros adjacent to the absolute maximum.

Let us first assume that the angles are small, so that \(\sin \chi \simeq \chi\).
A simple derivation is the following. The zeros in the intensity are given by equation (46.05.10):
\[
d \sin \chi=m \frac{\lambda}{N}
\]

The two zeros adjacent to a maximum are separated by \(|\Delta m|=2\) and therefore equation (46.05.10) implies:
\[
\begin{equation*}
\left|\sin \left[\chi_{+}\right]-\sin \left[\chi_{-}\right]\right| \simeq\left|\chi_{+}-\chi_{-}\right| \equiv \Delta \chi=\frac{2 \lambda}{N d} \tag{46.05.11}
\end{equation*}
\]

Let us now assume that the angles are not small and let us carry on a more precise derivation. One obtains:
\[
\begin{gathered}
\delta=\frac{k d \sin \left[\chi_{\mathrm{M}}\right]}{2}=m \pi \\
N \delta_{-}=\frac{N k d \sin \left[\chi_{+}\right]}{2}=(m N-1) \pi \\
N \delta_{+}=\frac{N k d \sin \left[\chi_{-}\right]}{2}=(m N+1) \pi, \\
\left|\sin \left[\chi_{+}\right]-\sin \left[\chi_{-}\right]\right| \simeq\left|\cos \left[\chi_{\mathrm{M}}\right]\right|\left|\chi_{+}-\chi_{-}\right| \equiv\left|\cos \left[\chi_{\mathrm{M}}\right]\right| \Delta \chi=\frac{2 \lambda}{N d}
\end{gathered}
\]
with the correction factor \(\left|\cos \left[\chi_{M}\right]\right|\) taking into account the non linear relation between \(\chi\) and its sinus.
The result shows the increasing the number of sources, at fixed distance, the width of the peak decreases (while the value of the maximum intensity increases).

\section*{Plots}

Plots of the radiation diagram as a function of \(\delta\), not \(\chi\).

Figure 46.5: ..
46.05.03 Linear Array of Identical Oscillating Electric Dipoles: Linear Phase Relation

This § is referenced at pages:
[2233, 2233]
Consider now the problem similar to the one in \(\S 46.05 .02\) - Interference but with a linear array of \(N\) Dipoles with a phase constant varying linearly:
\[
\phi_{n}=\phi_{0}+n \Delta \phi \quad \Delta \phi_{n} \equiv \phi_{n}-\phi_{1}=(n-1) \Delta \phi
\]

Then the calculation in \(\S\) 46.05.02 - Interference is modifies as follows:
\[
\begin{aligned}
\bar{\psi}[\mathbf{r}, t] & =\frac{\bar{A}}{R}\left(\exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right]+\exp \left[\beth\left(k r_{2}-\omega t-\phi_{2}\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-\omega t-\phi_{N}\right)\right]\right), \\
& =\frac{\bar{A}}{\bar{R}} \exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right]\left(1+\exp \left[\beth\left(k r_{2}-k r_{1}-\phi_{2}+\phi_{1}\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-k r_{1}-\phi_{N}+\phi_{1}\right)\right]\right), \\
& =\frac{\bar{A}}{\bar{R}} \exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right]\left(1+\exp \left[-\beth\left(k d \sin \chi+\Delta \phi_{2}\right)\right]+\ldots+\exp \left[-\beth\left(k(N-1) d \sin \chi+\Delta \phi_{N}\right)\right]\right), \\
& =\frac{\bar{A}}{\bar{R}} \exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right](1+\exp [-\beth(k d \sin \chi+\Delta \phi)]+\ldots+\exp [-\beth(k(N-1) d \sin \chi+(N-1) \Delta \phi)]), \\
& =\frac{\bar{A}}{R} \exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right] \sum_{j=0}^{N-1}(\exp [-\beth(k d \sin \chi+\Delta \phi)])^{j}, \\
& =\frac{\bar{A}}{R} \exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right] \exp [-\beth(N-1) \delta] \frac{\sin [N \delta]}{\sin \delta}
\end{aligned}
\]

The expression for the sum of the terms of a geometrical progression (12.04.02) was used.
Finally:
\[
|\psi|=\frac{|\bar{A}|}{R}\left|\frac{\sin [N \delta]}{\sin \delta}\right|
\]

The result is again a spherical wave whose amplitude is modulated by a position-dependent factor depending again on the quantity modified by the phase shift among two neighboring sources:
\[
\begin{equation*}
\delta \equiv \frac{k d \sin \chi+\Delta \phi}{2} \tag{46.05.12}
\end{equation*}
\]

The intensity for the \(N\) sources, as a function of the intensity of a single source in the same conditions, \(I_{0}\), is thus:
\[
\begin{equation*}
I=I_{0}\left(\frac{\sin [N \delta]}{\sin \delta}\right)^{2} \tag{46.05.13}
\end{equation*}
\]

The phase \(\Delta \phi\) can be used to shift the central maximum away from \(\chi=0\) : for in-phase sources the maximum is at \(\chi=0\), while for a linear phase-shift \(\Delta \phi\) it is at: \(\sin \chi=-\Delta \phi /(k d)\).
This result may be applied, for instance, to steer ElectroMagnetic waves produced by a set of antennas, not by moving the antennas, but by introducing an appropriate delay between the different transducers in the circuitry. Similarly, if the antenna is used to receive, its sensitivity can be steered introducing an appropriate delay between the different transducers in the circuitry. This can be extended to bidimensional arrays and steering, read § 46.07- Interference.

\section*{Discussion of the Results}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
All the discussion done for the case of sources in-phase \((\Delta \phi=0)\) can be repeated here with the result that the plots are shifted by \(\Delta \phi\).

\subsection*{46.05.04 Linear Array of Identical Oscillating Electric Dipoles: Random Phases}

This § is referenced at pages:
[2232, 2232, 2284, 2284]
Read also § 49.03 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter. Consider now the problem similar to the one in § 46.05.02 - Interference but with a linear array of \(N\) Dipoles, with overall fixed length \((N-1) d\), but each source with random phases.

As for the two cases of equations (46.05.02), (46.05.03) one now starts from:
\[
\bar{\psi}[\mathbf{r}, t]=\frac{\bar{A}}{R}\left(\exp \left[\beth\left(k r_{1}-\omega t-\phi_{1}\right)\right]+\exp \left[\beth\left(k r_{2}-\omega t-\phi_{2}\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-\omega t-\phi_{N}\right)\right]\right)
\]
where the phase factors, \(\phi_{k}\), are now random numbers and the observation point is at large distance, \(r \gg(N-1) d\).

For a very large number of sources, \(N \rightarrow \infty\) such that \((N-1) d\) remains constant, the sum tends to zero. In fact, the sum in parenthesis is a sum of independent random variables with zero average value and variance, \(\sigma_{0}\), of the order of unity:
\[
\begin{gathered}
\Lambda \equiv \sum_{p=0}^{N} \exp [+\beth \alpha p] \exp \left[+\beth \phi_{p}\right] \equiv \sum_{p=0}^{N} \lambda_{p}\left[\alpha, \phi_{p}\right] \sim 0+\sigma_{0} \sqrt{N} \\
\left\langle\lambda_{p}\left[\alpha, \phi_{p}\right]\right\rangle=0 \quad \sigma^{2}\left[\lambda_{p}\left[\alpha, \phi_{p}\right]\right] \equiv \sigma_{0}^{2} \propto|\bar{\psi}[\mathbf{r}, t]|^{2} \\
\langle\Lambda\rangle=0 \quad \sigma^{2}[\Lambda]=N \sigma_{0}^{2} \quad \sigma[\Lambda]=\sqrt{N} \sigma_{0}
\end{gathered}
\]

The result is that the resultant electric field scales as \(\sqrt{N}\) and the intensity as \(N\), so that interference does not exist: that is the total intensity is the sum of intensities.

An alternative calculations starts from squaring the summed amplitudes. to find a factor \(N\) from the square of the single amplitudes plus \(N(N-1) / 2\) terms with random phase differences, averaging to zero. These terms are not independent, as any phase appears in \(N-1\) terms but, as a sum of terms, the mean value is the sum of mean values, no matter independence, so the sum of intensities is found as well.

Note: the average field is zero, while the average squared field is non-zero. But the field has zero average and \(\sim \sqrt{N}\) fluctuations.

\subsection*{46.05.05 Linear Array of Identical Oscillating Electric Dipoles: Random Positions}

This § is referenced at pages:
[2284, 2284]
Read also § 49.03 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter. Consider now the problem similar to the one in \(\S 46.05 .02\) - Interference but with a linear array of \(N\) Dipoles, with overall fixed length \((N-1) d\), but each source with random positions.
As for the two cases of equations (46.05.02), (46.05.03) one now starts from:
\[
\bar{\psi}[\mathbf{r}, t]=\frac{\bar{A}}{R}\left(\exp \left[\beth\left(k r_{1}-\omega t-\phi\right)\right]+\exp \left[\beth\left(k r_{2}-\omega t-\phi\right)\right]+\ldots+\exp \left[\beth\left(k r_{N}-\omega t-\phi\right)\right]\right)
\]
where every \(r_{i}\) is now uniformly random in a interval of width \(d\) centered at the positions defined by equation (46.05.06). The same result then obtained as in \(\S 46.05 .04\) - Interference is obtained and interference does not exist: that is the total intensity is the sum of intensities.

Note: the average field is zero, while the average squared field is non-zero. But the field has zero average and \(\sim \sqrt{N}\) fluctuations.

\section*{Interference in the Generalized Young Experiment}

Consider the interference among long thin linear equi-spaced parallel slits on a plane opaque screen when the opaque screen is illuminated by a MPW at normal|oblique incidence, the generalized Young experiment.
This is actually a bi-dimensional problem corresponding exactly to § 46.05.02 - Interference and § 46.05.03 - Interference considered in the plane perpendicular to the dipoles, at \(\theta=\pi / 2\).

\section*{Interference From Bi-Dimensional Sources}

This § is referenced at pages:
[2231, 2231, 2252, 2252]
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|8.4||
For a bi-dimensional set of identical sources located in the \(x y\) plane the expression of the relative intensity is just a generalization of the expression for a linear array. Assume a rectangular array of identical point sources in the \(x y\) plane with spacing \(d_{x}\) and \(d_{y}\) and centered at the origin.
This gives, in terms of the angles \(\chi_{x}\) and \(\chi_{y}\) that the position vector from the origin to the observation point forms with the \(z y\) and \(z x\) planes from equation (??):
\[
\delta_{x} \equiv \frac{k d_{x} \sin \chi_{x}}{2} \quad \delta_{y} \equiv \frac{k d_{y} \sin \chi_{y}}{2},
\]
the expression:
\[
\begin{equation*}
I=I_{0}\left(\frac{\sin ^{2}\left[N_{x} \delta_{x}\right]}{\sin ^{2} \delta_{x}}\right)\left(\frac{\sin ^{2}\left[N_{y} \delta_{y}\right]}{\sin ^{2} \delta_{y}}\right) \tag{46.07.01}
\end{equation*}
\]

In practice the intensity decreases away from the center due to the effect of diffraction from the finite size sources (read § 47 - Diffraction).

\subsection*{46.10.05 Interference From a Thin Lamina}

This § is referenced at pages:
[2143, 2143, 2143, 2143, 2143, 2143]
Interference effects are often observed in thin films, such as a thin layer of oil on water or the thin surface of a soap bubble. The colors observed when white light is incident on such films come from the interference of waves reflected from the two surfaces of the film.
Consider a plane transparent lamina made of a non magnetic medium with refractive index \(n[\omega]\) immersed in a non magnetic medium with refractive index \(n[\omega]_{0}\). Light is incident on the lamina at a certain angle. This is actually a problem of multiple interference, but it will be treated in a simplified form as a problem of interference between two sources, neglecting the effects of multiple reflections.
Let the layer have refractive index \(\mathrm{n}[\omega]\) and thickness \(H\). Let the refractive index of the outside medium be \(\mathrm{n}[\omega]_{0}=1\).
The difference in the phases is due to the optical paths inside the layer, for one ray, and the geometrical difference in the paths to the receiver, outside the layer.
Moreover, a \(\pm \pi\) phase change has to be accounted for, possibly, due to the two reflections. This can be easily seen for Polarization perpendicular to the incidence plane: there is always change of phase of \(\pm \pi\) on reflection at the first surface and there is never change of phase on reflection at the second surface.
The case of Polarization parallel to the incidence plane is similar with the additional complication carried by the different behavior of the change of phase according to the value of the angle of incidence
with respect to the Brewster angle. The two cases, incidence angle larger/smaller than the Brewster angle, must be treated separately, but they give rise to the same final result, that an overall change of phase of \(\pm \pi\) is present, as one can see inspecting the plots 44.1 and 44.2. First note that if light is incident at the Brewster angle on the lamina, the refraction angle exactly corresponds to Brewster angle for the passage from the lamina medium to the external medium. Secondly note that the change of phase by \(\pm \pi\) depends on the convention chosen when deriving Fresnel equation, even if the final result does not. Therefore if the incidence angle is smaller than the Brewster angle, there is no phase change at the reflection on the first surface, \(r_{\|}>0\), but there is a \(\pm \pi\) change of phase on reflection at the second surface, \(r_{\|}<0\), such that, if the two optical paths are identical, the two fields recombine out-of-phase of \(\pm \pi\). On the other hand, if the incidence angle is larger than the Brewster angle, the change of phase of \(\pm \pi\) happens at the first surface.
There is never change of phase in transmission.
We only consider, for simplicity, the case of almost normal incidence.
Let the ray 1 be the reflected only ray and let the ray 2 be the refracted-reflected-refracted ray. The change of phase, \(\Delta \Phi\), is given, by the difference of the optical paths, \(\Delta \Phi^{\prime}\), plus the \(\pm \pi\) change of phase due to reflections:
\[
\begin{aligned}
\Delta \Phi & =\Delta \Phi^{\prime} \pm \pi \\
k & =\mathrm{n}[\omega] \frac{\omega}{c}, \\
\Delta \Phi_{1} & =2 k H \tan \theta_{T} \sin \theta_{I}=\frac{2 \omega H}{c} \tan \theta_{T} \sin \theta_{I}, \\
\Delta \Phi_{2} & =2 k H \frac{1}{\cos \theta_{T}}=\frac{2 \omega H}{c} \frac{\mathrm{n}[\omega]}{\cos \theta_{T}}, \\
\Delta \Phi^{\prime} & \equiv \Delta \Phi_{2}-\Delta \Phi_{1}=\frac{2 \omega H}{c}\left(\frac{\mathrm{n}[\omega]}{\cos \theta_{T}}-\tan \theta_{T} \sin \theta_{I}\right)=\frac{2 \omega \mathrm{n}[\omega] H}{c} \cos \theta_{T},
\end{aligned}
\]
where the last passage comes from Snell law: \(\sin \theta_{I}=\mathrm{n}[\omega] \sin \theta_{T}\). Constructive interference happens for \(\Delta \Phi=2 m \pi \quad \Leftrightarrow \quad \Delta \Phi^{\prime}=(2 m+1) \pi\).
Note that when \(H\) tends to zero destructive interference can be observed at any angle with \(\Delta \Phi^{\prime}=0\). This is caused by the \(\pm \pi\) change of phase. If the \(\pm \pi\) would not be included one would expect constructive interference for a vanishingly thin lamina, which is not observed experimentally.
The interfering rays will not have the same amplitude and therefore the minimum intensity will not be exactly zero. In reality, there are infinite multiple reflection, with decreasing successive amplitudes.
In case the lamina has a large thickness it is difficult to observe the interference fringes because for non perfectly monochromatic light there are different frequencies interfering destructively/constructively in such a way that the overall effect is negligible.
As the constructive interference depends on the wavelength one will observe constructive interference at different angles for different wavelength. This explains the colored fringes which are seen in white light.

© \(\mid\) False paradoxes of superposition in electric and acoustic waves|R. C. Levine|Am.J.Phys, , ..., ..., ...Ed., .... 48, 28 (1980)|
The argument is often tricky.
When there are two sources, it is possible that the sources interact each-other, changing the emission characteristics and/or the power used by the source generator.

Note that the superposition principle at fixed sources, strictly speaking, can only be applied when it can be assumed that none of the sources and none of the waves affects in any way the behavior of any other source. In many cases this might be a good approximation.

One typical example might be interference between different nearby antennas radiating ElectroMagnetic waves: the application of the superposition principle implicitly assumes that the ElectroMagnetic waves radiated by one antenna do not affect the radiation properties of the other antenna.

A second typical example is two sound sources, where the sound waves emitted by one source may affect the other emitter.

Additionally whenever one source/wave affects another source, it may happen that the power emitted by each source changes with respect to the power which would be emitted by the source itself alone. As a consequence the energy density/flux carried away by the waves may be different from the sum of the power produced by the sources alone.
© - QUOTE
©|R.C.Levine|False paradoxes of superposition in electric and acoustic waves|Am.J.Phys, , ..., ..., ...Ed., .... 48, 28 (1980); doi: 10.1119/1.12.

When acoustic or ElectroMagnetic waves cancel by destructive interference, the wave impedance reflected to the sources of the wave energy changes so that the input power is reduced correspondingly. Because this rather subtle point is not discussed in most instructional treatments of wave physics, misconceptions concerning the apparently "missing" energy are widespread, as reflected in semi-popular science writing.
© - QUOTE
©|N.Gauthier|What happens to energy and momentum when two oppositely-moving wave pulses overlap?|Am.J.Phys,

As a result, the net energy density for the superposed solution is always equal to the sum of the energy densities of the right-moving and the left-moving pulses, considered separately. From the perspective of energy conservation, the two pulses are transparent to one another.

We again see that the cross terms, which represent the overlapping of the pulses, cancel exactly, just as they did in the total energy density of the superposed pulses. The total momentum density is equal to the algebraic sum of the local momentum densities of each pulse everywhere in space, just as if they didn't overlap at all. In this configuration, the total momentum of the system is always conserved and there is no need to evaluate complicated spatial integrations to prove it.

Read § 47.07.02 - Diffraction.

\subsection*{46.10.08 Applications - Phased Array}

The possibility to have a high intensity in a well defined direction in space (in two dimensions) is used in Radio-astronomy to point arrays of Radio-telescopes in a certain direction with high directionality. It is also being used in 5G technology for beam steering.

Diffraction demonstrates the wave-like character of a phenomenon.
Interference arises when the number of sources is finite or a countable infinity set. Interference, as discussed in § 46 - Interference is a useful preliminary to the study of diffraction.
Diffraction can be considered as interference in the case when there is an infinite continuum of sources. In this sense it is only technically, but not conceptually, different from interference and the conceptual discussion made in section § 46.01 - Interference.
In this section, as in the previous § 46 - Interference on interference, the discussion will be limited to observations at very large distances from the sources, in such a way that, in both the longitudinal and the transverse wave cases, one can often just sum the components of the Perturbation|Disturbance|Signals, as explained in § 46.01 - Interference. Large distance means: large distance with respect to the dimensions of the sources.
In this section, as in the previous section on interference, we are more interested in the relative intensity than in the absolute intensity of the diffraction pattern. Therefore proportionality constants will not be taken seriously into account. However, while in the case of interference it is customary to express the resulting intensity in terms of the intensity of the single source, which is a well-defined concept, in the case of diffraction there is a continuous distribution of infinitesimal sources and therefore there is no such a thing as the intensity of the single source to use as a reference. Therefore the resulting intensity is usually normalized such that it is one at maximum.
The analytical treatment of diffraction is a very difficult problem; because of mathematical difficulties, approximate methods must be used in most practical cases.
Our concerns are only with the classical limit, wheremany photons are present simultaneously and their associated ElectroMagnetic fields can be described by Maxwell equations.
The distinguishing feature of diffraction is the deviation from rectilinear propagation when the wave is obstructed in some way.
While interference and diffraction are phenomena proper to any kind of waves, the discussion will be limited to ElectroMagnetic waves, due to their huge interest.

Until coherence is presented, in § 48 - Interference Diffraction Wave-Fields and Coherence, all sources are assumed to be strictly monochromatic point sources. Therefore, they appear as generators of spherical (possibly non isotropic) waves. At large enough distance, waves appear as MPW.

\subsection*{47.01.01 Some Diffraction Phenomena and Applications}
- William Herschel knew as early as 1779 that stars appeared much larger in telescopes than they really were, but he did not know why. When Thomas Young demonstrated interference and the wave nature of light this was unambiguously explained.
- Arago/Poisson spot is the luminous point which appears at the center of the shadow of a circular object illuminated by a point source. It is due to constructive interference caused by the cylindrical symmetry of the problem.
- The common experience that sound can be heard also after obstacles is due to diffraction phenomena which allow long-wavelength waves to travel past obstacles with dimensions smaller that the wavelength. Beware that in the case of sound, in everyday experience, not only diffraction but also reflection effects may be important.
- A common experience with diffraction is provided by water waves passing around obstacles.

\section*{© - QUOTE}

Adapted from E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., .....
Imagine to have an opaque plane screen \(\Sigma\) containing one single small aperture which is illuminated by MPW perpendicular to the screen, coming from a very distant point source. The plane of observation is a screen parallel with \(\Sigma\).
- When the plane of observation is very close to \(\Sigma\), an image of the aperture is projected onto the screen, which is clearly recognizable despite some slight fringing around its periphery.
- The plane of observation is moved away from \(\Sigma\).
- If the plane of observation is moved farther away from \(\Sigma\), the image of the aperture, though still easily recognizable, becomes increasingly more structured as the fringes become more prominent. This phenomenon is known as Fresnel or near-field diffraction.
- If the plane of observation is moved out still farther, a continuous change in the fringes results. At a very great distance from \(\Sigma\) the projected pattern will have spread out considerably, bearing little or no resemblance to the actual aperture. This is intermediate-field diffraction.
- Thereafter moving the screen essentially changes only the size of the pattern and not its shape. This is Fraunhofer or far-field diffraction.
- Reduce the wavelength of the source.
- If at that point we could sufficiently reduce the wavelength of the incoming radiation, the pattern would revert to the Fresnel case.
- If the wavelength were decreased even more, so that it approached zero, the fringes would disappear, and the image would take on the limiting shape of the aperture, as predicted by Geometrical|Ray Optics.
- Returning to the original setup, if the point source was now moved toward \(\Sigma\), spherical waves would impinge on the aperture, and a Fresnel pattern would exist, even on a distant plane of observation.

\section*{Wave-Optics Versus Geometrical|Ray Optics}

Geometrical|Ray Optics is the regime when the propagation of waves can be described in terms of light rays, propagating rectilinearly in homogeneous media and satisfying Snell laws at boundaries.
It is typically characterized by:
\[
\lambda \ll D \quad D \text { dimensions of the obstacles in the path }
\]

Geometrical|Ray Optics is thus the limit of wave-optics when the wavelength is much smaller than the relevant dimensions. This is confirmed by the results of diffraction, showing that diffraction, which implies non-rectilinear light-ray propagation, is only relevant when sizes of obstacles are small with respect to wavelength.
All these qualitative considerations can be made precise.
Diffraction
- Huygens Principle and the Fresnel- ...

©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|8.3.2||
The mathematical theory of diffraction is really complex and one should not be carried away from the physical phenomena by the mathematics. Several approximations and simplifications must be accounted for.
Huygens principle, in the improved Fresnel-Kirchhoff diffraction formula, provides an approximate method to solve wave-propagation problems which works very well in practice.
The Huygens-Fresnel-Kirchhoff principle makes the basic approximation that the amplitude and phase of the waves involved can be described by a scalar, not vector, field, and that any effect arising from the polarization of transverse waves can be neglected. It is in fact called the scalar-wave approximation.
Huygens principle states that every point on a wave-front can be considered as a source of secondary wavelets that combine so that the envelope of the secondary wavelets constitutes the advancing wavefront. In order to make quantitative statements, the principle must be supplemented by other quantitative conditions, to ensure that the secondary waves are preferentially produced in the direction of wave propagation and that the wave-front is the result of interference among the secondary waves. All this is made quantitative by Fresnel-Kirchhoff diffraction formula.

Huygens principle implemented by the Fresnel-Kirchhoff formula can be used for computing the diffraction patterns from an illuminated aperture. It is normally used in two complementary limits, called the Fraunhofer and Fresnel regimes.
It actually applies to any point of the wave field: the screen does not matter, it is just an help to understanding and visualization.

\subsection*{47.03.01 Fresnel-Kirchhoff Scalar Diffraction Formula for MPW Incident Perpendicular to a Flat Opaque Screen}
©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|§ 8.3.2||
In the case of a plane aperture on a flat opaque screen, oriented as \(\hat{\mathbf{n}}\), invested by a MPW perpendicularly to the screen, the Huygens-Fresnel-Kirchhoff scalar diffraction formula takes, for a generic scalar field or for any component of the field, the simplified form:

\[
\begin{equation*}
\cos \chi \equiv \frac{\hat{\mathbf{n}} \cdot(\mathbf{x}-\mathbf{w})}{|\mathbf{x}-\mathbf{w}|} \tag{47.03.01}
\end{equation*}
\]
\[
\mathbf{r} \equiv \mathbf{x}-\mathbf{w}
\]
where \(\mathbf{x}\) is the observation point and \(\mathbf{w}\) is the position of the elementary source on the screen aperture
Obliquity factor is the name given to the term \((1+\cos \chi) / 2\).
Depending on the scalar/vector nature of the diffracting field, the validity equation (47.03.01), might be limited to very large distances, where the addition of different wavelets consists of adding the components, all parallel to each other, and with the same Polarization, when transverse waves are involved.
The incoming MPW, perpendicular to the screen, has the same intensity at all the points of the aperture, that is the source surface density is uniform on the aperture.
Every point on the aperture is a secondary emitter of non isotropic spherical waves.

The obliquity factor gives the angular dependence to the spherical wave, that is maximum in the forward direction and zero backwards.

\section*{Fraunhofer Diffraction}

\subsection*{47.04.01 The Fraunhofer regime}

Under the conditions of equation (47.03.01), one can further simplify the formulas in the so-called Fraunhofer regime, the most common situation used in interference|Diffraction where the detector is set at a very large distance from the screen.
It will be assumed that the following large-distance/small-obliquity conditions apply.
- Infinite distance of the observation screen. In particular, the dimensions of the aperture, \(D\), are much smaller than the distance from the aperture to the observation point, \(R\) : \(D \ll R\). actually, any distance involved beyond the diffracting screen has to be smaller than the distance between the diffracting and the observation screen. This includes the wavelength, even if this is normally true.
- The obliquity factor can be set constant and equal to one and taken out of the integral, that is the angular spread of the observed rays, with respect to the normal to the screen, is small: \(\cos \chi \simeq 1\). That is, everything happens at a small angle in front of the aperture on the diffracting screen.
- The variation with distance of the outgoing spherical wave comes primarily from the exponential factor and the denominator can be taken outside the integral as a constant; this implies, in particular, that the observation is taken at places whose distances from all the points of the slit are about the same, a condition strictly linked, in turn, to the fact that the observation angle is small.
The approximation that the variation of the outgoing spherical wave due to the denominator can be neglected while the one coming from the exponential factor cannot be neglected, is the same approximation as in \(\S 46.05 .01\) - Interference. It is due to the fact that, inside the phase the factor, \(r\) appears multiplied by the wave-number \(k\) and therefore any change of \(r\) of the order of the wavelength \(\lambda\) changes the phase by a large amount. On the other hand, as normally \(r \gg \lambda\), a change of the order of the wavelength \(\lambda\) gives a very small relative change to the denominator. Consider, in fact, the effect of a change of one wavelength in distance for the exponential and for the factor \(r\) at denominator:
\(r \longrightarrow r \pm \lambda \Longrightarrow\left\{\begin{array}{l}\exp [\beth k r] \longrightarrow \exp [ \pm 2 \pi \beth] \exp [\beth k r] \\ \frac{1}{r} \longrightarrow \frac{1}{r \pm \lambda} \simeq \frac{1}{r}\left(1 \mp \frac{\lambda}{r}\right) \quad \Delta\left(\frac{1}{r}\right)=\left|\frac{1}{r}-\frac{1}{r+\lambda}\right| \sim \frac{\lambda}{r^{2}} \quad \frac{\Delta(1 / r)}{1 / r}=\frac{\lambda}{r}\end{array}\right.\)
In the first case the change is big, due to the large relative change in the phase \(\exp [ \pm 2 \pi \beth]\) which can bring a change of sign of the term, with big effects, for instance, in the case of oscillating terms. In the second case it is just an effect of the order \(\lambda / r\).
Consequently the Huygens-Fresnel-Kirchhoff formula for normally incident MPW, in the large-distance/small-obliquity regime, takes the very simple form:
\(\psi[\mathbf{x}, t]=C \iint_{\Sigma} \exp [\beth k r] \mathrm{d} S \quad\) large-distance/small-obliquity regime with perpendicularly incident MPW
(47.04.01)

\subsection*{47.04.02 Geometry of Fraunhofer regime}

The Fraunhofer regime is defined by the additional condition: in the exponential factor only the linear term is relevant for the calculation of \(k r\), equivalent to
\[
\begin{equation*}
D^{2} \ll R \lambda \tag{47.04.02}
\end{equation*}
\]

On the other hand, the Fresnel regime is defined by the condition:
\[
\begin{equation*}
D^{2}>R \lambda \text {, } \tag{47.04.03}
\end{equation*}
\]
meaning that the quadratic in the exponential is not negligible with respect to the linear term.
In fact, consider a flat screen described by the \(\{x, y\}\) orthonormal Cartesian Coordinates Coordinate System; let the \(z\) axis be oriented in the direction of propagation of the diffracted light. Look at the diffraction pattern (the intensity) on a parallel screen, described by the \(\{X, Y\}\) orthonormal Cartesian Coordinates Coordinate System with its axis, \(Z\), coincident with the \(z\) axis. Let the origin of the orthonormal Cartesian Coordinates Coordinate System be on the flat screen inside the aperture (at the geometrical center, or Center-Of-Mass, for instance).
The distance between the generic elementary source (at coordinates \(\mathbf{w} \equiv\{x, y, 0\}\) ) and the generic observation point (at coordinates \(\mathbf{x} \equiv\{X, Y, Z\}\) is:
\[
\begin{aligned}
R & \equiv \sqrt{X^{2}+Y^{2}+Z^{2}}, \\
r & \equiv\left((X-x)^{2}+(Y-y)^{2}+Z^{2}\right)^{+1 / 2}=, \\
& =\left(X^{2}+Y^{2}+Z^{2}+x^{2}+y^{2}-2 x X-2 y Y\right)^{+1 / 2} \equiv\left(R^{2}+x^{2}+y^{2}-2 x X-2 y Y\right)^{+1 / 2}=, \\
& =R\left(1-2 \frac{x X+y Y}{R^{2}}+\frac{x^{2}+y^{2}}{R^{2}}\right)^{+1 / 2}=R\left(1-\frac{x X+y Y}{R^{2}}+\mathcal{O}\left[\left(\frac{x^{2}+y^{2}}{R^{2}}\right)^{2}\right]\right), \\
& \simeq R-\frac{x X+y Y}{R}=R-\left(x \sin \chi_{x}+y \sin \chi_{y}\right),
\end{aligned}
\]
all coherent with equations (47.04.02), (??) and truncation of the exponential to the linear term, as from equation (47.04.02). In fact, the second-order term is of the order \(\sim k R D^{2} / R^{2} \simeq 2 \pi D^{2} /(R \lambda)\). Therefore the condition to neglect it inside the phase of the exponential is \(D^{2} \ll R \lambda\), that is the condition for Fraunhofer regime (47.04.02). Note that the comparison between the linear and quadratic terms provides the condition \(D \ll R\), which has already been assumed.
As in section \(\S 46.07\) - Interference, the variables \(X\) and \(Y\) are linked to the angles \(\chi_{x}\) and \(\chi_{y}\), the position vector of the observation point with the planes \(z y\) and \(z x\) :
\[
\begin{equation*}
\sin \chi_{x} \equiv \frac{X}{R} \quad \sin \chi_{y} \equiv \frac{Y}{R} \quad k \alpha_{x} \equiv k \frac{X}{R} \equiv k \sin \chi_{x} \equiv u \quad k \alpha_{y} \equiv k \frac{Y}{R} \equiv k \sin \chi_{x} \equiv v \tag{47.04.04}
\end{equation*}
\]

In the slightly more general case that the incoming wave is a MPW, but not perpendicular to the screen, the formula can be expanded to:
\[
\begin{aligned}
& \psi[X, Y] \propto \int_{\Sigma} \psi_{0}[x, y] \exp \left[-\beth k\left(\alpha_{x} x+\alpha_{y} y\right)\right] \mathrm{d} x \mathrm{~d} y= \\
& \iint_{\Sigma} \psi_{0}[x, y] \exp \left[-\beth k\left(x \sin \chi_{x}+y \sin \chi_{y}\right)\right] \mathrm{d} x \mathrm{~d} y= \\
& \iint_{\Sigma} \psi_{0}[x, y] \exp \left[-2 \pi \beth\left(x \sin \chi_{x} / \lambda+y \sin \chi_{y} / \lambda\right)\right] \mathrm{d} x \mathrm{~d} y= \\
& \quad \iint_{0}[x, y] \exp [-2 \pi \beth(u[X] x+v[Y] y)] \mathrm{d} x \mathrm{~d} y
\end{aligned}
\]
which is the Fraunhofer regime from a plane aperture for incident PW.

\subsection*{47.04.03 Fraunhofer Diffraction From a Single Narrow Slit}

By single slit one means a narrow rectangular aperture very long, \(L\), with respect to its width \(b\). Let \(z\) be the coordinate normal to the plane, \(x\) the coordinate along the slit long side and \(y\) the coordinate along the slit short side. One has:
\[
\begin{aligned}
& r=R-y \sin \chi \\
& \beta \equiv \frac{k b \sin \chi}{2}
\end{aligned}
\]
\[
\begin{gathered}
\psi[\mathbf{x}, t]=C L \int_{-b / 2}^{+b / 2} \exp [\beth k r] \mathrm{d} y=C L \int_{-b / 2}^{+b / 2} \exp [\beth k(R-y \sin \chi)] \mathrm{d} y=C L \exp [\beth k R] \int_{-b / 2}^{+b / 2} \exp [-\beth k y \sin \chi] \mathrm{d} y \\
\psi[\mathbf{x}, t] \simeq C L b \exp [\beth k R] \frac{\sin \beta}{\beta} \propto L b \frac{\sin \beta}{\beta}
\end{gathered}
\]

Note that the amplitude of the field is proportional to the area of the slit.
Note that, strictly speaking if the slit were of infinite length, the transferred energy would be infinite and therefore the constant obtained by integrating along the infinite slit, would be infinite as well. In fact, one should use a very long slit, rather than an infinite one: \(L \gg b\).
The intensity is given by:
\[
I=I_{\mathrm{M}}\left(\frac{\sin \beta}{\beta}\right)^{2}
\]

The quantity \(I_{\mathrm{M}}\) is the intensity at the maximum of the intensity, \(\beta=0\).
The extrema of the function \(\sin \beta / \beta\) are determined by the equation: \(\tan \beta=\beta\). The absolute maximum is at \(\beta=0\), as the denominator causes the ratio to decrease at increasing \(\beta\).

The zeros are at
\[
\beta=m \pi \quad \Leftrightarrow \quad \sin \chi=m \frac{\lambda}{b} \quad(m \neq 0)
\]

This can be easily understood when observing that, when the path difference among the two edges of the slit is an integer number of wavelengths, the resulting field is a superposition of a continuous distributions of infinitesimal sources with phases uniformly distributed in an integer number of \(2 \pi\) intervals, so that they sum to zero.
The width of the diffraction peak is given by the angular with of the first zeros. We have assumed the hypothesis that \(|\chi| \ll 1\) therefore:
\[
\left|\sin \left[\chi_{+}\right]-\sin \left[\chi_{-}\right]\right| \simeq\left|\chi_{+}-\chi_{-}\right| \equiv \Delta \chi=2 \frac{\lambda}{b} \quad(m= \pm 1)
\]

\subsection*{47.04.04 Fraunhofer Diffraction From a Single Rectangular Slit}
©|J.P.Pérez et al., Optique, ..., DUNOD, ...Ed., WEB - URL.|pag. 245||
For a rectangular slit located in the \(x y\) plane the expression of the relative intensity is just a generalization of the expression for a linear slit. Assume a rectangular slit of sides \(b_{x}\) and \(b_{y}\) in the \(x y\) plane centered at the origin.
This gives, in terms of the angles \(\chi_{x}\) and \(\chi_{y}\) that the position vector from the origin to the observation point forms with the \(z y\) and \(z x\) planes:
\[
\beta_{x} \equiv \frac{k b_{x} \sin \chi_{x}}{2} \quad \beta_{y} \equiv \frac{k b_{y} \sin \chi_{y}}{2}
\]

The intensity is given by:
\[
I=I_{M}\left(\frac{\sin \beta_{x}}{\beta_{x}}\right)^{2}\left(\frac{\sin \beta_{y}}{\beta_{y}}\right)^{2}
\]

The quantity \(I_{M}\) is the intensity at the maximum of the intensity.

\subsection*{47.04.05 Fraunhofer Diffraction From a Single Circular Slit}

Consider a circular slit of radius \(R\) and diameter \(D \equiv 2 R\). The intensity is given in terms of:
\[
\begin{equation*}
\rho \equiv \frac{k D \sin \chi}{2}, \tag{47.04.05}
\end{equation*}
\]
by:
\[
\begin{equation*}
I=I_{\mathrm{M}}\left(\frac{2 J_{1}[\rho]}{\rho}\right)^{2}, \tag{47.04.06}
\end{equation*}
\]
where \(J_{1}\) is a Bessel function of first kind \({ }^{1}\) and \(I_{\mathrm{M}}\) is the intensity at the maximum of the intensity (that is on the axis).
The first zero of the intensity is at:
\[
\rho=3.832 \quad \sin \chi=1.22\left(\frac{\lambda}{D}\right)
\]

Figure 47.1: \(\mathcal{F J G U R E}\)

\subsection*{47.04.06 Resolving Power and Rayleigh Criterion}

From the previous discussion it should be clear that nature puts an intrinsic limit to the resolving power of any optical instrument, due to the wave nature of light and diffraction.
The conventional definition of resolving power is the Rayleigh criterion. Two points are resolved if the maxima of the diffraction figures of the two points are at a distance larger that the half-width of the diffraction figure.
According to this criterion the resolving power is given by the relations in section § 47.04 - Diffraction.

\footnotetext{

}

\subsection*{47.04.07 Fraunhofer Interference|Diffraction From a Interference|Diffraction Grating}

When one needs to separate light of different wavelengths with high resolution a Interference|Diffraction Grating may be used, consisting in a large number of parallel, closely spaced slits. The Interference|Diffraction Grating leads to many applications for measurements.

One knows that a linear array of in-phase sources gives peaks whose position depends on the wavelength and on the inverse separation between sources (at a fixed order of the maximum, \(m\) ). Moreover, the width of the peak decreases while increasing the number of sources. In order to separate different close wavelengths it is then necessary to use many sources with small spacing. This implies that the sources must be very thin slits (for instance). But this unavoidably introduce a significant diffraction.

Thanks to the large number of slits the intensity at the maximum is very sharp and the peak intensities are much higher while increasing the number of slits.
Let a Interference|Diffraction Grating be made of long, \(L\), narrow rectangular slits having a width \(b\) ad a separation \(d\).
\[
\beta \equiv \frac{k b \sin \chi}{2} \quad \delta \equiv \frac{k d \sin \chi}{2}
\]

The intensity is given by:
\[
I=I_{\mathrm{M}}\left(\frac{\sin \beta}{\beta}\right)^{2}\left(\frac{\sin [N \delta]}{N \sin \delta}\right)^{2}
\]

In order to keep the usual interpretation of the quantity \(I_{M}\) as the maximum intensity, the expression has been normalized dividing by \(N^{2}\). The result is the result of a linear array whose amplitude is modulated by the diffraction term.

The smaller the slit the less evident is the effect of diffraction, consistently with the results obtained for the interference of a linear array of point sources. In fact, in this case, every single slit tends to become an isotropic emitter, thus realizing the linear array of isotropic antennas. The flatter the diffraction term the more and more maxima can be observed. If \(b \ll d\) the modulation effect on the interference curve is small. In fact the limiting case \(b=0\) gives back the pure interference formula among \(N\) sources.

Some of the maxima of the interference figure might be missing if they coincide with zeros of the diffraction pattern.

The Interference|Diffraction Grating is normally simply called diffraction grating even if the name interference grating would be more appropriate, as it exploits interference among the slits.

\section*{Plots}

\subsection*{47.04.07.01 Resolving Power of a Interference|Diffraction Grating}

The maximum of order \(m\) of a Interference|Diffraction Grating with spacing \(d\) is given by:
\[
\sin \chi=m \frac{\lambda}{d} \quad m \text { integer }
\]

In the small angle approximation the angles where the maxima of order \(m\) for two different wavelengths are located are linked by:
\[
\left|\sin \left[\chi_{\mathrm{M} \mid 2}\right]-\sin \left[\chi_{\mathrm{M} \mid 1}\right]\right| \simeq\left|\chi_{\mathrm{M} \mid 2}-\chi_{\mathrm{M} \mid 1}\right|=m \frac{\left|\lambda_{2}-\lambda_{1}\right|}{d} \equiv m \frac{\Delta \lambda}{d}
\]

The half-width of the interference peak, at the average wavelength, \(\bar{\lambda} \equiv\left(\lambda_{1}+\lambda_{2}\right) / 2\), is, from equation (46.05.11),
\[
\Delta \chi_{\mathrm{HW}}=\frac{\bar{\lambda}}{N d} .
\]

In order to have separation of the two lines one then needs:
\[
\frac{\bar{\lambda}}{N d}=\Delta \chi_{\mathrm{HW}}<\left|\chi_{\mathrm{M} \mid 2}-\chi_{\mathrm{M} \mid 1}\right|=m \frac{\Delta \lambda}{d}
\]
and the resolution is therefore:
\[
\frac{\Delta \lambda}{\bar{\lambda}}=\frac{1}{m N}
\]

Note that in order to have a large spread of different wavelengths it is necessary to have a small \(d\) and this implies a small \(b\) so that diffraction is not negligible.

It might be better called a interference grating.

\section*{Example: A Interference|Diffraction Grating}

Assume: \(\frac{\mathrm{d} N}{\mathrm{~d} L}=10^{4}\) lines \(/ \mathrm{cm}\) and \(L=1.0 \mathrm{~cm}\) width. Therefore: \(N=10^{4}\) lines.
The first-order maximum \((m=1)\) gives: \(\frac{\Delta \lambda}{\bar{\lambda}}=10^{-4}\). For \(\lambda=5 \cdot 10^{-7} \mathrm{~m}\) this implies: \(\Delta \lambda=0.5 \cdot 10^{-10} \mathrm{~m}\). This is, roughly, the size of an hydrogen atom.

Approximations In Diffraction and Realistic Diffraction situations

This § is referenced at pages:
[2236, 2236]
In the case of diffraction the single source must be coherent, that is, whatever the phase difference between any two infinitesimal sources, it remains constant in time, on average of time periods long with respect to the period of the monochromatic signal. Read § 46.09- Interference.

\section*{Examples and Physical Applications}

\subsection*{47.07.01 Diffraction From a Slit as a Limiting Case of the Interference of Infinite Sources}

The diffraction from a single slit can be derived as a limiting case from the results of § 46.05.02 Interference.

Consider an increasing number of sources, \(N\), in a fixed interval \(b\) with spacing \(d\) such that: \(b=N d\). Let the number of sources tend to infinity with \(b\) constant. In equation (46.05.08) \(I_{0}\) is the intensity of a single source. In our limit we have an infinite number of infinitesimal sources. The limit shall be done by keeping a constant maximum intensity. It is then useful to normalize equation (46.05.08) to its maximum intensity, as it is normally done for diffraction:
\[
I=\frac{I_{\mathrm{M}}}{N^{2}}\left(\frac{\sin [N \delta]}{\sin \delta}\right)^{2}=I_{\mathrm{M}}\left(\frac{\sin [N \delta]}{N \sin \delta}\right)^{2} \longrightarrow I_{\mathrm{M}}\left(\frac{\sin \beta}{\beta}\right)^{2}
\]

Read § 46.10.07 - Interference.

\subsection*{47.07.03 Resolving Power of a Telescope}

In astronomy one likes optical instruments with large aperture both to collect more light from faint sources and to reduce the effects of diffraction.

Mount Palomar telescope: \(D=5 \mathrm{~m}\).
It follows, for \(\lambda=500 \mathrm{~nm}, \Delta \chi \simeq \lambda / D=10^{-7}\) (diffraction limit).
The actual optical resolution is actually less than that due to the adverse effects of atmospheric turbulence which destroys the phase coherence.

\subsection*{47.07.04 Angular Spread of a Laser-Pen}

Assume a circular aperture with \(D=1 \mathrm{~mm}\).
It follows, for \(\lambda=500 \mathrm{~nm}, \Delta \chi \simeq \lambda / D=5 \cdot 10^{-4}\).
At a distance \(L=100 \mathrm{~m}\) this gives a spot size of \(\approx 5 \mathrm{~cm}\).
47.07.05 Resolving Power of the Human Eye (Rayleigh Criterion)

Assume a circular aperture with \(D=3 \mathrm{~mm}\).
The Rayleigh criterion gives, for \(\lambda=500 \mathrm{~nm}, \Delta \chi \simeq \lambda / D=42^{\prime \prime}\).
47.07.06 Observation of Car-Lights (Rayleigh Criterion)

Find the maximum distance such that a typical human eye is capable to separate the two front lights of a car assuming their distance is \(d=1 \mathrm{~m}\).

In this section only a few basic concepts of the important theory of coherence will be given.
The waves from a distant, monochromatic point source is effectively a MPW and is said to be a perfectly coherent wave.

\section*{© - QUOTE}
E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....

It is often convenient, even if artificial, to divide coherence effects into two classifications, temporal and spatial. The former relates directly to the finite bandwidth of the source, the latter to its finite extent in space.

It is convenient to classify coherence effects into two different classes: temporal coherence and spatial coherence.
Temporal coherence relates directly to the finite bandwidth, that is to the monochromaticity, of the source. For a single point source, the self-coherence (time-coherence) is essential for interference to occur and monochromaticity is implicit. It is also named longitudinal coherence.
Spatial coherence relates to the finite extent in space of the source. Real/Natural sources are typically made of a huge number of independent elementary sources at the atomic level and are said spatially incoherent sources, because, usually, there is no fixed relation among the waves emitted by the different elementary sources. Moreover, the intensities of the different sources may be different. For an extended source, the mutual coherence of the different component point sources is an essential point, even if each point source is self-coherent, in order to observe Interference|Diffraction. It is also named lateral coherence

\section*{© - QUOTE}
R.Blandford \& K.Thorne, Applications Of Classical Physics, ..., ..., ...Ed., WEB - URL WEB - URL .
lateral or spatial coherence (coherence in the angular structure of the radiation field), and temporal or longitudinal coherence (coherence in the field's temporal structure, which clearly must imply something also about its frequency structure).
for both types of coherence there is a measurable quantity, called the degree of coherence, that is the Fourier transform of either the radiation's angular intensity distribution (energy flux per unit angle or solid angle, as a function of direction) or its spectral energy flux (energy flux per unit angular frequency, as a function of angular frequency).

Independent sources may interfere as long as they are coherent sources; typical example are two different lasers, if they have a sufficient degree of mutual coherence.

\subsection*{48.02.01 Again on Necessary Conditions for Interference to Occur}

In order to observe interference it is necessary to get rid of the randomness of the wave emission: interferometers may use only one source and apply either division of front or division of amplitude.
In order to have interference between two sources it is necessary that the two sources are, at least partially, coherent.
- One-dimensional case: the de-phasing at the observation point is only due to the two phase constants: there is no path-difference in the one-dimensional case, unless there are inversions of the velocity.
- Two/Three-dimensional case: the de-phasing at the observation point may also come from the difference in the two paths.

\subsection*{48.02.02 Natural Emission of ElectroMagnetic Waves}

Two independent natural quasi-point sources do not normally interfere because of the randomness of natural emission, normally made of random wave-trains, independently emitted by quasi-point molecular|atomic|particle sources.
The wave-trains of an ElectroMagnetic MPW are emitted in a random way, which can be modeled in a simplified form as:
\[
\psi=A \cos \left[\omega_{0} t+\phi\right] \hat{\mathbf{e}},
\]
with \(A\) and \(\phi\) real numbers, describing amplitude and phase, \(\hat{\text { e a }}\) a unit complex vector, describing the Polarization state (read § 42.03.03-ElectroMagnetic Waves). The parameters \(A\), phi and ê are assumed to vary in a random way over times of the order of the coherence time, \(\tau_{c}\).
Moreover, as the MPW is not strictly monochromatic, the frequency has a spectral distribution around some central frequency, \(\omega_{0}\), instead of being a fixed value.
Some examples follow.
- \(\tau_{c} \sim 10^{-13} \mathrm{~s}\) for an Hg lamp at \(\lambda_{0}=546 \mathrm{~nm}\) with spectral width \(\Delta \lambda_{1 / 2}=10 \mathrm{~nm}\) : very short wave-trains of \(\ell_{c} \sim 30 \mu \mathrm{~m}\), a few wavelengths long.
- \(\tau_{c} \sim 0.7 \cdot 10^{-9}\) s for a He-Ne laser at \(\lambda_{0}=632.8 \mathrm{~nm}\) with spectral width \(\Delta \nu_{1 / 2}=1.4 \mathrm{GHz}\) : relatively \(\log\) wave-trains of \(\ell_{c} \sim 20 \mathrm{~cm}\), many wavelengths long.
- \(\tau_{c} \sim 10^{-6} \mathrm{~s}\) for a stabilized He-Ne laser at \(\lambda_{0}=632.8 \mathrm{~nm}\)
long wave-trains of \(\ell_{c} \sim 400 \mathrm{~m}\), very many wavelengths long.
The period of the harmonic oscillations, for visible light, is of the order of \(T \sim 10^{-14} \mathrm{~s}\) so that for the above cases \(\tau_{c} \gg 1 / \nu\).
Intensity is typically measured averaging over detection times, \(T_{D}\), much longer than \(\tau_{c}\), for instance tenths of seconds by the human eye and milli-seconds by a CCD camera; the detection time is also typically longer than the period of the harmonic oscillation:
\[
\begin{equation*}
T_{D} \gg \tau_{c} \quad T_{D} \gg 1 / \omega . \tag{48.02.01}
\end{equation*}
\]

\subsection*{48.02.03 Quasi-Monochromatic Point Source - Coherence Time and Lengths}

This § is referenced at pages:
[Never referenced.]
Consider a quasi-monochromatic point source whose emission has the following characteristics: the wave is strictly monochromatic for a certain time \(\tau_{c}\), then the phase of the sinusoid|Cosinusoid changes abruptly in a random fashion, with uniform probability density for all possible values of the phase. The sequence repeats itself indefinitely. The time length \(\tau_{c}\) is called the coherence time and it is clearly linked to the self-correlation function of the signal.
The ElectroMagnetic fields at any point can be expressed as:
\[
\mathbf{F}=\mathbf{F}_{0} \exp \left[-\beth \omega_{0} t\right] \exp [-2 \pi \beth \phi[t]]
\]
where \(\phi[t]\) is a random step function with uniform probability distribution between zero and one. One can regard the above kind of field as an approximation for the radiation emitted by an atom.
Suppose the beam of light is divided into two beams that are subsequently brought together to interfere. It can be shown that the normalized auto-correlation function is given by:
\[
\left\{\begin{array}{l}
\gamma[\tau]=\left(1-\frac{\tau}{\tau_{c}}\right) \exp \left[\beth \omega_{0} t\right] \quad \text { for } \tau<\tau_{c} \\
\gamma[\tau]=0 \quad \text { for } \tau \geq \tau_{c}
\end{array}\right.
\]

The result means, in particular, that the path difference to observe interference must not exceed the coherence length:
\[
\ell_{c} \equiv c \tau_{c}=\frac{c}{\Delta \nu_{1 / 2}}=\frac{\lambda^{2}}{\Delta \lambda_{1 / 2}}
\]
expressed in terms of the speed of the ElectroMagnetic wave, \(c\).
Temporal coherence is a manifestation of spectral purity. If the waves were ideally monochromatic they would be a perfect sinusoids with an infinite coherence length. All real sources fall short of this, and all real sources actually emit a range of frequencies, albeit sometimes quite narrow.

\subsection*{48.02.04 Mutual Coherence of Two Different Monochromatic Point Sources}

Two different point sources are said to be mutually coherent when the time-average of their phases is a non zero constant:
\[
\langle\cos \Delta \Phi\rangle=\text { constant } \neq 0
\]
where the averaging is taken over averaging time \(\mathcal{T}\) such that:
\[
\begin{equation*}
\mathcal{T} \gg \tau_{c} \quad \mathcal{T} \gg 1 / \omega . \tag{48.02.02}
\end{equation*}
\]

Two different point sources are said to be mutually incoherent when
\[
\langle\cos \Delta \Phi\rangle=0
\]
where the averaging is taken over the detection time, \(T_{D}\).

\subsection*{48.02.05 Longitudinal|Transverse Spatial Coherence}

Consider a single quasi-monochromatic quasi-point source.

\subsection*{48.02.05.01 Longitudinal Spatial Coherence}

Consider two points aligned with the source, only differing in their distance from the source. The coherence between the fields at the two points will measure the longitudinal spatial coherence of the fields. It is clear that the longitudinal spatial coherence is just related to how large is the distance between the two points and the coherence length|time of the fields.

\subsection*{48.02.05.02 Transverse Spatial Coherence}

Consider two points at the same distance from the source, only differing in their direction with respect to the source. The coherence between the fields at the two points will measure the transverse spatial coherence of the fields. In case the source is a strictly point source, the time dependence at the two points will be exactly the same, that is the fields at the two points will be totally coherent. In case the source is not a point source, but its size is small with respect to the distance between the two points where coherence is being studied, the time dependence at the two points will not be the same, in general.

\subsection*{48.02.06 Extended Source - Coherence at Different Points in Space - Transverse Coherence Length}

This § is referenced at pages:
[Never referenced.]
This section deals with the problem of the coherence between two fields at different points in space. It depends on the size of the source.
Natural sources are typically made of independent almost-monochromatic almost-point sources, located at different positions. Each one must be treated as a single source and the combined effect of all the sources must be studied.

\subsection*{48.02.06.01 Extended Quasi-Monochromatic Source}

Consider an extended quasi-monochromatic source. It can be considered made of a number of quasimonochromatic quasi-point sources. The problem can be simplified by considering the extreme case of two point sources at the two edges of the extended source.
Assume that both the distance between the two point sources and the point where the fields are observed is small with respect to the distance between the sources and the observation point. It can be shown that the transverse coherence width is expressed, in terms of the wavelength, \(\lambda\), and the angular separation of the sources as it is seen from the observation point, \(\theta_{s}\), as:
\[
\ell_{t}=\frac{\lambda}{\theta_{s}}
\]

It is called the transverse spatial coherence width. The transverse spatial coherence width gives the approximate dimensions of the width of the region of high mutual coherence of two different point sources. In fact, any two points at a distance \(D\) will have coherent wave-fields, that is wave-fields having a constant, on average, phase difference, as long as:
\[
D \ll \ell_{t}
\]

\section*{Special case: demonstration from Young two-slits fenditure}

Consider Young two-slits experiment with a source whose maximum dimension along the direction of the flat screen perpendicular to the slits is \(D\), its distance from the screen is \(L\). Two elementary quasi monochromatic quasi-point sources at the two extreme points will produce interference figures separated or not according to Rayleigh criterion depending on:
\[
\theta_{s} \equiv \frac{D}{L} \leftrightarrow \frac{\lambda}{d} .
\]

The interference figure is observed if and only if:
\[
\theta_{s} \equiv \frac{D}{L} \ll \frac{\lambda}{d} \text {. }
\]

Consider a slit experiment with a source whose maximum dimension along the direction of the flat screen perpendicular to the slits is \(D\), its distance from the screen is \(L\). Two elementary quasi monochromatic quasi-point sources at the two extreme points will produce diffraction figures separated or not according to Rayleigh criterion depending on:
\[
\theta_{s} \equiv \frac{D}{L} \leftrightarrow \frac{\lambda}{b} .
\]

The diffraction figure is observed if and only if:
\[
\theta_{s} \equiv \frac{D}{L} \ll \frac{\lambda}{b} \text {. }
\]

In both cases, the source has to be small enough to observe interference|diffraction.
In both cases, increasing the wavelength and|or decreasing \(d \mid b\) helps to observe interference|diffraction, for a given source.
If one starts from a situation such that interference|diffraction is observed and \(d \mid b\) is then increased, the interference|diffraction pattern, sooner or later, will smoothly disappear. Read § 48.04.03 - Interference Diffraction Wave-Fields and Coherence.

Typical stellar diameters of large and nearby stars are in the range of \(10^{-7} \mathrm{rad}\). This implies that the transverse coherence width at the Earth is of the order of a few meters.
A method to measure the angular diameter of stars was invented by Michelson, by observing the Young interference pattern with variable distance of the two slits. This is determined by just observing the disappearance of the interference fringes when the distance between the two slit is increased. Michelson thus measured the angular diameter of Betelgeuse to be \(2.3 \cdot 10^{-7} \mathrm{rad}\).
It works by detecting the appearance and disappearance of the interference fringes when changing the distance between two parallel telescopes operating as an interferometer. The appearance and disappearance of the interference fringes is related to the size of the source, which can then be measured.

\subsection*{48.04.04 Radio-Telescope Interferometry}
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|problem 9.57|Interesting deep discussion|

\subsection*{48.04.05 Source Extension}

This section is a special case of the discussion of the coherence width in § 48.02 - Interference Diffraction Wave-Fields and Coherence.
Suppose that one wants to look for diffraction from a circular slit of diameter \(D=0.2 \mathrm{~mm}\) in a black screen with light with \(\lambda=500 \mathrm{~nm}\). We want to determine the maximum extension of the source to observe the diffraction figure if the source is located just behind the slit perpendicularly to the black screen at a distance \(L\) for the screen.
Two different point sources, constituents of the extended source and totally incoherent (actually independent), whose distance projected parallel to the black screen is \(\ell\) (lateral distance), will give two central maxima of the diffraction figure separated, approximately, by
\[
\chi \approx \frac{\ell}{L}
\]

This must be much smaller than the width of the central peak itself in order that the two diffraction figures are not distinguishable:
\[
\chi \approx \frac{\ell}{L} \ll \frac{\lambda}{D} .
\]

Therefore the maximum lateral extension of the source is:
\[
\ell \ll \frac{\lambda}{D} L
\]

\section*{Example}

Assume: \(\lambda=500 \mathrm{~nm}, D=1 \mathrm{~mm}\) and \(L=0.1 \mathrm{~m}\).
Then \(\ell=5 \cdot 10^{-5} \mathrm{~m}\).

©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|6|Good text.| ©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|7.5||

When ElectroMagnetic waves go cross matter, the electric charge of any obstacle, which might be electrons, ions, atoms, molecules, ..., are set into oscillatory motion by the ElectroMagnetic fields of the incident wave. Those accelerated charges re-radiate electromagnetic energy in all directions, a priori. This secondary radiation is called the radiation scattering by the obstacle. Scattering is given by excitation and subsequent re-radiation. In addition to re-radiating ElectroMagnetic energy, the excited elementary charges may transform part of the incident energy into other forms (thermal energy, for example): it is radiation absorption. Scattering and absorption are not mutually independent processes. The overall loss of energy is called extinction: scattering plus absorption. Read § 42.04 - ElectroMagnetic Waves.

\section*{© - QUOTE}
J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....

The scattering of ElectroMagnetic waves by systems whose individual dimensions are small when compared to the wavelength is a common case. It is convenient to think of the incident ElectroMagnetic fields as inducing electric and magnetic Multipoles oscillating with a definite phase relationship with respect to the incident ElectroMagnetic wave and radiate energy in directions other than the direction of incidence. The form of the angular distribution of radiated energy is governed by the coherent superposition of Multipoles induced by the incident ElectroMagnetic fields and in general also depends on the state of Polarization of the incident ElectroMagnetic wave. If the wavelength of the radiation is long compared to the size of the scatterer, only the lowest Multipoles, usually Electric|Magnetic Dipoles, are important and, in these circumstances, the induced Dipoles can be calculated from static or quasi-static boundary-value problems.

Electric and Magnetic Dipoless, oscillating with a definite phase relationship with respect to the incident ElectroMagnetic wave, are usually the dominant terms with respect to higher-order multipole fields.
When ElectroMagnetic waves interact with matter:
- the electric field excite Polarization, and the induced Electric Dipoles re-radiate Electric Dipole radiation;
- the magnetic field excite Magnetization, and the induced Magnetic Dipoles re-radiate Magnetic Dipole radiation.
Normally Electric Dipole radiation is more intense intense than Magnetic Dipole radiation due to relative weakness of magnetic versus electric susceptibility for common LHI media (read § 45.07.05-Radiation of ElectroMagnetic Waves).
As the media which can be treated with simple models are basically linear media and because of the fact that linear magnetic media are restricted to paramagnetic and diamagnetic substances, whose MagneticPermeability is very close to one, normally, the Magnetic-Permeability will be assumed to be exactly one at any frequency in this section.

\section*{Drude-Lorentz Dispersion Model for a Dilute non-dipolar and Non-Magnetic Medium}

This § is referenced at pages:
[2282, 2282, 2294, 2294]
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|excellent!!!!!!!!!!!!!!||
The simplified and approximate classical Drude-Lorentz model for the Polarization of a medium when subject to external ElectroMagnetic waves is presented. In spite of its limitations the model clearly explains the physical bases of the fact that the electric susceptibility is frequency dependent and it is a complex number, implying a phase shift between the applied (external) field and the Polarization|Magnetization.
The relevant particles, in this context, are typically electrons in molecules, as will be clear at the end. Therefore it can be typically assumed that the molecules, thanks to their large mass, are subject to negligible motion when compared to electrons. However different sets of electrons must be considered as well, because different electrons might be subject to different restoring forces and|or different friction forces. The position will be typically either the position of the electron with respect to the atomic nucleus or the Center-Of-Mass of the molecule. The dominant effect of electrons is confirmed by the results which will show an inverse dependence on the mass of the particles, thus consolidating the model based on electron oscillations.
The model, while not really suitable for realistic quantitative predictions, is definitely suitable to explain the qualitative aspects of the interaction between time-varying ElectroMagnetic fields and matter.
Consider a homogeneous, isotropic and linearly Polarizable medium with negligible magnetic properties:
\[
\mu_{\mathrm{R}}=1,
\]
as justified in § 45.07.05-Radiation of ElectroMagnetic Waves.
Consider different sets of particles with masses \(m_{s}\) and charges \(q_{s}\) whose position is \(\mathbf{x}\) and displacement from the equilibrium position, \(\mathbf{x}_{0}\), is \(\mathbf{r} \equiv \mathbf{x}-\mathbf{x}_{0}\). Assume each set of particles is subject to:
- a linear (elastic) restoring forces with proper frequency \(\bar{\omega}_{s}, \mathbf{f}_{\mathrm{E}}=-m_{s} \bar{\omega}_{s}^{2} \mathbf{r}\), which is always applicable for small oscillations with respect to the equilibrium configuration;
- some kind of internal friction force, modeled by \(\mathbf{f}_{\mathrm{F}}=-m_{s} \Gamma_{s} \dot{\mathbf{x}}=-m_{s} \Gamma_{s} \dot{\mathbf{r}}\); this is a rough way to model energy losses, such those from ElectroMagnetic radiation and losses of kinetic energies by collisions.
Other ElectroMagnetic properties (such as Electric|Magnetic Dipole moments) are assumed to have a negligible effect. It is also assumed that the magnetic part of the Lorentz force has a negligible effect. Note that the latter assumption is not always acceptable, because the magnetic part of the Lorentz force is the one which determines the radiation pressure from ElectroMagnetic waves on matter.

According to this model, the medium is a conducting medium if and only if there exist one set of particles, let us say \(s=\widetilde{s}=0\), with zero proper frequency, that corresponds to particles free to move with no restoring force:
\[
s=\widetilde{s}=0 \quad \Leftrightarrow \quad \bar{\omega}_{\widetilde{s}}=0
\]

Therefore, we assume here:
\[
\sigma=0
\]
and will interpret in § 49.01.01 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter the results for the electrons with zero restoring force in terms of conductivity. This approach, instead of separately considering free and bound electrons, is simpler for calculations as treats all electrons in the same way.

Consider a ElectroMagnetic MPW, in vacuum, with a definite Polarization, and a particular set of particles, possibly located near the origin of a given Coordinate System. In the general case superposition of fields might be used.

Assume that the wavelength of the ElectroMagnetic wave is much larger than the dimensions of the system,
\[
\begin{equation*}
\left|\mathbf{x}-\mathbf{x}_{0}\right| \ll \lambda \tag{49.01.01}
\end{equation*}
\]
such that the ElectroMagnetic fields can be considered uniform on the set of charges.
Consider a dilute medium, so that the difference between applied (external) field and the local field on the particles can be neglected. If that is not the case the same arguments used for deriving ClausiusMossotti relation may be used.

Assuming a non relativistic motion of the charges near the equilibrium position at \(\mathbf{x}_{0}\), so that \(\mathbf{x} \simeq \mathbf{x}_{0}\), the equation of motion is written in terms of the applied (external) field at \(\mathbf{x}\) :
\[
\begin{gathered}
\mathbf{r} \equiv \mathbf{x}-\mathbf{x}_{0}, \\
\overline{\mathbf{E}}_{0} \exp [+\beth \mathbf{k} \cdot \mathbf{x}] \exp [-\beth \omega t]=, \\
\overline{\mathbf{E}}_{0} \exp [+\beth \mathbf{k} \cdot \mathbf{r}] \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t] \simeq \quad, \\
\overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t] \quad \text { as } \mathbf{k} \cdot \mathbf{r} \ll 1 \text { thanks to }\left|\mathbf{x}-\mathbf{x}_{0}\right| \ll \lambda
\end{gathered}
\]

Therefore, for any charge of type \(s\), with \(\mathbf{r} \equiv \mathbf{x}-\mathbf{x}_{0}\) :
\[
\ddot{\mathbf{r}}+\Gamma_{s} \dot{\mathbf{r}}+\bar{\omega}_{s}^{2} \mathbf{r}=\frac{q_{s}}{m_{s}} \overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t] \quad \mathbf{r} \equiv \mathbf{x}-\mathbf{x}_{0}
\]

Any general state of Polarization is included in the description of the applied (external) field \(\overline{\mathbf{E}}_{0}\).
The steady-state solution for the position as a function of time for one specific specie of particle, \(s\), near \(\mathrm{x}_{0}\) is:
\[
\begin{gather*}
\mathbf{r}_{s}[t]=\frac{\mathrm{p}_{s}[t]}{q_{s}} \equiv \frac{\mathrm{p}_{0 s}[t]}{q_{s}} \exp [-\beth \omega t]=\frac{q_{s}}{m_{s}}\left(\frac{\overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t]}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right)  \tag{49.01.02}\\
\mathrm{p}_{0 s}=\frac{q_{s}^{2}}{m_{s}}\left(\frac{\overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right]}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right) \tag{49.01.03}
\end{gather*},
\]

In the case of a dilute medium it is possible to neglect the distinction between local and average field and the Polarization can be written as:
\[
\begin{equation*}
\mathbf{P}\left[\mathbf{x}_{0}, t\right]=\sum_{s} \eta_{s} q_{s} \mathbf{r}_{s}[t]=\sum_{s} \frac{\eta_{s} q_{s}^{2}}{m_{s}}\left(\frac{\overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t]}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right) \tag{49.01.04}
\end{equation*}
\]
where the number density of particles of the specie \(s, \eta_{s}\), has been introduced. The resulting equation is simply the equation of a forced damped harmonic oscillator.

In the case the applied (external) field differs from the average local field the appropriate correction factors need to be introduced. Read § 49.01.02 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter for the case of a non-dilute, that is dense, medium.

The relation (49.01.04) shows the fundamental result that a phase-shift is present between the applied (external) electric field and the Polarization if and only if there is a non-zero damping term, \(\Gamma_{s} \neq 0\). In order to better grasp the meaning of the relation (49.01.04) is it useful to make explicit the real and imaginary parts of the complex amplitude (the so-called absorptive and elastic amplitudes, read § 23.05.02 - Oscillations of a few mass points):
\(\frac{1}{\bar{\omega}^{2}-\omega^{2}-\beth \omega \Gamma}=\left(\frac{\bar{\omega}^{2}-\omega^{2}}{\left(\bar{\omega}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma^{2}}\right)+\beth\left(\frac{\omega \Gamma}{\left(\bar{\omega}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma^{2}}\right) \equiv \mathcal{A}_{\mathrm{E}}[\omega]+\beth \mathcal{A}_{\mathrm{A}}[\omega] \quad \mathcal{A}_{\mathrm{E}} \gtreqless 0\) and \(\mathcal{A}_{\mathrm{A}} \geq 0\)

Note that in the frequency region far away from the resonance one has: Therefore far away from the resonance the amplitude is essentially an elastic amplitude, as
\[
\frac{\left|\omega^{2}-\bar{\omega}^{2}\right| \gg \omega \Gamma \Longrightarrow\left\{\begin{array}{l}
\mathcal{A}_{\mathrm{E}} \approx \frac{1}{\bar{\omega}^{2}-\omega^{2}}, \\
\mathcal{A}_{\mathrm{A}} \approx \frac{\omega \Gamma}{\left(\omega^{2}-\bar{\omega}^{2}\right)^{2}} \ll \frac{1}{\left|\omega^{2}-\bar{\omega}^{2}\right|} \ll \frac{1}{\omega \Gamma},
\end{array}\right.}{\left|\mathcal{A}_{\mathrm{E}}\right| \approx \frac{1}{\left|\bar{\omega}^{2}-\omega^{2}\right|} \gg \mathcal{A}_{\mathrm{A}}},
\]

When there are many resonance frequencies the curve become more complex if the different peaks are superimposed but easy quantitative conclusion can be drawn if the peaks are well separated.
It is worth remembering that the resonance curves in equation (49.01.05) have, mathematically, a very strong resemblance with the ones obtained from quantum-relativistic calculations, justifying their use regardless of the approximate derivation.

The electric susceptibility and Electric-Permittivity follow, where we denote them with a prime to make clear that they also include the contribution from conduction charges:
\(\epsilon_{\mathrm{R}}^{\prime}=1+\chi_{\mathrm{E}}^{\prime}=1+\sum_{s} \frac{\eta_{s} q_{s}^{2}}{\varepsilon_{0} m_{s}}\left(\frac{1}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right)=1+\sum_{s} \frac{\eta_{s} q_{s}^{2}}{\varepsilon_{0} m_{s}}\left(\frac{\bar{\omega}_{s}^{2}-\omega^{2}}{\left(\bar{\omega}_{s}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma_{s}^{2}}+\beth \frac{\omega \Gamma_{s}}{\left(\bar{\omega}_{s}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma_{s}^{2}}\right)\).
(49.01.07)

The separation of conduction from bound charges gives:
\(\epsilon_{\mathrm{R}}^{\prime}=1+\chi_{\mathrm{E}}^{\prime}=1+\sum_{s} \frac{\eta_{s} q_{s}^{2}}{\varepsilon_{0} m_{s}}\left(\frac{1}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right)=1+\frac{\eta_{0} q_{0}^{2}}{\varepsilon_{0} m}\left(\frac{1}{-\omega^{2}-\beth \omega \Gamma_{0}}\right)+\sum_{s>0} \frac{\eta_{s} q_{s}^{2}}{\varepsilon_{0} m_{s}}\left(\frac{1}{\bar{\omega}_{s}^{2}-\omega^{2}-\beth \omega \Gamma_{s}}\right)\)
(49.01.08)

In the above expressions, equations (49.01.07), (49.01.08), the factor of the amplitudes is a squared frequency called plasma frequency, for charges of the specific type:
\[
\begin{equation*}
\left(\omega_{p}^{2}\right)_{s} \equiv \frac{\eta_{s} q_{s}^{2}}{\varepsilon_{0} m_{s}} \tag{49.01.09}
\end{equation*}
\]
see also equations (50.02.14).
Using the generic dispersion relation in equation (50.02.04) (read § 42.06 - ElectroMagnetic Waves):
\[
k^{2}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}+\beth \omega \mu_{\mathrm{R}} \mu_{0} \sigma \equiv \epsilon_{\mathrm{R}}^{\prime} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}
\]
the relation between the electric susceptibility/Electric-Permittivity with/without inclusion of the conduction charges give:
\[
\begin{equation*}
\epsilon_{\mathrm{R}}^{\prime}=\epsilon_{\mathrm{R}}+\beth \frac{\sigma}{\omega \varepsilon_{0}} \quad \chi_{\mathrm{E}}^{\prime}=\chi_{\mathrm{E}}+\beth \frac{\sigma}{\omega \varepsilon_{0}} \tag{49.01.10}
\end{equation*}
\]

In case of dilute media:
\[
\eta \alpha_{e} \ll 1 \Longrightarrow \mathrm{n}[\omega] \equiv \sqrt{1+\chi_{\mathrm{E}}} \simeq 1+\chi_{\mathrm{E}} / 2 .
\]

\subsection*{49.01.01 Result of the Drude Model for Conductors}

This § is referenced at pages:
[2274, 2274, 2294, 2294]
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|ST9|Detailed and complete discussion|
In conductors, the bound charges give rise to a Polarization current as it is the case for insulators. However in non-static situations there is no real difference between free and bound charges.
And finally the model, equation (49.01.08) and (49.01.10), gives the expression for the conductivity, essentially Drude model:
\[
\sigma=\frac{\eta_{0} q_{0}^{2}}{m_{0}}\left(\frac{1}{\Gamma_{0}-\beth \omega}\right) .
\]

The parameter \(\Gamma_{0}\) is determined by the measured value of the conductivity at low frequency (the static conductivity).

Figure 49.1: \(\mathcal{F J G U R E}\)
Note that, as the model is a resonant model, the real part of electric susceptibility becomes negative in narrow energy range around the resonance frequencies, the anomalous dispersion region.

\subsection*{49.01.02 Dense Media}

This § is referenced at pages:
[2275, 2275]
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
If the density of the medium is not small enough the distinction between local and average field must be accounted for; read § 35.09 - Electric Properties of Matter, \(\S 35.09\) - Electric Properties of Matter. It will be assumed that this distinction only applies to bound charges, because, free charges typically feel the average fields, as long as they move on distances which are large on the microscopic scale; in this case they just feel what is, by definition, the average field. This is of course a reasonable assumption, but it is an assumption. In general, for bound electrons, the correction might be required.
Assume a non magnetic medium, \(\mu_{\mathrm{R}}=1\). One proceeds as in the case of Clausius-Mossotti, introducing the polarisability, \(\alpha\), and writing the equation, for simplicity, for one single type of charges:
\[
\begin{gathered}
\mathbf{E}_{\mathrm{L}}=\mathbf{E}+\frac{\mathbf{P}}{3 \varepsilon_{0}} \\
\mathbf{P}=\eta_{\mathrm{N}} \alpha \varepsilon_{0} \mathbf{E}_{\mathrm{L}} \\
\mathbf{P}=\frac{3 \eta_{\mathrm{N}} \alpha \varepsilon_{0}}{3-\eta_{\mathrm{N}} \alpha \varepsilon_{0}} \mathbf{E} \\
\frac{\epsilon_{\mathrm{R}}-1}{\epsilon_{\mathrm{R}}+2}=\frac{\eta_{\mathrm{N}} \alpha}{3}=\frac{\eta q^{2}}{3 \varepsilon_{0} m}\left(\frac{1}{\bar{\omega}^{2}-\omega^{2}-\beth \omega \Gamma}\right)
\end{gathered}
\]
where the expression (49.01.07) was used.
Distinguishing between the local and average field one finds:
\[
\frac{\epsilon_{\mathrm{R}}-1}{\epsilon_{\mathrm{R}}+2}=\frac{\eta \alpha_{e}}{3}=\frac{\eta q^{2}}{3 \varepsilon_{0} m}\left(\frac{\overline{\mathbf{E}}_{0} \exp \left[+\beth \mathbf{k} \cdot \mathbf{x}_{0}\right] \exp [-\beth \omega t]}{\bar{\omega}^{2}-\omega^{2}-\beth \omega \Gamma}\right)
\]

In the case of a dense medium with the different resonance frequencies widely spaced the use of ClausiusMossotti equation with expression (49.01.07) is roughly equivalent to replace, in expression (49.01.07) the proper resonance frequency according to:
\[
\begin{equation*}
\bar{\omega}^{2} \rightarrow \bar{\omega}^{2}-\frac{\eta q^{2}}{3 m \varepsilon_{0}} \tag{49.01.11}
\end{equation*}
\]

\subsection*{49.01.03 Take-away Lessons From the Microscopic Model}

The simple microscopic model shows a few important facts.
- The electric susceptibility depends on the inverse mass of the oscillating particle and therefore it is justified to assume that the effect of electrons is dominant. One expects that the smaller the mass of the oscillating particle the larger its resonance frequencies, as this is typically inversely proportional to the mass of the particle, as for the harmonic oscillator.
- The electric susceptibility depends on the frequency of the applied EM fields.
- The electric susceptibility is a complex number, that is a phase shift is in general present between the applied ElectroMagnetic fields and the Polarization, if and only if there is some form of damping.
- In the case of resonance frequencies widely spaced, that is with peaks located at large distances with respect to the peak width, the electric susceptibility is almost a pure imaginary number, near the resonance frequencies, while far-away from the resonances the electric susceptibility is almost a real number.
- The electric susceptibility tends to zero for very large frequencies. The microscopic model allows to interpret this as due to the fact that the motions of the charges cannot follow the applied field for fields of very high frequency.

The relations between wave-vector, refractive index and phase-velocity are all frequency dependent:
\[
k^{2}[\omega]=\omega^{2} \varepsilon_{0} \mu_{0} \epsilon_{\mathrm{R}}^{\prime}[\omega] \mu_{\mathrm{R}}[\omega]=\frac{\omega^{2}}{c^{2}} \epsilon_{\mathrm{R}}^{\prime}[\omega] \mu_{\mathrm{R}}[\omega]
\]

In the most common case of \(\mu_{\mathrm{R}}=1\) one has:
\[
\mathbf{k} \equiv \mathbf{k}_{\mathrm{R}}+\beth \mathbf{k}_{\mathrm{I}} \Longrightarrow \mathbf{k} \cdot \mathbf{k}=k_{\mathrm{R}}^{2}-k_{\mathrm{I}}^{2}+2 \beth \mathbf{k}_{\mathrm{R}} \cdot \mathbf{k}_{\mathrm{I}}=\frac{\omega^{2}}{c^{2}} \epsilon_{\mathrm{R}}^{\prime}[\omega]
\]

It follows that the fact that the Electric-Permittivity is a complex number requires an imaginary part of the wave-vector, that is absorption if the EM waves. This is consistent with the fact that the imaginary part of the Electric-Permittivity is significantly different from zero only near the resonances when there is a damping factor, \(\Gamma_{s}\), such that energy is transferred away from the ElectroMagnetic fields.

Also the refractive index depends on the frequency:
\[
\mathrm{n}[\omega]^{2}[\omega]=\epsilon_{\mathrm{R}}^{\prime}[\omega] \mu_{\mathrm{R}}[\omega] \quad \mathrm{n}[\omega][\omega]=\sqrt{\epsilon_{\mathrm{R}}^{\prime}[\omega] \mu_{\mathrm{R}}[\omega]}
\]

The fact that the refractive index depends on the frequency has no special consequence if one only considers monochromatic ElectroMagnetic waves at a fixed frequency, except that one needs to use the exact values for the refractive index at the right frequency.

In the case of superposition of two or more frequencies there is no rigid propagation of the wave pulse any longer, as the different frequency components travel at different speeds. Moreover, the effect is also visible in different refraction angles for ElectroMagnetic waves of different frequencies.

\subsection*{49.01.04 Normal and Anomalous Dispersion and Cauchy Relation}

One speaks of normal dispersion in the frequency regions where the refractive index is an increasing function of the frequency, which is seen to be everywhere except just above any resonance frequency. One speaks of anomalous dispersion in the regions where the refractive index is a decreasing function of the frequency, which is seen to be just above any resonance frequency.

The name came from light dispersion: normal dispersion is the normal sequence of rainbow colors: shorter wavelengths (for instance blue with respect to red) are more refracted than longer wavelengths (blue more refracted than red) as the refractive index of blue is larger than the refractive index of red; anomalous dispersion is the inverted sequence of rainbow colors.

Many materials have proper resonance frequencies in the UV and therefore anomalous dispersion cannot be observed in visible light. At frequencies \(\omega \ll \bar{\omega}\) and for small enough damping the refractive index, considering only one term is the sum, that is the closest higher resonance frequency, can be written for sufficiently dilute media, as:
\(\left|\bar{\omega}^{2}-\omega^{2}\right| \gg \omega \Gamma \Longrightarrow \mathrm{n}[\omega] \simeq 1+\frac{\chi_{\mathrm{E}}}{2} \simeq \frac{\eta_{\mathrm{N}} q^{2}}{m \varepsilon_{0}} \frac{1}{\left(\bar{\omega}^{2}-\omega^{2}\right)}=\frac{\eta_{\mathrm{N}} q^{2}}{m \varepsilon_{0} \bar{\omega}^{2}} \frac{1}{1-\omega^{2} / \bar{\omega}^{2}} \simeq A+\frac{B}{\lambda^{2}}+\frac{C}{\lambda^{4}}+\ldots\).

\subsection*{49.01.05 Phase-Velocity Greater Than Speed of Light in Vacuum}

In the case of a refractive index less than one the phase-velocity turns out to be larger that the phasevelocity of light in vacuum. This is not a real problem, however, because a MPW carries no information and therefore there is no violation of the relativity principles.
49.01.06 Extinction of ElectroMagnetic Waves in Matter
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|1.31|Clear demonstration of the physical principles \(\mid\) ©|M.Born \& E.Wolf, Principles Of Optics, 1986, CUP, 6thEd., ....|§ 2||

It can be shown that an external ElectroMagnetic disturbance traveling with the velocity of light in vacuum is exactly canceled out in matter and replaced by a secondary disturbance traveling with the velocity of ElectroMagnetic wave in matter. This is the so-called Ewald-Oseen extinction theorem.
One should remember that the total ElectroMagnetic field is always given by the sum of the EM fields produced by all the charges in the universe. Moreover, the radiation field produced by any charge, is the retarded field, with retardation speed always given by the speed of light in vacuum, \(c\), even inside matter.

\subsection*{49.01.07 Link Between the Microscopic and the Macroscopic Descriptions}

Read § 42.06 - ElectroMagnetic Waves.

Figure 49.2: \(\mathcal{F J G U R E}\)

\title{
Radiation Scattering From Atoms|Molecules in a Dilute Gas
}
© |R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|1.32||
After having discussed the effect of ElectroMagnetic waves on matter at a microscopic level, we have to account for the fact that charges accelerated by the incoming ElectroMagnetic wave will radiate ElectroMagnetic radiation; this is called radiation scattering. Read § 42.04.01 - ElectroMagnetic Waves.
Only the case of a dilute gas is considered where the different Atoms|Molecules do not significantly interact each other.
Since the induced Magnetic Dipole moments of most gas molecules are negligible compared to the induced Electric Dipole moments, the scattering is purely Electric Dipole in character.
Consider the simplified model of § 49.01 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter for electric Dipole radiation from Atoms|Molecules under the action of an incoming monochromatic ElectroMagnetic wave. Consider the massive molecule fixed and the motion of the electrons in the molecule. Electrons are supposed to be elastically bound to the molecule with friction force. Assume the wavelength is much longer than the dimension of the molecule so that the electric field is basically constant over the extension of the molecule.
Equation (49.01.02) can be used, for the motion of the particle, together with equation (45.07.07), for the total radiated energy. Considering, for simplicity, only one proper frequency, one finds:
\[
\begin{equation*}
\frac{\mathrm{d} \varepsilon}{\mathrm{~d} t}[\omega]=\frac{1}{4 \pi \varepsilon_{0}} \frac{\omega^{4}\left|p_{0}\right|^{2}}{3 c^{3}}=\frac{1}{4 \pi \varepsilon_{0}}\left(\frac{e^{4}\left|E_{0}\right|^{2}}{3 c^{3} m^{2}}\right)\left(\frac{\omega^{4}}{\left(\bar{\omega}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma^{2}}\right) \tag{49.02.01}
\end{equation*}
\]

The above formula is usually written introducing a length, called, for historical reasons, the classical radius of the electron:
\[
\begin{gather*}
r_{e} \equiv \frac{1}{4 \pi \varepsilon_{0}} \frac{e^{2}}{m c^{2}} \equiv \frac{q_{e}^{2}}{m c^{2}}=3 \cdot 10^{-15} \mathrm{~m}  \tag{49.02.02}\\
\frac{\mathrm{~d} \varepsilon}{\mathrm{~d} t}[\omega]=\frac{c \varepsilon_{0}\left|E_{0}\right|^{2}}{2}\left(\frac{8 \pi r_{e}^{2}}{3}\right)\left(\frac{\omega^{4}}{\left(\bar{\omega}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma^{2}}\right) \equiv \frac{c \varepsilon_{0}\left|E_{0}\right|^{2}}{2} \sigma[\omega] \tag{49.02.03}
\end{gather*}
\]

Equation (49.02.03) expresses the scattered power as a product of the incoming radiant intensity times a factor which is by definition the scattering cross-section (see section § 28.06 - Introduction to ManyParticles Systems):
\[
\sigma \equiv \frac{\text { Total Energy Scattered per unit time }}{\text { Energy incident per unit area per unit time }}
\]

The scattered light can be Polarized, whatever the Polarization of the incident wave. In fact, considering the Electric Dipole radiation one realizes that, for instance, looking at the incoming radiation, the scattered radiation has the same Polarization as the incident radiation. However, when looking at a right angle with respect to the incoming radiation, the transversality of the incoming radiation produces linearly Polarized scattered radiation.
Note that this simplified purely classical model is inconsistent, strictly speaking, when one realizes that the electrons moving around the nucleus should radiate continuously loosing energy. Only Quantum Physics can solve this issue.
By accounting for all species of electrons in matter one would write:
\[
\sigma[\omega] \equiv \frac{8 \pi r_{e}^{2}}{3} \sum_{s}\left(\frac{\omega^{4}}{\left(\bar{\omega}_{s}^{2}-\omega^{2}\right)^{2}+\omega^{2} \Gamma_{s}^{2}}\right)
\]
- For electrons in molecules in air: \(\nu_{0} \approx 10^{17} \mathrm{~Hz}(\mathrm{UV})\).
- For visible light: \(\nu_{0} \approx 10^{14} \mathrm{~Hz}\).

\subsection*{49.02.01 Validity of the No-Excitation Coherent-Scattering Regime}

The above description is correct as long as the energy of the photons is not large enough to excite the molecules to higher energy levels, the no-Excitation approximation.
Moreover, the wavelength must be large with respect to the physical dimension of the molecules in order to have the coherent scattering, that is the whole molecule coherently oscillating due to the ElectroMagnetic fields, the Coherent-Scattering approximation.

\subsection*{49.02.02 Rayleigh Scattering}

At low frequency:
\[
\begin{equation*}
\omega \longrightarrow 0 \quad\left(\omega \ll \omega_{s}\right) \quad \Longrightarrow \frac{\mathrm{d} \varepsilon}{\mathrm{~d} t}[\omega] \propto \omega^{4}=\frac{1}{\lambda^{4}} . \tag{49.02.04}
\end{equation*}
\]

It is responsible for the blue of the sky and the red of Sun at sunset. It is also responsible for the visibility of a beam of light in a purified atmosphere.

\subsection*{49.02.03 Thomson Scattering}

At high frequency:
\[
\begin{align*}
\omega \longrightarrow+\infty \quad\left(\omega \gg \omega_{s}\right) & \Longrightarrow \frac{\mathrm{d} \varepsilon}{\mathrm{~d} t}[\omega]=\frac{c \varepsilon_{0}\left|E_{0}\right|^{2}}{2} \frac{8 \pi r_{e}^{2}}{3} \equiv \frac{c \varepsilon_{0}\left|E_{0}\right|^{2}}{2} \sigma_{T}  \tag{49.02.05}\\
\sigma_{T} & =0.67 \cdot 10^{-28} \mathrm{~m}^{2} \equiv 0.67 \text { barn } \tag{49.02.06}
\end{align*}
\]

It also applies to the scattering from free charges. The quantity \(\sigma_{T}\) is called the Thomson scattering cross-section: it is very large, as a cross-section, in fact, on a microscopic scale. It is, in fact, of the order of the barn, the unit of measure of cross-section.
Thomson scattering is responsible of the visibility of the Solar Corona during eclipses: the Solar Corona is made of a plasma and it is visible thanks to Thomson scattering on free electrons.

Read § 46.05.04 - Interference, § 46.05.05 - Interference.
It can be shown that for a gas with regularly arranged molecules the scattering is zero. In fact, for any molecule scattering in one specific direction, one can always find another molecule scattering in the same direction but with opposite phase, so that total destructive interference happens, except for the forward direction. However density fluctuations in gases will produce a scattered intensity given by the sum of all the intensities.
Scattering from liquids and solids is smaller, due to the smaller density fluctuations with respect to gases, even if the density is larger than for gases.
Moreover, the molecules are in motion so that, actually the scattered radiation will have a slightly different frequency due to the Doppler effect.

The scattering from \(N\) identical bodies is a three-dimensional interference problem and one has the following.
- Random positions: sum of the intensities.
- Regular arrangement: the scattered light is zero in almost all the directions, except for forward scattering, where there must be constructive interference, for sure. In other special directions there might be interference (for instance at \(\pi / 4\) for a cubic crystal in Bragg interference with X-rays). At \(\pi / 2\) there is destructive interference.

\subsection*{49.04.01 The Refractive Index of Water}

Values in the visible light range:
\[
\mathrm{n}[\omega][400 \mathrm{~nm}<\lambda<700 \mathrm{~nm}] \approx 1.3 \quad \mathrm{n}[\omega][\omega \rightarrow 0] \approx 9
\]
49.04.02 Thomson Scattering in the Solar Corona

Estimation:
\[
L \approx 7 \cdot 10^{8} \mathrm{~m} \quad \eta_{\mathrm{N}}=10^{15} \text { electrons } / \mathrm{m}^{3} \quad \frac{1}{\lambda}=\eta_{\mathrm{N}} \sigma_{T} \Longrightarrow \lambda=1.5 \cdot 10^{13} \mathrm{~m} \quad \frac{\Delta I}{I}=5 \cdot 10^{-5} .
\]
49.04.03 Blue Sky Light and Red Sun at Sunset
49.04.04 Polarization of Blue Sky Light and Use for Orienteering

\subsection*{49.04.05 Clouds}

Huge scattering from clouds is due to the fact that clouds are condensates of many particles. All the particles in a water drop scatters in phase thus leading to constructive interference. It does not increase ad infinitum because for too large dimensions (comparable with the incident radiation wavelength) the scatterers are not in phase any longer.

\subsection*{49.04.06 Microscopical Explanation of Brewster Angle}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||

\subsection*{49.04.07 Mie Scattering}

The scattering from molecules and tiny particles is predominantly the Rayleigh scattering. For particle sizes larger than a wavelength the so-called Mie scattering predominates. This scattering produces a pattern like an antenna lobe with a sharper and more intense forward lobe for larger particles.
Mie scattering is not strongly wavelength dependent and produces the almost white glare around the sun when a lot of particulate material is present in the air. It also gives the white light from mist and fog.
49.04.08 Tyndall Effect

The Tyndall effect, also known as Tyndall scattering, is the scattering of light by colloidal particles or particles in suspension.

Demonstrate equation (49.01.11).

\section*{49-003 Elastic And Absorptive Amplitude and de-phasing}

From equation (49.01.05) show that:
- for \(\omega \rightarrow 0\), electric field an polarization are in-phase;
- for \(\omega=\bar{\omega}\), electric field an polarization are in-quadrature;
- for \(\omega \rightarrow+\infty\), electric field an polarization are opposite.

\section*{49-004 Elastic And Absorptive Amplitude Far From Resonance}

Demonstrate equation (49.01.06).
49-005 Elastic and Absorptive Amplitude limits
©|Berkeley Physics Course, Vol. 3, Waves, 1968, McGraw-Hill, ...Ed., ....|3.2 pag 109||
Consider single resonance. Find the frequency range where
\[
\left|\frac{\mathcal{A}_{\mathrm{E}}}{\mathcal{A}_{\mathrm{A}}}\right| \leq \alpha .
\]

\section*{SOLUTION}
\[
\begin{gathered}
\left|\frac{\mathcal{A}_{\mathrm{E}}}{\mathcal{A}_{\mathrm{A}}}\right|=\frac{\left|\bar{\omega}^{2}-\omega^{2}\right|}{\omega \Gamma} \leq \alpha, \\
-\frac{\alpha \Gamma}{2}+\sqrt{\bar{\omega}^{2}+\frac{\alpha^{2} \Gamma^{2}}{4} \leq \omega \leq+\frac{\alpha \Gamma}{2}+\sqrt{\bar{\omega}^{2}+\frac{\alpha^{2} \Gamma^{2}}{4}}}=\text {. }
\end{gathered}
\]

The width of the frequency range turns out to be proportional to \(\alpha \Gamma\) and it is centered on a location depending on \(\alpha \Gamma\), at a frequency larger than \(\bar{\omega}\).
For \(\alpha=1\) one finds: \(\Delta \omega=\Gamma / 2\).

When dealing with ElectroMagnetic waves in material media one should keep in mind that ElectroMagnetic fields in matter always refer to average ElectroMagnetic fields and real matter is not really a continuum. In particular this means that the description of matter as a continuum with average ElectroMagnetic fields breaks down when the ElectroMagnetic fields change significantly over distances comparable with the inter-molecular distances (for instance, in the case of harmonic fields, when the wavelength becomes so short to be comparable with inter-molecular distances). See the discussion in section § 34.02.01 - Electric|Magnetic Properties of Matter.

\section*{Work Done by the ElectroMagnetic Fields on the Matter}

\author{

}

The Electric-Permittivity, the Magnetic-Permeability and the conductivity are in general, complex quantities. In this case they represent, for a harmonic time dependence, a proportionality with a shift in time. See section § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter for a modeling of these effects. This is further discussed in the next sections § 50.02.04.01 ElectroMagnetic Waves in Matter and §50.02.02 - ElectroMagnetic Waves in Matter, for the ElectricPermittivity and the conductivity. As far as the Magnetic-Permeability is concerned this is, usually, negligibly close to one in the case of linear magnetic materials.
A non magnetic medium will be assumed: \(\mu_{\mathrm{R}}=1\). In this case the current is given by the free current plus the Polarization current, as the Magnetization current is zero for a non magnetic medium.
An harmonic time-dependence will be assumed.
The current is current from bound charges plus the current from free charges, that is one should coherently use, in the expression of the current in \(\mathbf{j} \cdot \mathbf{E}\), either one of the two expressions:
\[
\left\{\begin{array}{l}
\mathbf{j}^{\mathrm{P}}=-\beth \omega \varepsilon_{0} \chi_{\mathbf{E}}^{\prime} \mathbf{E} \\
\hline \mathbf{j}^{\mathrm{F}}=\sigma \mathbf{E} \quad \mathbf{j}^{\mathrm{P}}=-\beth \omega \varepsilon_{0} \chi_{\mathbf{E}} \mathbf{E} \\
\hline
\end{array}\right.
\]

\subsection*{50.01.01 Via the Complex Electric-Permittivity Only}

Use the description in terms of complex Electric-Permittivity only, such that free charges are just described as bound charges with zero restoring force and thus zero proper oscillation frequency.
The current is just the Polarization current as the free charges are described as weakly bound charges. The time-averaged work per unit volume done by the ElectroMagnetic fields on the matter is given by:
\[
\begin{gather*}
\left\langle\frac{\mathrm{d} W}{\mathrm{~d} \tau}\right\rangle=  \tag{50.01.01}\\
\frac{1}{2} \operatorname{Re}\left(\overline{\mathbf{j}} \cdot \overline{\mathbf{E}^{\star}}\right)=\frac{1}{2} \operatorname{Re}\left(\overline{\left.\mathbf{j}^{\overline{\mathrm{P}}} \cdot \overline{\mathbf{E}}^{\star}\right)=\frac{1}{2} \operatorname{Re}\left(-\beth \omega \overline{\mathbf{P}} \cdot \overline{\mathbf{E}}^{\star}\right)=\frac{1}{2} \operatorname{Re}\left(-\beth \omega \varepsilon_{0} \overline{\chi_{\mathrm{E}}^{\prime}} \overline{\mathbf{E}} \cdot \overline{\mathbf{E}^{\star}}\right)=}\right. \\
\frac{1}{2} \omega \varepsilon_{0}|\overline{\mathbf{E}}|^{2} \operatorname{Jm}\left(\overline{\chi_{\mathrm{E}}^{\prime}}\right) \geq 0
\end{gather*}
\]

The work done on matter, that is the energy transferred from the ElectroMagnetic wave to matter, that is the energy absorbed from the ElectroMagnetic fields is thus proportional to the imaginary part of the electric susceptibility.
The work done is normally positive, at least in the usual case of passive matter. This is formalized by the fact that the imaginary part of the complex susceptibility is positive. Read § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter.

\subsection*{50.01.02 Via the Complex Electric-Permittivity Plus Explicit Conductivity for Free Charges}

Use the description in terms of complex Electric-Permittivity plus explicit conductivity for free charges. The part attributed to the Polarization current gives the same result as in equation (50.01.01). The part attributed to the free current is calculated in a similar way:
\[
\begin{gather*}
\left\langle\frac{\mathrm{d} W}{\mathrm{~d} \tau}\right\rangle=  \tag{50.01.04}\\
\frac{1}{2} \omega \varepsilon_{0}|\overline{\mathbf{E}}|^{2} \operatorname{Im}\left(\overline{\chi_{\mathrm{E}}}\right)+\frac{1}{2} \operatorname{Re}\left(\overline{\left.\mathbf{j}^{\overline{\mathrm{F}}} \cdot \overline{\mathbf{E}}^{\star}\right)=\frac{1}{2} \omega \varepsilon_{0}|\overline{\mathbf{E}}|^{2} \operatorname{Im}\left(\overline{\chi_{\mathrm{E}}}\right)+\frac{1}{2} \operatorname{Re}\left(\sigma \overline{\mathbf{E}} \cdot \overline{\mathbf{E}}^{\star}\right)=}\right.  \tag{50.01.05}\\
\frac{\frac{1}{2} \omega \varepsilon_{0}|\overline{\mathbf{E}}|^{2} \operatorname{Im}\left(\overline{\chi_{\mathrm{E}}}\right)+\frac{1}{2}|\overline{\mathbf{E}}|^{2} \operatorname{Re}(\bar{\sigma}) \geq 0}{} .
\end{gather*}
\]

The work done on matter, that is the energy transferred from the ElectroMagnetic wave to matter, that is the energy absorbed from the ElectroMagnetic fields is thus proportional to the imaginary part of the electric susceptibility and to the real part of the conductivity.
The work done is normally positive, at least in the usual case of passive matter. This is formalized by the fact that the imaginary part of the complex susceptibility and the real part of the complex conductivity are positive. Read § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter.

\subsection*{50.01.03 Absorption of Energy: Energy Transfer From ElectroMagnetic Waves to Matter}

From the previous results it follows that energy absorption comes from both the real part of the conductivity and the imaginary part of the Electric-Permittivity (or, equivalently, the electric susceptibility). This is consistent with relation (50.02.05).

\subsection*{50.02.01 Introduction}

In this section complex quantities will not be explicitly denoted as ... for the sake of simplification of the notation, as it will be always clear when the variable is either a complex or a real variable.
In a insulator medium the free charge|current density were set to zero, as it is totally appropriate for both vacuum and globally neutral strictly insulator media. The case of a conducting medium involves those media where there are charges free to move, not bound to any particular site. Obviously the results obtained for insulator media must be obtained as limiting cases for conducting medium with limiting zero conductivity. However in the case of conductors the flow of charge is not independently controlled and in general the free current density is not zero. Therefore in a conducting medium the Maxwell Equations with both free charges and currents must be employed, a priori.
The free charge density can be assumed to be zero in most conducting media, as it is shown in § 33.18.18 - Basic Laws of ElectroMagnetism. The relaxation time for this process is
\[
\begin{equation*}
\tau=\frac{\varepsilon_{0} \epsilon_{\mathrm{R}}}{\sigma} \tag{50.02.01}
\end{equation*}
\]

Therefore, at least in the case of ElectroMagnetic fields impinging on a globally neutral conductor from outside, the free charge density remains zero. From the expression for the relaxation time one can anticipate that the free charge in a conductor will have enough time to rearrange itself continuously for frequencies of the ElectroMagnetic fields such that:
\[
\tau \lesssim \omega^{-1} \Longrightarrow \frac{\varepsilon_{0} \epsilon_{\mathrm{R}} \omega}{\sigma} \lesssim 1
\]

Under these conditions the conducting medium will behave basically as in static conditions, that is it will continue to behave as a good conductor even in a non-static situation. The electric field inside the conductor will be basically zero. In summary we have the following.
- A perfect conductor is such that: \(\sigma=\infty\) and \(\tau=0\).
- A good conductor is such that: \(\epsilon_{\mathrm{R}} \varepsilon_{0} \omega \ll \sigma\).
- A poor conductor is such that: \(\epsilon_{\mathrm{R}} \varepsilon_{0} \omega \gg \sigma\).

For perfect and good conductors it can be assumed that the free-charge is zero, as it is supposed that free-charge has enough time to rearrange itself during the relaxation time. In case there is some free charge density inside the medium one can still set \(\rho^{\mathrm{F}}=0\) after a transient time given by equation (50.02.01). It turns out that, except for poor conductors the assumption \(\rho^{\mathrm{F}}=0\) is justified.
For instance, \(\sigma[\mathrm{Cu}]=59.6 \cdot 10^{6} \mathrm{SI}\) and \(\sigma[\mathrm{Ag}]=63.0 \cdot 10^{6} \mathrm{SI}\) so that they are good conductors up to frequencies \(\omega \approx 10^{18} \mathrm{~Hz}\).
Obviously the free current density is not zero. One should remember that the zero free charge density implies that there are equal amounts of free positive and negative charges, balancing themselves, in each volume of the conductor. Therefore in a conductor at rest the free charges must include both the free
conduction electrons and as many fixed positive charges as needed to balance the free conduction electrons. Similar arguments must be applied when dealing with other types of conductors, for instance electrolytic solutions and plasmas.

A conducting medium, in general, is expected to be non transparent to ElectroMagnetic waves, because currents normally imply Joule dissipation of energy, in the present case energy taken way from the ElectroMagnetic wave itself. In other words: conducting \(\Longrightarrow\) dissipative.

\subsection*{50.02.02 Modeling of Free|Bound Charges}

This § is referenced at pages:
[2290, 2290]
The dispersion relation is deduced by replacing a MPW into the equations (42.06.29), (42.06.07). The wave-vector is now necessarily complex
\[
\begin{equation*}
\mathrm{k}=\mathrm{k}_{\mathrm{R}}+\beth \mathrm{k}_{\mathrm{I}} . \tag{50.02.02}
\end{equation*}
\]

For the present purposes one can assume that the wave-vector has a form less general than the one in equation (50.02.02), that is the real and imaginary parts are parallel:
\[
\begin{equation*}
\mathbf{k}=k \hat{\boldsymbol{\kappa}} \tag{50.02.03}
\end{equation*}
\]
where \(\hat{\boldsymbol{\kappa}}\) is a real unit vector: \(\boldsymbol{\kappa} \cdot \boldsymbol{\kappa}=1\). This is the case of homogeneous MPW. The more general case of non-homogeneous PW is much more complex and has less practical interest.

The general dispersion relation takes the form:
\[
\begin{equation*}
k^{2}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}+\beth \omega \mu_{\mathrm{R}} \mu_{0} \sigma \tag{50.02.04}
\end{equation*}
\]

Note that a general discussion of equation (50.02.04) is basically impossible, due to the many different parameters and properties of the materials; therefore only special cases under specific hypothesis/approximations are usually treated. Two main hypotheses are:
\(\rightarrow\)
- almost real parameters, \(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\) and \(\sigma\), as described in \(\S 50.02 .03\) - ElectroMagnetic Waves in Matter;
- behavior dominated by conduction charges, as described in §50.02.04-ElectroMagnetic Waves in Matter.

\subsection*{50.02.02.01 Relation Between Electric-Permittivity and Conductibility}

It is clear from equations (50.02.04) that in the general case of complex \(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\) and \(\sigma\) the ElectricPermittivity and the conductivity are, to some extent, interchangeable for describing free charges. Actually in presence of time varying fields the distinction between conduction current of free charges and Polarization current is, to a large extent, arbitrary. From the physical point of view this reflects the fact that, for time varying harmonic fields, there is no qualitative difference between the motion of a free charge and the motion of a bound charge: both of them are harmonic motions. On the other hand there is a significant qualitative difference in the static case, as a bound charge will move until it reaches the equilibrium position, while a free charge will continue to move until the conditions to which it is subject change (for instance: boundaries, change of fields).

Let us denote, for the sake of clarity, with \(\epsilon_{\mathrm{R}}\) the Electric-Permittivity due to bound charges only and use explicitly \(\sigma\) to describe the free charges. On the other hand let us denote with \(\epsilon_{\mathrm{R}}^{\prime}\) the Electric-Permittivity due to all charges, both bound and free charges.
From the formal point of view the relation among \(\epsilon_{\mathrm{R}}, \epsilon_{\mathrm{R}}^{\prime}\) and \(\sigma\) can be understood by first writing equation (50.02.04) as:
\[
k^{2}=\varepsilon_{0} \mu_{0} \mu_{\mathrm{R}} \omega^{2}\left(\epsilon_{\mathrm{R}}+\beth \frac{\sigma}{\varepsilon_{0} \omega}\right)
\]

This equations confirms that actually, for non static situations, it is to some extent an arbitrary choice to express the properties of the material either in terms of a conductivity, \(\sigma\), plus an Electric-Permittivity, \(\epsilon_{\mathrm{R}}\), describing only bound charges, or in terms of a Electric-Permittivity, \(\epsilon_{\mathrm{R}}^{\prime}\), describing all charges:
\[
\begin{equation*}
\epsilon_{\mathrm{R}}^{\prime} \longleftrightarrow\left(\epsilon_{\mathrm{R}}+\beth \frac{\sigma}{\varepsilon_{0} \omega}\right) \tag{50.02.05}
\end{equation*}
\]

Read also § 50.04.01 - ElectroMagnetic Waves in Matter.
In general \(\epsilon_{\mathrm{R}}, \epsilon_{\mathrm{R}}^{\prime}\) and \(\sigma\) may all be complex.
In view of the physical interpretation given above, equation (50.02.05) amounts to choose between two equivalent descriptions of the response of matter to ElectroMagnetic fields. In fact, one realizes that the concept of Electric-Permittivity can describe free charges as well by considering free charges as bound charges with an infinitely weak restoring force. Read § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter.
- Describe the free charges by means of a conductivity, \(\sigma\), and the bound charge by means of the Electric-Permittivity, \(\epsilon_{\mathrm{R}}\).
- Describe both free and bound charges by means of single parameter, the Electric-Permittivity, \(\epsilon_{\mathrm{R}}^{\prime}\).

In what follows the notation for the Electric-Permittivity will be normally \(\epsilon_{\mathrm{R}}\) as it will be clear from the context which one of the two approaches one is following, according to whether the conductivity is explicitly mentioned or not. The first approach (separate accounting for the conductivity and ElectricPermittivity of bound charges) will be normally employed, unless stated otherwise.
Actually, in the general case, one has to assume that the parameters in equation (50.02.04) ( \(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\) and \(\sigma\) ) are complex. In this case they represent, for a harmonic time dependence, a proportionality with a shift in time. Read § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter for a modeling of these effects.
Following the approach to separately accounting for the conductivity and Electric-Permittivity of bound charges, the behavior of a material as conductor or insulator can be defined by the following limits:
- good conductor: \(|\sigma| \gg \omega \varepsilon_{0}\left|\epsilon_{\mathrm{R}}\right|\), conduction current much larger than the displacement current, the medium behaves as a conductor characterized by its conductivity;
- good insulator: \(|\sigma| \ll \omega \varepsilon_{0}\left|\epsilon_{\mathrm{R}}\right|\), conduction current much smaller than the displacement current, the medium behaves as an insulator characterized by its Electric-Permittivity.
Most materials have an intermediate behavior with respect to these two extreme limits.
Note, however, that in general both conductivity and Electric-Permittivity are complex quantities. It should be anticipated that: the Electric-Permittivity is typically a real quantity except for the regions of frequency near the proper resonance frequencies of the charges in matter; the conductivity is a real parameter at low frequencies.

\subsection*{50.02.03 Almost Real Parameters}

This § is referenced at pages:
[2293, 2293, 2295, 2295]
Assume that all the parameters in equation (50.02.04) \(\left(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\right.\) and \(\left.\sigma\right)\) are almost real, and a non magnetic medium. Therefore the conditions
\[
\begin{equation*}
\mu_{\mathrm{R}}=1 \quad \operatorname{Im}\left(\epsilon_{\mathrm{R}}\right) \simeq 0 \quad \operatorname{Im}(\sigma) \simeq 0 \tag{50.02.06}
\end{equation*}
\]
will be implicitly assumed except when specified otherwise. If that is not the case some of the results obtained in this section must be adapted.
It can be shown (read § 49.01 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter, § 49.01.01 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter) that this hypothesis is well satisfied for non magnetic media ( \(\mu_{R}=1\) ), far from proper resonance frequencies \(\left(\epsilon_{\mathrm{R}}\right)\) and at low enough frequencies \((\sigma)\). In fact the assumptions for \(\epsilon_{\mathrm{R}}\) is well justified far-away
from the resonance frequencies of the matter, where the Electric-Permittivity is essentially a real quantity. As far as the Magnetic-Permeability is concerned it is basically one for linear magnetic media in most cases. It is demonstrated in § 50.02.04.01 - ElectroMagnetic Waves in Matter that the conductivity of good conductors remains almost real up to large frequencies; it is anyway a real quantity at low frequencies, as it is well-known.
The above conditions are often satisfied in visible light as the resonance frequencies are often in the UV. The real and imaginary parts of the wave-vector are then:
\[
\begin{aligned}
& k_{\mathrm{R}}^{2}-k_{\mathrm{I}}^{2}=\frac{\omega^{2} \epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}{c^{2}}, \\
& 2 \mathbf{k}_{\mathrm{R}} \cdot \mathbf{k}_{\mathrm{I}}=\omega \mu_{\mathrm{R}} \mu_{0} \sigma \quad \Longrightarrow \quad\left(2 k_{\mathrm{R}} k_{\mathrm{I}}=\omega \mu_{\mathrm{R}} \mu_{0} \sigma \quad \text { because } \mathbf{k}=k \hat{\boldsymbol{\kappa}}\right)
\end{aligned}
\]
and the solution for the real and imaginary parts of the wave-vector is:
\[
k_{\mathrm{R}}=\frac{\omega}{c} \sqrt{\frac{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}{2}} \sqrt{\sqrt{1+\left(\frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right)^{2}}+1}
\]
\[
k_{\mathrm{I}}=\frac{\omega}{c} \sqrt{\frac{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}{2}} \sqrt{\sqrt{1+\left(\frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right)^{2}}-1}
\]

Note that, from the algebraic point of view, the latter solutions are only valid assuming that all the parameters on the right-hand side are real.
The result shows that, as long as all the parameters in equation (50.02.04) are real, a necessary and sufficient condition to have an imaginary part of the wave-vector is that the conductivity is different from zero. In fact, in presence of conduction charge, one normally expects some absorption to be present, because the current excited by the external ElectroMagnetic fields will dissipate energy.

\subsection*{50.02.03.01 Good/Bad Conductors}

Equation (50.02.04) is the basic equation describing the propagation of MPW inside matter. It can be re-written as the complex expression:
\[
\begin{equation*}
k^{2} \equiv \mathbf{k} \cdot \mathbf{k}=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \varepsilon_{0} \mu_{0} \omega^{2}\left(1+\beth \frac{\sigma}{\epsilon_{\mathrm{R}} \varepsilon_{0} \omega}\right)=\epsilon_{\mathrm{R}} \mu_{\mathrm{R}} \frac{\omega^{2}}{c^{2}}\left(1+\beth \frac{1}{\omega \tau}\right) \tag{50.02.07}
\end{equation*}
\]
where the first term corresponds to the displacement current while the second term corresponds to the conduction current and the relaxation time of equation (50.02.01) has been introduced.
Further progress can be done by assuming that \(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\) and \(\sigma\) are real quantities, possibly frequency dependent, as mentioned and explained in section §50.02.03 - ElectroMagnetic Waves in Matter. In absence of a microscopic model, this is a kind of hypothesis which is needed to make further progress. The use of a microscopic model is described in § 50.02.04 - ElectroMagnetic Waves in Matter.
The following notation is often introduced:
\[
k=\beta+\beth \frac{\alpha}{2} \equiv k_{\mathrm{R}}+\beth k_{\mathrm{I}}
\]

The Electric|Magnetic fields can be written, in general, as a function of the unit vector \(\hat{\boldsymbol{\kappa}}\) in the direction of the wave-vector \(\mathbf{k}\) :
\[
\begin{aligned}
& \mathbf{E}=\mathbf{E}_{0} \exp [-\alpha / 2 \boldsymbol{\kappa} \cdot \mathbf{x}] \exp [\beth \beta \boldsymbol{\kappa} \cdot \mathbf{x}-\beth \omega t], \\
& \mathbf{B}=\mathbf{B}_{0} \exp [-\alpha / 2 \boldsymbol{\kappa} \cdot \mathbf{x}] \exp [\beth \beta \boldsymbol{\kappa} \cdot \mathbf{x}-\beth \omega t] .
\end{aligned}
\]

Admit therefore that \(\epsilon_{\mathrm{R}}, \mu_{\mathrm{R}}\) and \(\sigma\) are all real. Note that if this hypothesis is not satisfied one must start from equation (50.02.07) in any case.

\section*{Bad Conductors}

This § is referenced at pages:
[2305, 2305]
A bad conductor, to first-order, gives an almost real refractive index:
\[
\begin{aligned}
\left|\frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right| \ll 1 \Longrightarrow & \\
& k=\beta+\beth \frac{\alpha}{2} \equiv k_{\mathrm{R}}+\beth k_{\mathrm{I}} \simeq \frac{\omega}{c} \sqrt{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}\left(1+\beth \frac{\sigma}{2 \omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right) \quad \text { to first-order in } \frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}
\end{aligned}
\]

Under this approximation the real part of the wave-vector is much larger than the imaginary part and the latter is independent of the frequency, except for possible dependencies induced by the ElectricPermittivity and conductivity. The wave-vector is thus almost real: there is absorption and the medium is, in the two extreme cases, either basically transparent, in case the attenuation length is much longer than the dimension of the sample, or basically a black-body, in case the attenuation length is much shorter than the dimension of the sample.
Note that actually the result is the same (almost real wave-vector) as long as the condition \(|\sigma| \ll\left|\omega \varepsilon_{0} \epsilon_{\mathrm{R}}\right|\) is satisfied irrespective of the reality or not of the conductivity \(\sigma\).
The magnetic field is given by:
\[
\mathbf{B}_{0}=\frac{k}{\omega} \hat{\boldsymbol{\kappa}} \times \mathbf{E}_{0}
\]
but it should be kept in mind that the wave-vector is complex, and therefore the electric and magnetic fields are out-of-phase. However, thanks to the smallness of the imaginary part with respect to the real part of the wave-vector, the Electric|Magnetic fields are almost in phase.
The wave-impedance of a bad conductor, from equation (42.06.20), is given by:
\[
\begin{equation*}
\mathbf{E} \cdot \mathbf{E} \equiv Z^{2} \mathbf{H} \cdot \mathbf{H} \Longrightarrow Z \equiv \sqrt{\frac{\mu_{0} \mu_{\mathrm{R}}}{\varepsilon_{0} \epsilon_{\mathrm{R}}^{\prime}}}=\sqrt{\frac{-\beth \mu_{0} \mu_{\mathrm{R}} \omega}{\sigma-\beth \varepsilon_{0} \epsilon_{\mathrm{R}} \omega}} \tag{50.02.08}
\end{equation*}
\]

In this case the wave-number is almost real and the refractive index is given by:
\[
\mathrm{n}[\omega]=\frac{c k}{\omega}=\sqrt{\epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}\left(1+\beth \frac{\sigma}{2 \omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right) .
\]

In case of a non-magnetic medium: \(\mu_{\mathrm{R}}=1\). If it can be assumed that the effect of the bound charges is negligible (free charges are accounted for by the conductivity) the Electric-Permittivity can be set to one: \(\epsilon_{\mathrm{R}}=1\). In this case the refractive index becomes:
\[
\mathrm{n}[\omega] \simeq\left(1+\beth \frac{\sigma}{2 \omega \varepsilon_{0}}\right)
\]

An ElectroMagnetic wave impinging at normal incidence onto such kind of material from vacuum is only weakly reflected because the reflectance is:
\[
\varrho \simeq\left(\frac{\sigma /\left(2 \omega \varepsilon_{0}\right)}{2}\right)^{2} \ll 1
\]

The wave is thus almost completely transmitted/absorbed. If the thickness of the sample is large with respect to the attenuation length the wave will be totally absorbed inside the medium. Such a medium thus will appear as a black body. If the thickness of the sample is small with respect to the attenuation length the wave will be totally transmitted inside the medium. Such a medium thus will appear as a transparent one.

\section*{Good Conductors}

This § is referenced at pages:
[2305, 2305]
A good conductor, to first-order, gives real and imaginary parts for the refractive index which are almost equal:
\[
\begin{aligned}
\left|\frac{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}{\sigma}\right| \ll 1 \Longrightarrow & \\
& k=\beta+\beth \frac{\alpha}{2} \equiv k_{\mathrm{R}}+\beth k_{\mathrm{I}}=\sqrt{\mu_{\mathrm{R}} \mu_{0} \sigma \omega}\left(\frac{1+\beth}{\sqrt{2}}\right) \quad \text { to first-order in } \frac{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}{\sigma}
\end{aligned}
\]

The magnetic field is given by:
\[
\mathbf{B}_{0}=\frac{k}{\omega} \hat{\boldsymbol{\kappa}} \times \mathbf{E}_{0}
\]
but it should be kept in mind that the wave-vector is complex, and therefore the electric and magnetic fields are out-of-phase.
The wave-impedance of a good conductor, from equation (42.06.20), is given by:
\[
\begin{equation*}
\mathbf{E} \cdot \mathbf{E} \equiv Z^{2} \mathbf{H} \cdot \mathbf{H} \Longrightarrow Z \equiv \sqrt{\frac{\mu_{0} \mu_{\mathrm{R}}}{\varepsilon_{0} \epsilon_{\mathrm{R}}^{\prime}}}=\sqrt{\frac{-\beth \mu_{0} \mu_{\mathrm{R}} \omega}{\sigma}} \tag{50.02.09}
\end{equation*}
\]

The real and imaginary parts of the wave-vector are equal in a good conductor. It follows that the Electric|Magnetic fields are out-of-phase by \(\pi / 4\). Moreover, the magnetic field is much larger than it would be in vacuum for the same electric field and therefore the energy of the wave is largely of magnetic type.
The imaginary part of the wave-vector gives the inverse attenuation length of the wave:
\[
k_{\mathrm{I}} \equiv \frac{\alpha}{2}=\sqrt{\frac{\mu_{\mathrm{R}} \mu_{0} \sigma \omega}{2}} \equiv \delta^{-1}
\]
which is half the inverse attenuation length of the energy:
\[
\begin{equation*}
2 k_{\mathrm{I}} \equiv \alpha=\sqrt{2 \mu_{\mathrm{R}} \mu_{0} \sigma \omega} . \tag{50.02.10}
\end{equation*}
\]

The ElectroMagnetic fields thus penetrates the good conductor by a depth \(\delta\) (the so-called skin-depth):
\[
\begin{equation*}
\delta \equiv \sqrt{\frac{2}{\mu_{\mathrm{R}} \mu_{0} \sigma \omega}} . \tag{50.02.11}
\end{equation*}
\]

The consequence of the latter result is the so-called skin effect such that ElectroMagnetic fields at high frequency do no enter inside conductors and currents mainly flow near the surface.
For instance: copper at \(\omega \approx 10^{15} \mathrm{~Hz}\) has \(\delta \simeq 10^{-8} \mathrm{~m}\).

\subsection*{50.02.04 Drude-Lorentz Model for Conducting Media}

This § is referenced at pages:
[2293, 2293, 2295, 2295]
In this section it is assumed that the behavior of the material is dominated by the free conduction charges. This is well justified, among other cases, when all the proper resonance frequencies are far away from the wavelength region of interest. In fact in this case the contribution to the susceptibility from bound charges is very close to zero. Moreover, a non magnetic material is assumed.
Therefore the conditions
\[
\begin{equation*}
\mu_{\mathrm{R}}=1 \quad \epsilon_{\mathrm{R}} \simeq 1 \tag{50.02.12}
\end{equation*}
\]
will be implicitly assumed except when specified otherwise. If that is not the case some of the results obtained in this section must be adapted.
The simplified microscopic classical model for the dispersion described in section §49-Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter and equation (49.01.07) when applied to the case when one subset of charges, \(k=0\), has \(\bar{\omega}_{0}=0\), that is they are free charges, gives, under the hypotheses in (50.02.12):
\[
\begin{equation*}
\epsilon_{\mathrm{R}}^{\prime}=\epsilon_{\mathrm{R}}+\frac{\eta_{0} q_{0}^{2}}{\varepsilon_{0} m}\left(\frac{1}{-\omega^{2}-\beth \omega \Gamma_{0}}\right)=\epsilon_{\mathrm{R}}+\frac{\eta_{0} q_{0}^{2}}{\varepsilon_{0} m \omega}\left(\frac{\beth}{\Gamma_{0}-\beth \omega}\right) \Longrightarrow \epsilon_{\mathrm{R}}^{\prime}=1+\frac{\omega_{p}^{2}}{\omega}\left(\frac{\beth}{\Gamma_{0}-\beth \omega}\right) \tag{50.02.13}
\end{equation*}
\]
where the so-called plasma frequency, \(\omega_{p}\),
\[
\begin{equation*}
\omega_{p}^{2} \equiv \frac{\eta_{0} q_{0}^{2}}{\varepsilon_{0} m} \equiv \frac{\eta_{0} q_{e}^{2}}{\varepsilon_{0} m_{e}}, \tag{50.02.14}
\end{equation*}
\]
was introduced (read § 50.02.04.02 - ElectroMagnetic Waves in Matter).
The comparison of equation (50.02.13) with equation (49.01.10) gives the following expression for the conductivity:
\[
\begin{equation*}
\sigma[\omega]=\frac{\eta_{0} q_{0}^{2}}{m_{0}}\left(\frac{1}{\Gamma_{0}-\beth \omega}\right)=\varepsilon_{0} \omega_{p}^{2}\left(\frac{1}{\Gamma_{0}-\beth \omega}\right) \quad \sigma[\omega=0]=\frac{\eta_{0} q_{0}^{2}}{m_{0} \Gamma_{0}} \tag{50.02.15}
\end{equation*}
\]
\(\rightarrow\)
22982300
2309

This is essentially Drude model, read section \(\S 50.02 .15-50.02 .15\). Equation (50.02.15) allows one to calculate the electric conductivity at various frequencies, after determining the damping constant, \(\Gamma_{0}\), by using the values at low frequencies.
The result (50.02.15) shows that the conductivity is a real quantity, at very low frequencies, while it is a pure imaginary quantity, at very high frequencies.

\subsection*{50.02.04.01 Low Frequency Limit (Purely Resistive Regime)}

This § is referenced at pages:
[2290, 2290, 2294, 2294]
At low frequencies, \(\omega \ll \Gamma_{0}\), the conductivity is real and independent of the frequency, as in the static case. This is called the purely resistive regime, because the conductivity is basically the static conductivity. The charges, in fact, will be basically always at the terminal velocity appropriate to the instantaneous electric field. The contribution to the electrical susceptibility is an imaginary one.
The square of the refractive index is:
\[
\mathrm{n}[\omega]^{2}=1+\beth \frac{\omega_{p}^{2}}{\omega \Gamma_{0}} .
\]

Two limiting cases arise for a resistive medium: dilute and dense.

\section*{A Dense Resistive Medium}

The condition \(\omega \ll \Gamma_{0}\) is complemented by the additional conditions:
\(\omega \ll \omega_{p} \quad \frac{\omega_{p}^{2}}{\Gamma_{0}} \gg \omega\)

It is called dense medium because \(\omega_{p}^{2}\) is proportional to the density.
The refractive index is thus:
\[
\mathrm{n}[\omega]=\mathrm{n}[\omega]_{\mathrm{R}}+\beth \mathrm{n}[\omega]_{\mathrm{I}} \simeq 1+\beth \frac{\omega_{p}^{2}}{2 \omega \Gamma_{0}} \quad \text { with }\left|\mathrm{n}[\omega]_{\mathrm{I}}\right| \gg \mathrm{n}[\omega]_{\mathrm{R}}=1
\]

The refractive index is thus essentially a imaginary number:
\[
\mathrm{n}[\omega] \simeq \sqrt{\beth \frac{\omega_{p}^{2}}{\omega \Gamma_{0}}}=\sqrt{\beth \frac{\sigma}{\omega \varepsilon_{0}}} \quad \text { with }\left|\mathrm{n}[\omega]_{\mathrm{I}}\right| \gg \mathrm{n}[\omega]_{\mathrm{R}}=1
\]

The real and imaginary parts of the wave-vector are thus equal and large with respect to the vacuum value, \(\omega / c\).
The mean penetration distance of the wave is small with respect to the vacuum wavelength. A wave is then reflected with negligible absorption, because there is so little penetration that a little energy is absorbed.
The reflectivity is than almost equal to one.
A dense resistive medium gives almost complete reflection.

\section*{A Dilute Resistive Medium}

The condition \(\omega \ll \Gamma_{0}\) is complemented by the additional conditions:
\[
\omega_{p} \ll \Gamma_{0} \quad \frac{\omega_{p}^{2}}{\Gamma_{0}} \ll \omega
\]

It is called dilute medium because \(\omega_{p}^{2}\) is proportional to the density.
The refractive index is thus:
\[
\mathrm{n}[\omega]=\mathrm{n}[\omega]_{\mathrm{R}}+\beth \mathrm{n}[\omega]_{\mathrm{I}} \simeq 1+\beth \frac{\omega_{p}^{2}}{2 \omega \Gamma_{0}} \quad \text { with }\left|\mathrm{n}[\omega]_{\mathrm{I}}\right| \ll \mathrm{n}[\omega]_{\mathrm{R}}=1
\]

The wave-vector is:
\[
k=\mathrm{n}[\omega] \frac{\omega}{c}=k_{\mathrm{R}}+\beth k_{\mathrm{I}} \simeq \frac{\omega}{c}+\beth \frac{\sigma_{0}}{2 \varepsilon_{0} c} \quad \text { with }\left|k_{\mathrm{I}}\right| \ll k_{\mathrm{R}}
\]

The real part of the wave-vector is the same as in vacuum. The fact that the imaginary part of the wave-vector is much smaller than the real one implies that the attenuation length is much larger than the vacuum wavelength.
The reflectivity is much smaller than one.
The wave-vector is thus almost real: there is absorption and the medium is, in the two extreme cases, either basically transparent, in case the attenuation length is much longer than the dimension of the sample, or basically a black-body, in case the attenuation length is much shorter than the dimension of the sample.

\subsection*{50.02.04.02 High Frequency Limit (Purely Elastic Regime)}

This § is referenced at pages:
[2298, 2298]
At sufficiently high frequencies the Electric-Permittivity of any substance tends to one (see section § 49 - Microscopic Classical Model for Interaction of ElectroMagnetic Waves and Matter). This happens when the frequency is well above all the resonance frequencies of the system: \(\omega \gg \bar{\omega}_{\text {MAX }}\), in terms of the highest resonance frequency of the system, \(\bar{\omega}_{\text {max }}\). Therefore, in this case, the hypothesis, \(\epsilon_{\mathrm{R}}=1\), invoked in (50.02.12), is certainly satisfied.
At high frequencies, \(\omega \gg \Gamma_{0}\), the conductivity is imaginary and dependent of the frequency as \(\omega^{-1}\).
Therefore at sufficiently high frequencies the conclusions of this section are of rather general applicability.
The conductivity at very high frequencies, \(\omega \gg \Gamma_{0}\), according to equation (50.02.15), gives:
\[
\sigma[\omega]=\beth \frac{\eta_{0} q_{0}^{2}}{m \omega}
\]

By using this expression in the dispersion relation (50.02.04) one finds:
\[
k=\frac{1}{c} \sqrt{\omega^{2}-\omega_{p}^{2}}
\]

\section*{Below the Plasma Frequency (Reactive Frequency Range)}

The conditions \(\omega \gg \Gamma_{0}\) and \(\omega_{p} \gg \Gamma_{0}\), in this case, are complemented by the additional condition:
\[
\omega<\omega_{p} \Longrightarrow-\frac{\omega_{p}^{2}}{\Gamma_{0}} \ll \mathrm{n}[\omega]^{2} \leq 0
\]

Below the plasma frequency, if the conditions \(\omega \gg \Gamma_{0}\) (and \(\omega \gg \bar{\omega}_{\text {MAX }}\) ) are satisfied, the refractive index and wave-vector are imaginary. The wave decays exponentially with attenuation length given by \(k_{\mathrm{I}}{ }^{-1}\). The wave is totally reflected without absorption.

\section*{Above the Plasma Frequency (Dispersive Frequency Range)}

The conditions \(\omega \gg \Gamma_{0}\) and \(\omega_{p} \gg \Gamma_{0}\), in this case, are complemented by the additional condition:
\[
\omega>\omega_{p}
\]

Above the plasma frequency, if the conditions \(\omega \gg \Gamma_{0}\) (and \(\omega \gg \bar{\omega}_{\text {MAX }}\) ) are satisfied, the wave-number becomes real: the wave is transmitted without any absorption. The refractive index is:
\[
\mathrm{n}[\omega]=\sqrt{1-\frac{\omega_{p}^{2}}{\omega^{2}}} \leq 1
\]

It follows that the refractive index is less than one and the phase-velocity is larger than the phase-velocity of ElectroMagnetic waves in vacuum:
\[
v[\omega] \equiv \frac{\omega}{k}=\frac{\omega c}{\sqrt{\omega^{2}-\omega_{p}^{2}}} \geq c
\]

Actually the phase-velocity tends to infinity when the frequency approaches the plasma frequency.
As the refractive index is real, positive and less than one it follows that the medium is transparent and there is no absorption.
This regime applies to X-rays in good conductors.

\end{tabular} \\
\hline
\end{tabular}

The properties of any conductor may be summarized as follows.
- At low enough frequency any conductor is a dense resistive medium. It gives almost total reflection with very little absorption.
- At high enough frequency any conductor is a dispersive medium. It is then transparent. Conductors can then be divided into three classes, according to the relative values of \(\Gamma_{0}\) and \(\omega_{p}\).
- If \(\Gamma_{0} \gg \omega_{p}\) has a frequency range where it is a dilute resistive medium. In that range i can absorb a wave without reflection. Such a conductor cannot have a purely reactive frequency range and therefore it cannot give total reflection at any frequency.
- If \(\Gamma_{0} \ll \omega_{p}\) has a frequency range where it is a purely reactive medium. In that range it can give total reflection without absorption. Such a conductor cannot have a dilute resistive frequency range and therefore it cannot give total absorption without reflection.
- If \(\Gamma_{0} \approx \omega_{p}\) it has no frequency range where it is purely reactive nor dilute resistive medium.

\subsection*{50.02.05.01 Summary Results}

Consider ElectroMagnetic MPW at a certain fixed frequency reaching a non-magnetic material ( \(\mu_{\mathrm{R}}=1\) ) and coming from a material with real refractive index \(n[\omega]_{0}\) (typically \(n[\omega]_{0} \simeq 1\) ) at normal incidence for simplicity.
\[
k=\mathrm{n}[\omega] \frac{\omega}{c}
\]

Recall the expressions of reflectivity and transmissivity at normal incidence for non-magnetic media:
\[
\varrho=\left(\frac{\mathrm{n}[\omega]_{0}-\mathrm{n}[\omega]}{\mathrm{n}[\omega]_{0}+\mathrm{n}[\omega]}\right)^{2} \quad \tau=1-\varrho .
\]
- If \(\mathrm{n}[\omega]\) is purely real, then we have a perfectly transparent material and the energy which enters, determined by \(\varrho\) and \(\tau\), is transmitted without absorption:
\[
\begin{equation*}
\alpha=0 \tag{50.02.16}
\end{equation*}
\]
- If \(n[\omega]\) is pure imaginary, and the refractive index \(n[\omega]_{0}\) of the first medium is real, there is no penetration of the wave but only exponential attenuation in the material. Moreover: \(\varrho=1\) and \(\tau=0\) and there is no energy entering the material.
- If \(\operatorname{Re}(\mathrm{n}[\omega]) \simeq \operatorname{Im}(\mathrm{n}[\omega])\) we have a penetration by the skin-depth
\[
\begin{equation*}
k_{\mathrm{I}}=\alpha / 2=\delta^{-1}=\sqrt{\frac{\mu_{0} \mu_{\mathrm{R}} \sigma \omega}{2}} \tag{50.02.17}
\end{equation*}
\]
and there is penetration of a harmonic damped wave.
- If \(\mathrm{n}[\omega]=A+\beth_{\epsilon}\) with \(|\epsilon| \ll A, A\) real, and \(\mathrm{n}[\omega]_{0}\) is the real refractive index of the first medium, the reflectivity can be very small if \(A \simeq\), in fact:
\[
\begin{equation*}
\varrho=\left|\frac{A-\mathrm{n}[\omega]_{0}}{A+\mathrm{n}[\omega]_{0}}\right|^{2} \tag{50.02.18}
\end{equation*}
\]
the wave is absorbed in the material or not depending on the relationship between the attenuation length and the dimension of the material (either a black-body or a transparent medium).
- If \(\mathrm{n}[\omega]=1+\epsilon+\beth B\) with \(|\epsilon| \ll|B|\) there is high reflection and high absorption of the energy which enters the medium, but little energy enters to be absorbed, depending on the refractive index \(n[\omega]_{0}\) of the first medium.

\section*{Materials With Negative Electric-Permittivity and/or Magnetic-Permeability}

This § is referenced at pages:
[2101, 2101]
Read \(\S 42.08\) - ElectroMagnetic Waves for general properties.
Most materials have positive Electric-Permittivity |Magnetic-Permeability.
Artificial materials exist with both negative Electric-Permittivity and Magnetic-Permeability. These materials feature unusual properties.
© - QUOTE
Wave Propagation From Electrons to Photonic Crystals and Left-Handed Materials Peter Markoš Costas M. Soukoulis
It is important to note that we are not aware of the existence of such materials in nature. However, recently man-made composites were prepared, which exhibit, in a certain frequency region, negative effective permittivity and permeability. "Effective" means that these parameters describe the response to an external electromagnetic field with a frequency \(\nu\) such that the wavelength of the field, \(k=2 \pi c / \nu\), is much larger than any spatial in-homogeneity of the material.

See WEB - URL.

\section*{Examples and Physical Applications}

\subsection*{50.04.01 Conductivity and Electric-Permittivity With/Without Bound Charges}

This § is referenced at pages:
[2294, 2294]
Consider a conducting LHI medium ( \(\mathrm{j}^{\mathrm{F}}=\sigma \mathbf{E}\) ) with a normal Electric-Permittivity, \(\epsilon_{\mathrm{R}}\), describing the behavior of bound charges only. The Maxwell-Ampère relation, in presence of an harmonic time dependence, \(\exp [-\beth \omega t]\), becomes:
\[
\operatorname{rot} \mathbf{B}=\mu_{0} \mu_{\mathrm{R}} \sigma \mathbf{E}+\epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{0} \mu_{\mathrm{R}} \partial_{t} \mathbf{E} \Longrightarrow \beth \mathbf{k} \times \mathbf{B}=\mu_{0} \mu_{\mathrm{R}} \sigma \mathbf{E}-\beth \omega \epsilon_{\mathrm{R}} \varepsilon_{0} \mu_{0} \mu_{\mathrm{R}} \mathbf{E}=\mu_{0} \mu_{\mathrm{R}}\left(\sigma-\beth \omega \epsilon_{\mathrm{R}} \varepsilon_{0}\right) \mathbf{E},
\]
showing that, under the specified hypotheses, a conducting medium can described by the same equation as an insulator medium by using an electric susceptibility/Electric-Permittivity, \(\epsilon_{\mathrm{R}}^{\prime}\) and \(\chi_{\mathrm{E}}^{\prime}\), given by (equation (49.01.10)):
\[
\epsilon_{\mathrm{R}}^{\prime} \equiv \epsilon_{\mathrm{R}}+\beth \frac{\sigma}{\omega \varepsilon_{0}} \quad \chi_{\mathrm{E}}^{\prime} \equiv \chi_{\mathrm{E}}+\beth \frac{\sigma}{\omega \varepsilon_{0}}
\]

If one does not introduce the relation \(\mathbf{j}^{\mathrm{F}}=\sigma \mathbf{E}\) and all the behavior of the medium is attributed to its Polarizable material properties the latter must be described by the electric susceptibility/ElectricPermittivity, \(\epsilon_{\mathrm{R}}\) and \(\chi_{\mathrm{E}}\), only.
These considerations show that the distinction between insulators and conductors is largely artificial, at least for non-zero frequencies.

\subsection*{50.04.02 Radio-Wave Propagation in the Ionosphere}

Radio-Communication: \(\nu \approx 3 \mathrm{GHz}\) (short waves).

\subsection*{50.04.03 Radio-Communication Black-Out With a Spaceship at Reenter Into the Atmosphere}

If the plasma created around the spaceship by the atmospheric drag is such that the plasma frequency around the spaceship becomes larger (high enough density) than the radio-communication frequency the radio waves to the spaceship are reflected before reaching it.

\subsection*{50.04.04 MicroWave Cooking}
©|G.Bekefi \& A.H.Barrett, Vibrazioni Elettromagnetiche Onde E Radiazione, 1981, Zanichelli, ...Ed., ....|||
Typical MicroWave oven frequency: assume \(\nu=3 \mathrm{GHz}\); actually the resonance frequency of water is at \(\nu=2.45 \mathrm{GHz}\) but one should not stay too close to the resonance frequency otherwise there is little energy penetration. Assume the following parameters for fat animal tissues at the given frequency: \(\epsilon_{R}=5.5\), \(\sigma=0.15(\Omega \cdot \mathrm{~m})^{-1}\). In this case
\[
\left|\frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right| \simeq 0.16 \Longrightarrow k \simeq \omega \sqrt{\varepsilon_{0} \mu_{0} \epsilon_{\mathrm{R}} \mu_{\mathrm{R}}}\left(1+\frac{\beth \sigma}{2 \omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right)=(1+0.08 \beth) \omega \sqrt{\varepsilon_{0} \mu_{0} \epsilon_{\mathrm{R}} \mu_{\mathrm{R}}},
\]
and therefore neither the bad conductor nor the good conductor approximations are suitable (Read § 50.02.03.01 - ElectroMagnetic Waves in Matter, § 50.02.03.01 - ElectroMagnetic Waves in Matter). The full calculation is required.

One then finds:
\[
\begin{aligned}
& \lambda_{0}=c / \nu=10 \mathrm{~cm} \\
& k_{\mathrm{R}}=1.5 \cdot 10^{2} \mathrm{~m}^{-1} \\
& \lambda=\frac{2 \pi}{k_{\mathrm{R}}}=4.2 \mathrm{~cm} \\
& k_{\mathrm{I}}=1.2 \cdot 10^{1} \mathrm{~m}^{-1} \\
& \delta \equiv{k_{\mathrm{I}}}^{-1}=8.3 \mathrm{~cm}
\end{aligned}
\]

Note that:
\[
\frac{k_{\mathrm{I}}}{k_{\mathrm{R}}} \simeq 0.08 \simeq \frac{1}{2}\left|\frac{\sigma}{\omega \varepsilon_{0} \epsilon_{\mathrm{R}}}\right|
\]
as it should.
The process involved is the oscillation of the permanent Dipole moments of water molecules.
Note that one should not stay at the resonance frequency because in that case the microwave is reflected. One should not stay too much far away from it, because in this case the amount of absorption is too small. The real frequency is a compromise.

\subsection*{50.04.05 Reflection From Conducting Materials}
50.04.06 Selective Reflectance From Conductors

\subsection*{50.04.07 Skin Effect}

The skin effect, that is the fact that high-frequency ElectroMagnetic fields penetrates into a conductor by a typically small amount given by the skin depth (equation (50.02.11)), implies, as a consequence, that high-frequency currents only flow at the surface of a conductor. As a consequence the effective resistivity of a conductor is much larger, at high-frequency, than expected from considerations based on the geometry of the wire itself.
This explains, among other things, the use of copper braids as ground connections for high-frequency currents.

\subsection*{50.04.08 Color}

When looking at any object one sees either the light emitted by the object, for light emitting sources, or the light, coming from some source, reflected by the object. In the latter case the light might come from both surface reflection (surface color) and body reflection (body color). A third way to see an object is by observing the absorption by the object of the light coming from a source behind it.
Extinction of an ElectroMagnetic wave inside matter is caused by both absorption (energy transfer from ElectroMagnetic energy into internal energy) and scattering (energy spread around as ElectroMagnetic energy).

\subsection*{50.04.08.01 Surface Color}

Typical for high reflectivity bodies.
It is determined by the properties of the surface. Selective reflection: when some wavelength is reflected more than others the body, when seen in reflection, will appear colored of the colors best reflected. When observed in transmission it will appear colored of the complementary color.

\subsection*{50.04.08.02 Body Color}

Typical for low reflectivity bodies.
It is determined by the properties of the body. The wave penetrates and some frequencies are more absorbed than others, which are scattered. Selective scattering will give rise to the color, and scattering is in all directions. In this case the color is the same in reflection and transmission.
A typical example is the blue of the sky produced by Rayleigh scattering of the solar light: the radiation received is not coming from the surface of the medium but from all the medium itself.
Other examples are the color of water (sea-water, for instance) and colored glasses.

\subsection*{50.04.09 Reflection From a Good Conductor}

Consider, for simplicity, ElectroMagnetic waves at normal incidence on a medium from vacuum. A non magnetic medium will be assumed: \(\mu_{\mathrm{R}}=1\).
In general terms the presence of absorption, at fixed real part of the refractive index, always increases the reflection. In fact:
\[
\begin{gathered}
\mathrm{n}[\omega] \equiv \mathrm{n}[\omega]_{\mathrm{R}}+\beth \mathrm{n}[\omega]_{\mathrm{I}}, \\
\mathrm{n}[\omega]^{2} \equiv\left(\mathrm{n}[\omega]_{\mathrm{R}}+\beth \mathrm{n}[\omega]_{\mathrm{I}}\right)^{2} \equiv \epsilon_{\mathrm{R}}^{\prime} \mu_{\mathrm{R}} \simeq \epsilon_{\mathrm{R}}^{\prime}=\operatorname{Re}\left(\epsilon_{\mathrm{R}}^{\prime}\right)+\beth \operatorname{Im}\left(\epsilon_{\mathrm{R}}^{\prime}\right)=\left(\mathrm{n}[\omega]_{\mathrm{R}}\right)^{2}-\left(\mathrm{n}[\omega]_{\mathrm{I}}\right)^{2}+2 \beth \mathrm{n}[\omega]_{\mathrm{R}}[\omega]_{\mathrm{I}} \quad, \\
\operatorname{In}\left(\epsilon_{\mathrm{R}}^{\prime}\right) \neq 0 \quad \Leftrightarrow \quad \mathrm{n}[\omega]_{\mathrm{R}} \mathrm{n}[\omega]_{\mathrm{I}} \neq 0, \\
\varrho \equiv\left|\frac{\mathrm{n}[\omega]-1}{\mathrm{n}[\omega]+1}\right|^{2}=\frac{\left(\mathrm{n}[\omega]_{\mathrm{R}}-1\right)^{2}+\mathrm{n}[\omega]_{\mathrm{I}}{ }^{2}}{\left(\mathrm{n}[\omega]_{\mathrm{R}}+1\right)^{2}+\mathrm{n}[\omega]_{\mathrm{I}}^{2}} \geq \frac{\left(\mathrm{n}[\omega]_{\mathrm{R}}-1\right)^{2}}{\left(\mathrm{n}[\omega]_{\mathrm{R}}+1\right)^{2}} .
\end{gathered}
\]

The above formula makes clear the fact that the amplitude reflection coefficient is large in either of the two cases:
\(\mathrm{n}[\omega]_{\mathrm{I}} \gg 1 \Longrightarrow \varrho \simeq 1 \quad\) strong absorption: total reflection with little energy penetrating to be absorbed , \(\mathrm{n}[\omega]_{\mathrm{R}}=0 \Longrightarrow \varrho \simeq 1 \quad\) it applies to good conductors at frequencies: \(\Gamma_{0} \ll \omega \ll \omega_{p}\).
In the case of incidence on a conductor a phase shift is normally present, because the reflection and amplitude transmission coefficients are complex number, as long as the refractive index is a complex number. Therefore in presence of absorption there is always a phase shift in the reflected and refracted wave.

\subsection*{50.04.10 Relationship Between Absorption and Surface Reflection}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
High absorption is caused by a high value of the imaginary part of the refractive index, that is from a large imaginary part of the wave-vector. This implies a amplitude reflection coefficient close to one. Then almost all the energy is reflected and little energy remains to be absorbed inside the medium.
As an example, a red body, if red is caused by surface (that is interface) reflection, appears blue in transparency because red is reflected and absorbed while other frequencies are preferentially transmitted.

Reflection From Gold and Silver
Silver has an almost uniform and high ( \(>0.9\) ) reflectivity in the visible wavelength range. Therefore it reflects strongly and uniformly all the visible light. Then it appears metallic white.
Gold has an almost uniform and high ( \(>0.9\) ) reflectivity in the visible wavelength range down to about \(0.5 \mu \mathrm{~m}\) (yellow). Below that value the reflectivity drops to a smaller value. Therefore white light is selectively reflected by gold, with preferential reflection of the long wavelengths, giving to light reflected by gold the typical yellowish aspect. For the same reasons, white light transmitted by a thin sheet of gold has the complementary greenish color, because light below about \(0.5 \mu \mathrm{~m}\) is well transmitted.

\section*{Introduction}

\subsection*{51.01.01 Applicability of Geometrical|Ray Optics}

Geometrical|Ray Optics is a model for the description of the propagation of electromagnetic waves with small wavelength compared to the relevant dimensions \((\lambda \longrightarrow 0)\). In this case it is possible to neglect, as a first approximation, the wave effects and consider the propagation of ElectroMagnetic waves as a propagation of rays of light.
Geometrical|Ray Optics is an approximate method to solve the wave-equation that works very well in the short wavelength limit. When Geometrical|Ray Optics fails other methods must be used, such as Huygens principle or exact diffraction theory.

\subsection*{51.01.02 Refractive Index}

Dal punto di vista dell'ottica geometrica le caratteristiche ottiche di un mezzo sono completamente caratterizzate dal suo indice di rifrazione, definito in ottica geometrica come il rapporto tra la velocità (di fase) della luce nel vuoto, \(c\), e la velocità (di fase) della luce nel mezzo in questione, \(v\) :
\[
\mathrm{n}[\omega] \equiv \frac{c}{v}
\]

Si noti che l'indice di rifrazione può anche essere minore di uno in quanto la velocità di fase della luce in un mezzo può anche essere maggiore della velocità di fase della luce nel vuoto. In generale l'indice di rifrazione dipende dalla lunghezza d'onda e dallo stato di Polarizzazione della luce ed è complesso.
Un mezzo otticamente omogeneo è un mezzo in cui la velocità di fase della luce non dipende dal punto. Un mezzo otticamente isotropo è un mezzo in cui la velocità di fase della luce in ogni punto non dipende dalla direzione di propagazione né dalla Polarizzazione della luce.

Fermat Principle: a light ray, moving through any set of linear and isotropic (non necessarily homogeneous) media, in going from any fixed point S to any fixed point P must traverse an optical path
\[
\begin{equation*}
\Delta t \propto \int_{S}^{P} \mathrm{n}[\omega][\mathbf{x}] \mathrm{d} s \propto \int_{S}^{P} \mathrm{~d} t \tag{51.02.01}
\end{equation*}
\]
with length stationary with respect to small variations of the optical path; that is, such as to render its optical path length (nearly) equal to the length of other paths closely adjacent to the actual one. In short, the optical path length is a stationary functional of path (not necessarily a minimum). In this case, there is at P constructive interference, as the phases at arrival are synchronized to within some tolerance.
The key to Fermat principle is constructive interference|diffraction among nearby optical paths with almost equal path-lengths. Read § 46.02 - Interference.
The formalism required to handle such kind of problems is variational calculus:
\[
\begin{equation*}
\delta \int_{S}^{P} \mathrm{n}[\omega][\mathbf{x}] \mathrm{d} s=\delta \int_{S}^{P} \frac{c}{v[\mathbf{x}]} \mathrm{d} s=0 \tag{51.02.02}
\end{equation*}
\]

For a sequence of linear and isotropic media, \(k\) :
\[
\sum_{k} \Delta t_{k}=0 \quad \text { for a sequence of linear and isotropic media }
\]

\section*{© - QUOTE}
E.Hecht, Optics, 2002, Addison Wesley Longman, 4thEd., ....

Suppose that a beam of light advances through a homogeneous isotropic medium so that a ray passes from points S to P. Atoms within the material are driven by the incident disturbance, and they re-radiate in all directions. Wavelets progressing along paths in the immediate vicinity of a stationary straight-line path will reach P by routes that differ only slightly in OPL. They will therefore arrive nearly in-phase and reinforce each other. Think of each wavelet represented by a tiny phasor that rotates once around as the wave advances one wavelength along any ray path. Because the OPLs are all about the same, the phasors at P all point in more or less the same direction, and even though they're all small they combine to make the dominant contribution. Wavelets taking other paths far from the stationary one will arrive at P appreciably out-of-phase with each other and will therefore tend to cancel. In other words, there will be large angles between the little phasors; placed tip-to-tail they'll spiral around producing only a tiny net contribution. Keep in mind that we've just drawn three ray paths - the argument would be better made with millions of them in each group. We can conclude that energy will effectively propagate along the ray from \(S\) to \(P\) that satisfies Fermat's Principle. And this is true whether we're talking about interfering electromagnetic waves or photon probability amplitudes (p. 138). We can expect that this same logic holds for all propagation processes.

\subsection*{51.02.01 Principle of Reversibility of the Optical Paths}

The principle of reversibility of the optical paths follows from Fermat principle: a light beam going from \(B\) to \(A\) will travel in the opposite direction along the same trajectory traveled by a light beam going from \(A\) to \(B\).

\subsection*{51.02.02 Consequences of Fermat Principle}

\subsection*{51.02.02.01 Reflection}

Reflection from a plane surface: minimum optical path.

\subsection*{51.02.02.02 Refraction}

Read § 21-014 - Kinematics of Points and Reference Frames.

\subsection*{51.02.02.03 Example of Maximum Optical Length Path}

Spherical internally reflecting mirror with point source at one point on the surface: the effective optical path, source-sphere-source, is the one with reflection at the point diametrically opposite to the source; among all possible paths, source-sphere-source, this is the longest optical path one.

\subsection*{51.02.02.04 Example of Stationary Optical Length Path}

An elliptical mirror with one point source at one focus and point detector at the other one: all paths with reflections have identical paths lengths, and therefore there is a stationary point, but longer than the shortest one, going directly from one focus to the other. There exist other paths, not stationary paths, but shorter than the one-reflection path.

Propagation of Light Rays in Linear Isotropic piece-wise homogeneous media

\subsection*{51.03.01 Rectilinear Propagation in Homogeneous Isotropic Media}

\subsection*{51.03.02 Reflection at a Plane Interface}

At the interface between two isotropic media, a light ray is (partially) reflected; the reflected ray lies in the plane of incidence determined by the incident light ray and the surface normal at the point of incidence; the angles of incidence and reflection, \(\theta\) and \(\theta^{\prime \prime}\), are equal:
\[
\theta=\theta^{\prime \prime}
\]

Let \(\hat{\mathbf{u}}\) be the unit vector at the incidence point; the reflected ray direction, \(\mathbf{k}^{\prime \prime}\), is given by:
\[
\begin{equation*}
\mathbf{k}^{\prime \prime}=\mathbf{k}-2 \hat{\mathbf{u}}(\mathbf{k} \cdot \hat{\mathbf{u}}) \tag{51.03.01}
\end{equation*}
\]

Note that no information is provided by Fermat principle about the reflection or transmission coefficients: just a geometrical information is provided. Moreover, Fermat principle applies to the case of specular reflection, that is, to one perfectly smooth interface surface. Basically, it means that the imperfections of the surface (roughness) are much smaller than the wavelength. In the case of a surface with significant roughness, also diffuse reflection occurs.

\subsection*{51.03.03 Refraction at a Plane Interface}

At the interface between two isotropic media, a light ray is (partially) transmitted; the transmitted ray lies in the plane of incidence determined by the incident light ray and the surface normal at the point of incidence; the angles of incidence and transmission, \(\theta\) and \(\theta^{\prime}\), are linked by:
\[
\mathrm{n}[\omega] \sin \theta=\mathrm{n}[\omega]^{\prime} \sin \theta^{\prime}
\]

Let \(\hat{\mathbf{u}}\) be the unit vector at the incidence point; the transmitted ray direction, \(\mathbf{k}^{\prime}\), is given by:
\(\mathrm{n}[\omega]^{\prime} \mathbf{k}^{\prime}=\mathrm{n}[\omega] \mathbf{k}+\hat{\mathbf{u}}\left(\mathrm{n}[\omega](\mathbf{k} \cdot \hat{\mathbf{u}})-\sqrt{\mathrm{n}[\omega]^{\prime 2}-\mathrm{n}[\omega]^{2}+\mathrm{n}[\omega]^{2}(\mathbf{k} \cdot \hat{\mathbf{u}})^{2}}\right)=\mathrm{n}[\omega]\left(\mathbf{k}+\hat{\mathbf{u}}\left((\mathbf{k} \cdot \hat{\mathbf{u}})-\sqrt{\left(\frac{\mathrm{n}[\omega]^{\prime}}{\mathrm{n}[\omega]}\right)^{2}-1+(\mathbf{k} \cdot \hat{\mathbf{u}})^{2}}\right)\right)\),
which only depends on the ratio between the two refractive indexes.
Note that no information is provided by Fermat principle about the reflection or transmission coefficients: just a geometrical information is provided. Moreover, Fermat principle applies to the case of one perfectly smooth interface surface. Basically, it means that the imperfections of the surface (roughness) are much smaller than the wavelength. In the case of a surface with significant roughness, also diffuse transmission occurs.

\subsection*{51.03.04 Paraxial Reflection|Refraction at a Spherical Surface}

Beware that different conventions exist in the literature concerning the signs of the different quantities entering equations.

\subsection*{51.03.04.01 Paraxial Reflection at a Spherical Mirror}

This § is referenced at pages:
[2316, 2316]
Both refraction and reflection in general do exist (read § 51.03.04.04-Geometrical|Ray Optics) at a surface, even if there are cases when one of the two can be negligible.

Small angles approximation.
\[
\begin{align*}
& \frac{1}{p}+\frac{1}{q}=-\frac{2}{R} \equiv \frac{1}{f}  \tag{51.03.03}\\
& f_{1}=-\frac{2}{R} \quad \text { for } q \longrightarrow+\infty \\
& f_{2}=-\frac{2}{R} \quad \text { for } p \longrightarrow+\infty
\end{align*}
\]

The equation (51.03.03) shows focusing: the distance \(q\) does not depend on the angle of the ray leaving the object.
Sign Conventions for Reflecting Surfaces:
- Light-side, incoming light, along the \(z\) axis, from left to right (the optical axis);
- Objects on incident-light side: \(p\) is positive;
- Images on reflected-light side: \(q\) is positive, along \(-z\);
- Center of curvature right of \(\mathrm{V}: R\) is positive;
- \(\rho\) positive above the optical axis, erect object and/or image;
- Parameters are negative if they don't meet the above criteria for being positive.

\subsection*{51.03.04.02 Paraxial Refraction at a Spherical Refracting Interface}

This § is referenced at pages:
[2316, 2316, 2317, 2317]
Both refraction and reflection in general do exist (read §51.03.04.01 - Geometrical|Ray Optics) at a surface, even if there are cases when one of the two can be negligible.

Small angles approximation.
\[
\begin{gather*}
\sin _{\frac{\mathrm{n}[\omega]_{1}}{p}+\frac{\mathrm{n}[\omega]_{2}}{q}=\frac{\mathrm{n}[\omega]_{2}-\mathrm{n}[\omega]_{1}}{R}}^{f_{1}=\frac{\mathrm{n}[\omega]_{1} R}{\mathrm{n}[\omega]_{2}-\mathrm{n}[\omega]_{1}}} \quad \text { for } q \longrightarrow+\infty  \tag{51.03.04}\\
f_{2}=\frac{\mathrm{n}[\omega]_{2} R}{\mathrm{n}[\omega]_{2}-\mathrm{n}[\omega]_{1}} \\
\text { for } p \longrightarrow+\infty \\
\hline
\end{gather*}
\]
\[
\rightarrow
\]
\[
2316
\]

The equation (51.03.04) shows focusing: the distance \(q\) does not depend on the angle of the ray leaving the object.
Sign Conventions for Refracting Surfaces:
- Light-side, incoming light, along the \(z\) axis, from left to right (the optical axis);
- Objects on incident-light side: \(p\) is positive;
- Images on refracted-light side: \(q\) is positive, along \(+z\);
- Center of curvature right of \(\mathrm{V}: R\) is positive;
- \(\rho\) positive above the optical axis, erect object and/or image;
- Parameters are negative if they don't meet the above criteria for being positive.

\subsection*{51.03.04.03 Paraxial Refraction at Two|More Close Spherical Interfaces}

This § is referenced at pages:
[Never referenced.]
Consider the surfaces at the same position, that is with zero distance between them. Consider a sequence such that the image of any surface is the object of the next one, accounting for their signs:
\[
\begin{equation*}
p \equiv p_{1} \quad q_{1}=-p_{2} \ldots q_{N-1}=p_{N} \quad q \equiv q_{N} \tag{51.03.05}
\end{equation*}
\]

\subsection*{51.03.04.04 Paraxial Refraction at a Thin Lens}

This § is referenced at pages:
[2316, 2316, 2317, 2317]
Using equation (51.03.05) the equation for the thin lens is found.
Small angles approximation.
\[
\begin{equation*}
\frac{1}{p}+\frac{1}{q}=\frac{\mathrm{n}[\omega]_{L}-\mathrm{n}[\omega]_{0}}{\mathrm{n}[\omega]_{0}}\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right) \equiv \frac{1}{f} \tag{51.03.06}
\end{equation*}
\]

\subsection*{51.03.05 Paraxial Refraction at a Generic Surface}

Small angles approximation.
It goes as in § 51.03.04.04-Geometrical|Ray Optics with the local properties of the surface.
In fact, Reflection|Refraction depend on local properties of the surface only. Therefore, as every surface can be locally approximated, most often, with a quadratic surface, the understanding of spherical surfaces is very important. In fact, within every normal plane, the surface intersection with the normal plane can be approximated with a circumference, so that inside each normal plane ray tracing can benefit from the discussion of spherical surfaces.

\subsection*{51.03.06 Special Paraxial Rays}

Consider a cylindrically symmetrical optical system.
Special Rays for Refracting|Reflecting Surfaces are defined as follows, with reference to either the ray or its extension, forward or backward as required.
- The principle of reversibility of optical paths applies.
- Any ray that passes through the focal point: the Refracting|Reflecting ray is parallel to the central axis, as it is focused to infinity.
- A ray that is initially parallel to the central axis: the Refracting|Reflecting ray passes through the focal point, also form reversibility from the previous point.
- A ray that passes through the center of curvature: the Refracting|Reflecting ray propagates along the same direction as the incident ray.
- A ray that arrives at the vertex of a thin lens passes with the same angle with respect to the axis,
as the two surfaces are parallel each other and perpendicular to the axis.
- A ray that arrives at the vertex of a mirror is reflected with the same angle with respect to the axis, as the surface is perpendicular to the axis.

\subsection*{51.03.07 General Refraction at a Generic Interface}

Equation (51.03.02) must be used, with the local properties of the surface.

\subsection*{51.03.08 Type of lenses|mirrors}

Figure 51.1: Biconvex Lens - WEB - URL.

Figure 51.2: Biconcave Lens - WEB - URL.

\subsection*{51.04}

\section*{General Properties of Optical Systems}
- A real object is one such that light rays physically emanate from the object.
- A real image is one such that light rays physically intersect at the image point.
- A virtual object is one from which light rays appear to emanate, but physically do not.
- A virtual image is one in which light rays do not physically intersect at the image point, but appear to diverge from that point.
- Real images may be displayed on a screen while virtual images may not.

Un sistema ottico è detto stigmatico per una coppia di punti \(P\) e \(P^{\prime}\) se per un cono di raggi luminosi che escono dal punto \(P\) esiste un corrispondente cono di raggi luminosi che passano per il punto \(P^{\prime}\). In tal caso \(P^{\prime}\) è detto immagine perfetta di \(P\).

\subsection*{51.04.01 Object and Image}

Un punto oggetto è un punto che emette raggi luminosi in tutte le direzioni. L'immagine di un punto è un punto in cui convergono i raggi luminosi emessi da un punto oggetto. I due punti sono detti coniugati.

\subsection*{51.04.02 Real and Virtual}

Un raggio reale è un raggio luminoso realmente esistente ed accessibile. Un raggio virtuale si riferisce all'estrapolazione ad una zona non fisica di un raggio reale, non accessibile.

Figure 51.3: Real Image - WEB - URL.

Figure 51.4: Virtual Image - WEB - URL.

\subsection*{51.05}

\section*{Centered Optical Systems}

Un sistema ottico si dice centrato quando il sistema ha simmetria di rotazione attorno ad un asse, detto asse ottico del sistema. I sistemi ottici centrati coprono una gran parte dei sistemi ottici di uso pratico.

\subsection*{51.05.01 Paraxial Approximation}

Dato un sistema ottico centrato nell'approssimazione parassiale si considerano solo i raggi che raggiungono la superficie in un punto a distanza dall'asse ottico piccola rispetto ai raggi di curvatura delle superfici e con angolo piccolo rispetto all'asse ottico.

\subsection*{51.05.02 Magnification}

Il caso di gran lunga più interessante in pratica è quello di un oggetto piano e di una superficie ricevente piana, entrambi perpendicolari all'asse ottico.
L'ingrandimento trasversale è il rapporto tra l'altezza (distanza dall'asse), con segno, dell'immagine, \(h^{\prime}\), e quella dell'oggetto \(h\), con segno:
\[
m_{T} \equiv \frac{h^{\prime}}{h},
\]
è una grandezza che può assumere qualunque valore reale.
L'ingrandimento longitudinale o assiale, lungo l'asse ottico \(z\), è il rapporto tra la lunghezza (con segno) dell'immagine e quella dell'oggetto (con segno) nel limite di piccole lunghezze:
\[
m_{L} \equiv \frac{\Delta z^{\prime}}{\Delta z}
\]
è una grandezza che può assume qualunque valore reale.
L'ingrandimento angolare è il rapporto tra l'angolo (con segno) tra due punti dell'immagine e l'angolo (con segno) tra gli stessi due punti dell'oggetto, nel limite di piccoli angoli:
\[
m_{\alpha} \equiv \frac{\Delta \alpha^{\prime}}{\Delta \alpha}
\]
è una grandezza che può assume qualunque valore reale.

\subsection*{51.05.02.01 Visual Magnification}

Con strumenti ottici la percezione visiva delle dimensioni dell'oggetto dipende dalla sua estensione angolare. L'ingrandimento visuale è il rapporto tra l'estensione angolare dell'immagine relativa a quella dell'oggetto visto direttamente. L'estensione angolare dell'oggetto visto direttamente dipende dalla distanza. Si considera l'oggetto posizionato al punto più vicino che consente visione distinta, convenzionalmente scelta come \(\mathcal{D}=25 \mathrm{~cm}\).

\subsection*{51.05.03 Cardinal and Principal Planes nodal points and planes}

Un qualunque sistema ottico centrato è caratterizzato completamente, nell'approssimazione parassiale, dalla posizione dei suoi piani cardinali.

Un fascio di raggi paralleli all'asse ottico viene focalizzato in un punto dell'asse ottico (secondo fuoco). Il piano passante per il secondo fuoco e perpendicolare all'asse ottico è il secondo piano focale. Un fascio di raggi che escono parallelamente all'asse ottico ha come punto oggetto un punto dell'asse ottico detto primo fuoco. Il piano passante per il primo fuoco e perpendicolare all'asse ottico è il primo piano focale.
Esiste una coppia di piani coniugati (piano oggetto e piano immagine) che sono l'uno l'immagine dell'altro con ingrandimento trasversale unitario. Tali piani sono detti i piani principali.
Esistono due punti dell'asse ottico detti punti nodali: points of an optical system for which an incoming ray, directed at a nodal point, leaves the system with the same direction. I piani corrispondenti perpendicolari all'asse ottico sono detti piani nodali e sono caratterizzati da ingrandimento angolare unitario.
In the frequently encountered situation where the refractive index is the same in front of and behind the optical system, the nodal points coincide with the principal points.

\subsection*{51.05.04 Thin Lenses}

La lunghezza focale di una lente sottile in aria (indice di rifrazione uguale ad uno) è
\[
\frac{1}{f}=(\mathrm{n}[\omega]-1)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}\right)
\]
dove \(R_{1}\) ed \(R_{2}\) sono i raggi di curvatura rispettivamente della prima e della seconda superficie, adottando la convenzione descritta sopra.

Per una lente sottile si ha l'equazione nella forma gaussiana
\[
\begin{equation*}
\frac{1}{o}+\frac{1}{i}=\frac{1}{f} \tag{51.05.01}
\end{equation*}
\]
\(\rightarrow\)
2324

Definendo \(z_{i} \equiv i-f\) e \(z_{o} \equiv o-f\) (distanze rispetto ai fuochi) si ha l'equazione nella forma di Newton
\[
z_{i} z_{o}=f^{2} .
\]

L'ingrandimento lineare vale
\[
M=-\frac{i}{o}
\]

\subsection*{51.05.04.01 Combinazione Di Lenti Sottili}

La distanza focale di una combinazione di due lenti sottili è
\[
\frac{1}{f}=\frac{1}{f_{1}}+\frac{1}{f_{2}}-\frac{d}{f_{1} f_{2}},
\]
dove \(d\) è la distanza tra le due lenti.

\subsection*{51.05.05 Thick Lenses}

La lunghezza focale di una lente spessa è data da
\[
\frac{1}{f}=(\mathrm{n}[\omega]-1)\left(\frac{1}{R_{1}}-\frac{1}{R_{2}}-\frac{t(\mathrm{n}[\omega]-1)}{\mathrm{n}[\omega] R_{1} R_{2}}\right)
\]
dove \(t\) è lo spessore della lente.
Le posizioni dei piani principali sono date da
\[
\begin{aligned}
& d_{1}=f t\left(\frac{1-\mathrm{n}[\omega]}{\mathrm{n}[\omega] R_{2}}\right), \\
& d_{2}=f t\left(\frac{1-\mathrm{n}[\omega]}{\mathrm{n}[\omega] R_{1}}\right) .
\end{aligned}
\]

In una lente spessa tutte le distanze nello spazio oggetto e nello spazio immagine sono misurate a partire dai piani principali e si applica la relazione (51.05.01).

\subsection*{51.07 \\ Optical Aberrations}

Le deviazioni dall'ottica parassiale sono dette aberrazioni che si dividono in aberrazioni monocromatiche, esistenti anche per luce di lunghezza d'onda definita, e cromatiche che dipendono dal fatto che l'indice di rifrazione è in generale funzione della lunghezza d'onda.
L'ottica parassiale si ottiene considerando tutte le relazioni esatte approssimate al primo ordine. Nell'approssimazione successiva, al terzo ordine, le aberrazioni si possono classificare in cinque tipi: aberrazione sferica, coma e astigmatismo, che deteriorano la qualità dell'immagine, distorsione e curvatura di campo che deformano l'immagine senza deteriorarla.

\section*{Examples and Physical Applications}

\subsection*{51.08.01 ParaxialOffAxisRayTracing}

From the fundamental paraxial relations, equations (51.03.03) and (51.03.06), it is easy to trace rays crossing the axis and|or passing by the focii.

Demonstrate, from geometric considerations, that all rays emitted by an off-axis point at an arbitrary angle with the axis in the paraxial approximation are always all focused at the same point.
\[
\frac{f h}{h-f-\frac{f p}{p-f}=\frac{f h(p-f)-f p(h-f)}{()\left(1-f p-h f^{2}-f p h+f^{2}\right.}}
\]

\[
\begin{aligned}
& \frac{p h}{p-n} \frac{p-f}{f k} \quad \| 110 \\
& q^{\prime}=\frac{t h}{h-f}=?
\end{aligned}
\]

\section*{Introduction}

This § is referenced at pages:
[Never referenced.]
While Special Relativity is often presented starting from mechanical experiments and measurements of times and distances, the real historical development originates from analysis classical electromagnetism, as A.Einstein first paper confirms: On the electrodynamics of moving bodies.
Classical ElectroMagnetism turned out to be fully consistent with the Theory of Relativity, while GalileiNewton Mechanics did not. Therefore, Galilei-Newton Mechanics had to be modified in order to make it consistent with the Theory of Relativity. ElectroMagnetism did not require any fundamental modification, but just required to be re-written using the relativistic formalism as well as understood and interpreted in the proper context of the Theory of Relativity, shedding more light on ElectroMagnetic phenomena.
The basic element of the Theory of Relativity is Lorentz Transformation for time and space coordinates, affecting the time-space coordinates of the world. Lorentz Transformation is therefore the basic tool required for physics, before any other development and deserves a very detailed discussion.

After defining the Lorentz Transformation for time and space, the Lorentz group will be used to define the general scalars, vectors and tensors (for the Lorentz group) for any other physical quantity.

\section*{Experimental Basis of Special Relativity}
© \(\mid\) T.Roberts \& S.Schleif \& J.M.Dlugosz|The experimental basis of Special Relativity|Excellent, extensive and detailed|

\section*{© - QUOTE}
©|T.Roberts \& S.Schleif \& J.M.Dlugosz|WEB - URL||

Physics is an experimental science, and as such the experimental basis for any physical theory is extremely important. The relationship between theory and experiments in modern science is a multi-edged sword.
- It is required that the theory not be refuted by any undisputed experiment within the theory's domain of applicability.
- It is expected that the theory be confirmed by a number of experiments that:
- cover a significant fraction of the theory's domain of applicability;
- examine a significant fraction of the theory's predictions.

\section*{Phenomenology}

\subsection*{53.03.01 Asymmetries in the Description of ElectroMagnetic Phenomena}

This § is referenced at pages:
[2425, 2425, 2440, 2440, 2440, 2440]
The example of the bar moving in a constant and uniform magnetic field (section § 33.18.20-Basic Laws of ElectroMagnetism , § 33.18.21 - Basic Laws of ElectroMagnetism) shows that the observer moving with the bar must see an electric field in order to explain the induced currents. This is perfectly coherent with Galilei Transformation (53.04.01).
However, even if this explanation is perfectly correct, the observer moving with the bar seems to be unable to attribute the electric field to any electric charge nor to a time-varying magnetic field, and therefore the appearance of the electric field seems to be a sort of a mystery to him. Apparently he does not know the origin of the electric field: one will discover later on that there are indeed electric charges producing the observed electric field, in its judgment.
Moreover, even if the two observers make the same predictions, they explain the situation in two different ways: what is seen as a magnetic field by one observer is seen as an electric plus magnetic field by another observer in relative motion: while \(\mathbf{B}\) does not change from one observer to the other, \(\mathbf{E}\) does change.
Therefore:
- either the two observers are not equivalent, as they describe in a different way the same phenomena;
- or Electric|Magnetic fields are strictly connected and there is a common underlying framework for both observers.
Note that the asymmetry is only in the description of ElectroMagnetic induction phenomena, not in the phenomena themselves, nor in the predictions that the two observers make. Actually the two observers give the same predictions while describing the phenomena in a different way. Moreover, the observer moving with the bar is troubled by his lack of identification of real charges producing the electric field he is observing. Is this a violation of the Principle of Relativity? Is this just an accident or is it the result of the fact that the two observers are in fact equivalent but this equivalence is a more subtle one?

\subsection*{53.03.02 Internal Forces of a Pair of Moving Charges}

Consider the forces exchanged between two identical charged point particles moving at the same constant velocity \(\mathbf{v}\). Any observer at rest with respect to the particles attributes the force to the Coulomb law only. Other observers must also consider the magnetic field produced by each particle, which acts on the other moving electric charges according to \(\mathbf{v} \times \mathbf{B}\).
Consider now a particular case of two particles such that their velocities are orthogonal to their relative position (they somewhat run side-by-side). The magnetic field force term is opposite to the force term due to the electric field repulsion, thus reducing the repulsive force with respect to the Coulomb force, as the two particles are actually two identical parallel currents. This leads to different relative accelerations observed in the two Rest Frame, which is in contrast with the Galilean relativity principle. Actually the two observers give different predictions and describe the phenomena in different ways; this is an apparent violation of the Principle of Relativity.
How is this explained? Actually forces transform from one Reference Frame to another, in relativistic mechanics, at variance from the Galilei-Newton world, so that the comparison in this example requires a different analysis.

\subsection*{53.03.03 Relative Motion Between a Point Charge and a Small Magnet}

This § is referenced at pages:
[2450, 2450]
Consider the following situation in the light of sections § 56.09.08 - ElectroMagnetism and Relativity. A point charge moves along the positive direction of the \(x\) axis. A small magnet is fixed in the \(x y\) plane with its Magnetic Dipole moment along the positive direction of the \(y\) axis and it is located at some \(y>0\).
For the observer fixed with the magnet, the charge produces a magnetic field at the location of the magnet and the magnet therefore experiences a torque whose direction is along the positive direction of the \(x\) axis.
For an observer in the Rest Frame of the point charge, the magnet is seen moving along the negative direction of the \(x\) axis. It is not immersed in any magnetic field but only in the electric field of the point charge. Therefore the magnet does not experience any torque.
Actually the two observers give different predictions and describe the phenomena in different ways: this is an apparent violation of the Principle of Relativity.
The explanation for this issue has to be found in the fact that, according to Relativity, a moving Magnetic Dipole also possesses an Electric Dipole moment. As the predictions are different, this example is even more troublesome than that in § 33.18.20-Basic Laws of ElectroMagnetism, § 33.18.21 - Basic Laws of ElectroMagnetism.

\section*{SOLUTION}

It turns out that the moving magnet will acquire an Electric Dipole moment and will experience a torque in the electric field of the stationary charge, according to § 56.09.08 - ElectroMagnetism and Relativity.

\subsection*{53.03.04 Action-Reaction Principle (Apparent) Violation in EM}

This § is referenced at pages:
[1320, 1320]
A charge in motion at constant velocity in a Inertial Reference Frame, \(S\), the source charge, sets up a magnetic field. Another charge, the test charge, moves through this ElectroMagnetic field with a velocity u: the test charge experiences a magnetic force in the \(S\) Inertial Reference Frame. Consider an observer in another Inertial Reference Frame, \(S^{\prime}\), which moves relative to \(S\), either with the velocity of the test charge in \(S\) or with the velocity of the source charge in \(S\). In either one of these Rest Frame there will be no magnetic force, for either the velocity of the test charge is zero, or the source charge is at rest and there is no magnetic field: is there or isn't there a magnetic force?

Read § 22.15.02-Galilei-Newton Mechanics of General Systems.

\subsection*{53.04.01 ElectroMagnetism and Galilei-Invariance}

This § is referenced at pages:
[1300, 1300, 2432, 2432]
©|J.A.Heras|The Galilean limits of Maxwell's equations|Am. J. Phys., 78, 1048 (2010); WEB - URL.|

See §22.15.03 - Galilei-Newton Mechanics of General Systems, § 56.03.05 - ElectroMagnetism and Relativity.

The non-relativistic limit of ElectroMagnetism is tricky. This might be expected because ElectroMagnetism is a truly relativistic theory: there are zero mass photons, with zero-mass particles only making sense in relativistic theories, see § 22.04.01 - Galilei-Newton Mechanics of General Systems.

Moreover, charge conservation is a local one, as required by any relativistic theory. On the other hand, in Galilei-Newton Mechanics, charge conservation can be non-local, because simultaneity is an absolute concept: two equal and opposite charges can simultaneously and instantaneously appear at large distances.

Note that in the SI (read § B - International System of Units), the units for the electric field and magnetic field are different. Therefore it is sometimes useful to reduce them to the same units, to better show the relativistic symmetry between the two fields. This can be done by using, instead of the magnetic field, the reduced magnetic field:
\[
\mathbf{B} \rightarrow c \mathbf{B} \equiv \mathbf{B}^{\prime}
\]
as suggested by the Lorentz force, by the relation between the fields in ElectroMagnetic waves in vacuum and by the expressions of the energy densities. This convention makes the transformation formulas for the field a symmetrical one, as for the time-space Lorentz Transformation.

The Galilei-Newton Mechanics transformation law for ElectroMagnetic fields, the so-called instantaneous limit, can be determined as follows.

Galilei Transformation imply that the accelerations in the two inertial Reference Frame are the same but velocities are different. Therefore, when dealing with a velocity dependent force, such as the Lorentz force, one should be careful. In Galilei-Newton Mechanics, the accelerations are the same, so that the Lorentz forces on one point charge are also the same in both Reference Frames. Therefore:
\[
\begin{gathered}
\mathbf{v}=\mathbf{v}^{\prime}+\mathbf{u} \\
\mathbf{E}^{\prime}+\mathbf{v}^{\prime} \times \mathbf{B}^{\prime}=\mathbf{E}+\left(\mathbf{v}^{\prime}+\mathbf{u}\right) \times \mathbf{B} \quad \text { for any } \mathbf{u} \text { and any } \mathbf{v}^{\prime} \\
\mathbf{v}^{\prime}=0 \Longrightarrow \mathbf{E}^{\prime}=\mathbf{E}+\mathbf{u} \times \mathbf{B} \\
\Longrightarrow \mathbf{v}^{\prime} \times\left(\mathbf{B}-\mathbf{B}^{\prime}\right) \quad \text { for any } \mathbf{v}^{\prime} \Longrightarrow \mathbf{B}=\mathbf{B}^{\prime}
\end{gathered}
\]

Therefore, Galilei-Invariance implies:
\[
\begin{equation*}
\mathbf{E}^{\prime}=\mathbf{E}+\mathbf{u} \times \mathbf{B} \quad \mathbf{B}^{\prime}=\mathbf{B} \quad \rho^{\prime}=\rho \quad \mathbf{j}^{\prime}=\mathbf{j}-\rho \mathbf{u} \tag{53.04.01}
\end{equation*}
\]

In fact, many of the equations of ElectroMagnetism, starting with the Lorentz force law, make explicit reference to the velocity of the charge, which presupposes the choice of a Reference Frame with respect to which velocities are to be measured.

However the above relations, technically making the so-called instantaneous limit, are only a part of a much more complex history, see \(\S 56.03 .05\) - ElectroMagnetism and Relativity, and different nonrelativistic limits do exist.
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
Speed of light should always be understood to mean the speed of light in free vacuum space unless it is explicitly stated otherwise. The speed of light in a material medium is, in general, different from \(c\).
It is an experimental fact that no faster method of sending signals has ever been discovered.
The speed of light, in the theory of Relativity, was raised to a fundamental constant of nature, in the sense that it is postulated that there exists a limiting speed, \(c\), that ElectroMagnetic waves or photons in vacuum travel at the limiting speed \(c\) and that this speed is independent of the motion of both the source and the receiver.
It is believed that ElectroMagnetic waves or photons are not unique in this respect but, actually, any massless particle/field would travel, in vacuum, at the same speed as the speed of light, independently of the motion of both the source and the receiver. So, in more general terms, one should say that there exist one and only one invariant speed in vacuum, including, as the most prominent example, the speed of light \({ }^{1}\).
If there is something mysterious in special relativity this is the invariance of the speed of light. Once the invariance of the speed of light is granted, then everything else follows directly and fairly simply, even if many results may appear paradoxical and it is often difficult to feel comfortable with them. Every new situation must be analyzed carefully, without prejudices.
It will be shown, when discussing relativistic dynamics, that an infinite energy is required to accelerate a particle with non-zero mass to the speed of light. Therefore no massive particle can reach the speed of light. On the other hand relativistic dynamics shows that massless particles always travel at the speed of light. The speed of light, therefore, stands out as a limiting, maximum possible, speed. Read § 53.12.01 - From Galilei Transformation to Lorentz Transformation.

Relativistic effects are negligible in real life because the speed of light is so large with respect to everyday speeds. In fact it will be shown that all relativistic effects disappear when the speed of light tends to infinity.

\subsection*{53.05.01 Measurements of the Speed of Light}

It was understood since a long time that light had some finite, even if very large, speed. One should in fact remember the experiments carried on by Galilei with a lamp and an distant friend.
The following basic methods had been employed, historically, to measure the speed of light \({ }^{2}\).
- Prediction of the eclipses times of the main satellite of Jupiter by Romër.
- Measurements of the stellar aberration by Bradley.
- Rotating mirrors and toothed wheels.
- Cavity resonator.
- Electro-optic switch via the Kerr cell.

\footnotetext{
\({ }^{1}\) In fact, following common usage, speed of light will be used, in short
\({ }^{2}\) Read Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., .....
}

\subsection*{53.05.02 Michelson-Morley Experiment}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|15||

The Michelson-Morley experiment was designed to try to detect the ether wind. In fact, it was realized that any effect of the ether wind was indeed very small and therefore only very sophisticated experiments might be able to detect it.

The idea was to measure the speed of light in different directions in the ether frame, to try to detect the changes in the speed of light due to the Earth moving with respect to the ether frame, by also exploiting the annual motion of the Earth. In fact, one would expect different speeds in different directions.

The experiment clearly showed that the ether does not exist, as it did not detect any ether wind, because the measured speed was the same in all directions, while the experiment was in principle sensitive to measure the predicted ether wind.

The null result of Michelson-Morley experiment could only be understood if the speed of light is infinite, but it was known that this is not the case.

On the basis of experimental evidence Einstein then postulated that Galilei Transformation are not correct and must be replaced with new linear transformation law, Lorentz Transformation. As a consequence ElectroMagnetism was all right while Galilei-Newton Mechanics had to be updated.

The new postulate changed drastically the way space and time are conceived.
The invariance of the laws of ElectroMagnetism (Lorentz-Invariance) was taken to apply to all physical phenomena.

The new transformation law must be such that the speed of light is invariant when passing from one inertial Reference Frame to another. Moreover, the new transformation law must transform a motion at uniform velocity into another with uniform velocity and therefore they have to be linear.

\subsection*{53.05.02.01 Analysis of the Michelson-Morley Experiment}

Read also § 48.03.01.02 - Interference Diffraction Wave-Fields and Coherence.
Let the speed of light be have module \(c\) in the unknown ether frame.
Let the Earth travel at a speed \(\mathbf{v}\) with respect to the ether frame.
The Michelson-Morley experiment, using the Michelson interferometer, basically compares, with highprecision, the time for light to travel forth and back a segment, one of the arms of the Michelson interferometer, comparing the travel times along two orthogonal arms.

Assume, for simplicity, that the two orthogonal arms are one parallel and the other one perpendicular to the speed of the Earth, \(\mathbf{v}\), with respect to the ether frame.
\[
\begin{gathered}
v \approx 30 \mathrm{~km} / \mathrm{s} \\
\Delta t_{\|}=\frac{L}{c-v}+\frac{L}{c+v}=\frac{2 L}{c\left(1-v^{2} / c^{2}\right)} \\
\Delta t_{\perp}=\frac{2 L}{c \sqrt{1-v^{2} / c^{2}}} \\
\left|\Delta t_{\perp}-\Delta t_{\|}\right| \simeq \frac{2 L}{c}\left|\left(1+\frac{v^{2}}{2 c^{2}}\right)-\left(1+\frac{v^{2}}{c^{2}}\right)+\mathcal{O}\left[\left(\frac{v}{c}\right)^{4}\right]\right|=\frac{L v^{2}}{c^{3}} \approx 0.3 \cdot 10^{-16} \mathrm{~s}
\end{gathered}
\]
a very small time interval but measurable with a good interferometric technique.

\section*{Postulates of Special Relativity}

All the consequences of the special theory of relativity follow from the following two postulates:
1. The Principle of (Einsteinian) Relativity, § 53.06.01 - From Galilei Transformation to Lorent Z Transformation;
2. The Principle of Invariance of the Speed of Light, § 53.06.02 - From Galilei Transformation to Lorentz Transformation.

\subsection*{53.06.01 Principle of (Einsteinian) Relativity}

This § is referenced at pages:
[2346, 2346]
The relativity principle is assumed to be a principle valid for all the laws of physics, not only for mechanics.
The principle of relativity: space is isotropic and uniform; the fundamental laws of physics are identical for any two inertial observers in uniform relative motion.
Corollary: there exist at least one inertial Reference Frame (and therefore infinite).
53.06.02 Principle of Invariance of the Speed of Light

This § is referenced at pages:
[2346, 2346]
The null result of the Michelson-Morley experiment to detect the drift of the Earth through an ether (as well as other results) can be understood by assuming the following new principle.
The principle of invariance of the speed of light: the speed of light in empty space is independent of both the motion of the light source and the receiver; light propagates in free empty space with a definite velocity \(c\), a universal constant of nature.

\subsection*{53.06.03 Clock Hypothesis/Postulate}

This § is referenced at pages:
[2362, 2362]
The clock hypothesis states that the tick rate of a clock when measured in an inertial frame depends only upon its velocity relative to that frame and it is independent of its acceleration or higher derivatives of position.
It relies on the experiments, such those described in § 53.12.02 - From Galilei Transformation to Lorentz Transformation.

\section*{© - QUOTE}
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
On Accelerated Clocks.
The special theory of relativity describes and relates measurements which are independent of the detailed structure of real bodies. It makes no prediction about the dynamical effects of acceleration,
such as the stresses induced by acceleration. If such stresses are absent or may be ignored, the theory does give us an unambiguous description of the effect of acceleration on clock rates. The result is as if at each instant an accelerated clock had a different velocity, with a rate to be calculated using in Eq. (11.11) the appropriate instantaneous velocity. If this prediction is correct, two consequences follow.
- If the speed is constant but the direction varies, Eq. (11.11) holds without change. The frame of the clock is non-inertial. If the speed is constant except for brief moments of acceleration or deceleration (moments negligibly short in comparison with the total time), then Eq. (11.11) will still describe accurately the relation between the proper time and the stationary laboratory time. A fast charged particle in a constant magnetic field experiences an acceleration perpendicular to its motion, but the speed never changes.
- If the particle is unstable, the measured half-life should be exactly the same as if it moved with the same speed in a straight line with no magnetic field present. This forecast is confirmed by experiments on the \(J / \psi\)-meson, which decays with a proper mean life of \(2.2 \cdot 10^{-6} \mathrm{~s}\) into an electron and neutrinos. The same proper lifetime is observed for \(J / \psi\)-meson which are free or spiraling in a magnetic field or allowed to come to rest. It is believed that the special theory of relativity gives a good description of the circular (accelerated) motion of particles in a magnetic field.
53.06.04 Ultimate Speed

\section*{© - QUOTE}

Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....
... Many other experiments suggest, as this one does, that \(c\) is the upper limit to the velocity of particles. Thus we believe firmly that \(c\) is the maximum signaling speed with either particles or ElectroMagnetic waves: \(c\) is the ultimate speed.

It is, in the end, an experimental fact.

\subsection*{53.07.01 Synchronization of Clocks}

\section*{© - QUOTE}
©|R.Resnick, Introduction To Special Relativity, 1968, J.Wiley \& Sons, ...Ed., ....|||
Some obvious methods of synchronizing clocks turn out to be erroneous. For example, we can set the two clocks so that they always read the same time as seen by observer A. This means that whenever A looks at the B clock it reads the same to him as his clock. The defect here is that if observer B uses the same criterion (that is, that the clocks are synchronized if they always read the same time to him), he will find that the clocks are not synchronized if A says that they are. For this method neglects the fact that it takes time for light to travel from B to A and vice versa. The student should be able to show that, if the distance between the clocks is \(L\), one observer will see the other clock lag his by \(2 L / c\) when the other observer claims that they are synchronous. We certainly cannot have observers in the same Rest Frame disagree on whether clocks are synchronized or not, so we reject this method. An apparent way out of this difficulty is simply to set the two clocks to read the same time and then move them to the positions where the events occur. In principle, we need clocks everywhere in our Rest Frame to record the time of occurrence of events, but once we know how to synchronize two clocks we can, one by one, synchronize all the clocks. The difficulty here is that we do not know ahead of time, and therefore cannot assume, that the motion of the clocks (which may have different velocities, accelerations, and path lengths in being moved into position) will not affect their readings or time-keeping ability. Even in classical physics, the motion can affect the rate at which clocks run.

\subsection*{53.07.02 Reference Frame- Rigid Rulers and Synchronized Clocks}

A Reference Frame is defined as a set of rigid rulers and synchronized clocks.
- Rigid bodies are incompatible with the finite speed of propagation of light. Therefore, starting from a fixed origin and one single clock, one defines the coordinate position of any point from the known speed of light and measurement of the round-trip propagation time: origin-point-origin. In this way, a position label can be attached to every point in space. Note that measuring time on a closed path allows to avoid any problem with synchronization of clocks: only one clock is used.
- Secondly, one puts identical clocks at every point in space; the clocks are then synchronized from the known distance from the origin and the known speed of light. In this way, all clocks can be synchronized with the one at the origin. It is then assumed transitivity of the clocks are synchronized relation.

\subsection*{53.07.03 Events and Lorentz Intervals}

An event is a well defined and unambiguously identifiable circumstance happening at a well defined time and at a well defined place, in any Reference Frame. It is thus characterized by a time and space coordinate:
\[
\mathcal{E} \equiv\{t, \mathbf{x}\}
\]

Given two events, \(\mathcal{E}_{1} \equiv\left\{t_{1}, \mathbf{x}_{1}\right\}\) and \(\mathcal{E}_{2} \equiv\left\{t_{2}, \mathbf{x}_{2}\right\}\) their Lorentz invariant interval is defined as:
\[
\begin{equation*}
(\Delta s)^{2} \equiv c^{2}(\Delta t)^{2}-(\Delta \mathbf{x})^{2}=c^{2}\left(t_{2}-t_{1}\right)^{2}-\left(\mathbf{x}_{2}-\mathbf{x}_{1}\right)^{2} \tag{53.07.01}
\end{equation*}
\]

The quantity \(\Delta s\) has the same value for any inertial observer when calculated between the same to events. The invariance of the Lorentz interval can be checked for the special cases discussed above.

This § is referenced at pages:
[2354, 2354]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
Whenever a inertial Reference Frame moves with respect to another Reference Frame with relative velocity \(\mathbf{u}\) it is common practice to introduce the shorthand notations:
\[
\beta_{u} \equiv \beta[u] \equiv \frac{u}{c} \quad \gamma_{u} \equiv \gamma[u] \equiv \frac{1}{\sqrt{1-u^{2} / c^{2}}}
\]

Whenever there is no possibility of confusion about which velocity beta and gamma refer to, the notation is usually simplified to: \(\beta_{u} \equiv \beta, \gamma_{u} \equiv \gamma\).

\subsection*{53.08.01 Relativity of Simultaneity}

Consider a light source at the center of a freight-car moving with constant velocity \(\mathbf{u}\).
The light source emits a lamp at a certain time and the arrival of the light signals at the two extremes of the freight-car (of rest length \(L^{\prime}\) ) are recorded (events \(\varepsilon_{+}\)and \(\varepsilon_{-}\)).
The observer inside the freight-car says that the two events are simultaneous, and that the light travel lasts
\[
\Delta t^{\prime}=L^{\prime} /(2 c)
\]

The observer on the ground measures two different time durations, \(\Delta t_{+}\)and \(\Delta t_{-}\), as the freight-car is moving during the light travel:
\[
\begin{aligned}
c \Delta t_{+}=L / 2+u \Delta t_{+} & c \Delta t_{-}=L / 2-u \Delta t_{-} \\
\Delta t_{+}=L /(2(c-u)) & \Delta t_{-}=L /(2(c+u))
\end{aligned}
\]

Here we are looking at both the moving photon and the two moving ends of the freight-car and calculate the mutual velocity between the photon and the leading/trailing side of the freight-car, read § 54.01.05Relativistic Kinematics. There is no problem here: the same observer is looking at two different objects and finds mutual velocities \(u-c\) and \(u+c\), for the leading/trailing side of the freight-car.
Therefore simultaneity is a relative concept: two events which happen at the same time, but at different places, for one observer may be not simultaneous for another observer.
Note that in the case of infinite speed of propagation of light, \(c \gg u\), the simultaneity is recovered as \(\Delta t_{+}=\Delta t_{-}\). In fact the freight-car has to be going very fast in order the discrepancy becomes easily detectable.
Note that \(L\) and \(L^{\prime}\), the two lengths, are not the same, a priori, but this does not affect the conclusion that the two events \(\mathcal{E}_{+}\)and \(\mathcal{E}_{-}\)are simultaneous in one Reference Frame and are not in the other.
Two events that are simultaneous at different places in one Inertial Reference Frame may be not simultaneous, in general, in another Inertial Reference Frame .
Note that the relativity of simultaneity makes problematic the application of the action-reaction principle. Consider in fact the case of time-dependent forces: action-reaction must be equal and opposite at the same time but, as simultaneity is a relative concept, another observer may not agree on the fact that action and reaction are equal and opposite. Only in the case of point-contact interactions, with the two forces applied at the same physical point (as well as in the trivial case where the forces are constant), the action-reaction principle can be retained.
Note also that the effect is a real one, depending on how time floes, not to be confused with spurious effects such as the time delay between lighting and thunder.

\subsection*{53.08.02 Time Dilatation (Time Interval Between the Same Two Events)}

Consider a light source at the center of the ceiling of a freight-car moving with constant velocity \(\mathbf{u}\).
Consider a light ray which strikes the floor just below the light source for the observer inside the freight-car. Let \(H^{\prime}\) be the rest height of the lamp from the floor.
For the observer inside the freight-car the time between light emission and light reaching the floor is:
\[
\Delta t^{\prime}=H^{\prime} / c
\]

For the observer on the ground the time between light emission and light reaching the floor is:
\[
c^{2} \Delta t^{2}=H^{2}+u^{2} \Delta t^{2} \quad \Delta t=H / \sqrt{c^{2}-u^{2}},
\]
with the same same speed \(c\), but for this observer the light makes a longer travel as the freight-car is moving.
Note that the height of the freight-car is the same for both observers, as demonstrated in § 53.08.03From Galilei Transformation to Lorentz Transformation:
\[
H^{\prime}=H
\]

Therefore one finds the time dilatation formula:
\[
\begin{equation*}
\Delta t=\gamma \Delta t^{\prime} \tag{53.08.01}
\end{equation*}
\]
the time elapsed between the same two events (light leaves light source and light strikes the floor just below the light source) is different for the two observers.
Running clocks, thus, run slow.
The proper time is the time in the Reference Frame where the two events happen at the same place ( \(\mathrm{x}_{1}=\mathrm{x}_{2}\) ) or, as a weaker condition applying in this problem, at the same place only in the coordinate along the velocity \(\mathbf{u}\).
Note that the result concerns time itself, not the way clocks work, as it is experimentally demonstrated by experiments on many systems.
Note that in the case of infinite speed of propagation of light, \(c \gg u\), the time dilatation disappears. In fact the freight-car has to be going very fast in order the discrepancy becomes easily detectable.
It might appear that the time dilatation, in particular the fact that running clocks run slow, violates the principle of relativity, but it does not. In fact consider how two different observers measure the rate at which a moving clock is running: they are measuring two different things.

\subsection*{53.08.03 Length Contraction (Distance Between the Same Two Events at the Same Time)}

This § is referenced at pages:
[2351, 2351, 2354, 2354]
Note that every measure of length must be carried on by taking the position of all the points at the same time: as simultaneity is a concept relative to the observer, length measurements may depend on the observer.

\subsection*{53.08.03.01 Length Contraction Along the Direction of Motion}

As the speed of light in free space is, by hypothesis, a universal constant, it can be used to measure lengths.
Consider a light source at one end of a freight-car moving with constant velocity \(\mathbf{u}\). There is reflecting mirror on the other side.
For the observer inside the freight-car the travel time is related to the length, \(\Delta L^{\prime}\), of the freight-car by:
\[
\Delta t^{\prime}=\frac{2 \Delta L^{\prime}}{c}
\]

For the observer on the ground the travel time is related to the length, \(\Delta L\), of the freight-car by:
\[
\Delta t=\Delta t_{+}+\Delta t_{-}=\frac{\Delta L}{(c-u)}+\frac{\Delta L}{(c+u)} \Longrightarrow \Delta t=\frac{2 \Delta L c}{\left(c^{2}-u^{2}\right)}
\]
as given by the sum of two travel times \(\Delta t_{+}\)and \(\Delta t_{+}\)with mutual velocity \(c+u\) and \(c-u\) between the light and the freight-car.

Here, again, the mutual velocity as seen by the ground observed, between light and the freight-car, is used.
These two time intervals are related by the time dilatation formula (53.08.01), so that we obtain the length contraction formula:
\[
\begin{equation*}
\Delta L=\Delta L^{\prime} / \gamma \tag{53.08.02}
\end{equation*}
\]

Moving objects are thus shortened.
Note that in the case of infinite speed of propagation of light, \(c \gg u\), the length contraction disappear. In fact the freight-car has to be going very fast in order the discrepancy becomes easily detectable.

Note that it does not matter that the path is asymmetrical for the moving observer one just uses the correct formula relating time and space.

\subsection*{53.08.03.02 Length (Non)-Contraction Perpendicularly to the Direction of Motion}

It should be emphasized that moving objects are shortened only along the direction of motion (that is parallel to the velocity \(\mathbf{u}\) ).
There is no shortening in the direction perpendicular to motion.
The following argument applies \({ }^{3}\). Suppose the train is running near a wall where a horizontal blue line is painted at one meter height from the ground. A woman inside the train leans out the window and paints a horizontal red line one meter above the ground. Which of the two lines is higher? If, for instance, lengths in direction perpendicular to the velocity contracts, then the man on ground would predict the red line is lower than the blue line. On the other hand the woman on the train would predict the red line is higher than the blue line (as the wall is moving for the woman). The principle of relativity allows us to conclude that the two lines must coincide:
\[
\begin{array}{|lll|}
\hline x^{\prime}=x & y^{\prime}=y & \text { for } \mathbf{u} \| \hat{\mathbf{e}}_{3} \\
\hline
\end{array}
\]

Note that no subtlety of synchronization enters this reasoning.
Of course, there is no direct experimental measurement of Lorentz contraction, because it is not practically possible to get an object of measurable size going near the speed of light.

\title{
Lorentz Transformation of Space-Time Coordinates
}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 12.1.3|Alternative derivation.|

\subsection*{53.09.01 Special Transformations of Space-Time coordinates}

This § is referenced at pages:
[Never referenced.]
© |Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|11|A more general Ansatz.|
This special case contains all the essential ingredients of Relativity without too much non essential mathematical complexity.
Consider the special case when the Cartesian axes of both Coordinate System are parallel and with the same orientation, that the two origins coincide at times \(t=t^{\prime}=0\) and that the velocity of Reference Frame \(\mathcal{J}^{\prime}\) with respect to Reference Frame \(\mathcal{J}\) is parallel to both \(z\) and \(z^{\prime}\) axes and let its component along \(z\) be \(\mathbf{u} \equiv u \hat{\mathbf{e}}_{3}\).

Note that the transformation must be a linear one, as the inertia principle requires that a uniform rectilinear motion is transformed into a uniform rectilinear motion.
Assume that at \(t=t^{\prime}=0\) a short light lamp is emitted at the coincident origins of the two Reference Frames: \(\mathbf{r}=\mathbf{r}^{\prime}=0\).
The equation of motion of the light front is a spherical one, in both Reference Frames, thanks to the isotropy of space and the speed of light is the same, for both Reference Frames:
\[
x^{2}+y^{2}+z^{2}=c^{2} t^{2} \quad x^{\prime 2}+y^{\prime 2}+z^{\prime 2}=c^{2} t^{\prime 2} .
\]

In fact every inertial observer must see a spherical light front, independently on the velocity of the light source.
The correct time-space transformations must transform the first expression into the second one:
\[
x^{2}+y^{2}+z^{2}=c^{2} t^{2} \longrightarrow x^{\prime 2}+y^{\prime 2}+z^{\prime 2}=c^{2} t^{\prime 2} .
\]

\subsection*{53.09.01.01 Special Galilei Transformation Are Not Compatible With the New Postulates}

This § is referenced at pages:
[2354, 2354]
When using Galilei Transformation (22.15.02) in the second equation one finds:
\[
x^{2}+y^{2}+z^{2}+\left(u^{2} t^{2}-2 z u t\right)=c^{2} t^{2}
\]

It is therefore clear that Galilei Transformation cannot manage the equality of the speed of light in both Reference Frames, due to the Galilean law of addition of the velocities.
Moreover, in order to cancel the undesired time dependence \(u^{2} t^{2}-2 z u t\) one needs to invoke a dependence on time of the space component \(z\). In fact, since the distances perpendicular to the speed \(\mathbf{u}\) cannot change, it is assumed that \(t^{\prime}\) only depends on \(z^{\prime}\).
As a result of the previous reasoning we are led to § ?? - ??.

\subsection*{53.09.01.02 Derivation of the Special Lorentz Transformation}

Continue as in \(\S 53.09 .01 .01\) - From Galilei Transformation to Lorentz Transformation.
The relativity of time intervals, derived in section \(\S 53.08\) - From Galilei Transformation to Lorentz Transformation, unavoidably compels us to assume a transformation which includes and mixes space and time coordinates.

In order to be consistent with the principle of inertia the space-time transformations between any two inertial Reference Frames must be a linear one, as any uniform motion must be mapped into a uniform motion.

The principle of reciprocity is also assumed: whenever the velocity of Reference Frame \(\mathcal{J}^{\prime}\) with respect to Reference Frame \(\mathcal{J}\) is \(\mathbf{u}\), the velocity of Reference Frame \(\mathcal{J}\) with respect to Reference Frame \(\mathcal{J}^{\prime}\) is \(-\mathbf{u}\).

In order to find the one-dimensional Lorentz Transformation (and its inverse) one can try the following educated guess, in terms of the so far unknown parameter \(\gamma\) :
\[
u \equiv \mathbf{u} \cdot \hat{\mathbf{e}}_{3} \gtreqless 0
\]
\[
z^{\prime}=\gamma(z-u t) \quad \Leftrightarrow \quad z=\gamma\left(z^{\prime}+u t^{\prime}\right)
\]
by inverting the second one above to find \(t^{\prime}\) and using the first one above to replace \(z^{\prime}\) one finds:
\[
t^{\prime}=\gamma t+\frac{z}{u}\left(\frac{1-\gamma^{2}}{\gamma}\right) \quad \Leftrightarrow \quad t=\gamma t^{\prime}-\frac{z}{u}\left(\frac{1-\gamma^{2}}{\gamma}\right)
\]

The, so far unknown, factor \(\gamma\) is necessarily a function of the module of the velocity \(\mathbf{u}\), thanks to the isotropy of space.

In order to preserve the orientation of the flow of time we must impose: \(\gamma \geq 0\).
Note that the principle of reciprocity has been used, so that the double implication applies in equations (53.09.01.02), (53.09.01.02) as the observer \(\mathcal{J}^{\prime}\) sees the inertial Reference Frame \(\mathcal{J}\) moving with velocity \(-\mathbf{u}\).

The constancy of the speed of light implies
\[
\begin{equation*}
\left\{z=c t \quad \Leftrightarrow \quad z^{\prime}=c t^{\prime}\right\} \tag{53.09.01}
\end{equation*}
\]
and using equations (53.09.01.02), (53.09.01.02) in the first relation above and comparing the result with the second relation above, one has
\[
\begin{equation*}
\gamma^{2}=\frac{1}{1-u^{2} / c^{2}} \geq 1 \tag{53.09.02}
\end{equation*}
\]

Note that the above relation (53.09.01) cannot be satisfied by any Galilei Transformation (except for \(c \rightarrow \infty)\).

It follows that:
\[
t^{\prime}=\gamma\left(t-\frac{u z}{c^{2}}\right) \quad \Leftrightarrow \quad t=\gamma\left(t^{\prime}+\frac{u z^{\prime}}{c^{2}}\right)
\]

Moreover, we already know (read § 53.08.03 - From Galilei Transformation to Lorentz Transformation) that:
\[
x^{\prime}=x \quad y^{\prime}=y .
\]

Let
\[
\beta \equiv \frac{u}{c} \quad \gamma \equiv \frac{1}{\sqrt{1-\beta^{2}}} .
\]

\subsection*{53.09.01.03 The Special Lorentz Transformation}

All in all we have the special Lorentz Transformation:
\[
\begin{equation*}
z^{\prime}=\gamma(z-u t) \tag{53.09.05}
\end{equation*}
\]

And the inverse Lorentz Transformation:
\[
\begin{gather*}
\begin{array}{c}
t=\gamma\left(t^{\prime}+u z^{\prime} / c^{2}\right) \\
x=x^{\prime} \\
y=y^{\prime} \\
z=\gamma\left(z^{\prime}+u t^{\prime}\right) \\
\hline
\end{array},  \tag{53.09.07}\\
. \tag{53.09.08}
\end{gather*}
\]

In the instantaneous non-relativistic limit the Lorentz Transformation become the Galilei Transformation.

\subsection*{53.09.01.04 Special Lorentz Transformation in Matrix Form}

The special Lorentz Transformation read, in matrix form:
\[
r \equiv\{c t ; x, y, z\} \equiv\{c t ; \mathbf{r}\} \quad r^{\prime}=\mathbb{L} r \quad \text { with } \quad \mathbb{L}=\left(\begin{array}{cccc}
\gamma & 0 & 0 & -\beta \gamma \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-\beta \gamma & 0 & 0 & \gamma
\end{array}\right)
\]

\subsection*{53.09.01.05 Inverse Special Lorentz Transformation}

Inverse special Lorentz Transformation can be obtained by the replacement \(\beta \rightarrow-\boldsymbol{\beta}\). It can be shown by direct calculation that the inverse Lorentz Transformation, given replacing \(\beta \rightarrow-\beta\), is described by the matrix inverse of the Lorentz Transformation one (according to (53.09.17)):
\[
\{\boldsymbol{\beta} \rightarrow-\boldsymbol{\beta}\} \quad \Leftrightarrow \quad\left\{\mathbb{L} \rightarrow \mathbb{L}^{-1}\right\}
\]

\subsection*{53.09.01.06 Composition of Two Special Lorentz Transformation Along the Same Direction}

Imagine to apply two different Lorentz Transformation along the same \(z\) direction, from the Reference Frame \(\mathcal{J}_{1}\) to \(J_{2}\) (with velocity \(v_{12}\) along \(z\) ) and from the Reference Frame \(\mathcal{J}_{2}\) to \(\mathcal{J}_{3}\) (with velocity \(v_{23}\) along \(z)\).
Determine the Lorentz matrix corresponding to the composite Lorentz transformation from the Reference Frame \(\mathcal{J}_{1}\) to \(\mathcal{J}_{3}\) (with velocity along \(z\) ).
By explicit calculation of the product of the two matrices, \(\mathbb{L}_{23}\left[v_{23}\right]\) and \(\mathbb{L}_{12}\left[v_{12}\right]\), and remembering that the matrix of a special Lorentz Transformation has the main diagonal \(\{\gamma, 1,1, \gamma\}\) one finds:
\[
\mathbb{L}_{13}=\mathbb{L}_{23}\left[v_{23}\right] \mathbb{L}_{12}\left[v_{12}\right]=\mathbb{L}_{13}\left[\frac{v_{12}+v_{23}}{1+v_{12} v_{23} / c^{2}}\right]
\]

The following algebraic identity must be used:
\[
\gamma[v] \equiv \frac{1}{\sqrt{1-v^{2} / c^{2}}} \quad \gamma\left[v_{12}\right] \gamma\left[v_{23}\right]\left(1+v_{12} v_{23} / c^{2}\right)=\gamma\left[\frac{v_{12}+v_{23}}{1+v_{12} v_{23} / c^{2}}\right]
\]
53.09.01.07 Special Lorentz Transformation and Rapidity
©|Am.J.Phys, , ..., ..., ...Ed., .... 47 (12) 1979|Additivity, rapidity, relativity||
The special Lorentz Transformation can be written in the alternative form in terms of hyperbolic functions (read § 12.03.02 - Basic Mathematical Relations):
\[
r^{\prime}=\mathbb{L} r \quad \text { with } \quad \mathbb{L}=\left(\begin{array}{cccc}
+\operatorname{coh} \chi & 0 & 0 & -\operatorname{sih} \chi \quad, \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & , \\
-\sin \chi & 0 & 0 & +\operatorname{coh} \chi
\end{array}\right)
\]
where the \(\chi\) parameter, defined by relations:
\[
\begin{array}{|c|}
\hline \gamma \equiv \operatorname{coh} \chi \equiv \frac{\exp [+\chi]+\exp [-\chi]}{2} \\
\hline \beta \gamma \equiv \sin \chi \equiv \frac{\exp [+\chi]-\exp [-\chi]}{2} \\
\hline \beta \equiv \operatorname{tah}[\chi] \equiv \frac{\exp [+\chi]-\exp [-\chi]}{\exp [+\chi]+\exp [-\chi]} \\
\hline
\end{array},
\]
is called rapidity.
Special Lorentz Transformation expressed in terms of rapidity have the nice property that the special Lorentz Transformation corresponding to two special Lorentz transformations in series, both with the velocities parallel to the same \(z=z^{\prime}=z^{\prime \prime}\) axes, has a rapidity given by the algebraic sum of the rapidities of the two transformations in series (hyperbolic functions).
This is analogous to the fact, from elementary geometry, that when composing two rotations in series in the same plane the overall rotation has a rotation angle given by the algebraic sum of the angles of the two rotations. This is manifest when using the rotation angle as a parameter for the rotation (trigonometric functions). It is not at all obvious if one would use, for instance, the cosinus or the sinus of the angle as the rotation parameter: in this case the overall rotation would not be described by the sum of the parameters of the two rotations.

Therefore, note the similarity between the Lorentz matrix in terms of rapidity and the one describing ordinary rotations in euclidean space.

\subsection*{53.09.02 Boosts}

This § is referenced at pages:
[Never referenced.]
As a second particular case of Lorentz Transformation, consider the case when the Cartesian axes of both Coordinate System are parallel to each other and with the same orientation, that the two origins coincide at times \(t=t^{\prime}=0\) and the velocity of Reference Frame \(\mathcal{J}^{\prime}\) with respect to Reference Frame \(\mathcal{J}\) is the arbitrary, \(\mathbf{u}\). These kind of transformation is called boost or pure Lorentz Transformation.

The transformation can be obtained by simply decomposing the spatial portion of the vectors into vectors parallel and perpendicular to the velocity and read:
\[
\begin{gathered}
t^{\prime}=\gamma(t-\boldsymbol{\beta} \cdot \mathbf{r} / c) \\
\mathbf{r}^{\prime}=\mathbf{r}+\boldsymbol{\beta}\left(\frac{\gamma^{2}}{\gamma+1}(\boldsymbol{\beta} \cdot \mathbf{r})-\gamma c t\right)=\mathbf{r}+\boldsymbol{\beta}\left(\frac{\gamma-1}{\beta^{2}}(\boldsymbol{\beta} \cdot \mathbf{r})-\gamma c t\right)
\end{gathered}
\]

The following identity is often useful to deal with the above expressions:
\[
\frac{\gamma^{2}}{\gamma+1}=\frac{\gamma-1}{\beta^{2}}
\]

The Lorentz Transformation matrix has the following form for a boost along a direction indicated by the unit vector:
\[
\mathbb{L}=\left(\begin{array}{cc}
\mathbb{L}_{\cdot 0}^{0 \cdot} & \mathbb{L}_{\cdot j}^{0 \cdot}  \tag{53.09.13}\\
\mathbb{L}_{\cdot 0}^{k \cdot} & \mathbb{L}_{\cdot j}^{k \cdot}
\end{array}\right)=\left(\begin{array}{cc}
\gamma & -\beta \gamma \hat{n}_{j} \\
-\beta \gamma \hat{n}^{k} & (\gamma-1) \hat{n}^{k} \hat{n}_{j}^{\cdot}+\delta_{\cdot j}^{k \cdot}
\end{array}\right) \quad \hat{\mathbf{n}} \equiv \frac{\mathbf{u}}{u}
\]

Note that, for three-dimensional vectors, the position of the index, either high or low, is not relevant:
\[
\hat{\mathbf{n}} \equiv\left\{\hat{n}_{\cdot}^{k}\right\}=\left\{\hat{n}_{k}\right\} \equiv \hat{\mathbf{n}}
\]

This expression is coherent with equation (53.09.17): to take the inverse matrix one must change \(+\mathbf{n} \longrightarrow-\mathbf{n}\).

One should not forget that the 3-vectors in equations (53.09.11) and (53.09.12) must be considered in a pure algebraic sense, that is as triples of real numbers as they actually belong to different Euclidean spaces. In other words, they do not transform as the 3 -vectors under spatial rotations, \(\mathrm{SO}(3)\).

\subsection*{53.09.02.01 Transformation of the Parallel and Transverse Components of the Time-Space Four-Vector}

From the equations \((53.09 .11)\), \((53.09 .12)\) one can derive the following relations, for the Lorentz Transformation of the space components:
\[
\begin{equation*}
\mathbf{r}_{\|}^{\prime}=\gamma\left(\mathbf{r}_{\|}-c \boldsymbol{\beta} t\right) \quad \mathbf{r}_{\perp}^{\prime}=\mathbf{r}_{\perp} \tag{53.09.14}
\end{equation*}
\]

They are consistent with the special case of the special Lorentz Transformation.

\subsection*{53.09.03 Rotations - sub-group of Lorentz Transformation}

\subsection*{53.09.04 General Lorentz Transformation}

Consider two Inertial Reference Frames, \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\). Assume that \(\mathcal{J}^{\prime}\) is moving, with respect to \(\mathcal{J}\), with a speed u. Assume that a orthonormal Cartesian Coordinates Coordinate System and a time coordinate are defined in both Inertial Reference Frames.

Lorentz Transformation give the relation between the time-space coordinates of the Inertial Reference Frame \(\mathcal{J}\), the four-tuple of real numbers \(x^{\mu} \equiv\left\{c t, x_{1}, x_{2}, x_{3}\right\}\), and the time-space coordinates of the Inertial Reference Frame \(\mathcal{J}^{\prime}\), the four-tuple of real numbers \(x^{\prime \mu} \equiv\left\{c t^{\prime}, x^{\prime}{ }_{1}, x^{\prime}{ }_{2}, x^{\prime}{ }_{3}\right\}\). Note that the Greek four-dimensional indexes \(\{\ldots\}^{\mu}\) are placed high.

Define the real \(4 \times 4\) matrix of the linear transformation between \(x^{\mu} \equiv\left\{c t, x_{1}, x_{2}, x_{3}\right\}\) and \(x^{\prime \mu} \equiv\left\{c t^{\prime}, x^{\prime}{ }_{1}, x^{\prime}{ }_{2}, x^{\prime}{ }_{3}\right\}\) as \(\mathbb{L}\) :
\[
x \longrightarrow x^{\prime} \quad x^{\prime}=\mathbb{L} x
\]

Let:
\[
x^{0} \equiv c t \quad x^{\prime 0} \equiv c t^{\prime}
\]

The Lorentz Transformation can be written, with explicit indexes, as:
\[
x^{\prime \mu} \cdot=\mathbb{L}_{\cdot \nu}^{\mu \cdot} x_{\cdot}^{\nu}
\]

The general Lorentz Transformation between \(x^{\mu} \equiv\{c t, x, y, z\}\) and \(x^{\prime \mu} \equiv\left\{c t^{\prime}, x^{\prime}, y^{\prime}, z^{\prime}\right\}\) are derived from the basic postulates of the relativity theory as the set of linear transformations leaving invariant the matrix \(\boldsymbol{\eta}\) (the metric tensor):
\[
\eta_{\mu \nu} \equiv \eta^{\mu \nu} \ldots\left(\begin{array}{cccc}
+1 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & -1
\end{array}\right) .
\]

As a matrix \(\boldsymbol{\eta}\) has the following properties (by direct calculation):
\[
\eta=\boldsymbol{\eta}^{-1}=\boldsymbol{\eta}^{\mathrm{T}} \quad \boldsymbol{\eta} \boldsymbol{\eta}=\mathbb{I} .
\]

The matrix \(\boldsymbol{\eta}\) with high indexes is defined as the inverse of the \(\boldsymbol{\eta}\) with low indexes which therefore equals \(\boldsymbol{\eta}\) with high indexes as \(\boldsymbol{\eta}=\boldsymbol{\eta}^{-1}\) :
\[
\eta^{\mu \nu} . \equiv\left(\eta^{-1}\right)_{\mu \nu}^{\curvearrowleft} \quad \text { no index convention }
\]

In components one finds:
\[
\eta_{\cdot}^{\alpha \rho} \eta_{\rho \beta} \ddot{\theta}=\delta_{\cdot \beta}^{\alpha \cdot} \equiv \eta_{\cdot \beta}^{\alpha \cdot} .
\]

In fact the \(\boldsymbol{\eta}\) matrix, the metric tensor, is used to raise and lower the indexes (read \(\S 18\) - Coordinate Transformations Tensors and Physical Laws).
Lorentz Transformation are defined by the set of real \(4 \times 4\) matrices, \(\mathbb{L}\), satisfying the Lorentz condition:
\[
\begin{equation*}
\boldsymbol{\eta}=\mathbb{I}^{\mathbb{T}} \boldsymbol{\eta} \mathbb{L} \tag{53.09.15}
\end{equation*}
\]

In terms of explicit indexes condition (53.09.15) becomes:
\[
\begin{equation*}
\boldsymbol{\eta}=\mathbb{L}^{\mathrm{T}} \boldsymbol{\eta} \mathbb{L} \Longrightarrow \eta_{\mu \nu}^{\ddot{ }}=\mathbb{L}^{\mathrm{T}} \cdot{ }_{\mu} \cdot \eta_{\dot{\alpha} \dot{\beta}} \mathbb{L}^{\beta} \cdot{ }_{\nu}^{\prime}=\mathbb{L}_{\cdot}^{\alpha} \cdot \tilde{\mu}^{\beta} \cdot{ }_{\nu}^{\beta \cdot} \eta_{\alpha \dot{\beta}} \tag{53.09.16}
\end{equation*}
\]

The inverse Lorentz Transformation matrix can be derived in a straightforward way from the condition (53.09.15) by right multiplying by \(\mathbb{L}^{-1}\) and left multiplying by \(\eta\) :
\[
\begin{equation*}
\mathbb{L}^{-1}=\boldsymbol{\eta} \mathbb{L}^{\mathrm{T}} \boldsymbol{\eta} \tag{53.09.17}
\end{equation*}
\]

The Lorentz matrix inversion thus amounts to just transposing and changing the sign of the elements on the first row and first column, except for the \(L_{.0}^{0}\) element as implied by equation (53.09.17).

From equation (53.09.17), after left multiplication by \(\mathbb{L}\) and right multiplication by \(\boldsymbol{\eta}\), one also obtains:
\[
\begin{equation*}
\boldsymbol{\eta}=\mathbb{L} \boldsymbol{\eta} \mathbb{L}^{\mathrm{T}} \Longrightarrow \eta_{\mu \nu}^{\ddot{ }}=\mathbb{L}_{\mu}^{\cdot} \cdot{ }^{\alpha} \cdot \eta_{\alpha \dot{\beta}} \mathbb{L}^{\mathrm{T}} \cdot \nu=\mathbb{L}_{\mu} \cdot{ }_{\mu}^{\alpha} \mathbb{L}_{\nu} \cdot{ }^{\beta} \cdot \eta_{\dot{\alpha} \dot{\beta}} . \tag{53.09.18}
\end{equation*}
\]

Finally, from equation (53.09.17), one obtains:
\[
\begin{equation*}
\left(\mathbb{L}^{-1}\right)^{\mathrm{T}}=\left(\mathbb{L}^{\mathrm{T}}\right)^{-1}=\boldsymbol{\eta} \mathbb{L} \boldsymbol{\eta} \tag{53.09.19}
\end{equation*}
\]

When handling Lorentz matrices and indexes one should carefully remember the rules/conventions stated in § 18.02.03 - Coordinate Transformations Tensors and Physical Laws.
The following additional conditions define the orthochronous proper Lorentz Transformation:
\[
\begin{array}{|ll|}
\hline \operatorname{det}[\mathbb{L}]=+1 & \mathbb{L}_{\cdot 0}^{0 .} \geq 1  \tag{53.09.20}\\
\hline
\end{array}
\]
\[
1,-1+\rightarrow
\]
which corresponds to exclude from Lorentz Transformation both Space-Inversion parity inversion and time inversion.

\subsection*{53.09.04.01 Algebra of Lorentz Matrices}
©|E.Massa|Appunti di Fisica Matematica||
The Lorentz Transformation form a group, the Lorentz group, defined as the group of all the \(4 \times 4\) real matrices such that the Lorentz condition (53.09.16) is satisfied:
\[
\boldsymbol{\eta}=\mathbb{L}^{\mathrm{T}} \boldsymbol{\eta} \mathbb{L} .
\]

The additional restrictions (53.09.20)
\[
\operatorname{det}[\mathbb{L}]=+1 \quad \mathbb{L}_{\cdot 0}^{0} \geq 1
\]
correspond to exclude both the Space-Inversion parity inversion and the Time-Reversal, thus defining a sub-group of the Lorentz group, the orthochronous and proper Lorentz group.
The general Lorentz Transformation matrix can be written, in block form, as:
\[
\mathbb{L}=\left(\begin{array}{ll}
\gamma & \mathbb{R} \\
\mathbb{C} & \mathbb{M}
\end{array}\right)
\]
where:
- \(\mathbb{R}\) is a \(1 \times 3\) matrix, and \(R\) is a mnemonics for row;
- \(\mathbb{C}\) is a \(3 \times 1\) matrix, and \(C\) is a mnemonics for column;
- \(\mathbb{M}\) is a \(3 \times 3\) matrix, and \(M\) is a mnemonics for matrix.

We have:
\[
\mathbb{I}^{\mathbb{T}}=\left(\begin{array}{cc}
\gamma & \mathbb{C} \\
\mathbb{R}^{\mathbb{R}} & \mathbb{M}^{\mathbb{T}}
\end{array}\right)
\]

Moreover, equations (53.09.17) implies:
\[
\mathbb{L}^{-1}=\left(\begin{array}{cc}
\gamma & -\mathbb{C} \\
-\mathbb{R}^{\mathbb{R}} & \mathbb{M}^{\mathbb{1}}
\end{array}\right)
\]

The constraints imposed by the Lorentz condition can be derived from:
\[
\mathbb{L}^{-1} \mathbb{L}=\mathbb{L}^{-1}=\mathbb{I}
\]

One finds the two set of relations:
\[
\begin{gather*}
\mathbb{C} \mathbb{C}=\gamma^{2}-1  \tag{53.09.21}\\
\gamma \mathbb{R}=\mathbb{C}^{\mathbb{M}},  \tag{53.09.22}\\
\gamma \mathbb{R}^{\mathbb{T}}=\mathbb{M}^{\mathbb{T}} \mathbb{C},  \tag{53.09.23}\\
\mathbb{I}=\mathbb{M}^{\mathbb{P}} \mathbb{M}-\mathbb{R}^{\mathbb{R}} \mathbb{R}, \tag{53.09.24}
\end{gather*}
\]
and
\[
\begin{gather*}
{\mathbb{R} \mathbb{R}^{\mathbb{T}}}^{2} \gamma^{2}-1  \tag{53.09.25}\\
\gamma \mathbb{C}^{T}=\mathbb{R M}^{\mathbb{P}}  \tag{53.09.26}\\
\gamma \mathbb{C}=\mathbb{M}^{\mathbb{T}}  \tag{53.09.27}\\
\mathbb{I}=\mathbb{M}^{\mathbb{P}}-\mathbb{C} \mathbb{C}^{\mathbb{T}} \tag{53.09.28}
\end{gather*}
\]

\subsection*{53.09.04.02 Rotations}

It can be shown that the matrix
\[
\mathbb{D}=\mathbb{M}-\frac{\mathbb{C} \mathbb{R}}{\gamma+1} \quad \mathbb{D}^{\mathbb{T}}=\mathbb{M}^{\mathbb{P}}-\frac{\mathbb{R}^{\mathbb{R}} \mathbb{C}}{\gamma+1}
\]
\[
(53.09 .29) \quad \underset{2275}{\rightarrow}
\]
is a rotation matrix, that is an orthogonal matrix in \(\mathrm{O}(3)\) :
\[
\mathbb{P}^{\mathbb{T}} \mathbb{D}=\mathbb{D}_{\mathbb{D}^{\mathbb{T}}}=\mathbb{I}
\]

It can be shown that a necessary a sufficient condition for a Lorentz matrix to be a rotation matrix is that its inverse is equal to its transpose:
\[
\begin{equation*}
\mathbb{L}^{-1}=\mathbb{L}^{\mathrm{T}} \tag{53.09.30}
\end{equation*}
\]

\subsection*{53.09.04.03 Boosts}

A Lorentz Transformation without rotation is defined by \(\mathbb{D}=\mathbb{I}\), that is by the condition:
\[
\mathbb{M}=\mathbb{I}+\frac{\mathbb{C} \mathbb{R}}{\gamma+1} \quad \mathbb{M}^{\mathbb{P}}=\mathbb{I}+\frac{\mathbb{R}^{\mathbb{P}} \mathbb{C}^{\mathbb{T}}}{\gamma+1}
\]

By using the relations (53.09.21), (53.09.25) one can show that this implies:
\[
\mathbb{R}=\mathbb{C} \quad \mathbb{R}^{\mathbb{T}}=\mathbb{C} .
\]

All in all a boost, a transformation without rotation, can be written as:
\[
\mathbb{L}=\left(\begin{array}{ccc}
\gamma & \mathbb{R} & , \\
\mathbb{R}^{\mathbb{R}} & \mathbb{I}+\frac{\mathbb{R}^{\mathbb{R}} \mathbb{R}}{\gamma+1}
\end{array}\right)=\left(\begin{array}{ccc}
\gamma & \mathbb{C}^{\mathbb{T}} & , \\
\mathbb{C} & \mathbb{I}+\frac{\mathbb{C}}{} \mathbb{C}^{\mathbb{T}} \\
\gamma+1
\end{array}\right) .
\]

That is the Lorentz pure transformation matrix, in addition to satisfying the Lorentz condition, is also symmetrical:
\[
\begin{equation*}
\mathbb{L}=\mathbb{L}^{\mathrm{T}} \text {. } \tag{53.09.31}
\end{equation*}
\]

Note that the boost do not form a sub-group of the Lorentz group, while rotations do, because the product of two symmetrical matrices, in general, is not symmetrical.
It can be shown that the composition of two pure transformations is a pure transformation if and only if the velocities are parallel to each other. If the two velocities are not parallel to each other the resulting transformation is not a pure one: the resulting rotation is called Thomas rotation (or precession).

\subsection*{53.09.04.04 General Lorentz Transformation}

The following results can be demonstrated. A general Lorentz Transformation can be factorized in different ways.
- Consider one specific rotation. The general Lorentz Transformation can be factorized into:

> | - one pure transformation followed by the rotation;
- the rotation followed by one pure transformation.

The two pure transformations, applied before/after the same rotation, are in general different. this corresponds to the physical fact that the two pure transformations have the same velocity but expressed in components with respect to different Coordinate System.
- The general Lorentz Transformation can be also factorized into: one rotation to align the \(z\) axis along the velocity followed by one special transformation followed by one rotation to align the \(z\) axis along the desired direction.

\section*{Consequences of the Lorentz Transformation}

Consider special Lorentz Transformation along the \(z\) axis for simplicity.

\subsection*{53.10.01 Time Dilatation and Proper Time (Special Lorentz Transformation)}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12||
Consider an object fixed in \(\mathcal{J}^{\prime}: \mathbf{r}_{1}^{\prime}=\mathbf{r}^{\prime}{ }_{2}\).
The time interval between any two events happening at the same place is so-called proper time. More generally: the proper time is the time between two events whenever:
\[
\Delta \mathbf{r}^{\prime}=0 \quad \text { same position along the direction of } \mathbf{u} \text { is enough } .
\]

Therefore one needs to relate: \(\Delta t^{\prime}, \Delta t\) and \(\Delta \mathbf{r}^{\prime}=0\). From the appropriate expressions of the Lorentz Transformation (equation (53.09.07)) one finds:
\[
\Delta \tau \equiv \Delta t^{\prime}=\Delta t / \gamma
\]

Any clock in motion runs slower. However the effect is only noticeable when the clock travels at relativistic speeds.
Moreover: \(\Delta z=u \Delta t\), as it is obvious from the definition of velocity for a point fixed in \(\mathcal{J}^{\prime}\).
The observer who sees the clock moving, J, will not agree that the positions have been recorded at the same place but it will measure a difference of position \(\Delta z=u \Delta t\), as it is obvious from the definition of velocity for a point fixed in \(J^{\prime}\).
Note that \(\mathbf{r}^{\prime}\) is held fixed, because we are watching one specific clock moving. If one would keep \(\mathbf{r}\) fixed then one would watch a whole series of different clocks in \(\mathfrak{J}^{\prime}\) passing by and this would not tell us whether one of them is running slow or not.
Of course no physical effect has happened to the clock: it is only the process of measurement in the moving Reference Frame which has given a different result.
It can be shown that the time dilatation is a reciprocal effect among the two observers, such that any of the two sees the clocks of the other observer running slower \({ }^{4}\).
Note that moving clocks are not synchronized among each other as synchronization is not an invariant concept so that if the clocks are synchronized in the frame where they are at rest they are not in other systems; therefore it is essential when checking time dilation to focus attention on a single moving clock.
Proper time is normally denoted as \(\Delta \tau\) or \(\mathrm{d} \tau\). Proper time of an object, that is time measured by a clock at rest with the object, is clearly an invariant, by definition. In many cases it is a quantity more useful than time.

\footnotetext{
\({ }^{4}\) D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ...., § 12.1.2
}

\subsection*{53.10.01.01 Proper Time and Proper Rest Frame}

The definition of proper time is not limited to objects moving at constant velocity.
Consider any Reference Frame, \(\mathcal{J}^{\prime}\), moving arbitrarily, without rotations, with respect to the observer
J. That is assume that the two Reference Frames are always linked by a pure Lorentz Transformation, at any time, a different boost at any time.
At any instant the relations between the times measured in the two Reference Frame is given by:
\[
\mathrm{d} t=\gamma \mathrm{d} t^{\prime} \equiv \gamma \mathrm{d} \tau
\]

The invariant \(\mathrm{d} \tau\) is the proper time that is the time measured in the proper Rest Frame, because that gives the time interval when \(\mathrm{dx}=0\), that is the time measured by an observer at rest with respect to the system.
In fact it is a basic postulate of Relativity that time only depends on the speed of the clock, not on acceleration nor any other higher-order derivative, read §53.06.03-From Galilei Transformation to Lorentz Transformation.

\subsection*{53.10.02 Length Contraction and Proper/Rest Length (Special Lorentz Transformation)}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12||
It is necessary to understand precisely what the length represents: length is the distance between two points taken at the same instant of time as judged in the Reference Frame of the observer. However the criterion of simultaneity is different for any other observer, and hence the result of measuring the length can be different, too.

In order to measure the length of a moving segment one needs to pick-up the position of the two ends of the segment at the same time: one looks at the position labels of the points coincident with the two extremes of the moving segment at the same time, as measured by the two clock at the two points.
Proper/Rest Length is defined as the length measured when the object is at rest.
Consider an object at rest in \(\mathcal{J}^{\prime}\), whose ends are fixed at \(\mathbf{r}^{\prime}{ }_{1}\) and \(\mathbf{r}^{\prime}{ }_{2}\).
When observing from the Reference Frame \(\mathcal{J}\) the observer must take the position of the two ends at the same time in order to measure its length, so that:
\[
\Delta t=0 \text {. }
\]

Therefore one needs to relate: \(\Delta \mathbf{r}, \Delta \mathbf{r}^{\prime}\) and \(\Delta t=0\). From the appropriate expressions of the Lorentz Transformation (equation (53.09.06)) one finds:
\[
\Delta z^{\prime}=\gamma \Delta z
\]

On the other hand we don't need to care about times in \(\mathcal{J}^{\prime}\) because the segment is at rest in \(J^{\prime}\). In fact for the \(\mathcal{J}\) observer the positions of the two ends are a function of its time, while for the \(\mathcal{J}^{\prime}\) observer the positions of the two ends are time-independent and therefore the time in \(\mathcal{J}^{\prime}\) does not enter.
The observer at rest with the object, \(\mathcal{J}^{\prime}\), will not agree that the positions have been recorded at the same time but it will measure a difference of time \(\Delta t^{\prime}=-u \Delta z^{\prime} / c^{2}\).
Any object in motion appears to be shorter along the direction of motion. However the effect is only noticeable when the objects travels at relativistic speeds.

Of course no physical effect has happened to the rod: it is only the process of measurement in the moving Reference Frame which has given a different result.
It can be shown that the length contraction is a reciprocal effect among the two observers, such that any of the two sees length of the objects at rest with respect the other observer being shorter \({ }^{5}\).

\footnotetext{
\({ }^{5}\) D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ...., § 12.1.2
}
© - QUOTE
A.P.French, Vibrations And Waves, 1971, M.I.T. Introductory Physics Series, ...Ed., ....

Despite the fact that the relativistic transformations are founded on the complete equivalence of inertial frames, there may still seem to be something paradoxical about the length- contraction and time-dilation phenomena. Suppose we have two identical meter sticks in relative motion along the direction of their length. If I am riding in the rest frame of one of them I shall measure the length of the other to be less than 1 m . How, then, can I avoid the conclusion that my meter stick appears more than I m long to an observer in the rest frame of the other stick? You need never be perplexed by such a question if you once realize that each inertial frame must speak for itself, as it were. Observations made in one frame provide a description of events from the standpoint of that frame alone. The observations that lead A to say that B's meter stick is shrunk are A's observations; the conclusions drawn from those observations are valid for A but not for B. B can make his own observations-similar to A's, but not the same-and his conclusion is that A's meter stick is contracted. Both are correct. There is no contradiction, because it is physically impossible for both sets of observations to refer to one and the same Rest Frame.

\subsection*{53.10.03 Transformation Law for the Volume}

Consider a parallelepiped, fixed with respect to the moving Reference Frame \(\mathcal{J}^{\prime}\), with its sides either parallel or perpendicular to the speed \(\mathbf{u}\). The sides perpendicular to the speed \(\mathbf{u}\) do not contract. The side along the speed \(\mathbf{u}\) contracts by a factor \(\gamma\). Therefore volumes change as:
\[
\Delta V=\Delta V^{\prime} / \gamma
\]

This § is referenced at pages:
[Never referenced.]
Read § 18.03.06 - Coordinate Transformations Tensors and Physical Laws, § 18.03.07 - Coordinate Transformations Tensors and Physical Laws for the general quotient law and principle of covariance, which are applied in this section in the context of Lorentz Transformation of Physical Quantities and Laws.

\subsection*{53.11.01 Notations and Conventions}

Note that the system of units such that \(c=1\) will be often used except for some of the basic formulas. A four-vector has one index (always a Greek letter) which can have four values: \(0,1,2,3\). The index zero denotes the so-called time-component of a four-vector. The indexes \(1,2,3\), denote the so-called space-component of a four-vector. More general tensors have more indexes with the same characteristics as the four-vectors. Note that the position of the vector/tensor indexes (high/low) are important and high/low indexes are not equivalent. Therefore, any meaningful equality must carry indexes in the same position. Whenever a pair of indexes are summed one of them must be high while the other one must be low. As Lorentz Transformation mixes the time and space components, it is necessary that the four components have the same physical dimensions; in fact the Lorentz matrix is dimensionless. When grouping together two different physical quantities to form a four-vector we will use the convention of retaining the physical dimensions of the tri-vector and modifying with suitable constants the physical dimensions of the zero-component.
Three dimensional space position vectors will be denoted either as
\[
\mathbf{r} \equiv r_{k} \equiv r^{k}=\{x, y, z\} \quad \text { or } \quad \mathbf{x} \equiv x_{k} \equiv x^{k}=\left\{x_{1}, x_{2}, x_{3}\right\} .
\]

The position of the vector/tensor indexes (high/low) is not relevant.
Four dimensional time-space four-vectors will be denoted either as
\[
r \equiv r^{\mu}=\{c t, \mathbf{r}\}=\{c t, x, y, z\} \quad \text { or } \quad x \equiv x^{\mu}=\{c t, \mathbf{x}\}=\left\{c t, x_{1}, x_{2}, x_{3}\right\} .
\]

The position of the vector/tensor indexes (high/low) are important and high/low indexes are not equivalent.

\subsection*{53.11.02 Scalars Under Lorentz Transformation}

By definition a Lorentz scalar is any physical quantity which has the same value in any inertial Reference Frame, that is any physical quantity which is invariant under Lorentz Transformation:
\[
S^{\prime}=S
\]

Examples of Lorentz scalar quantities are: the Lorentz interval between any two events, the mass of any system and the electric charge.

\subsection*{53.11.03 Four-Vectors Under Lorentz Transformation}

A four-vector is any set of four physical quantities transforming, under Lorentz transformation:
- either as the differentials of the time-space coordinates (a contravariant vector);
- or as the partial derivatives with respect to the time-space coordinates (a covariant vector);

Read also § 18 - Coordinate Transformations Tensors and Physical Laws.
In fact two different possible transformations laws exists for four-vectors under Lorentz Transformation, as it is the case for general coordinate transformations, read \(\S 18\) - Coordinate Transformations Tensors and Physical Laws. The two kinds of four-vectors are distinguished by:
- upper (high) indexes, contravariant vectors;
- lower (low) indexes, covariant vectors.

\subsection*{53.11.03.01 Contravariant and Covariant Form of Four-Vectors}

The following heuristic considerations can be carried on.
It can be shown that the \(\boldsymbol{\eta}\) matrix can be used to raise and lower the indexes (read \(\S 18\) - Coordinate Transformations Tensors and Physical Laws), so that contravariant and covariant form of a four-vectors are just different ways to represent the same four-vector.

The relation between contravariant, \(V^{\alpha}\), and covariant, \(V_{\alpha}\), form of a four-vector is:
\[
V_{\alpha}=\eta_{\alpha \dot{\beta}} V^{\beta} \quad V^{\alpha}=\eta_{\stackrel{\alpha}{\alpha \beta} V_{\beta}}
\]

By definition the time-space four-vector is (contravariant/covariant forms):
\[
x^{\alpha} \equiv\{c t,+\mathbf{x}\} \quad \Leftrightarrow \quad x_{\alpha} \equiv\{c t,-\mathbf{x}\}
\]

By definition the time-space four-gradient is (contravariant/covariant forms)::
\[
\partial_{\alpha} \equiv \frac{\partial}{\partial x^{\alpha}} \equiv\left\{\frac{1}{c} \partial_{t},+\frac{\partial}{\partial \mathbf{x}}\right\} \equiv\left\{\frac{1}{c} \partial_{t},+\boldsymbol{\nabla}\right\} \quad \Leftrightarrow \quad \partial^{\alpha} \equiv \frac{\partial}{\partial x_{\alpha}} \equiv\left\{\frac{1}{c} \partial_{t},-\frac{\partial}{\partial \mathbf{x}}\right\} \equiv\left\{\frac{1}{c} \partial_{t},-\nabla\right\} .
\]

The direct and inverse Lorentz Transformation in matrix form read:
\[
x^{\prime}=\mathbb{L} x \quad \Leftrightarrow \quad x=\mathbb{L}^{-1} x^{\prime} .
\]

The direct and inverse Lorentz Transformation with explicit indexes read:
\[
x^{\prime \alpha}=\mathbb{L}_{\cdot \beta}^{\alpha \cdot} x^{\beta} . \quad \Leftrightarrow \quad x^{\alpha} \cdot=\left(\mathbb{L}^{-1}\right)_{\cdot \beta}^{\alpha \cdot} x^{\prime \beta}
\]

The Jacobian matrices of the two transformations are:
\[
\frac{\partial x^{\prime \alpha} \cdot}{\partial x^{\beta}}=\mathbb{L}_{\cdot \beta}^{\alpha} \quad \Leftrightarrow \quad \frac{\partial x^{\alpha}}{\partial x^{\prime \beta}}=\left(\mathbb{L}^{-1}\right)_{\cdot \beta}^{\alpha}
\]

The differentials of the space-time coordinates transform, in matrix form, as:
\[
\mathrm{d} x^{\prime}=\mathbb{L} \mathrm{d} x
\]

Introduce the useful notation:
\[
\frac{\partial}{\partial x^{\mu}} \equiv \partial_{\mu} \quad \frac{\partial}{\partial x^{\prime \mu}} \equiv \partial_{\mu}^{\prime}
\]

The partial derivative of the space-time coordinates transform as:
\[
\frac{\partial}{\partial x^{\prime \beta}}=\frac{\partial}{\partial x_{\cdot}^{\alpha}} \frac{\partial x^{\alpha}}{\partial x^{\prime \beta}}=\frac{\partial}{\partial x^{\alpha}}\left(\mathbb{L}^{-1}\right)_{\cdot \beta}^{\alpha \cdot} \Longrightarrow \partial_{\beta}^{\prime}=\partial_{\alpha}\left(\mathbb{L}^{-1}\right)_{\cdot \beta}^{\alpha}
\]

It is therefore clear that for a given Lorentz Transformation the partial derivatives transform in a different way from the differentials: in matrix form the row four-gradient transformed vector is found from the product between the row four-gradient vector and the inverse Lorentz matrix \(\mathbb{L}^{-1}\).

The partial derivative of the space-time coordinates transform, in matrix form, as:
\[
\partial_{\beta}^{\prime}=\partial_{\alpha}\left(\mathbb{L}^{-1}\right)_{\cdot \beta}^{\alpha} \quad \Leftrightarrow \quad \partial^{T}=\not \mathscr{L}^{-1}
\]

In order to distinguish between the two different way of transformations of four-vectors under the same Lorentz Transformation:
1. the first type of four-vectors, those transforming as the differentials of the coordinates, have their Greek indexes in the high position and called contravariant four-vectors;
2. the second type of four-vectors, those transforming as the gradient of the coordinates, have their Greek indexes in the low position and called covariant four-vectors.

\subsection*{53.11.03.02 Properties of Four-Vectors}

It can be shown that the relations between the contravariant and covariant components of a four vector are:
\[
\begin{equation*}
V_{\mu}^{\dot{*}}=\eta_{\mu \nu}^{\dot{\circ}} V_{\cdot}^{\nu} \quad V_{\cdot}^{\mu}=\eta_{\cdot}^{\mu \nu} V_{\nu}^{\dot{ }} \tag{53.11.01}
\end{equation*}
\]

Contravariant vectors, by definition, transforms as the differentials of the coordinates, that is:
\[
\begin{equation*}
V^{\prime \mu}=\mathbb{L}_{\cdot \nu}^{\mu \cdot} V_{\cdot}^{\nu} \quad V^{\prime}=\mathbb{L} V \quad \text { in matrix form } \tag{53.11.02}
\end{equation*}
\]

Covariant vectors, by definition, transforms as the gradient of the coordinates, that is:
\[
\begin{equation*}
V_{\mu}^{\prime \cdot}=\mathbb{L}_{\mu}^{\cdot \nu} \cdot V_{\nu}^{\cdot} \quad V^{T}=V^{T} \mathbb{L}^{-1} \quad \text { in matrix form } \tag{53.11.03}
\end{equation*}
\]

Note that the above result just comes from lowering-rising the indexes. It is a particular case of the more general treatment is section \(\S 18\) - Coordinate Transformations Tensors and Physical Laws which would be valid for any change between Coordinate System.

Read § 53-018 - From Galilei Transformation to Lorentz Transformation.

\subsection*{53.11.03.03 Scalar Product of Four-Vectors}

It can be shown that in order to produce a scalar as product of two four-vectors one needs to use the contravariant form of one four-vector and the covariant form of the other one:
\[
A \cdot B \equiv A^{\mu} B_{\mu}=A_{\mu} B^{\mu}
\]

The invariance of the scalar product is clear from the above relations (53.11.02), (53.11.03). In fact by considering the contravariant form as a column vector and the covariant form as a row vector the scalar product can be written in matrix form as:
\[
A_{\mu} B^{\mu}=A^{T} \cdot B=B^{\mathrm{T}} \cdot A=B_{\mu} A^{\mu}
\]
as the transpose of a \(1 \times 1\) matrix is the same number.
It is then clear from equations (53.11.02), (53.11.03) that applying a Lorentz Transformation the result does not change as the Lorentz matrix and its inverse cancel out.

It immediately follows that in order to have a scalar one needs to sum one high and one low index.

\subsection*{53.11.04 Higher Order Tensors Under Lorentz Transformation}

This § is referenced at pages:
[Never referenced.]
They are defined according to the general procedure outlined in § 18-Coordinate Transformations Tensors and Physical Laws.
By definition, a Lorentz tensor of rank \(m=h+l\) is a physical quantity with an ordered set of \(h\) contravariant indexes and \(l\) covariant indexes:
\[
\begin{equation*}
\left(\mathbb{T}^{\prime}\right)^{r_{1} \cdot r_{2} \cdots r_{h} \cdot \cdot \cdot}=\mathbb{L}^{r_{1}} \cdot s_{1} \mathbb{L}_{a_{1}} \cdot b_{1} \cdot \mathbb{L}^{r_{2}} \cdot s_{2} \ldots a_{l} \ldots \mathbb{L}^{r_{h}} \cdot{s_{h}}^{L_{a_{2}} b_{2}} \mathbb{L}_{a_{l}} \cdot b_{l}(\mathbb{T})^{s_{1} \cdot b_{1} \cdot s_{2} \cdots s_{h} \cdot \cdot \cdot b_{2} \cdots b_{l}} \tag{53.11.04}
\end{equation*}
\]

Some examples follow.
1. Rank two constant tensors: \(\eta_{\mu \nu}^{\ddot{ }}\) and \(\delta_{\cdot \beta}^{\alpha}\).
2. Rank three tensor: the totally anti-symmetrical Levi-Civita \(\underset{\mu \nu \sigma \rho}{\ldots}\) in Minkowski space.
3. The orbital Boost-AngMomentum Tensor, with respect to the origin of the Coordinate System, is defined, as a function of the Energy-LinMomentum four-vector, as:
\[
\gamma_{. 月}^{\alpha \beta} \equiv x^{\alpha} p^{\beta}-x^{\beta} p^{\alpha}
\]

\subsection*{53.11.04.01 Relativistic Angular Momentum}

In relativity, angular momentum is a part of a second-order anti-symmetric tensor. Therefore it is wrong to treat the relativistic transformation of angular momentum as those of a vector. It is a second-order anti-symmetric tensor. Its transformation law, is such that the vector angular momentum transforms the other way round with respect to the space part of real four-vector: its longitudinal component does not change, while its transverse component does change. This is the same as for the Electric|Magnetic field, not surprisingly, as they are also part of a second-order anti-symmetric tensor, read section § 56.05.02ElectroMagnetism and Relativity.
Read also § ?? - ??.

\subsection*{53.11.04.02 Examples of Lorentz Tensors}

Important scalars (invariants) include:
- the mass;
- the electric charge.

Important four-vectors include:
- the time-space four-vector;
- the Energy-LinMomentum (Four-Momentum) four-vector (proportional to the four-velocity);
- the frequency-wave-vector (four-wave-vector) four-vector;
- the charge-current (Four-Current) four-vector;
- the ElectroMagnetic four-potential;
- the spin four-vector.

Usually, the physical dimensions of the zero component is adapted to the physical dimension of the 3 -vector to get a four-vector with all components having the same dimensions.
Similarly, usually, the name of the four-vector is taken from the name of the 3-vector quantity (fourposition, four-momentum, four-current, four-wave-vector).
Important tensors of second order include:
- the ElectroMagnetic field tensor;
- the energy momentum tensor.

\subsection*{53.11.06 Transformation of Fields Under Lorentz Transformation}

Read § ?? - ??.

\subsection*{53.11.07 Invariant Conserved Constant Physical Quantities}

One has to be careful to avoid confusion between the concept of a scalar (invariant) quantity and the concept of a conserved quantity.
- A quantity that is constant does not change with time.
- A Lorentz scalar (Lorentz invariant) is a quantity which has the same numerical value in any inertial Reference Frame.
- A conserved quantity is a quantity which does not change before and after some process/encounter.

The speed of light in a vacuum is constant and invariant. These are entirely different and independent statements.
The rest mass is a scalar. However the rest mass of a complex system (also called the invariant mass) is not, in general, conserved. The rest mass (just called mass) of an elementary entity (particle) is an intrinsic properties of the entity: if it changes we assume that the identity of the elementary entity has changed.
Energy-LinMomentum of an isolated system is a conserved quantity, but it is also conserved in collisions/interactions internal to the system.
Electric charge is both a scalar and a conserved quantity.
Velocity is neither conserved nor invariant.

\subsection*{53.11.08 Tensors Under Lorentz Versus Tensors Under Galilei}

Rotation transformations (leave \(\mathbb{I}\) invariant):
\[
\begin{gathered}
\mathbb{I}=\mathbb{R}^{\mathbb{T}} \mathbb{R}=\mathbb{R}^{\mathbb{T}} \Longrightarrow \mathbb{R}^{-1}=\mathbb{R}^{\mathbb{T}} \mathbb{I}, \\
\delta_{p q}^{\bullet \cdot}=R_{p}^{\cdot a} \cdot R_{q}^{\cdot b} \cdot \delta_{a b}^{*}
\end{gathered}
\]

Note that equation (53.11.08) actually means that \(\delta\) is a second order tensor for the rotations group, actually an invariant one, that has the same components in any Coordinate System.
Lorentz Transformation (leave \(\boldsymbol{\eta}\) invariant):
\[
\begin{gathered}
\boldsymbol{\eta}=\mathbb{L}^{\mathrm{T}} \boldsymbol{\eta} \mathbb{L}=\mathbb{L} \boldsymbol{\eta} \mathbb{L}^{\mathrm{T}} \Longrightarrow \mathbb{L}^{-1}=\boldsymbol{\eta} \mathbb{L}^{\mathrm{T}} \boldsymbol{\eta}, \\
\eta_{\mu \nu}^{\bullet}=\mathbb{L}_{\mu}^{\cdot \alpha} \cdot \mathbb{L}_{\nu}^{\cdot \beta} \cdot \eta_{\alpha \beta}^{\prime \cdot}
\end{gathered},
\]

Note that equation (53.11.08) actually means that \(\eta\) is a second order tensor for the Lorentz group, actually an invariant one, that has the same components in any Reference Frame.

\section*{© - QUOTE}
R.Hagedorn, Relativistic Kinematics, 1963, W.A.Benjamin,, ...Ed., WEB - URL.

I wish to stress once more the following point: scalars, vectors, tensor operators and such things are defined abstractly as physical or geometrical quantities. As soon as a system of coordinates is introduced, these quantities will be represented by components with respect to the coordinate axes. This representation will depend on the choice of the coordinates whereas the abstract quantities are independent: their existence logically precedes the existence of coordinates. If in the following we shall find different representations of, for instance, a four vector by covariant and contravariant components, and if these representations are different in different metrics they nevertheless represent one and the same physical quantity.

\section*{© - QUOTE}
R.Hagedorn, Relativistic Kinematics, 1963, W.A.Benjamin,, ...Ed., WEB - URL.

If a question is of such a nature that its answer will always be the same, no matter in which Lorentz system one starts, it must be possible to formulate the answer entirely with the help of those invariants which one can build with the available four-vectors. One then finds the answer in a particular Lorentz system which one can choose freely and in such a way that the answer is there obvious or most easy. One looks then how the invariants appear in this particular system, expresses the answer to the problem by these invariants, and one has found at the same time the general answer. This looks sometimes like Hocus-Pocus, as you will see in the following examples. It is worthwhile to devote some thinking to this method of calculation until one has completely understood that there is really no jugglery or guesswork in it and that it is absolutely safe.

\section*{© - QUOTE}
R.Hagedorn, Relativistic Kinematics, 1963, W.A.Benjamin,, ...Ed., WEB - URL.

If an equation given in any particular Lorentz Reference Frame can be written in a manifestly covariant form (that is, both sides have the same transformation properties under Lorentz Transformation) which in the particular Lorentz frame reduces to the equation given originally, which is a known exact equation, this covariant form is the unique generalization of the equation given.

\section*{Examples and Physical Applications}

\subsection*{53.12.01 Speed of Light as a Limiting Speed}

This § is referenced at pages:

© \(\mid\) W.Rindler|Special relativity: kinematics|WEB - URL|

\section*{© - QUOTE}
W.Rindler, Relativity, 2006, Oxford, 2ndEd., ....

The \(\gamma\) factor of Lorentz Transformation becomes infinity, for \(u=c\), and imaginary, for \(u>c\). Therefore the relative velocity between two different Reference Frames must be less than the speed of light, if finite real-valued coordinates in one Reference Frame must correspond to finite real-valued coordinates in any other Reference Frame. Based on this line of reasoning, it follows that no particle can move super-luminally relative to any Reference Frame, because any set of such particles moving parallel among each other would constitute a Reference Frame moving super-luminally relative to the first Reference Frame.
Other indications show that the speed of particles and of all physical signals, is upper-limited by \(c\), such as violation of causality in presence of super-luminal signal transmission. Consider, in fact, any signal or process whereby a first event causes a second event (or whereby information is sent from the first event to the second event) at super-luminal speed, \(U\), relative to some inertial Reference Frame. By applying Lorentz Transformation it is then possible to find an inertial Reference Frame, moving at speed \(u\), such that \(c^{2} / U<u<c\), where the time-ordering of the two events is inverted. Therefore there would exist some inertial Reference Frame in which the second event precedes the first one, so that cause and effect are reversed and the signal is considered to travel in the opposite spatial direction.
The whole concept of super-luminal signaling is seen to produce paradoxes. We are thus led to accept the axiom that no super-luminal signals can exist, so that \(c\) is an upper-limit to the speed of macroscopic information-conveying signals. In particular, this speed limit must apply to particles, since they can convey messages.
Relativistic mechanics provides a speed limit by having the mass of particles increase beyond all bounds as their speed approaches the speed of light. Any massive particle that constantly accelerates, no matter how strongly, approaches but never attains the speed of light.
One consequence of the upper relativistic speed limit is that such things as rigid-bodies and incompressible fluids have become impossible objects, even as idealizations or limits: in fact, by definition, they would transmit signals instantaneously.
Note, however that arbitrarily large velocities are possible for moving points that carry no information. The sweep of a light spot from the Earth on the Moon surface, where a movable laser beam from Earth impinges, or the intersection point of two rulers that cross each other at an arbitrarily small angle are two such examples.

\subsection*{53.12.02 Experimental Tests of Special Relativity}

This § is referenced at pages:
[2346, 2346]
© \(\mid\) T.Roberts \& S.Schleif \& J.M.Dlugosz|WEB - URL|Excellent, extensive and detailed|
Experimental tests of special relativity are particularly important because either special relativity has many counter-intuitive predictions and, in order to appreciate relativistic results, it is necessary to have objects moving close to the speed of light, which is difficult to attain.
Experiments on the contraction of lengths are clearly impossible, as this would require to run physical objects close to the speed of light.
Experiments on the dilatation of time are easier.
Read also § 54.02.05-Relativistic Kinematics for wave-related experiments.

\subsection*{53.12.02.01 Atmospheric Muons Lifetime Paradox}

This § is referenced at pages:
[2374, 2374, 2422, 2422, 2422, 2422]
The lifetime increase of a high-energy particle is often used in High-Energy Physics to observe the decay point of a short-lived particle away from the production point.

Muons, for instance, have a lifetime \(\tau_{0}=2.2 \cdot 10^{-6} \mathrm{~s}\) and mass \(m=0.105 \mathrm{GeV} / \mathrm{c}^{2}\).
1. What energy is necessary to a muon to reach the Earth surface once it was produced in the high part of the atmosphere at \(H=10 \mathrm{~km}\) while running radially?
2. How is the kinematics described by the observer at the Earth and by an observer moving with the muon?

\section*{SOLUTION}
\[
H=\tau_{0} \gamma \beta c=\frac{\tau_{0} p}{m}=\frac{\tau_{0} \beta \varepsilon}{m c} \longrightarrow \varepsilon=1.6 \mathrm{GeV} \quad \text { assuming } \beta \simeq 1
\]

Description of the observer at the Earth: the muon lives \(\tau_{0} \gamma\) and travels \(H=\tau_{0} \gamma \beta c\) (time dilatation).
Description of the muon: the muon lives \(\tau_{0}\) and si standing still. The atmosphere, of length \(H\), is traveling towards the muon, with velocity \(\beta c\) (length contraction). The muon feels a shorter life, by a factor \(\gamma\), but it sees distances contracted, by a factor \(\gamma\), so that the atmosphere she is seeing is only \(H / \gamma\) long.
Therefore the two descriptions, the one given by the muon and the one given by the ground observer, are totally coherent.

\subsection*{53.12.02.02 Atomic Clocks on Commercial Airplanes}

© \(\mid J\). Hafele \& R.Keating ||WEB - URL|
They flew cesium atomic clocks on commercial airliners around the world in both directions and compared the time elapsed on the airborne clocks with the time elapsed on an earthbound clock.
The effect includes both an effect of special relativity and an effect of general relativity.

\subsection*{53.12.02.03 Lifetime of Muons in Storage Rings}

Bailey et al., Measurements of relativistic time dilation for positive and negative muons in a circular orbit, Nature 268 (July 28, 1977) Pag. 301.
They stored muons in a storage ring and measured their lifetime. When compared with measurements of the muon lifetime at rest this is a highly relativistic twin scenario as \(v \simeq 0.9994 c\), for which the stored muons are the traveling twin and return to a given point in the lab every few \(\mu\) s.
The experiment confirms the clock hypothesis stating that the tick rate of a clock when measured in an inertial frame depends only upon its velocity relative to that frame, and it is independent of its acceleration or higher derivatives with respect to time. In fact muons in the storage ring are accelerated and their lifetime could be measured to only depend on the velocity.

\subsection*{53.12.02.04 Time Dilatation and the Clock Hypotesis and the Twin Paradox}

The so-called twin paradox occurs when two clocks are synchronized, separated, one of them takes a long journey, rejoined and their readings are finally compared.
If one clock remains in an inertial frame then the other must be accelerated sometimes during its journey and it will display less elapsed proper time than the inertial clock at the end of the journey. Therefore the situation is not symmetrical between the two clocks.
This is a paradox only in that it appears to be inconsistent, but it is not.
This has been tested using muons stored in a storage ring and measured their lifetime. When combined with measurements of the lifetime of muons at rest (the twin at rest) this becomes a twin paradox experiment.

\subsection*{53.12.02.05 Experimental Test of the Second Postulate}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
Experiment performed at CERN, Geneva, Switzerland, in 1964: the speed of photons with \(\varepsilon=6 \mathrm{GeV}\) (speed \(0.99975 c\) ), produced in the decay of very energetic neutral pions, was measured by time of flight over paths up to 80 meters. Within the experimental errors it was found that the speed of the photons emitted by the extremely rapidly moving source was equal to \(c\).

\section*{Exercises Problems and Physical Applications}

\section*{53-001 Super-Luminal Motion}

Read § 53.12.01 - From Galilei Transformation to Lorentz Transformation for the explanation in the context of Relativity.
The value of \(c\) is the limiting speed for real material bodies and for processes that can be used for the transmission of a signal, that is the transmission of a certain amount of energy carrying some information.
Super-luminal motion refers to apparent speeds larger than the speed of light. It is only a visual effect, nothing is running faster than light, nothing carrying information.
Super-luminal motion also refers to motion which is faster than light but not for real objects nor for transfer of information.
As an example, imagine a machine-gun sending projectiles, at a rate of \(n \mathrm{~Hz}\) while rotating in the horizontal plane with a fixed angular speed \(\omega\). Consider a very far circular wall, centered on the machinegun, at distance \(D\), and consider the motion of the track of the impinging projectiles. Determine the speed of the track left by the projectiles on the wall. Projectiles arrive at the rate they leave the machine-gun, separated by an angular distance \(\Delta \theta=\omega \Delta t=\omega / n\) so that the distance on the wall is \(D \omega / n\) and the speed of the track is \(D \omega\), which can be as large as one desires provided \(D\) is large enough.

\section*{53-002 Lifetime of Unstable Particles}

The lifetime of short-lived particles is increased with their speed, see section § 53.12.02.01 - From Galilei Transformation to Lorentz Transformation.

\section*{53-003 Simultaneity Synchronization and Time Dilation}

Suppose that at time \(t=0\) the observer \(\mathcal{J}\) decides to examine all the clocks in \(\mathcal{J}^{\prime}\). He will find that they all read different times, depending on their location: those at negative \(z\) are ahead, and those at positive \(z\) are behind, by an amount that increases in proportion to their distance. Only the master clock at the origin reads \(t^{\prime}=0\).
How does the observer examines the clocks at rest in \(\mathcal{J}^{\prime}\) ? He needs to compare at any time the moving clock with its own clock at rest at the position of the moving clock.

\section*{53-004 Invariant Quantity of Lorentz Transformation}

Show, by direct calculation, that, for a special Lorentz Transformation:
\[
c^{2}(\Delta t)^{2}-(\Delta z)^{2}=c^{2}\left(\Delta t^{\prime}\right)^{2}-\left(\Delta z^{\prime}\right)^{2} .
\]

Any general Lorentz Transformation leaves invariant the quantity:
\[
c^{2}(\Delta t)^{2}-(\Delta \mathbf{x})^{2}=c^{2}\left(\Delta t^{\prime}\right)^{2}-\left(\Delta \mathbf{x}^{\prime}\right)^{2}
\]

\section*{53-005 An Algebraic Identity}

Show that:
\[
\frac{\gamma^{2}-1}{\gamma^{2}}=\beta^{2}
\]

\section*{53-006 Non-Relativistic Limit}

Show that Lorentz Transformation reduce to Galilei Transformation in the limit: \(c \rightarrow \infty\).

\section*{53-007 Composition of Lorentz Transformation}
© \(\mathbb{C}\) E. Byckling \& K.Kajantie, Particle Kinematics, 1993, J.Wiley \& Sons, ...Ed., WEB - URL.|problem 2.19||
Consider three Inertial Reference Frames, \(\mathcal{J}_{1}, \mathcal{J}_{2}\) and \(\mathcal{J}_{3}\). Let \(\mathbf{u}_{21}\) be the velocity of \(\mathcal{J}_{2}\) with respect to \(\mathcal{J}_{1}\), let \(\mathbf{u}_{32}\) be the velocity of \(\mathcal{J}_{3}\) with respect to \(\mathcal{J}_{2}\) and let \(\mathbf{u}_{31}\) be the velocity of \(\mathcal{J}_{3}\) with respect to \(\mathcal{J}_{1}\). Choose the Coordinate Systems in such a way that both transformations (1) \(\rightarrow(2)\) and (2) \(\rightarrow(3)\) are pure transformations.
Show that:
\[
\gamma_{\mathbf{u}_{31}}=\gamma_{\mathbf{u}_{21}} \gamma_{\mathbf{u}_{32}}\left(1+\frac{\mathbf{u}_{21} \cdot \mathbf{u}_{32}}{c^{2}}\right)
\]

\section*{53-008 Group Properties of the Lorentz Transformation}

Demonstrate that the Lorentz Transformation form a group.

\section*{53-009 Rotations in Lorentz Transformation}

Demonstrate that the matrix \((53.09 .29)\) is a rotation matrix.

\section*{SOLUTION}

By direct computation of \(\mathbb{D}^{T} \mathbb{D}=\mathbb{D}^{\mathbb{P}}=\mathbb{I}\), using relations (53.09.21), (53.09.25). It is long but straightforward.

\section*{53-010 Boosts in Lorentz Transformation}

Show that the composition of two boost is a boost if and only if the two velocities are parallel.

\section*{53-011 Infinitesimal Lorentz Transformation}

Show that for an infinitesimal Lorentz Transformation,
\[
\mathbb{L}=\mathbb{I}+\mathbb{B} \mathrm{d} \theta+\mathcal{O}\left[(\mathrm{d} \theta)^{2}\right]
\]
the matrix \(\mathbb{B}\) satisfies:
\[
\eta \mathbb{B}=-\eta \mathbb{B}^{\mathbb{T}}
\]
that is the matrix \(\eta \mathbb{B}\) is anti-symmetrical.

\section*{53-012 Thomas Precession}

\section*{53-013 Change of Angles}

The Reference Frame \(\mathcal{J}^{\prime}\) is related to the Reference Frame to \(\mathcal{J}\) by the special Lorentz Transformation (53.09.03).
Calculate in \(\mathcal{J}^{\prime}\) the length and the angle with the \(z^{\prime}\) axis of a rod of length \(L\) at an angle \(\theta\) with the \(z\) axis in \(J\).

\section*{53-014 Change of Direction in a Lorentz Transformation}

Show that, because of the length contraction in the direction of motion, only oriented segments either parallel or perpendicular to the velocity of the Lorentz Transformation keep the same direction after a Lorentz Transformation.

\section*{SOLUTION}

The formula of transformation of directions is:
\[
\boldsymbol{\lambda}=\frac{\lambda^{\prime}+\mathbf{u}\left(\left(\frac{1}{\gamma}-1\right) \frac{\mathbf{u} \cdot \lambda^{\prime}}{u^{2}}\right)}{\sqrt{1-\left(\mathbf{u} \cdot \boldsymbol{\lambda}^{\prime} / c\right)^{2}}}
\]

\section*{53-015 Change of Angles in a Lorentz Transformation}

Show that the concept of parallelism is invariant under Lorentz Transformation, but the concept of perpendicularity it is not.
Show that the angle does not change when both directions are either perpendicular or parallel to the velocity.

\section*{SOLUTION}

The formula of transformation of angles is:
\[
\cos \alpha=\frac{\cos \alpha^{\prime}-\frac{\left(\mathbf{u} \cdot \boldsymbol{\lambda}_{1}^{\prime}\right)\left(\mathbf{u} \cdot \boldsymbol{\lambda}_{2}^{\prime}\right)}{c^{2}}}{\left(1-\left(\mathbf{u} \cdot \boldsymbol{\lambda}^{\prime}{ }_{1} / c\right)^{2}\right)\left(1-\left(\mathbf{u} \cdot \boldsymbol{\lambda}^{\prime}{ }_{2} / c\right)^{2}\right)}
\]

\section*{53-016 Check of the Reciprocity Relation}

Use equation (54.01.01) and consider its inverse equation. Replace the inverse equation into (54.01.01) and check that the result is an identity.

\section*{53-017 Raising/Lowering Indexes}

Show that raising a previously lowered indexes as well as lowering a previously raised index recovers the original four-vector.

\section*{53-018 Relation Between Contravariant and Covariant Transformations}

This § is referenced at pages:
[2366, 2366]
Find the transformation law for covariant vectors from the one for contravariant vectors.

\section*{SOLUTION}
\[
\begin{equation*}
V_{\mu} \equiv \eta_{\mu \dot{\beta}}^{\cdot} V^{\beta} \Longrightarrow V^{\prime}{ }_{\mu}=\eta_{\mu \dot{\beta}}^{\cdot} V^{\prime \beta} \cdot=\eta_{\mu} \dot{\beta} \mathbb{L}^{\beta} \cdot{ }_{\alpha} V_{\cdot}^{\alpha}=\eta_{\mu \dot{\beta}} \mathbb{L}_{\cdot \alpha}^{\beta \cdot} \eta^{\alpha \nu}{ }_{\cdot}^{\alpha \nu} V_{\nu} \equiv \mathbb{L}_{\mu}^{\cdot} \cdot{ }^{\nu} \cdot V_{\nu} \tag{53.13.01}
\end{equation*}
\]

Note that the transformation matrix is exactly obtained by \(\mathbb{L}_{\cdot \nu}^{\mu}\) by lowering the first index and raising the second one.

\section*{53-019 Direct Check of Invariance}

Check by direct calculation for a special Lorentz Transformation that the scalar product of any two four-vectors is invariant.

\section*{53-020 Non-Invariance of d'Alembert Operator for Galilei Transformation}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|problem 11.1||

\section*{53-021 Matrix Form of the Covariant Transformation}

The above relation (53.11.03), describing the transformation of covariant vectors as a function of the transformation of contravariant vectors, can be written in matrix form as:
\[
V^{\prime}=(\boldsymbol{\eta} \mathbb{L} \boldsymbol{\eta}) V
\]

Beware that the vectors in the above equation are covariant vectors, obtained from the contravariant vectors from equation (53.11.01).

\section*{SOLUTION}

It is implicit in the last step of equation (53.13.01) when writing in matrix form the expression: \(\eta_{\mu \dot{\beta}} \mathbb{L}^{\beta} \cdot{ }_{\alpha} \eta^{\alpha \nu} \ldots\)

In order both to find the relation between the matrix \(\mathbb{L}_{\mu}^{\cdot} \cdot{ }^{\nu}\) and the matrix \(\mathbb{L}_{\cdot \nu}^{\mu \cdot}\) and to make this result consistent with the general discussion of § 18 - Coordinate Transformations Tensors and Physical Laws it is better to rewrite the above relation in a different way.
Moreover, using the symmetry of \(\eta\) and equation (53.09.17), one has:

Therefore:
\[
V_{\mu}^{\prime}=\left(\mathbb{L}^{-1}\right)_{\cdot \mu}^{\nu \cdot} V_{\nu}
\]

[Never referenced.]
Note that \(c=1\) will be often used except for some of the basic formulas.

\subsection*{54.01}

Transformation Laws of Velocity and Acceleration

The transformation law of velocities is a rather complex one, and it is a non-linear one. In fact the transformation law of the velocities requires to transform both the numerator and the denominator of the derivative and this makes the law complex.

\subsection*{54.01.01 Transformation Laws for the Velocity (Special Lorentz Transformation)}

This § is referenced at pages:
[2382, 2382]
Consider two Inertial Reference Frames, \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\). Assume the two Reference Frames are connected by a special Lorentz Transformation and that \(\mathcal{I}^{\prime}\) is moving, with respect to \(\mathcal{J}\), with a speed \(\mathbf{u} \equiv \beta c\) along the \(z \operatorname{axis}\left(\mathbf{u}=u \hat{\mathbf{e}}_{3}\right)\) :
\[
\begin{aligned}
v_{z}^{\prime} & \equiv \lim _{\Delta t^{\prime} \rightarrow 0} \frac{\Delta z^{\prime}}{\Delta t^{\prime}}, \\
v_{(x \mid y)}^{\prime} & \equiv \lim _{\Delta t^{\prime} \rightarrow 0} \frac{\Delta\left(x^{\prime} \mid y^{\prime}\right)}{\Delta t^{\prime}}
\end{aligned}
\]

When \(\Delta t^{\prime} \rightarrow 0\) then also \(\Delta x^{\prime} \rightarrow 0, \Delta y^{\prime} \rightarrow 0\) and \(\Delta z^{\prime} \rightarrow 0\).
Therefore Lorentz Transformation imply that \(\Delta t \rightarrow 0\) and also \(\Delta x \rightarrow 0, \Delta y \rightarrow 0\) and \(\Delta z \rightarrow 0\).
\[
\begin{gathered}
v_{z}^{\prime} \equiv \lim _{\Delta t^{\prime} \rightarrow 0} \frac{\Delta z^{\prime}}{\Delta t^{\prime}}=\lim _{\Delta t \rightarrow 0} \frac{\gamma(\Delta z-u \Delta t)}{\gamma\left(\Delta t-u \Delta z / c^{2}\right)}=\frac{v_{z}-u}{1-u v_{z} / c^{2}} \\
v_{(x \mid y)}^{\prime} \equiv \frac{\Delta\left(x^{\prime} \mid y^{\prime}\right)}{\Delta t^{\prime}}=\lim _{\Delta t^{\prime} \rightarrow 0} \frac{\Delta(x \mid y)}{\gamma\left(\Delta t-u \Delta z / c^{2}\right)}=\frac{v_{(x \mid y)}}{\gamma\left(1-u v_{z} / c^{2}\right)}
\end{gathered}
\]

The non-relativistic limit applies when all velocities (on the right-hand side of the above equations) are non relativistic: \(v_{z} \ll c, v_{(x \mid y)} \ll c\) and \(|u| \ll c\). In this limit the above relations reduce to the one predicted by Galilei Transformation and the resulting velocities on the left-hand side turns out to be non-relativistic.
These equations implement, among other things, the fact that the maximum possible velocity is the speed of light, so that no composition of velocities can lead to a speed greater than the speed of light. Consider, for instance, the special case \(v_{z}=c\), which implies \(v_{x}=v_{y}=0\), one has \(v_{z}^{\prime}=c\), which implies \(v_{x}^{\prime}=v_{y}^{\prime}=0\), whatever \(u\). The general case, for arbitrary velocity, is discussed in section § 54-003Relativistic Kinematics.
In summary, in the case of a special Lorentz Transformation along the \(z\) axis \(\left(\mathbf{u}=u \hat{\mathbf{e}}_{3}\right)\) :
\[
\begin{gathered}
v_{x}^{\prime}=\frac{v_{x}}{\gamma\left(1-u v_{z} / c^{2}\right)} \\
v_{y}^{\prime}=\frac{v_{y}}{\gamma\left(1-u v_{z} / c^{2}\right)} \\
v_{z}^{\prime}=\frac{v_{z}-u}{1-u v_{z} / c^{2}}
\end{gathered}
\]

Note that the transverse components of the velocity transform, because even if the transverse components of the position vector do not transform, one has to take into account the transformation law for the time at the denominator.

\subsection*{54.01.02 Transformation of the Velocity (Boost)}

Consider two Inertial Reference Frames, \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\). Assume the two Reference Frames are connected by a boost and that \(\mathcal{J}^{\prime}\) is moving, with respect to \(\mathcal{J}\), with a speed \(\mathbf{u} \equiv \boldsymbol{\beta} c\).

It can be straightforwardly derived, for a boost, from the transformation laws (53.09.11), (53.09.12):
\[
\begin{equation*}
\mathbf{v}^{\prime} \equiv \frac{\mathrm{d} \mathbf{x}^{\prime}}{\mathrm{d} t^{\prime}}=\frac{\mathrm{dx}}{}{ }^{\prime} \frac{\mathrm{d} t}{\mathrm{~d} t} \frac{\frac{\mathbf{v}}{\mathrm{~d} t^{\prime}}+\boldsymbol{\beta}\left(\left(1-\frac{1}{\gamma}\right) \frac{\boldsymbol{\beta} \cdot \mathbf{v}}{\beta^{2}}-c\right)}{1-\frac{\boldsymbol{\beta} \cdot \mathbf{v}}{c}}=\frac{\mathbf{v}+\boldsymbol{\beta}\left(\frac{\gamma^{2}}{\gamma+1}(\boldsymbol{\beta} \cdot \mathbf{v})-\gamma c\right)}{\gamma\left(1-\frac{\beta \cdot \mathbf{v}}{c}\right)} \tag{54.01.01}
\end{equation*}
\]
and the inverse:
\[
\begin{equation*}
\mathbf{v} \equiv \frac{\mathrm{d} \mathbf{x}}{\mathrm{~d} t}=\frac{\mathrm{d} \mathbf{x}}{\mathrm{~d} t^{\prime}} \frac{\mathrm{d} t^{\prime}}{\mathrm{d} t}=\frac{\frac{\mathbf{v}^{\prime}}{\gamma}+\boldsymbol{\beta}\left(\left(1-\frac{1}{\gamma}\right) \frac{\boldsymbol{\beta} \cdot \mathbf{v}^{\prime}}{\beta^{2}}+c\right)}{1+\frac{\boldsymbol{\beta} \cdot \mathbf{v}^{\prime}}{c}}=\frac{\mathbf{v}^{\prime}+\boldsymbol{\beta}\left(\frac{\gamma^{2}}{\gamma+1}\left(\boldsymbol{\beta} \cdot \mathbf{v}^{\prime}\right)+\gamma c\right)}{\gamma\left(1+\frac{\beta \cdot \mathbf{v}^{\prime}}{c}\right)} \tag{54.01.02}
\end{equation*}
\]

The expressions in the case the velocity \(\mathbf{v}\) is either parallel or orthogonal to the relative velocity \(\boldsymbol{\beta}\) can be derived by direct computation from equation (54.01.01):
\[
\mathbf{v}\left\|\mathbf{u} \Longrightarrow \mathbf{v}^{\prime}=\frac{\mathbf{v}-\mathbf{u}}{1-u v / c^{2}} \Longrightarrow \mathbf{v}^{\prime}\right\| \mathbf{u}
\]
\(\mathbf{v} \perp \mathbf{u} \Longrightarrow \mathbf{v}^{\prime}=\frac{\mathbf{v}}{\gamma}-\mathbf{u} \Longrightarrow \mathbf{v}^{\prime}\) is not perpendicular to \(\mathbf{u}\), differently than Galilei Transformation \(\quad \rightarrow \quad \rightarrow\)
These equations are consistent with equations coming from a special Lorentz Transformation § 54.01.01
- Relativistic Kinematics.

Equation (54.01.02), in fact, is the same as equation (54.01.01).
Equation (54.01.02), when \(v_{z}=0\), in fact, implies that:
- the component of \(\mathbf{v}^{\prime}\) parallel to \(\mathbf{u}\) is \(\mathbf{-} \mathbf{u}\), which is the same result coming from equation (54.01.01) when \(v_{z}=0\);
- the component of \(\mathbf{v}^{\prime}\) perpendicular to \(\mathbf{u}\) is \(\mathbf{v} / \gamma\), which is the same result coming from equations (54.01.01), (54.01.01) when \(v_{z}=0\).

\subsection*{54.01.03 Ordinary Velocity and Proper Velocity}

Ordinary velocity is defined as: \(\mathbf{v} \equiv \frac{\mathrm{dx}}{\mathrm{d} t}\); from now on it will be simply called velocity. Both quantities, \(\mathrm{d} \mathbf{x}\) and \(\mathrm{d} t\) are measured with respect to the inertial Reference Frame of the observer, for a moving object.

Sometimes it might be useful to consider the distance per unit proper time, which defines a hybrid quantity, the so-called proper-velocity: \(\mathbf{V} \equiv \frac{\mathrm{dx}}{\mathrm{d} \tau}\). In this case dx is measured with respect to the inertial Reference Frame of the observer but the proper time is measured in the Reference Frame at rest with the moving object.

In fact, while remembering the relation between time and proper time
\[
\mathrm{d} t=\gamma \mathrm{d} \tau
\]
one can define, alongside with the velocity, the proper velocity, \(\mathbf{V}\) :
\[
\begin{gathered}
\mathbf{v} \equiv \frac{\mathrm{d} \mathbf{x}}{\mathrm{~d} t} \quad \mathbf{V} \equiv \frac{\mathrm{~d} \mathbf{x}}{\mathrm{~d} \tau} \\
\mathbf{V}=\gamma_{v} \mathbf{v} \quad|u| \ll c \Longrightarrow \mathbf{V}=\mathbf{v}
\end{gathered}
\]

The definition can be extended to the four-dimensional quantity:
\[
V \equiv \frac{\mathrm{~d} x}{\mathrm{~d} \tau} \quad\left\{\begin{array}{l}
\mathbf{V} \equiv \frac{\mathrm{d} \mathbf{x}}{\mathrm{~d} \tau}=\gamma_{v} \mathbf{v} \\
V^{0} \equiv \frac{\mathrm{~d} x^{0}}{\mathrm{~d} \tau}=\gamma_{v} c
\end{array}\right.
\]
which is called the proper velocity four-vector.
The proper velocity, \(V\), will transform according to Lorentz Transformation, that is a much easier transformation law than the transformation law for velocity.
It immediately follows from its definition that:
\[
V \cdot V=c^{2}
\]

Note that the proper velocity is a hybrid quantity: it is the ratio of a displacement as measured by the Reference Frame of the observer, \(\mathcal{J}\), and the time, as measured by an observer at rest with the moving object, that is moving with respect to Reference Frame of the observer, J.

\subsection*{54.01.04 Transformation Laws for the Acceleration}

The transformation law for ordinary acceleration is rather complex. Therefore proper acceleration is most often used, which transforms as a four-vector:
\[
A \equiv \frac{\mathrm{~d} V}{\mathrm{~d} \tau} \equiv \frac{\mathrm{~d}^{2} x}{\mathrm{~d} \tau^{2}}
\]

It turns out that:
\[
V \cdot A=0
\]

\subsection*{54.01.05 Mutual and Relative Position Velocity Acceleration}

This § is referenced at pages:
[2350, 2350, 2390, 2390]
- The concept of mutual vector involves one single observer and two different observed points: mutual velocity between two points, \(A\) and \(B\), as seen by the observer. Consequently, the concept of mutual vector cannot involve the Galilei/Lorentz transformations, because there is only one observer.
- The concept of relative vector, based on the composition of vectors, involves two different observers and one observed vector: I am observing one and ask for it as seen by another observer. Consequently, the concept of relative vector involves the Galilei/Lorentz transformations.
The most interesting case is that of the velocity vector.
These are, therefore, two different concepts:
- mutual velocity between two points, as seen by one external observer: \(\mathbf{u}_{2}-\mathbf{u}_{1}\) (one observer but two different observed points);
- relative velocity of one point with respect to another Reference Frame, moving with respect to the observer, that is the velocity of one point as measured by another Reference Frame, moving with respect to the observer (two different observers but one observed point).
The two concepts coincide in Galilei-Newton Mechanics due to Galilei-Invariance.
While the expression \(\mathbf{v}_{1}-\mathbf{v}_{2}\) is invariant under Galilei transformations it is not invariant under Lorentz Transformation.

\section*{Transformation of Frequency and wave-vector for MPW}

This § is referenced at pages:
[2106, 2106]

\subsection*{54.02.01 Lorentz Invariance of the Phase of MPW}

Consider a MPW (a scalar one, for simplicity), with angular frequency \(\omega\) and wave-vector \(\mathbf{k}\) :
\[
\psi[t, \mathbf{x}]=\psi^{0} \cos [\mathbf{k} \cdot \mathbf{x}-\omega t-\phi] \quad \Phi[\mathbf{x}, t] \equiv \mathbf{k} \cdot \mathbf{x}-\omega t-\phi
\]
where \(\psi^{0}\) is a scalar, giving the scalar character to the MPW.
Thanks to the linearity of Lorentz Transformation the phase-factor, \(\cos [\mathbf{k} \cdot \mathbf{x}-\omega t-\phi]\), will transform into a similar phase factor in any other Reference Frame, and therefore the MPW will appear as a MPW.
As the phase of the MPW must be a Lorentz invariant, as demonstrated below, the transformed MPW will have the same scalar/vector/tensor character in any Reference Frame, the one given by the multiplicative factor to the phase-factor (the scalar \(\psi^{0}\) in our case).
The phase of the wave must be a scalar (that is Lorentz invariant) because the measurement of the difference of the phase at two different space-time events can be reduced to the number of counts of the wave-crests in between the two space-time events, which must give the same result in any Reference Frame.
As a first example consider the difference of the phase at two different space points at the same time:
\[
\Delta \Phi=\mathbf{k} \cdot\left(\mathbf{x}_{2}-\mathbf{x}_{1}\right)=k\left|\mathbf{x}_{2}-\mathbf{x}_{1}\right| \cos \theta
\]
where \(\theta\) is the angle between the vectors \(\mathbf{k}\) and \(\mathbf{x}_{2}-\mathbf{x}_{1}\). The difference of the phase is just the fractional number of wavelengths (space periods) between the two space points (times \(2 \pi\) ).
As a second example consider the difference of the phase at the same space point between two different times:
\[
\Delta \Phi=-\omega\left(t_{2}-t_{1}\right)
\]

The difference of the phase is just the fractional number of time periods passing away at the fixed space point between the times \(t_{1}\) and \(t_{2}\) (times \(2 \pi\) ).

\subsection*{54.02.02 Lorentz Transformation of Frequency and wave-vector}

If one defines, for a wave with phase-velocity \(v\), the object with four-components \(k^{\mu}\) :
\[
k^{\mu} \equiv\{\omega / c, \mathbf{k}\} \equiv\left\{k^{0}, \mathbf{k}\right\} \quad v|\mathbf{k}|=\omega
\]

The fact that the phase is invariant implies that \(k^{\mu}\) is a four-vector (thanks to the quotient law § 18.03.06 - Coordinate Transformations Tensors and Physical Laws): the frequency wave-vector four-vector. Note that the time-like component is always \(\omega / c\) and not \(\omega / v\), as it follows from the expression of the phase in equations (54.02.01). Its transformation laws give the Doppler effect and the aberration of fronts.

\subsection*{54.02.03 Motion of the Source}

\subsection*{54.02.04 EM Radiation}

In the case of ElectroMagnetic radiation:
\[
c|\mathbf{k}|=\omega \Longrightarrow k^{\mu} k_{\mu}=0
\]

In the ElectroMagnetic case the phase-velocity is always \(c\) in any Reference Frame.
Consider the Reference Frame \(\mathcal{J}\), where a MPW has four-vector \(k \equiv\{\omega / c, \mathbf{k}\}\), and an observer moving with a velocity \(\mathbf{u}\) with its Reference Frame \(\mathcal{J}^{\prime}\), seing the MPW with four-vector \(k^{\prime} \equiv\left\{\omega^{\prime} / c, \mathbf{k}^{\prime}\right\}\). A light ray is described by the unit vector \(\hat{\mathbf{n}}\), in Reference Frame \(\mathcal{J}\), and by the unit vector \(\hat{\mathbf{n}}^{\prime}\), in \(\mathcal{J}^{\prime}\).

Relativistic optics is rather simple as there is no privileged Reference Frame. Light rays in vacuum follow straight paths with speed \(c\) in any Inertial Reference Frame.

Let us consider the boost between the two inertial Reference Frames, \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\), the latter moving with velocity \(\mathbf{u}\) with respect to the former, and denote the velocities of the same light ray in the two Reference Frames with \(\mathbf{v} \equiv c \hat{\mathbf{n}}\) and \(\mathbf{v}^{\prime} \equiv c \hat{\mathbf{n}}^{\prime}\).

\subsection*{54.02.04.01 Aberration of Light}

The law of addition of the velocities gives:
\[
\begin{equation*}
\frac{\mathbf{v}^{\prime}}{c} \equiv \hat{\mathbf{n}}^{\prime}=\frac{\frac{\hat{\mathbf{n}}}{\gamma_{u}}+\mathbf{u}\left(\left(1-\frac{1}{\gamma_{u}}\right) \frac{\mathbf{u} \cdot \hat{\mathbf{n}}}{u^{2}}-\frac{1}{c}\right)}{1-\frac{\mathbf{u} \cdot \hat{\mathbf{n}}}{c^{2}}} \tag{54.02.02}
\end{equation*}
\]
with inverse law:
\[
\begin{equation*}
\frac{\mathbf{v}}{c} \equiv \hat{\mathbf{n}}=\frac{\frac{\hat{\mathbf{n}}^{\prime}}{\gamma_{u}}+\mathbf{u}\left(\left(1-\frac{1}{\gamma_{u}}\right) \frac{\mathbf{u} \cdot \hat{\mathbf{n}}^{\prime}}{u^{2}}+\frac{1}{c}\right)}{1+\frac{\mathbf{u} \cdot \hat{\mathbf{n}}^{\prime}}{c^{2}}} \tag{54.02.03}
\end{equation*}
\]

Alternatively the aberration can be described via the law of transformation of the wave-vector, \(\mathbf{k}\), such that for a pure transformation one has:
\[
\mathbf{k}^{\prime}=\mathbf{k}+\boldsymbol{\beta}\left(\frac{\gamma-1}{\beta^{2}}(\boldsymbol{\beta} \cdot \mathbf{k})-\gamma \frac{\omega}{c}\right)=\mathbf{k}+\boldsymbol{\beta}\left(\frac{\gamma^{2}}{\gamma+1}(\boldsymbol{\beta} \cdot \mathbf{k})-\gamma \frac{\omega}{c}\right)
\]

The relation between \(\hat{\mathbf{n}}\) and \(\hat{\mathbf{n}}^{\prime}\) can be deduced from equations (54.02.02), (54.02.03), describing light aberration.

Let us define:
\[
\begin{aligned}
\hat{\mathbf{n}} \cdot \mathbf{u} & \equiv-u \cos \alpha \\
\hat{\mathbf{n}}^{\prime} \cdot \mathbf{u} & \equiv-u \cos \alpha^{\prime}
\end{aligned}
\]

Using equations (54.02.02), (54.02.03) one finds:
\[
\cos \alpha^{\prime}=\frac{\cos \alpha+\frac{u}{c}}{1+\frac{u}{c} \cos \alpha}
\]

\subsection*{54.02.04.02 Doppler Effect}
\[
\omega^{\prime}=\gamma(\omega-\mathbf{u} \cdot \mathbf{k})
\]

\section*{Particular Case of Source at Rest in the Moving System}

If the source is at rest in \(J^{\prime}\), so that the \(k^{\prime} \equiv\left\{\omega^{\prime} / c, \mathbf{k}^{\prime}\right\}\) is the proper frequency-wave-vector of the source, the observer will see the source moving with velocity \(\mathbf{u}\) with respect to \(\mathcal{J}\). Assume that the incoming light wave-vector, \(\mathbf{k}\), is perpendicular with respect to the velocity \(\mathbf{u}\).

Therefore:
\[
\mathbf{k} \cdot \mathbf{u}=0 \Longrightarrow \omega^{\prime}=\gamma \omega \geq \omega
\]
so that the observer sees a smaller frequency than the proper frequency of the source, that is a red-shift with respect to the proper frequency of the source.

Therefore the transformation law for the frequency gives the so-called transverse Doppler effect when the source is moving perpendicularly the line of sight in the opinion of the observer, which is a consequence of time dilatation.

This is a purely relativistic effect, for classically one would not expect any frequency shift from a source that moves by right angles with respect to the line of sight.

\section*{Transverse Doppler Effect}

The transverse Doppler effect comes in when a light ray is reaching the observer Reference Frame, J, perpendicularly to the velocity, \(\mathbf{u}\), of \(\mathcal{J}^{\prime}: k \cdot u=0\).

Consider in fact the boost, equation (53.09.11), with \(\mathbf{k} \cdot \mathbf{u}=0\), one can write:
\[
\mathbf{k} \cdot \mathbf{u}=0 \Longrightarrow\left\{\begin{array}{l}
\omega^{\prime}=\gamma \omega \\
\mathbf{k}^{\prime}=\mathbf{k}-\boldsymbol{\beta} \gamma \omega / c
\end{array}\right.
\]

As a consistency check one can use the previous result to evaluate:
\[
\omega=\gamma\left(\omega^{\prime}+c \boldsymbol{\beta} \cdot \mathbf{k}^{\prime}\right)=\gamma\left(\omega^{\prime}+\beta^{2} \gamma \omega\right) \Longrightarrow \omega=\omega^{\prime} / \gamma
\]

Note that the presence of the source is, so-far, inessential.

\subsection*{54.02.05 Experimental Tests of Special Relativity With Waves}

This § is referenced at pages:
[2371, 2371]
54.02.05.01 Experimental Test of Special Relativity via the Stellar Redshift

\subsection*{54.02.05.02 Experimental Test of Special Relativity via the Ives-Stilwell Experiment}

In 1938 Ives and Stilwell observed the spectral lines of a high-velocity beam of hydrogen atoms. The spectral lines are blue shifted when looking in front of the incoming beam while they are red-shifted when looking at the beam from behind.
Show that the average forward-backward shift is blue shifted by a factor \(\gamma\).

\section*{Examples and Physical Applications}

\subsection*{54.03.01 Relativity and Absolute Quantities}

Note that there actually exist absolute quantities in relativity, indeed: the rest length of a rod is an absolute quantity, the same for all inertial observers; the proper time of a clock, which might better have been called the local time, is an invariant quantity.
Also, in non-relativistic physics, it is a common notion that measured physical quantities depend on the inertial Reference Frame: velocity, kinetic energy, frequency....

\section*{© - QUOTE}
R.Resnick, Introduction To Special Relativity, 1968, J.Wiley \& Sons, ...Ed., ....

Moreover, there are absolute lengths and times in relativity. The rest length of a rod is an absolute quantity, the same for all inertial observers: if a given rod is measured by different inertial observers by bringing the rod to rest in their respective frames, each will measure the same length. Similarly for clocks, the proper time (which might better have been called local time) is an invariant quantity: the frequency of oscillation of an ammonia molecule, for instance, would be measured to be the same by different inertial observers who bring the molecule to rest in their respective frames.

\subsection*{54.03.02 Lorentz Transformation of the Module of Speed}

Read § 54-003 - Relativistic Kinematics to demonstrate that the Lorentz transform of any speed less than \(c\) is less than \(c\) :
\[
\begin{equation*}
c^{2}-v^{\prime 2}=\frac{\left(c^{2}-v^{2}\right)\left(c^{2}-u^{2}\right)}{\left(c^{2}-\mathbf{u} \cdot \mathbf{v}\right)^{2}} \tag{54.03.01}
\end{equation*}
\]

\subsection*{54.03.03 Laser Cooling}
© - QUOTE
©|WEB - URLI||
Laser cooling refers to the number of techniques in which atomic and molecular samples are cooled through the interaction with one or more laser light fields. The first example of laser cooling, and also still the most common method of laser cooling (so much so that it is still often referred to as laser cooling) is Doppler cooling.
Doppler cooling, which is usually accompanied by a magnetic trapping force to give a magnetooptical trap, is by far the most common method of laser cooling. It is used to cool low density gasses down to the Doppler cooling limit, which for Rubidium 85 is around 150 microkelvin. As Doppler cooling requires a very particular energy level structure, known as a closed optical loop, the method is limited to a small handful of elements.
In Doppler cooling, the frequency of light is tuned slightly below an electronic transition in the atom. Because the light is detuned to the "red" (i.e. at lower frequency) of the transition, the atoms will absorb more photons if they move towards the light source, due to the Doppler effect. Thus if one applies light from two opposite directions, the atoms will always scatter more photons
from the laser beam pointing opposite to their direction of motion. In each scattering event the atom loses a momentum equal to the momentum of the photon. If the atom, which is now in the excited state, emits a photon spontaneously, it will be kicked by the same amount of momentum but in a random direction. The result of the absorption and emission process is to reduce the speed of the atom, provided its initial speed is larger than the recoil velocity from scattering a single photon. If the absorption and emission are repeated many times, the mean velocity, and therefore the kinetic energy of the atom will be reduced. Since the temperature of an ensemble of atoms is a measure of the random internal kinetic energy, this is equivalent to cooling the atoms.

\subsection*{54.03.04 Astronomical Apparently Super-Luminal Objects}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Problem 12.6||
Gli astronomi hanno scoperto oggetti che emettono getti di materia ad altissima velocità. Se la distanza dell'oggetto dalla Terra è nota (sia \(d\) ) la misura della velocità angolare alla quale si vede il getto muoversi sulla sfera celeste permette di determinare la velocità con cui il getto di materia è emesso dal nucleo centrale. In alcuni casi sono stati osservati getti in moto con velocità apparente superiore alla velocità della luce, fatto in apparente contraddizione con la teoria della relatività speciale. Mostrare come sia possibile ottenere velocità apparenti superiori a quella della luce e come ciò non contrasti con la relatività speciale considerando l'emissione del getto ad un angolo \(\theta\) rispetto alla linea di vista dell'osservatore terrestre.
1. Determinare la relazione tra velocità apparente e quella reale del getto di materia.
2. Determinare la velocità apparente di un sistema in cui la direzione di emissione del getto forma un angolo \(\theta=9.2^{\circ}\) con la direzione di vista supponendo la velocità di emissione pari a \(v=0.987 c\) (questa si può determinare dallo studio dello spostamento Doppler delle linee spettrali).
3. Determinare il valore dell'angolo \(\theta\) per cui la velocità apparente del getto sulla sfera celeste è massima e il valore di tale velocità massima.

\section*{SOLUTION}

Sia \(t_{0}\) l'istante di emissione del getto di materia in direzione \(\theta\) rispetto alla linea di vista. L'emissione del getto viene osservata da Terra al tempo \(t_{1}\) :
\[
t_{1}=t_{0}+d / c
\]

Il getto viene osservato da Terra, dopo che ha percorso la distanza \(v \Delta t\), all'istante
\[
t_{2}=t_{0}+\Delta t+\frac{d-v \Delta t \cos \theta}{c}
\]

L'intervallo di tempo \(\Delta t\) tra le due osservazioni da Terra è
\[
t_{2}-t_{1}=\Delta t\left(1-\frac{v \cos \theta}{c}\right)<\Delta t \quad(\text { se } \cos \theta>0)
\]

L'astronomo conosce la distanza \(d\) dell'oggetto e misura uno spostamento angolare \(\Delta \theta\) sulla sfera celeste da cui deduce uno spostamento apparente \(\Delta x\) del getto. Lo spostamento apparente \(\Delta x\) sulla sfera celeste vale
\[
\Delta x \equiv \Delta \theta d=\frac{v \Delta t \sin \theta}{d} d=v \Delta t \sin \theta
\]
è da notare il fatto che la relazione precedente è esatta essendo \(d \gg v \Delta t\) per cui non è necessario distinguere fra la distanza dell'oggetto che emette il getto, \(d\), e la distanza del getto al tempo \(t_{2}\) che vale \(\simeq d-v \Delta t \cos \theta\). La velocità apparente osservata risulta dunque:
\[
v_{\mathrm{app}}(\theta)=\frac{\Delta x}{t_{2}-t_{1}}=\frac{d \Delta \theta}{t_{2}-t_{1}}=\frac{v \sin \theta}{1-(v / c) \cos \theta}
\]
che può essere maggiore di \(c\).

Il massimo della velocità al variare dell'angolo di emissione \(\theta\) si trova derivando rispetto a \(\theta\) e ponendo la derivata uguale a zero:
\[
\frac{d v_{\mathrm{app}}(\theta)}{d \theta}=\frac{v \cos \theta-v^{2} / c}{(1-v / c \cos \theta)^{2}}=0
\]
da cui segue che l'angolo a cui si ottiene la velocità apparente massima e la velocità apparente massima valgono
\[
\cos \left[\theta_{\max }\right]=v /\left.c \quad v_{\mathrm{app}}\right|_{\max }=\frac{v}{\sqrt{1-v^{2} / c^{2}}}
\]

Con i dati del problema si ottiene \(v_{\mathrm{app}}=6.14 c\).

\section*{SOLUTION}
1. \(v_{\mathrm{app}}(\theta)=v \sin \theta /(1-(v / c) \cos \theta)\);
2. \(v_{\text {app }}=6.14 c\);
3. \(\cos \theta_{\max }=v / c\).

\section*{Exercises Problems and Physical Applications}

\section*{54-001 Airplane and Speeds}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12.2||

In order to appreciate the different use of the ordinary and proper velocity consider somebody flying on a airplane.

When the pilot is speaking about the velocity is speaking about the distance measured on ground divided by the time measured on ground, presumably. This is what you are concerned if you have an appointment after arrival.

On the other hand if you are interested in whether you will be hungry or not after arrival you are dealing with the proper time for you, and therefore you would like to know the hybrid proper velocity.

\section*{54-002 Composition of Two Velocities Close to the Speed of Light}

Assume \(|u| \leq c\) and \(u \simeq c\) as well as \(\left|v^{\prime}{ }_{z}\right| \leq c\) and \(v_{z}^{\prime} \simeq c\). Show that \(v_{z} \simeq c\).

\section*{54-003 Relation Between the Modules of the Velocities}

This § is referenced at pages:
[2381, 2381, 2387, 2387]
©|H.M.Schwartz, Introduction To Special Relativity, 1968, McGraw-Hill, ...Ed., ....|||
Show that the modules of the velocities are related by equation (54.03.01):
\[
c^{2}-v^{\prime 2}=c^{2} \frac{\left(c^{2}-v^{2}\right)\left(c^{2}-u^{2}\right)}{\left(c^{2}-\mathbf{u} \cdot \mathbf{v}\right)^{2}} .
\]

Note that the expression is symmetrical in \(\mathbf{u}\) and \(\mathbf{v}\).
Use this equation to show that the module of the velocity \(v^{\prime 2}\) will always be smaller than \(c\) as long as both modules of \(\mathbf{v}\) and \(\mathbf{u}\) are smaller than \(c\).
Show that the above equation can be also written as:
\[
v^{\prime 2}=c^{2} \frac{c^{2}(\mathbf{v}-\mathbf{u})^{2}-(\mathbf{v} \times \mathbf{u})^{2}}{\left(c^{2}-\mathbf{u} \cdot \mathbf{v}\right)^{2}} .
\]

\section*{54-004 Relation Between the Modules of the Velocities}
©|H.M.Schwartz, Introduction To Special Relativity, 1968, McGraw-Hill, ...Ed., ....|problem 3.3||
Show that:
\[
\gamma_{v^{\prime}}=\left(1-\frac{\mathbf{v} \cdot \mathbf{u}}{c^{2}}\right) \gamma_{v} \gamma_{u}
\]

\section*{54-005 Relative Velocity}

Read § 54.01.05-Relativistic Kinematics.
If one observer measures two objects to be traveling at velocities \(\mathbf{v}_{1}\) and \(\mathbf{v}_{2}\) respectively what is the relative speed between the two objects, that is what speed observer (1) would measure observer (2) to be traveling at, or vice versa.
In Galilean mechanics the relative velocity is just:
\[
\mathbf{v}_{21}=\mathbf{v}_{2}-\mathbf{v}_{1}
\]

Show that in relativistic mechanics the relative velocity is:
\[
\mathbf{v}_{21} \equiv \frac{\sqrt{\left(\mathbf{v}_{2}-\mathbf{v}_{1}\right)^{2}-\left(\mathbf{v}_{1} \times \mathbf{v}_{2}\right)^{2} / c^{2}}}{\left(1-\mathbf{v}_{1} \cdot \mathbf{v}_{2} / c^{2}\right)}
\]

\section*{54-006 Properties of the Four-Acceleration}

Show that:
\[
A \cdot A=A^{\alpha} A_{\alpha}=\gamma_{v}^{4}\left(\mathbf{a} \cdot \mathbf{a}+\gamma_{v}^{2}(\mathbf{v} \cdot \mathbf{a})^{2} / c^{2}\right)
\]

Show that in the particle rest-frame the module of the four-acceleration is the square of the proper acceleration, \(\mathbf{a}_{0}\).
Show that:
\[
A \cdot A=A^{\alpha} A_{\alpha}=\left|\mathbf{a}_{0}\right|^{2}=\gamma_{v}^{4}\left(a_{\perp}^{2}+\gamma_{v}^{2} a_{\|}^{2}\right)
\]

\section*{54-007 Relationship Between the 3-Velocity and the Four-Velocity}

For events along the world-line of a particle traveling with 3 -velocity \(\mathbf{u}\) we have the following result for the link between the 3 -velocity and the four-velocity:
\[
\begin{equation*}
V^{\alpha} \equiv \frac{\mathrm{d} x^{\alpha}}{\mathrm{d} \tau}=\frac{\mathrm{d} t}{\mathrm{~d} \tau} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} t}=\gamma_{v} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} t} \equiv \gamma_{v} v^{\alpha}=\left\{\gamma_{v} c, \gamma_{v} \mathbf{v}\right\} \tag{54.04.01}
\end{equation*}
\]

Show that:
\[
V \cdot V=V^{\alpha} V_{\alpha}=V_{\alpha} V^{\alpha}=c^{2} .
\]

\section*{54-008 Relationship Between the 3-Acceleration and the Four-Acceleration}

The relationship between the 3 -acceleration and the four-acceleration is less straightforward the corresponding one among velocities.
Introduce the four-acceleration:
\[
\begin{equation*}
A^{\alpha} \equiv \frac{\mathrm{d}^{2} x^{\alpha}}{\mathrm{d} \tau^{2}}=\frac{\mathrm{d} V^{\alpha}}{\mathrm{d} \tau}=\gamma_{v} \frac{\mathrm{~d} V^{\alpha}}{\mathrm{d} t}=\gamma_{v} \frac{\mathrm{~d}}{\mathrm{~d} t}\left(\gamma_{v} v^{\alpha}\right)=\gamma_{v} \frac{\mathrm{~d}}{\mathrm{~d} t}\left\{\gamma_{v} c, \gamma_{v} \mathbf{v}\right\} \tag{54.04.02}
\end{equation*}
\]

Show that:
\[
A^{\alpha}=\gamma_{v}\left(c \frac{\mathrm{~d} \gamma_{v}}{\mathrm{~d} t}, \gamma_{v} \mathbf{a}+\mathbf{v} \frac{\mathrm{d} \gamma_{v}}{\mathrm{~d} t}\right) \quad \text { where } \quad \mathbf{a} \equiv \frac{\mathrm{d} \mathbf{v}}{\mathrm{~d} t}
\]

Show that in the Rest Frame of the particle one has:
\[
V^{\alpha}=\{c, \mathbf{0}\} \quad A^{\alpha}=\{0, \mathbf{a}\} .
\]

Moreover, show that:
\[
V \cdot A=0 .
\]

\section*{SOLUTION}

The Rest Frame moves with the particle. Therefore in that system one has:
\[
\mathbf{v}=\mathbf{0} \quad \text { constant } \quad \gamma_{v}=1 \quad \text { constant } .
\]

It therefore follows:
\[
\frac{\mathrm{d} \gamma_{v}}{\mathrm{~d} t}=0
\]
and then
\[
V^{\alpha}=\{c, \mathbf{0}\} \quad A^{\alpha}=\{0,1 \cdot \mathbf{a}+\mathbf{v} \cdot 0\}=\{0, \mathbf{a}\} .
\]

\title{
Relativistic Energy/Linear Momentum and Power/Force
}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12||
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|11.5, 3rd ed.|Energy and linear momentum in relativity and L-invaria
The laws of Galilei-Newton Mechanics are not compatible with the postulates of relativity, because, among other things, a constant force can make the speed of any mass point arbitrarily large, if acting long enough. This is incompatible with the speed of light being a limiting speed, read § 53.12.01 - From Galilei Transformation to Lorentz Transformation. Moreover, for speeds approaching the speed of light, total energy and total linear momentum of an isolated system, as Newton defined linear momentum and energy, are not conserved; this is an experimental fact.

\subsection*{55.01.01 Relativistic Four-Momentum}

In Galilei-Newton Mechanics, linear momentum is a vector, defined as the product of mass times the velocity, \(\mathbf{p}=m \mathbf{v}\). Therefore it transforms as the velocity, not in the simple way of a Lorentz Transformation: it is not, in fact, the space part of a four-vector. Under Lorentz Transformation, the transformation law of the linear momentum of Galilei-Newton Mechanics, is the same as the transformation law of velocity: cumbersome and non linear.
Therefore when trying to extend the definition of linear momentum into relativistic physics one wonders whether ordinary or proper velocity needs to be used. Any extension of this concept must:
- reduce to the Galilei-Newton Mechanics expression at low velocities;
- ensure linear momentum conservation in isolated systems, regardless of the velocities of the particles relative to Reference Frame and this must be an invariant concept;
- be linked to the resultant of the external forces for non-isolated systems.

If one attempts to extend the concept of linear momentum using the four-velocity, instead of the ordinary velocity, one finds an expression whose space part transforms as the space part of a four-vector and reduces to the Galilei-Newton Mechanics expression of the ordinary velocity in the low velocity limit. Moreover, the time component of the four-velocity is proportional to \(\gamma\) : it is not clear, so far what it is.
One can then try the following definitions, waiting for confirmation that the resulting quantity is useful to describe the dynamics, that is:
- it is conserved for an isolated system;
- it is linked to the resultant of external forces for a non-isolated system.

See §55.01.03 - Relativistic Dynamics and § 55.01.02-Relativistic Dynamics.
Let us define the tentative Four-Momentum as the contravariant four-vector:
\[
\begin{gathered}
\hline p^{\mu} \equiv\{\varepsilon / c, \mathbf{p}\} \equiv m V^{\mu} \quad \text { whatever } p^{\mu} \text { is } \\
V \cdot V=c^{2} \Longrightarrow \quad p \cdot p=m^{2} c^{2}
\end{gathered}
\]

Moreover:
\[
\begin{gathered}
p^{0} \equiv \varepsilon / c=m \gamma c \\
\hline \mathbf{p \equiv m \mathbf { V } = m \gamma \mathbf { v }}, \\
\gamma \equiv \gamma_{v} \equiv\left(1-v^{2} / c^{2}\right) \\
\hline
\end{gathered}
\]

While the space-part looks like a sensible extension of the linear momentum of Galilei-Newton Mechanics, it is not clear what \(\varepsilon\) is, yet. It is anticipated that it is the energy, see \(\S 55.01 .03\) - Relativistic Dynamics. Linear momentum and energy are different concepts but in relativity they are combined and put on equal footing as for space and time.

All in all we have the special Lorentz Transformation for the Four-Momentum is:
\[
\begin{gathered}
\varepsilon^{\prime}=\gamma_{u}\left(\varepsilon-u p_{z}\right) \\
p_{x}^{\prime}=p_{x} \\
p_{y}^{\prime}=p_{y} \\
p_{z}^{\prime}=\gamma_{u}\left(p_{z}-u \varepsilon / c^{2}\right)
\end{gathered}
\]

And the inverse Lorentz Transformation:
\[
\begin{gathered}
\varepsilon=\gamma_{u}\left(\varepsilon^{\prime}+u p_{z}^{\prime}\right) \\
p_{x}=p_{x}^{\prime} \\
p_{y}=p_{y}^{\prime} \\
p_{z}=\gamma_{u}\left(p_{z}^{\prime}+u \varepsilon^{\prime} / c^{2}\right)
\end{gathered}
\]

One needs to understand what is the meaning of \(p^{0}\), the time component of the four-vector defined above. It is what was called relativistic mass in the past, but this term is misleading, as of today and should not be used. Nowadays it is usually called just the energy.

Squaring equation \((55.01 .01),(55.01 .01)\) and subtracting side by side one finds:
\[
\varepsilon=\sqrt{p^{2} c^{2}+m^{2} c^{4}}>0
\]

However, at this stage, it is not clear what \(\varepsilon\) is, yet; read \(\S 55.01 .03\) - Relativistic Dynamics. Dividing side by side equation \((55.01 .01)\) by \((55.01 .01)\) one finds:
\[
c^{2} \mathbf{p}=\varepsilon \mathbf{v} \quad \Leftrightarrow \quad \mathbf{v}=c^{2} \frac{\mathbf{p}}{\varepsilon} \quad|\mathbf{v}| \leq c
\]

\subsection*{55.01.01.01 Contravariant and Covariant Forms of Four-Momentum}

By definition the Energy-LinMomentum four-vector of any system is defined in terms of the energy and linear momentum as:
\[
p^{\alpha} \equiv\{\varepsilon / c,+\mathbf{p}\} \quad \Leftrightarrow \quad p_{\alpha} \equiv\{\varepsilon / c,-\mathbf{p}\}
\]
with
\[
p \cdot p=p^{\alpha} p_{\alpha}=p_{\alpha} p^{\alpha}=\varepsilon^{2} / c^{2}-\mathbf{p} \cdot \mathbf{p}=m^{2} c^{2} \quad m \text { is the mass }
\]

The mass \(m\) is what was called rest mass in the past, but this term is redundant, as of today. Nowadays it is usually called just the mass an intrinsic property of any system. Note that the mass, \(\varepsilon_{0}=m c^{2}\), is a Lorentz invariant but not conserved quantity.

\subsection*{55.01.02 Invariance and Four-Momentum Conservation for Isolated Systems}

This § is referenced at pages:
[2395, 2395, 2399, 2399]
Consider a collision problem among any number of particles in the initial state and any other number of particles in the final state, a priori different particles from the ones in the initial state.

For simplicity only, consider a one-dimensional collision problem with just two particles in the initial state and just two particles in the final state:
\[
\begin{equation*}
a+b \rightarrow A+B \quad(a+b+c+\ldots \rightarrow A+B+C+\ldots) \tag{55.01.01}
\end{equation*}
\]

\subsection*{55.01.02.01 Galilei Transformation and Classical Linear Momentum Conservation}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 12.2||
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
Using Galilei Transformation, if classical linear momentum, \(\mathbf{p}=m \mathbf{v}\), is conserved in one inertial Reference Frame it is conserved in another inertial Reference Frame if and only if the sum of the masses (the total mass) is conserved.
Note that there is no assumption that the number of incoming particles is equal to the number of outgoing particles, only that the total mass is conserved.
Even if it is known that Galilei Transformation are non correct in general this result shows that GalileiNewton Mechanics is self-consistent when it is valid, that is for velocities small with respect to the speed of light.

\section*{SOLUTION}
\[
\begin{gathered}
\left(p_{A}+p_{B}\right)-\left(p_{C}+p_{D}\right)=0, \\
\left(m_{A} v_{A}+m_{B} v_{B}\right)-\left(m_{C} v_{C}+m_{D} v_{D}\right)=0, \\
\left(m_{A}\left(v_{A}^{\prime}+u\right)+m_{B}\left(v_{B}^{\prime}+u\right)\right)-\left(m_{C}\left(v_{C}^{\prime}+u\right)+m_{D}\left(v_{D}^{\prime}+u\right)\right)=0, \\
\left(\left({p_{A}^{\prime}}_{A}+p_{B}^{\prime}\right)-\left(p_{C}^{\prime}+p_{D}^{\prime}\right)\right)+u\left(\left(m_{A}+m_{B}\right)-\left(m_{C}+m_{D}\right)\right)=0
\end{gathered}
\]
55.01.02.02 Lorentz Transformation and Classical Linear Momentum Non-Conservation
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 12.28||
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
It can be shown that the classical linear momentum, \(\mathbf{p}=m \mathbf{v}\) is incompatible with linear momentum conservation and Lorentz Transformation. It is not true that, using Lorentz Transformation, if classical linear momentum, \(\mathbf{p}=m \mathbf{v}\), is conserved in one inertial Reference Frame it is conserved in another inertial Reference Frame.
As it is known that Lorentz Transformation are the correct transformation rules among different Reference Frame, not Galilei Transformation, this implies that the notion of classical linear momentum of Galilei-Newton Mechanics must be abandoned.

\subsection*{55.01.02.03 Lorentz Transformation and Relativistic Linear Momentum Conservation}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|problem 12.28||
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
Using Lorentz Transformation, if relativistic linear momentum, \(\mathbf{p}=m \gamma \mathbf{v}\), is conserved in one inertial Reference Frame it is conserved in another inertial Reference Frame if and only if the sum of the relativistic energies (the total energy) is conserved.
As we know that Lorentz Transformation are the correct transformations in general, this result shows that in order to generalize the definition of classical linear momentum of Galilei-Newton Mechanics to something meaningful one needs to use the relativistic linear momentum defined as the product of mass times the proper velocity. This is necessary in order to have an invariant conservation of linear momentum.

\section*{SOLUTION}

\section*{Direct Calculation via the Velocity Transformations}

The direct calculation is long and tedious, because the transformation law for the velocity is complex. The following identity can be used:
\[
\gamma_{v} v=\gamma_{u} \gamma_{v^{\prime}}\left(u+v^{\prime}\right)
\]

Therefore:
\[
\begin{gathered}
v_{X}=\frac{v_{X}^{\prime}+u}{1+u v_{X}^{\prime} / c^{2}} \\
\left(p_{A}+p_{B}\right)-\left(p_{C}+p_{D}\right)=0, \\
\left(m_{A} \gamma_{v_{A}} v_{A}+m_{B} \gamma_{v_{B}} v_{B}\right)-\left(m_{C} \gamma_{v_{C}} v_{C}+m_{D} \gamma_{v_{D}} v_{D}\right)=0 \quad, \\
\left(m_{A} \gamma_{v_{A}}\left(\frac{v_{A}^{\prime}+u}{1+u v_{A}^{\prime} / c^{2}}\right)+m_{B} \gamma_{v_{B}}\left(\frac{v_{B}^{\prime}+u}{1+u v^{\prime} / c^{2}}\right)\right)-\left(m_{C} \gamma_{v_{C}}\left(\frac{v_{C}^{\prime}+u}{1+u v^{\prime} C_{C}^{2}}\right)+m_{D} \gamma_{v_{D}}\left(\frac{v_{D}^{\prime}+u}{1+u v_{D}^{\prime} / c^{2}}\right)\right)=0
\end{gathered}
\]
\[
\ldots \quad \text { by developing the calculations one is led to use: } \quad \gamma_{v} v=\gamma_{u} \gamma_{v^{\prime}}\left(u+v^{\prime}\right)
\]
\[
\left(m_{A} \gamma_{v_{A}} v_{A}+m_{B} \gamma_{v_{B}} v_{B}\right)-\left(m_{C} \gamma_{v_{C}} v_{C}+m_{D} \gamma_{v_{D}} v_{D}\right)=0
\]
\[
\left(m_{A} \gamma_{u} \gamma_{v^{\prime}}\left(u+v_{A}^{\prime}\right)+m_{B} \gamma_{u} \gamma_{v^{\prime}}\left(u+v_{B}^{\prime}\right)\right)-\left(m_{C} \gamma_{u} \gamma_{v^{\prime}}\left(u+v_{C}^{\prime}\right)+m_{D} \gamma_{u} \gamma_{v^{\prime}}\left(u+v_{D}^{\prime}\right)\right)=0
\]
\[
\gamma_{u}\left(\left(m_{A} \gamma_{v_{A}^{\prime}} v_{A}^{\prime}{ }_{A}^{\prime}+m_{B} \gamma_{v_{B}^{\prime}} v_{B}^{\prime}\right)-\left(m_{C} \gamma_{v_{C}^{\prime}} v_{C}^{\prime}+m_{D} \gamma_{v_{D}^{\prime}} v_{D}^{\prime} v_{D}^{\prime}\right)\right)+u \gamma_{u}\left(\left(m_{A} \gamma_{v_{A}^{\prime}}+m_{B} \gamma_{v_{B}^{\prime}}\right)-\left(m_{C} \gamma_{v_{C}^{\prime}}+m_{D} \gamma_{v^{\prime} D}\right)\right)=0 .
\]

\section*{Using the Four-Momentum Transformation Law}

By using the transformation law for the Four-Momentum the calculation is simpler:
\[
p=\gamma_{u}\left(p^{\prime}+u \varepsilon^{\prime} / c^{2}\right)
\]

The immediate result is:
\[
\begin{gathered}
\left(p_{A}+p_{B}\right)-\left(p_{C}+p_{D}\right)=0 \\
\left(\left(p_{A}^{\prime}+p_{B}^{\prime}\right)-\left(p_{C}^{\prime}+p_{D}^{\prime}\right)\right)+\frac{u}{c^{2}}\left(\left(\varepsilon_{A}^{\prime}+\varepsilon_{B}^{\prime}\right)-\left(\varepsilon_{C}^{\prime}+\varepsilon_{D}^{\prime}\right)\right)=0
\end{gathered}
\]

\subsection*{55.01.02.04 Galilei Transformation and Relativistic Linear Momentum Non-Conservation}

One might also show, by direct calculation, that it is false, in general, that: using Galilei Transformation, if relativistic linear momentum, \(\mathbf{p}=m \gamma \mathbf{v}\), is conserved in one inertial Reference Frame it is conserved in another inertial Reference Frame.
Obviously, the statement will be true in the Galilei-Newton Mechanics low-velocity limit, but it is not true in general.

\subsection*{55.01.03 Relativistic Energy}

This § is referenced at pages:
[2395, 2395, 2395, 2395, 2396, 2396]
Let us now try to figure out what the meaning of \(\varepsilon\) is.
- First of all, recall the strict link between the space and time components of the Four-Momentum induced by Lorentz invariance, as discussed in § 55.01.02 - Relativistic Dynamics.
- Consider the low-energy limit. When the object is at rest we obtain the rest energy, which is non-zero, for \(m>0\) :
\[
\begin{array}{|lllll|}
\hline \varepsilon_{0}=m c^{2} & \Leftrightarrow & \mathbf{p}=0 & \Leftrightarrow & \mathbf{v}=0 \\
\hline
\end{array}
\]

The remainder of the total energy when the rest energy is subtracted is defined as the kinetic energy, as it reduces to the kinetic energy of classical mechanics at low velocities:
\[
\begin{equation*}
\mathcal{K} \equiv \varepsilon-m c^{2} \quad \mathcal{K} \simeq \frac{1}{2} m v^{2}+\frac{3 m v^{4}}{8 c^{2}}+\ldots \quad \text { for low velocities }|\mathbf{v}| \ll c \tag{55.01.02}
\end{equation*}
\]

All in all, it makes sense to consider the zero component of the Four-Momentum as the relativistic extension of the total energy of a point-mass.

\subsection*{55.01.03.01 Massless Particles}

Note that in Galilei-Newton Mechanics there is no such thing as a massless particle. In fact for any massless system Galilei-Newton Mechanics predicts that the resultant of the external force must be zero and therefore the force applied by the massless system onto any other system is zero as well. Moreover, it has zero linear momentum and zero kinetic energy. Therefore a massless system in Galilei-Newton Mechanics has no interactions with nothing else.
Conversely in relativistic mechanics one has a meaningful:
\[
m=0 \Longrightarrow\left\{\begin{array}{lll} 
& \varepsilon=p c & |\mathbf{v}|=c
\end{array}\right\}
\]

The question arises what distinguishes two photons with different energies. Relativity provides no answer. Quantum physics shows that they differ in the frequency of the associated wave, which, in the case of photons, relates to the wavelength of the ElectroMagnetic radiation.

\subsection*{55.01.03.02 (Non/Ultra)-Relativistic Limits}

The non-relativistic and extreme relativistic limits are:
\[
\left\{\begin{array}{|l}
p \ll m c \Longrightarrow \varepsilon \simeq m c^{2}+\frac{p^{2}}{2 m} \\
p \gg m c \Longrightarrow \varepsilon \simeq p c+\frac{m^{2} c^{3}}{2 p}
\end{array},\right.
\]

\subsection*{55.01.03.03 On Relativistic Energy}

This § is referenced at pages:
[1300, 1300]
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|Problem 12.02 12.28||
So far what has been described in section §55.01 - Relativistic Dynamics may be just a useful notation, and nothing more with any physics content.
If all the velocities are so small that the non-relativistic approximation is valid, then the classical laws of conservation of mass and linear momentum are equivalent to the conservation of the time and space parts of Four-Momentum.
This suggests the use of Four-Momentum as an extension of the classical linear momentum.

\subsection*{55.01.03.04 Conservation of Energy}

\section*{©|TaylorWheeler|||}

The total energy of an isolated system is conserved. Total energy is conserved in all interactions: elastic and inelastic collisions as well as creations, transformations, decays and annihilations of particles. In contrast the total kinetic energy of a system calculated using Galilei-Newton Mechanics for low-speed is conserved only for elastic collisions, which are in fact defined as collisions in which kinetic energy is conserved. In inelastic collisions kinetic energy transforms into other forms of energy, such as internal energy, chemical energy, potential energy or other forms of energy. In Galilei-Newton Mechanics each of these forms of energy must be treated separately and conservation of energy must be invoked as a separate principle, as something beyond the Galilei-Newton Mechanics analysis of mechanical energy.

\subsection*{55.01.04 Relativistic Power and Force for Non Isolated Systems}

\subsection*{55.01.04.01 First Cardinal Equation for Relativistic Point Masses}

The First Cardinal Equations are still valid for point masses, provided the relativistic expressions of linear momentum and energy are used:
\[
\begin{gather*}
\pi \equiv \mathbf{v} \cdot \mathbf{f}=\frac{\mathrm{d} \varepsilon}{\mathrm{~d} t}  \tag{55.01.03}\\
\mathbf{f}=\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}  \tag{55.01.04}\\
\{\pi / c, \mathbf{f}\}=\frac{\mathrm{d}}{\mathrm{~d} t}\{\epsilon / c, \mathbf{p}\}=\frac{\mathrm{d} p}{\mathrm{~d} t}  \tag{55.01.05}\\
\hline
\end{gather*}
\]

The Second Cardinal Equations are still valid for point masses and pole at the point itself, provided the relativistic expressions are used:
\[
\begin{equation*}
\gamma=\frac{\mathrm{d} \mathbf{s}}{\mathrm{~d} t} \tag{55.01.06}
\end{equation*}
\]

\subsection*{55.01.04.02 Relation Between Force and Acceleration}

This § is referenced at pages:
[2416, 2416]
\[
\begin{equation*}
\mathbf{f}=\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}=m\left(\gamma \frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}+\mathbf{v} \frac{\mathrm{d} \gamma}{\mathrm{~d} t}\right)=m\left(\gamma \frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}+\mathbf{v} \frac{\gamma^{3} v}{c^{2}} \frac{\mathrm{~d} v}{\mathrm{~d} t}\right)=m\left(\gamma \mathbf{a}+\mathbf{v} \frac{\gamma^{3} v}{c^{2}} \frac{\mathrm{~d} v}{\mathrm{~d} t}\right) \tag{55.01.07}
\end{equation*}
\]

The component perpendicular to the velocity, which has contributions from the first term only in (55.01.07), is:
\[
\mathbf{f}_{\perp}=m \gamma\left(\frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}\right)_{\perp}=m \gamma \mathbf{a}_{\perp}
\]

The component parallel to the velocity, which has contributions from both terms in (55.01.07), is (read § 55.04.10 - Relativistic Dynamics):
\[
\mathbf{f}_{\|}=m \gamma^{3}\left(\frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}\right)_{\|}=m \gamma^{3} \mathbf{a}_{\|}
\]

Therefore:
\[
\begin{array}{r}
\mathbf{f}_{\|}=\left(\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}\right)_{\|}=m \gamma^{3} \mathbf{a}_{\|} \\
\mathbf{f}_{\perp}=\left(\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}\right)_{\perp}=m \gamma \mathbf{a}_{\perp}
\end{array}
\]

Note that the inertia to forces parallel/perpendicular to the velocity are different.
The relation can also be written as:
\[
\mathbf{f}=m \gamma\left(\mathbf{a}+\gamma^{2} \frac{\mathbf{v}(\mathbf{v} \cdot \mathbf{a})}{c^{2}}\right)
\]

The relation between force and acceleration is not that simple as it is in non-relativistic mechanics. Note that, even though it is caused by a force, acceleration does not generally point in the direction of the force: at high speeds the force is not, in general, parallel to the acceleration.

\section*{Non-relativistic limit}

For slow motions, the second term in equation (55.01.07) is negligible with respect to the first one and \(\gamma \rightarrow 1\), so the expression reduces to the non-relativistic one.

\subsection*{55.01.04.03 Transformation Laws for Force and Power}

Let \(\mathbf{v}\) be the velocity of the particle with respect to the Reference Frame \(\mathcal{J}\) and \(\mathbf{v}^{\prime}\) the velocity of the particle with respect to the Reference Frame \(\mathcal{J}^{\prime}\). Let and \(\mathbf{u}\) the velocity of the Lorentz Transformation from the Reference Frame \(\mathcal{J}\) to the Reference Frame \(\mathcal{J}^{\prime}\).
Let:
\[
\mathbf{u}=c \boldsymbol{\beta} \quad \gamma \equiv \gamma_{u} .
\]

The transformation law for force and power can be derived in the same way as the transformation law for the velocities. In case \(\beta \| \hat{\mathbf{e}}_{3}\) one finds:
\[
\begin{aligned}
\pi^{\prime} & =\frac{\pi-u_{z} f_{z}}{1-u_{z} v_{z} / c^{2}} \\
f_{z}^{\prime} & =\frac{f_{z}-\beta \pi / c}{1-\beta v_{z} / c} \\
f_{x \mid y}^{\prime} & =\frac{f_{x \mid y}}{\gamma\left(1-\beta v_{z} / c\right)} .
\end{aligned}
\]

In the general case:
\[
\begin{gather*}
\pi^{\prime}=\frac{\pi-c \boldsymbol{\beta} \cdot \mathbf{f}}{1-\boldsymbol{\beta} \cdot \mathbf{v} / c}  \tag{55.01.08}\\
\mathbf{f}^{\prime}=\frac{\mathbf{f}+\boldsymbol{\beta}\left(\frac{\gamma^{2}}{\gamma+1}(\boldsymbol{\beta} \cdot \mathbf{f})-\gamma \frac{\pi}{c}\right)}{\gamma(1-\boldsymbol{\beta} \cdot \mathbf{v} / c)} . \tag{55.01.09}
\end{gather*}
\]

\subsection*{55.01.04.04 Minkowski Four-Force}
©|W.K.H.Panoffsky \& M.Phillips, Classical Electricity And Magnetism, 1962, Addison-Wesley, 2ndEd., ....|18.3||
Similarly to what is done when passing from ordinary velocity to four-velocity one can formally introduce the quantities:
\[
\mathbf{f}_{\mathrm{M}} \equiv \gamma_{v} \mathbf{f} \quad \pi_{\mathrm{M}} \equiv \gamma_{v} \pi=\mathbf{v} \cdot \mathbf{f}_{\mathrm{M}} .
\]

The so-called Minkowski power and force, \(\pi_{M}\) and \(\mathbf{f}_{\mathrm{M}}\),
\[
f_{\mathrm{M}}^{\mu} \equiv\left\{\pi_{\mathrm{M}} / c, \mathbf{f}_{\mathrm{M}}\right\}=\frac{\mathrm{d} p}{\mathrm{~d} \tau}
\]
is a four-vector.

\subsection*{55.01.04.05 On the Practical Use}

The Minkowski four-force is easier to handle than ordinary power-force when doing Lorentz Transformation.
However, the Minkowski four-force is a hybrid quantity, relating Four-Momentum, measured in the Reference Frame of the observer, to the proper time, measured in the Rest Frame of the system. Therefore, it is often less useful than ordinary power-force, in practice, because the latter relates quantities measured in the Reference Frame of the observer.

\subsection*{55.01.05 Four-Momentum for Isolated and Non-Isolated System}

Physics lies in the experimental fact that Four-Momentum is conserved for every isolated system, that this is a Lorentz-Invariant property and that changes of Four-Momentum are related to the total external force.

\subsection*{55.01.05.01 Dynamical Invariants}

Relativistic invariants often lead to surprisingly simple calculations, avoiding long, tedious and error prone algebra.
If any question is of such a nature that its answer will be the same in any Inertial Reference Frame , then it must be possible to formulate its answer entirely using the invariants quantities which can be formed with the available Lorentz tensors.
One can then find the answer in a particular Inertial Reference Frame, freely chosen, in such a way that the answer is a simple one. One then looks at how suitable invariants quantities appear in that system and expresses the answer in term of invariants quantities. This gives the unique general answer. In fact if a Lorentz Invariant expression assumes the correct value in any specific Inertial Reference Frame, then it assumes that same value in any other Inertial Reference Frame, because it is invariant.

Refer to a single particle with Four-Momentum \(p=(\varepsilon, \mathbf{p})\). The following are invariants quantities.
\[
\begin{gathered}
p^{2}=\varepsilon^{2}-\mathbf{p} \cdot \mathbf{p}=m^{2} \quad \text { the mass of a particle }, \\
d \mathbf{p} / \varepsilon \quad \text { the phase-space factor } .
\end{gathered}
\]

For any given system of particles, \(k=1,2, \ldots n\), having four-momenta \(p_{k}\), the invariant mass of the system is defined as:
\[
\begin{equation*}
M_{0}^{2} \equiv\left(\sum_{k} p_{k}\right)^{2} \equiv s \tag{55.01.10}
\end{equation*}
\]
where the commonly used Mandelstam variable \(s\) has been introduced. Read §53-022 - From Galilei Transformation to Lorentz Transformation to check that the definition well-posed, as the square of the sum of time-like four-vectors is a time-like four-vector.
The invariant mass of a system of particles corresponds to the total energy in the CMRF. It is also the total energy available to produce new particles.

\subsection*{55.01.06 Energy and Linear Momentum and Relativistic Four-Momentum}

In Galilei-Newton Mechanics energy is a scalar: invariant under change of the Coordinate System but not invariant under changes of Reference Frame; linear momentum is a vector. They are entirely different quantities. Energy remains energy and linear momentum remains linear momentum under Galilei Transformation. In relativistic physics energy and linear momentum are mixed by Lorentz transformations, the same way as time and space are mixed.
In Galilei-Newton Mechanics the total mass is always conserved and therefore there is no such thing as energy conversion into/from mass. However in relativistic physics there is no such thing as mass conservation, but only energy conservation. This opens the way to energy conversion into/from rest mass.
55.01.06.01 Energy Versus Relativistic Mass

In the old times, in an attempt to keep the classical definition of linear momentum as the product of mass times velocity, it was said that mass changes with velocity (the Relativistic Mass).

Nowadays it is preferred to consider mass as a (relativistic invariant) intrinsic property of any specific system and assume that the expression of linear momentum as a function of velocity is different from the classical one. This approach perfectly fits the concept of linear momentum as a four-vector.
The name Relativistic Mass shall not be used.

\section*{Zero-Momentum Rest Frame}

The relativistic extension of the classical concept of the CMRF is the concept of Zero-Momentum frame (Center of Momentum frame).

\subsection*{55.02.01 Zero-Momentum Rest Frame- the General Case}

Let us consider a pair of particles having, in a certain frame of reference, the four-momenta ( \(\varepsilon_{1}, \mathbf{p}_{1}\) ) and \(\left(\varepsilon_{2}, \mathbf{p}_{2}\right)\). The derivation will show that the extension to the general case of an arbitrary number of particles is straightforward.
The CMRF is defined as that frame where the total 3 -momentum of the system of particles is zero. Let us call \(\mathbf{u}\) the velocity of CMRF with respect to the current frame and let us denote with * the quantities in the CMRF. Let: \(E \equiv \varepsilon_{1}+\varepsilon_{2}\) and \(\mathbf{P} \equiv \mathbf{p}_{1}+\mathbf{p}_{2}\). The equation to solve in order to find \(\mathbf{u}\) is thus:
\[
\mathbf{p}_{1}^{\star}+\mathbf{p}_{2}^{\star}=\mathbf{0} .
\]

From equation (53.09.11) and equation (53.09.12) one has:
\[
\begin{gathered}
\left(\mathbf{p}_{1}+\mathbf{p}_{2}\right)+\gamma \mathbf{u}\left(\frac{\gamma}{\gamma+1}\left(\mathbf{u} \cdot\left(\mathbf{p}_{1}+\mathbf{p}_{2}\right)\right)-\left(\varepsilon_{1}+\varepsilon_{2}\right)\right)=\mathbf{0} \\
\mathbf{P}+\gamma \mathbf{u}\left(\frac{\gamma}{\gamma+1}(\mathbf{u} \cdot \mathbf{P}-E)\right)=\mathbf{0}
\end{gathered}
\]

The equation can be solved for \(\mathbf{u}\) in the following way. First take the scalar product of the equation with \(\mathbf{u}\) and use the identity
\[
\gamma_{u}=1+\frac{u^{2} \gamma_{u}^{2}}{\gamma_{u}+1}
\]
to obtain
\[
u \cdot P=u^{2} E .
\]

Secondly use the latter equation in (55.02.01) to obtain the final result:
\[
\begin{equation*}
\mathbf{u}=\frac{\mathbf{P}}{E} . \tag{55.02.01}
\end{equation*}
\]

One then immediately finds that:
\[
\begin{equation*}
\gamma_{u} \equiv\left(1-u^{2}\right)^{-1 / 2}=\left(1-\left(\frac{\mathbf{P}}{E}\right)^{2}\right)^{-1 / 2}=\frac{E}{\sqrt{E^{2}-\mathbf{P}^{2}}}=\frac{E}{\sqrt{s}} \tag{55.02.02}
\end{equation*}
\]

Note that equations (55.02.01), (55.02.02) are consistent with the single particle case because \(\sqrt{s}\) is actually the invariant mass of the particle system.

\subsection*{55.03.01 Balance of Extensive Quantities in Relativistic Form}

This § is referenced at pages:
[1892, 1892, 2437, 2437]
Read § 19.01 - Some Miscellaneous Topics.
Laws describing the balance of some extensive quantity (read § 19.01 - Some Miscellaneous Topics) are expressed, in relativistic covariant form, by an equation of type:
\[
\partial_{\alpha} T_{\cdots}^{\alpha \beta \ldots}=G_{\cdots}^{\beta \ldots} \quad \text { balance law }
\]

Conservation laws, in particular, have the above form with \(G=0\) :
\[
\partial_{\alpha} T_{\cdots}^{\alpha \beta \cdots}=0 \quad \text { conservation law } .
\]

\subsection*{55.03.02 Energy-LinMomentum Tensor}
©|C.W.Misner \& K.S.Thorne \& J.A.Wheeler, Gravitation, 1973, W.H.Freeman and Co., ...Ed., WEB - URL.|||
The discussion in this section is just an heuristic introduction.
The covariant Energy-LinMomentum tensor is derived from field-theoretical considerations. Only an heuristic discussion and a few important facts are summarised here. The references are required for a more serious approach.
Relativistic physics shows that energy and linear momentum goes together as the component of a fourvector. Therefore either the conservation of energy/linear momentum (in the case of an isolated system) and the balance law of energy/linear momentum (in the case of a non-isolated system) must be packed together for a relativistically covariant description.
The covariant Energy-LinMomentum tensor, is built from:
- the energy volume density, \(u\);
- the energy flux, \(\mathbf{S}\);
- the linear momentum volume density, \(\mathbf{g}\);
- the three-dimensional stress-tensor, \(\Theta_{k j} \dot{j}\), representing the flux of linear momentum: flux along the direction \(k\) of the component \(j\) of linear momentum.
For each component of the Four-Momentum one can write a balance (conservation) law in term of their
volume density and their flux:
\[
\begin{aligned}
\partial_{t} u+\operatorname{div} \mathbf{S} & =\ldots(=0), \\
\partial_{t} g_{x}+\frac{\partial \Theta_{\dot{k x}}}{\partial x^{k}} & =\ldots(=0), \\
\partial_{t} g_{y}+\frac{\partial \Theta_{\dot{k y}}}{\partial x^{k}} & =\ldots(=0), \\
\partial_{t} g_{z}+\frac{\partial \Theta_{\dot{k} \ddot{z}}}{\partial x^{k}} & =\ldots(=0),
\end{aligned}
\]

This is a parallel development to the one for the ElectroMagnetic fields only (see section § 37 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum).

One therefore writes:
\[
T_{\stackrel{\alpha \beta}{\alpha \beta} \equiv\left(\begin{array}{ccc}
u & \mathbf{S} / c & , \\
c \mathbf{g} & \Theta_{\dot{k} j} & ,
\end{array}\right), ~, ~, ~}^{\text {. }}
\]
which can be shown to be a Lorentz tensor.
Note the usual dimensional convention has been used to take as it is the space-space part of the tensor and modify the other components accordingly. In fact:
\[
[\theta]=[\mathrm{u}]=\mathrm{J} / \mathrm{m}^{3} \quad[\mathrm{~g}]=\left(\mathrm{J} / \mathrm{m}^{3}\right) / \mathrm{c} \quad[\mathbf{S}]=\left(\mathrm{J} / \mathrm{m}^{3}\right) \mathrm{c}
\]

\subsection*{55.03.02.01 Symmetry of the Energy-LinMomentum Tensor}

In general: whenever there is a flow of energy of any kind, with speed of the energy flow equal to \(v\), the energy flowing per unit time across a unit surface perpendicular to the flow direction, when multiplied by \(c^{-2}\) gives the linear momentum per unit volume in space.

In fact the relativistic relation between energy and linear momentum is:
\[
\mathbf{v}=\frac{c^{2} \mathbf{p}}{\varepsilon} .
\]

\section*{First Demonstration}

The energy flux in direction \(k\) and density of the \(k\) component of the linear momentum are, respectively,
\[
\frac{\Delta \varepsilon}{\Delta V} v_{k} \quad \frac{\Delta p_{k}}{\Delta V} .
\]

The equality, to within a constant factor \(c^{2}\), comes from:
\[
\frac{\Delta \varepsilon}{\Delta V} v_{k}=\frac{\Delta \varepsilon}{\Delta V} \frac{c^{2} \Delta p_{k}}{\Delta \varepsilon}=\frac{\Delta p_{k}}{\Delta V} c^{2}
\]
that is:
\[
\mathbf{S}=c^{2} \mathbf{g}
\]

This allows to write the covariant Energy-LinMomentum tensor as:
\[
T^{\alpha \beta} \equiv\left(\begin{array}{ccc}
u & \mathbf{S} / c & , \\
\mathbf{S} / c & \Theta_{\ddot{k j}} & ,
\end{array}\right)=T^{\alpha \beta} \equiv\left(\begin{array}{ccc}
u & c \mathbf{g} & , \\
c \mathbf{g} & \Theta_{\ddot{k j}} & ,
\end{array}\right)
\]

The covariant Energy-LinMomentum tensor is thus symmetrical, or, better to say, the EnergyLinMomentum tensor of an isolated system can always be cast in a symmetrical form.

\section*{Second Demonstration}

A slightly different derivation is the following.
Assume that energy and linear momentum are carried by particles having energy \(\varepsilon\) and linear momentum \(\mathbf{p}\) while moving with speed \(\mathbf{v}\).
The energy flux, in terms of the number density, \(\rho_{\mathcal{N}}\), is given by:
\[
\mathbf{S}=\rho_{\mathcal{N}} \varepsilon \mathbf{v} .
\]

The linear momentum density, in terms of the number density, \(\rho_{\mathbb{N}}\), is given by:
\[
\mathbf{g}=\rho_{\lambda} \mathbf{p} .
\]

The relativistic relation between energy and linear momentum
\[
\mathbf{v}=\frac{c^{2} \mathbf{p}}{\varepsilon}
\]
then implies the desired relation that is:
\[
\mathbf{S}=c^{2} \mathbf{g}
\]

\subsection*{55.03.02.02 Balance Equation for the Energy-LinMomentum Tensor}

As in the case of the ElectroMagnetic fields, section § 37 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum), the balance equation for a system with symmetrical Energy-LinMomentum tensor \(\mathbb{T}\) is given by:
\[
\partial_{\alpha} T_{.}^{\alpha \beta}=S^{\beta},
\]
where the four-vector \(S^{\beta}\) is the generic source to changes in the Four-Momentum of the system, and originating externally of the system.
The Energy-LinMomentum tensor is defined only to within a divergence-less tensor of second rank. This is similar to the non-uniqueness of the Poynting vector.
The non-uniqueness of the Energy-LinMomentum tensor allows to symmetrise a non symmetrical tensor.

\subsection*{55.03.02.03 Conservation of the Energy-LinMomentum Tensor of an Isolated System}

An isolated system has \(S^{\beta}=0\) so that the total Energy-LinMomentum tensor of an isolated system is always conserved:
\[
\partial_{\alpha} T^{\alpha \beta}=0
\]

The conserved quantities that can be derived from the Energy-LinMomentum tensor are:
\[
\begin{array}{cc}
\hline P^{\mu} \equiv \iiint T^{\mu 0} \mathrm{~d} \mathbf{x} & \text { total Four-Momentum: four independent components } \\
\qquad \mathcal{\varepsilon \equiv P ^ { 0 } \equiv \int \int \int T ^ { 0 0 } \mathrm { d } \mathbf { x }}, \\
P^{k} \equiv \iiint T^{k 0} \mathrm{~d} \mathbf{x}
\end{array}
\]
which obviously are energy and linear momentum.
55.03.02.04 Mass Four-Velocity and Center-Of-Mass of the System

This § is referenced at pages:
[2417, 2417]
Define the invariant mass of the system as:
\[
M \equiv \sqrt{P^{\mu} P_{\mu}} \geq 0
\]

Define the four-velocity of the system (the Center-Of-Mass velocity) as:
\[
U^{\mu} \equiv \frac{P^{\mu}}{M} \quad \text { for } M>0
\]

Define the Center-Of-Mass (aka Center of Energy) of the system as:
\[
\mathbf{X}_{\mathrm{E}} \equiv \mathbf{X}_{\mathrm{CM}} \equiv \frac{1}{\mathcal{E}} \iiint \mathbf{x} T_{. .}^{00} \mathrm{~d} x
\]

The basic relativistic relation is thus:
\[
\frac{\mathrm{d} \mathbf{X}_{\mathrm{E}}}{\mathrm{~d} t}=c^{2} \frac{\mathbf{P}}{\varepsilon}
\]

\subsection*{55.03.03 Boost-AngMomentum Tensor}

The Boost-AngMomentum Tensor is defined as:
\[
M^{\gamma \alpha \beta} \equiv x^{\alpha} T^{\beta \gamma}-x^{\beta} T^{\alpha \gamma}=-M^{\gamma \beta \alpha} \quad \text { for } T_{\ldots}^{\alpha \beta}=T_{.}^{\beta \alpha}
\]
and it is by definition anti-symmetric in the second-third indexes.
The definition can be generalized by considering the Angular Momentum with respect to an arbitrary origin, the time-space event \(a^{\mu}\) :
\[
M^{\gamma \alpha \beta}[a] \equiv\left(x^{\alpha}-a^{\alpha}\right) T^{\beta \gamma}-\left(x^{\beta}-a^{\beta}\right) T^{\alpha \gamma}=-M^{\gamma \beta \alpha} \quad \text { for } T_{.}^{\alpha \beta}=T_{\cdots}^{\beta \alpha}
\]

If the Energy-LinMomentum tensor is conserved and symmetrical has:
\[
\partial_{\gamma} M^{\gamma \alpha \beta}=0
\]

The conserved quantities that can be derived from the Boost-AngMomentum Tensor are: \(J_{.}^{\alpha \beta} \equiv \iiint M^{0 \alpha \beta} \mathrm{~d} \mathbf{x}=-J^{\beta \alpha} \quad\) total Angular Momentum: six independent components \(J_{.}^{0 i} \equiv t P^{i}-\iiint x^{i} T_{.}^{00} \mathrm{~d} \mathbf{x}=-J_{. .}^{i 0} \quad\) boost-related part: three independent components \(J_{.}^{i j} \equiv \iiint\left(x^{i} T_{. .}^{j 0}-x^{j} T_{. \cdot}^{i 0}\right) \mathrm{d} \mathbf{x}=-J_{.}^{j i} \quad\) true Angular Momentum: three independent components.
The Angular Momentum defined by equation (55.03.01) transforms, under translation of the time-space coordinates by the amount \(a^{\alpha}\), as:
\[
x^{\gamma} \longrightarrow \hat{x}^{\gamma} \equiv x^{\gamma}+a^{\gamma} \Longrightarrow J_{.}^{\alpha \beta} \longrightarrow \hat{J}^{\alpha \beta} \equiv J_{.}^{\alpha \beta}+a^{\alpha} P^{\beta}-a^{\beta} P^{\alpha} .
\]

\subsection*{55.03.03.01 Intrinsic Boost-AngMomentum Tensor (Spin)}

The intrinsic Angular Momentum is defined as the angular momentum about any event on the world line of the Center-Of-Mass.

The part of the Angular Momentum which is independent of translation of the time-space coordinates is extracted via the spin four-vector as follows.

The spin four-vector is defined as the four-vector whose components in the Rest Frame is
\[
\{0, \mathbf{S}\} \quad \mathbf{S} \equiv \iiint\left(\mathbf{x}-\mathbf{x}_{\mathrm{CM}}\right) \times \mathbf{g} \mathrm{d} x
\]

It turns out that:
\[
\begin{aligned}
& S_{\alpha} \equiv \frac{1}{2} \epsilon_{\alpha \beta \gamma \delta} J^{\beta \gamma} U^{\delta} \quad \text { for } M>0 \\
& S_{\alpha} \equiv \frac{1}{2} \epsilon_{\alpha \beta \gamma \delta} J^{\beta \gamma} P^{\delta} \quad \text { for } M=0
\end{aligned}
\]

The spin four-vector has only three independent components because:
\[
S_{\mu} U^{\mu}=0
\]

In the system Rest Frame (CM frame) one has:
\[
U^{\mu}=\{1 ; \mathbf{0}\} \quad \text { in the Rest Frame }
\]
and therefore
\[
\begin{aligned}
& S_{0}=0 \\
& S_{1}=J^{23} \\
& S_{2}=J^{31} \\
& S_{3}=J^{12}
\end{aligned}
\]

This shows that the spin four-vector represents the internal/intrinsic angular momentum of a system.

\section*{Decomposition of Angular Momentum Into Intrinsic and Orbital Parts}

If one picks an arbitrary event, \(a\), whose perpendicular displacement from the Center-Of-Mass world line is \(Y^{\alpha}\), so that
\[
Y^{\alpha} U_{\alpha}=0
\]
then the angular momentum with respect to \(a\) is:
\[
J_{\ldots}^{\mu \nu}=U_{\alpha} S_{\beta} \epsilon_{\ldots}^{\alpha \beta \mu \nu}+Y^{\mu} P^{\nu}-Y^{\nu} P^{\mu}
\]

\section*{Examples and Physical Applications}

\subsection*{55.04.01 Kinematics of Ultra-Relativistic Particles at LEP}

The Large Electron-Positron (LEP) Collider operated at CERN from year 1989 to 2000. In the first phase of operation of the Collider electrons and positrons were colliding head-on, with opposite momenta, at a Center-Of-Mass-energy of \(\sqrt{s} \simeq 92 \mathrm{GeV}\). Determine the velocity of the electron/positron. If the energy is known with an uncertainty of \(\Delta \varepsilon\) determine the uncertainty in the velocity.

\section*{SOLUTION}

The relation between energy and velocity is given by the \(\gamma\) :
\[
v=c \sqrt{1-\frac{1}{\gamma^{2}}} \simeq c\left(1-\frac{1}{2 \gamma^{2}}\right)
\]

In this problem one has:
\[
\gamma=\frac{\varepsilon}{m_{e} c^{2}}=\frac{\sqrt{s}}{2 m_{e} c^{2}}=9.0 \cdot 10^{4},
\]
and therefore:
\[
1-\frac{v}{c}=6.2 \cdot 10^{-11}
\]

The error propagation gives:
\[
\beta[\gamma]=\sqrt{1-\frac{1}{\gamma^{2}}} \Longrightarrow|\Delta \beta|=\frac{1}{\gamma^{3} \sqrt{1-\frac{1}{\gamma^{2}}}}|\Delta \gamma|=\frac{1}{\gamma^{3} \beta}|\Delta \gamma| .
\]

In the current case \(\beta \simeq 1\) and therefore:
\[
|\Delta \beta|=\frac{1}{m_{e} c^{2} \gamma^{3}}|\Delta \varepsilon|=2.7 \cdot 10^{-15}|\Delta \varepsilon| \simeq \frac{|\Delta \beta|}{\beta},
\]
the latter equation coming from the fact that \(\beta \simeq 1\).

\subsection*{55.04.02 LHC Hadron Collider Parameters}

The Large Hadron Collider (LHC) at CERN will collide head-on two proton beams at \(\varepsilon=7 \mathrm{TeV} \oplus 7 \mathrm{TeV}\). Every beam is made of \(n_{b}=2808\) bunches of protons ( \(m=938 \mathrm{GeV} / \mathrm{c}^{2}\) ) and every bunch of protons has \(n_{p}=1.15 \cdot 10^{11}\) protons. The total length of the collider, which is approximately a circular one, is \(L=26.659 \mathrm{~km}\).
1. Calculate the gamma factor and velocity of the protons.
\[
\begin{aligned}
& \text { SOLUTION } \\
& \gamma=\frac{\varepsilon}{m c^{2}}=7.5 \cdot 10^{3} \gg 1 \quad \text { the protons have a very high } \gamma: \text { they are ultra-relativistic }, \\
& \frac{1}{\gamma}=\sqrt{1-\beta^{2}}=\sqrt{1-\beta} \sqrt{1+\beta} \simeq \sqrt{2(1-\beta)} \Longrightarrow \beta=1-\frac{1}{2 \gamma^{2}}=1-9.0 \cdot 10^{-9} .
\end{aligned}
\]
2. Determine the current.

\section*{SOLUTION}
\[
\begin{gathered}
\nu_{0}=\frac{v}{L} \simeq \frac{c}{L}=1.1253 \cdot 10^{4} \mathrm{~Hz}, \\
I=q \nu_{0} n_{p} n_{b}=0.58 \mathrm{~A} .
\end{gathered}
\]
3. Determine the average magnetic field required to keep the protons in the orbit.
SOLUTION
\(p=q \rho B\),
\(\rho=\frac{L}{2 \pi}=4.24 \mathrm{~km}\),
\(\gamma \gg 1 \Longrightarrow \varepsilon \simeq c p\),
\(B=\frac{7 \cdot 10^{12} \mathrm{eV} / c}{1.6 \cdot 10^{-19} 4.24 \cdot 10^{3} \mathrm{C} \cdot \mathrm{m}}=\frac{7 \cdot 10^{12} \hat{\mathrm{e}}_{\mathrm{SI}} / c \mathrm{~J}}{\hat{\mathrm{e}}_{\mathrm{SI}} \hat{\rho}_{\mathrm{SI}} \mathrm{Cm}}=5.5 \mathrm{~T}\)
4. Determine the total energy stored in the proton beams.

\section*{SOLUTION}
\[
E=2 n_{p} n_{b} \varepsilon=0.7 \mathrm{GJ}
\]

The stored energy can melt half-ton of Copper and corresponds to the kinetic energy of a Jumbo (bare mass equal to 181 tons) moving at \(314 \mathrm{~km} / \mathrm{h}\).
5. Compare the available energy in the Center-Of-Mass ( \(\sqrt{s}=2 \varepsilon=14 \mathrm{TeV}\) ) with the one that would be available by sending a proton beam at \(\varepsilon^{\prime}=14 \mathrm{TeV}\) against a fixed target.

\section*{SOLUTION}
\[
\sqrt{s}=\sqrt{2 m_{p}^{2}+2 m_{p} \varepsilon^{\prime}} \simeq \sqrt{2 m_{p} \varepsilon^{\prime}}=0.16 \mathrm{TeV}
\]

\subsection*{55.04.03 Hydrogen Atom}

\subsection*{55.04.04 Deuterium Nuclear Fission and Nuclear Fusion}

\subsection*{55.04.05 A Relativistic Totally Inelastic Collision}

Two objects, each one with mass \(m\), collide head-on with equal and opposite speeds and stick together.
1. If the speed is a typical speed of a gun projectile, \(v=300 \mathrm{~m} / \mathrm{s}=1 \cdot 10^{-6} c\), what is the relative increase of mass of the composite lump with respect to the sum of the masses of the two projectiles? Use:
\[
\gamma-1 \simeq \frac{1}{2}\left(\frac{v}{c}\right)^{2} \quad \text { for } v \ll c
\]
2. If the speed is \(v=0.6 c\), what is the mass of the composite lump?

\section*{SOLUTION}

Conservation of linear momentum is trivial.
Conservation of energy gives:
\[
2 m \gamma c^{2}=M c^{2}
\]

The final mass is larger than the sum of the initial masses: mass is not conserved; energy is conserved. Kinetic energy was converted into rest energy, so mass increased.
In a classical analysis one says that kinetic energy has been converted into internal energy: the composite object is hotter than the two original colliding objects. This is true also in the relativistic analyses. Internal energy is the sum of the random kinetic and potential energies as well as rest masses of all the particles, atoms and molecules of the objects. Relativity tells us that these microscopic energies are represented in the mass of the object: a hot object is heavier than a cold object as well as a compressed spring is heavier than a relaxed spring. This is normally not a large macroscopic quantity as internal energy, \(\mathcal{U}\), contributes an amount \(\mathcal{U} / c^{2}\) to the mass, and \(c^{2}\) is a very large number when compared to our typical units of measure. Therefore such kind of relativistic effects are hardly observable in the macroscopic world. However in the realm of elementary particles the effects can be very striking. Nuclear energy production, either by fission or fusion, rely on these kind of phenomena.
1.
\[
\frac{M-2 m}{2 m}=0.5 \cdot 10^{-12}
\]
2.
\[
2 m \gamma c^{2}=M c^{2} \Longrightarrow M=2.5 m>(m+m)
\]

\subsection*{55.04.06 Creation of a composite particle by fusion}

It is an example of conversion of energy into mass.
Si abbia una particella di massa \(m_{0}=1 \mathrm{GeV} / \mathrm{c}^{2}\) ed energia cinetica \(k=2 m_{0} c^{2}\). La particella interagisce con una particella fissa nel Reference Frame del laboratorio di massa \(2 m_{0}\).
- Le due particelle formano una stato legato: derminarne la massa e l'impulso.
- What the process looks like rolling time backwards? It would be an example of conversion of mass into energy.

\section*{SOLUTION}

Occorre anzitutto notare che la massa della particella finale non è \(3 m_{0}\), cioè la somma delle masse di riposo, perchè la massa tiene conto anche dell'energia di legame dello stato legato (come nei nuclei e negli atomi).
La conservazione dell'energia fornisce per l'energia dello stato finale:
\[
\varepsilon / c^{2}=\left(m_{0}+2 m_{0}\right)+2 m_{0}=5 m_{0}
\]

L'impulso del proiettile iniziale vale invece:
\[
\left|\mathbf{p}_{0}\right|=c \sqrt{\left(3 m_{0}\right)^{2}-m_{0}^{2}}=2.8 m_{0} c=2.8 \mathrm{GeV} / \mathrm{c}
\]

Per la conservazione dell'impulso questo è anche il valore dell'impulso dello stato finale. La massa dello stato finale vale dunque:
\[
M=\sqrt{\left(5 m_{0}\right)^{2}-8 m_{0}^{2}}=4.1 m_{0}=4.1 \mathrm{GeV} / \mathrm{c}^{2}
\]

This kind of process can be seen, for instance, as the time-reversed nuclear alpha decay.

\subsection*{55.04.07 Neutral Pion at Rest Decaying Into Two Photons}

It is an example of conversion of mass into energy.
A neutral pion at rest (mass \(M_{\pi^{0}}=135 \mathrm{GeV} / \mathrm{c}^{2}\) ) decays into two massless photons. Determine the energy and linear momentum of the outgoing photons.
In this process pure mass is transformed into pure energy.

\subsection*{55.04.08 Einstein Box and the Inertia of Energy}

The equivalence of energy and mass is such an important and striking result of Relativity that Einstein himself, after his derivation of the result, sought and found an alternative elementary physical line of reasoning that leads to the same conclusion. It is called Einstein box. The purpose of this thought experiment is to suggest that energy must have associated with it a certain inertial mass equivalent.
Consider the following thought experiment. One photon leaves one side of a freight-car, which is free to move on a rail, directed towards the other side. Due to linear momentum conservation, after the photon has started the freight-car recoils. The freight-car stops again when the photon is absorbed at the other side. However, the Center-Of-Mass seems to have moved for a massless photon. Assume that the freight-car moves at low velocity and therefore its dynamics can be described by the Galilei-Newton Mechanics.

\section*{A Simplified Solution}

Assume the velocity of the freight-car is \(|V| \ll c\) and the photon mass-equivalent, if any, is \(m \ll M\), much less that the freight-car mass \(M\).
Assume the photon has zero mass-equivalent. It follows:
\[
\begin{gathered}
p_{\gamma}=\frac{\varepsilon}{c}=-M V=M|V|>0, \\
\Delta Z=V \Delta t=\frac{V L}{c}=-\frac{p_{\gamma} L}{M c}<0 .
\end{gathered}
\]

The Center-Of-Mass has moved.
Now imagine that the photon carries some kind of mass-equivalent, \(m\). It follows that in order to keep the Center-Of-Mass fixed one needs to have:
\[
\begin{gathered}
M \Delta Z+m L=0 \\
m=-\frac{M \Delta Z}{L}=\frac{p_{\gamma}}{c}=\frac{\varepsilon}{c^{2}}
\end{gathered}
\]

The mass-equivalent, \(m\), associated to the photon is therefore, \(\frac{\varepsilon}{c^{2}}\).

\section*{A More Precise Solution}

Assume the photon has zero mass-equivalent. It follows:
\[
\begin{gathered}
p_{\gamma}=\frac{\varepsilon}{c}=-M V=M|V|>0, \\
z_{\mathrm{CM}}=\frac{L}{2} \\
\Delta t=\frac{L}{c-V}=\frac{L}{c+|V|}, \\
\Delta Z=V \frac{L}{c+|V|}<0 \\
z_{\mathrm{CM}}^{\prime}=\frac{L}{2}+\Delta Z
\end{gathered}
\]

Therefore the Center-Of-Mass seems to have moved.
Now imagine that the photon carries some kind of mass-equivalent, \(m\). It follows:
\[
\begin{gathered}
p_{\gamma}=\frac{\varepsilon}{c}=-M V=M|V|>0 \\
z_{\mathrm{CM}}=\frac{M L / 2}{m+M} \\
\Delta t=\frac{L}{c-V}=\frac{L}{c+|V|} \\
\Delta Z=V \frac{L}{c+|V|}<0 \\
z_{\mathrm{CM}}^{\prime}=\frac{M\left(\frac{L}{2}+\Delta Z\right)+m(L+\Delta Z)}{m+M} \\
z_{\mathrm{CM}}^{\prime}=z_{\mathrm{CM}} \\
\Longrightarrow \Delta Z=-L \frac{m}{m+M}<0 \\
\end{gathered}
\]

Therefore consistency is ensured by assuming the photon carries a mass equivalent to its energy (divided by \(c^{2}\) ). In other words: even if the rest mass of the photon is zero its energy has the role of a mass for the calculation of the Center-Of-Mass position.

A simplified derivation assuming \(m \ll M\) and \(|V| \ll c\) gives the same result.
The transport of mass by the photon can be understood only as a new feature of the raaiation itself.

\subsection*{55.04.09 Charged Pion at Rest Decaying Into a Muon and a Neutrino}

A charged pion at rest (mass \(M\) ) decays into a muon (mass \(m\) ) and a (massless) neutrino. Determine the energy of the outgoing muon in terms of the two masses.

Find the velocity of the muon.

\section*{SOLUTION}
\[
\varepsilon=c^{2} \frac{M^{2}+m^{2}}{2 M}
\]

\subsection*{55.04.10 Component Parallel to the Velocity of the Force}

This § is referenced at pages:
[2401, 2401]
\[
v a_{\|} \equiv \mathbf{v} \cdot \mathbf{a}=\mathbf{v} \cdot \frac{\mathrm{d} \mathbf{v}}{\mathrm{~d} t}=\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t}(\mathbf{v} \cdot \mathbf{v})=\frac{1}{2} \frac{\mathrm{~d} v^{2}}{\mathrm{~d} t}=v \frac{\mathrm{~d} v}{\mathrm{~d} t}
\]
\(a_{\|}=\frac{\mathrm{d} v}{\mathrm{~d} t} \quad\) as it is well-known from the representation in intrinsic coordinates of the acceleration,
\[
\begin{aligned}
\mathbf{f}_{\|} \equiv m\left(\gamma \mathbf{a}+\mathbf{v} \frac{\gamma^{3} v}{c^{2}} \frac{\mathrm{~d} v}{\mathrm{~d} t}\right) \cdot \frac{\mathbf{v}}{v}= & m\left(\gamma a_{\|}+\frac{v^{2} \gamma^{3}}{c^{2}} a_{\|}\right)=m \gamma a_{\|}\left(1+\frac{v^{2}}{c^{2}} \gamma^{2}\right)=m \gamma^{3} a_{\|} \\
& m \gamma^{3}\left(\frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}\right)_{\|}=m \gamma^{3} \mathbf{a}_{\|}
\end{aligned}
\]

\subsection*{55.04.11 Relativistic Motion From Rest Subject to a Constant Force}
©|Berkeley Physics Course, Vol. 1, Mechanics, 1965, McGraw-Hill, ...Ed., ....|||
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12.10||
An object of mass \(m\) is subject to a constant force \(\mathbf{F}=F \hat{\mathbf{e}}_{3}\), starting from rest at time \(t=t_{0}\). Determine the law of motion.

\section*{SOLUTION}

It can be solved by using the relations in \(\S 55.01 .04 .02\) - Relativistic Dynamics. Use:
\[
\int \gamma^{3} \mathrm{~d} V=\gamma v
\]

The law of motion is:
\[
\alpha \equiv \frac{m c}{F} \quad z[t]=c \sqrt{t^{2}+\alpha^{2}}-\alpha c \Longrightarrow v_{z}[t]=\frac{c t}{\sqrt{t^{2}+\alpha^{2}}} \leq c
\]

While in Galilei-Newton Mechanics a constant force gives a parabolic dependence of the position on time, in relativistic mechanics the position as a function of time is hyperbolic.
The asymptote of the hyperbola \(z[t] \approx c(t-\alpha)\) gives the limiting speed:
\[
z[t] \approx c t \quad \text { for very large times } t \gg \alpha \equiv \frac{m c}{F}
\]

The short-time behavior reproduces the classical result, as it is a low-speed result:
\[
z[t] \approx \frac{1}{2} \frac{c}{\alpha} t^{2}=\frac{1}{2} \frac{F}{m} t^{2} \quad \text { for very short times } t \ll \alpha \equiv \frac{m c}{F}
\]

Note that both energy and linear momentum increase indefinitely, but the speed never reaches the speed of light. In fact the linear momentum increase at a constant rate, as from the equation of motion, while the energy is always greater or equal to the linear momentum times the speed of light.

©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 12.2.4||

\section*{© - QUOTE}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|§ 12.2.4||
... Newton's third law does not, in general, extend to the relativistic domain. Indeed, if the two objects in question are separated in space, the third law is incompatible with the relativity of simultaneity. For suppose the force of A on B at some instant \(t\) is \(+\mathbf{F}\), and the force of B on A at the same instant is \(-\mathbf{F}\); then the third law applies in this Rest Frame.
But a moving observer will report that these equal and opposite forces occurred at different times; in his system, therefore, the third law is violated.
Only in the case of contact interactions, where the two forces are applied at the same physical point (and in the trivial case where the forces are constant) can the third law be retained. ...

Read also § 37.02.02 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum. It refers to microscopical mechanical momentum of moving particles, which must be included in the momentum balance together with the ones of ElectroMagnetic origin, also in case of static fields.

\section*{Exercises Problems and Physical Applications}

\section*{55-001 Angular Momentum for Non-Symmetrical Energy-LinMomentum Tensors}

Write the conservation of Boost-AngMomentum Tensors in the case the Energy-LinMomentum tensor is non-symmetrical.

\section*{55-002 Spin Four-Vector}

Show that the spin four-vector, defined in (55.03.03.01), is invariant under translations of the time-space coordinates.

\section*{55-003 Properties of the Spin Four-Vector}

Demonstrate that:
\[
S_{\mu} U^{\mu}=0
\]

This shows that the spin four-vector has only three independent components.

\section*{55-004 Properties of the Spin Four-Vector of a Free Particle or Isolated System}

Consider a free particle or an isolated system, such that Four-Momentum and angular momentum are conserved:
\[
\frac{\mathrm{d}}{\mathrm{~d} t} P^{\mu}=0 \quad \frac{\mathrm{~d}}{\mathrm{~d} t} J^{\alpha \beta}=0
\]

Demonstrate that:
\[
\frac{\mathrm{d}}{\mathrm{~d} t} S_{\mu}=0
\]

\section*{55-005 Spin Four-Vector in the System Rest Frame}

Demonstrate equation (55.03.03.01).

\section*{55-006 Kinetic Energy and Galilei Transformation in Galilei-Newton Mechanics}

Show that in Galilei-Newton Mechanics the transformation law for the kinetic energy of a system of point particles, assuming that the mass of a point particle is Galilei invariant, is:
\[
\mathcal{K}=\mathcal{K}^{\prime}+\frac{1}{2} M u^{2}+\mathbf{u} \cdot \mathbf{P} .
\]

Show, using the above relation, that a collision is elastic if and only if the total mass and total linear momentum are conserved.

\section*{SOLUTION}

Denote with a prime the quantities after the collision:
\[
\mathcal{K}=\mathcal{K}^{\prime}+\frac{1}{2} M u^{2}+\mathbf{u} \cdot \mathbf{P}=\mathcal{K}^{\prime \prime}+\frac{1}{2} M^{\prime} u^{2}+\mathbf{u} \cdot \mathbf{P}^{\prime}=\mathcal{K}^{\prime}
\]

\section*{55-007 Non-Relativistic and Ultra-Relativistic Approximation}

What is the maximum value of \(v\) and \(\gamma\) if the non-relativistic approximation for energy, \(\varepsilon \approx m c^{2}+p^{2} /(2 m)\), is to be used with an error less than \(\alpha\), that is with an absolute error on the energy equal to \(\alpha p^{2} /(2 m)\). Hence show that for an error of \(\alpha=0.01\) the linear momentum satisfies \(p \approx 0.2 \mathrm{mc}\).
What is the minimum value of \(v\) and \(\gamma\) if the ultra-relativistic approximation for energy, \(\varepsilon \approx p c\), is to be used with an error less than \(\alpha\), that is with an absolute error on the energy equal to \(\alpha p c\). Hence show that for an error of \(\alpha=0.01\) the linear momentum satisfies \(p \approx 7 \mathrm{mc}\).

\section*{55-008 Relation Between Kinetic Energy and Linear Momentum}

Determine the relativistic relation between kinetic energy and linear momentum.
L'approssimazione non relativistica vale per \(\mathcal{K} \ll m c^{2}\), equivalente a \(p \ll m c\) :
\[
\mathcal{K}=\varepsilon-m c^{2}=m c^{2}(\gamma-1)=\sqrt{p^{2} c^{2}+m^{2} c^{4}}-m c^{2} \simeq \frac{p^{2}}{2 m}
\]

L'approssimazione non relativistica corrisponde a \(v \ll c\), o equivalentemente, \(\varepsilon \ll m c^{2}\).

\section*{55-009 Head-Light Effect; the Exact Velocity Distribution}

This § is referenced at pages:
[Never referenced.]
Determine the exact velocity distribution of the photons as it is seen by the \(\mathcal{J}\) Reference Frame observer in problem § ?? - ??.

\section*{55-010 Mass of a Isolated System}
1. Does conservation of the Four-Momentum of an isolated system implies that collisions and interactions within an isolated system cannot change the total system mass?
2. Does conservation of the Four-Momentum of an isolated system implies that the constituents that enter a collision are necessarily the same in individual mass and in number as the constituents that leave that collision?
3. Is the mass of an isolated system composed of freely-moving objects obtained by adding the masses of the individual objects?

\section*{55-011 Relation Between Force and Power}

Show that equations (55.01.03), (55.01.04) imply:
\[
\pi=c^{2} \frac{\mathrm{~d}}{\mathrm{~d} t}(m \gamma)
\]

Show that equations (55.01.03), (55.01.04) imply:
\[
m \gamma \frac{\mathrm{~d} \mathbf{v}}{\mathrm{~d} t}=\mathbf{f}-\frac{\pi}{c^{2}} \mathbf{v} .
\]

The latter equation shows that in the relativistic case, in general, force and acceleration are not parallel, at variance with respect to the classical case. Force and acceleration are parallel if and only if either \(\mathbf{f} \| \mathbf{v}\) or \(\mathbf{f} \perp \mathbf{v}\).

\section*{55-012 Minkowski Force}

Show that the Minkowski force is a four-vector.

\section*{55-013 A Charged Particle in a Uniform and Constant Magnetic Field}

This § is referenced at pages:
[2416, 2416]
A charged particle is moving in a constant and uniform magnetic field. At a certain instant its velocity is perpendicular to the magnetic field.
The Lorentz force does no work and therefore the energy, velocity as well as the gamma factor, are constant:
\[
a_{\|}=\frac{\mathrm{d} v}{\mathrm{~d} t}=0
\]

The motion lies in plane as at the initial instant its velocity is perpendicular to the magnetic field.
The Lorentz force is perpendicular to the velocity, therefore equation (55.01.04.02) can be used at once as
\[
\mathbf{f}_{\perp}=\left(\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}\right)_{\perp}=m \gamma \mathbf{a}_{\perp}=m \gamma \frac{v^{2}}{\rho} \mathbf{e}_{N}=q \mathbf{v} \times \mathbf{B} \Longrightarrow \rho=\frac{m \gamma v}{q B}=\frac{p}{q B}=\text { constant }
\]

Note that, for a uniform circular motion:
\[
\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}=p \frac{\mathrm{~d} \theta}{\mathrm{~d} t} \hat{\mathbf{e}}_{\theta}=p \frac{v}{R} \hat{\mathbf{e}}_{\theta}
\]

\section*{55-014 Dynamic Properties of a Particle as Seen From the Rest System of Another Particle}

Two particles have four-momenta \(p_{1}\) and \(p_{2}\). Determine the energy, module of linear momentum and velocity of particle 2 as seen from the rest system of particle 1: \(E_{21},\left|\mathbf{p}_{21}\right|\) and \(\left|\mathbf{v}_{21}\right|\).

\section*{SOLUTION}

The answer is the same no matter in which Lorentz system we work. The answer must be therefore expressible in terms of invariants. The available invariants are:
\[
\begin{gathered}
p_{1}^{2}=m_{1}^{2} \quad p_{2}^{2}=m_{2}^{2}, \\
p_{1} \cdot p_{2} \quad \text { or } \quad\left(p_{1}+p_{2}\right)^{2} \quad \text { or } \quad\left(p_{1}-p_{2}\right)^{2}
\end{gathered}
\]

The energy of particle 2 as seen from the rest system of particle 1 is:
\[
E_{21}=\varepsilon_{2} \quad \text { in the system where } \mathbf{p}_{1}=\mathbf{0}
\]

It must be written in terms of invariants. In the rest system of particle 1 one has:
\[
p_{1} \cdot p_{2}=m_{1} \varepsilon_{2} \quad \text { in the system where } \mathbf{p}_{1}=\mathbf{0}
\]

In a general system the latter becomes:
\[
E_{21}=\frac{p_{1} \cdot p_{2}}{m_{1}} \neq E_{12}
\]

One can then calculate:
\[
\left|\mathbf{p}_{21}\right|^{2}=\frac{\left(p_{1} \cdot p_{2}\right)^{2}-m_{1}^{2} m_{2}^{2}}{m_{1}^{2}} \neq\left|\mathbf{p}_{12}\right|^{2}
\]

One can finally calculate:
\[
\left|\mathbf{v}_{21}\right|^{2}=\frac{\left|\mathbf{p}_{21}\right|^{2}}{E_{21}^{2}}=\frac{\left(p_{1} \cdot p_{2}\right)^{2}-m_{1}^{2} m_{2}^{2}}{\left(p_{1} \cdot p_{2}\right)^{2}}=\left|\mathbf{v}_{12}\right|^{2}
\]

\section*{55-015 Invariant Mass of a Pair of Particles}

Show that for any pair of particles having four-momenta \(p_{1}\) and \(p_{2}\) and masses \(m_{1}\) and \(m_{2}\), one has the identity:
\[
p_{1} \cdot p_{2}=\left(\frac{s-\left(m_{1}^{2}+m_{2}^{2}\right)}{2}\right),
\]
in terms of the invariant mass of the pair, \(M_{0}=\sqrt{s}\).

\section*{55-016 Outrun a Light Ray}

Suppose you are subject to a constant force and start a race with a light ray.
How much head start do you need in order that the light ray will never reach you?

\section*{55-017 Electron-Positron Annihilation}

The positron is the anti-particle of the electron, in all identical to the electron except for having its charges of the opposite sign.
A positron having kinetic energy equal to its mass strikes an electron at rest. They annihilate, creating two high-energy photons. One photon enters a detector placed at right angle with respet to the direction of the initial positron with respect to the interaction point.
Determine the energies of both photons and the direction of motion of the second photon.

\section*{55-018 Energy Production in the Sun}

This § is referenced at pages:
[2557, 2557]
Read § 59-004 - Work Energy Heat and the First Principle.
Energy from the Sun reaches the outer atmosphere of the Earth at a rate of about \(1.4 \mathrm{~kW} / \mathrm{m}^{2}\) (this is called the solar constant).
1. How much of the mass of the Sun is converted into energy every second to supply the energy that reaches the Earth.
2. What total mass is converted to energy every second in Sun?
3. Most of the energy comes from burning hydrogen nuclei (mostly protons) into helium nuclei (mostly a two-proton-two-neutron combination). How much hydrogen must be converted into helium per second?
4. Estimate how long Sun will continue to warm Earth, neglecting all other processes in Sun and emissions from Sun.

\section*{55-019 Isolated Photon}

Demonstrate that an isolated photon cannot split into two photons going into two different directions other than going both into the original direction.

\section*{55-020 Pair Production}

A high-energy photon may carry an energy larger than the rest energy of an electron-positron pair. Nevertheless it cannot give rise to an electron-positron pair in the absence of other particles
1. Prove that this process is incompatible with the laws of conservation of linear momentum and energy as employed in the laboratory frame of reference.
2. Repeat the demonstration in the Center-Of-Mass frame of the electron-positron pair.

\section*{55-021 Muon in the Atmosphere}

Refer to § 53.12.02.01 - From Galilei Transformation to Lorentz Transformation.
Assume, as a gross approximation, that the Earth magnetic field is 0.5 Gauss radially directed.
Determine how much the horizontal component of the velocity of the muon changes in direction if its energy is \(\alpha=1 / 100\) more than the one determined in section § 53.12.02.01 - From Galilei Transformation to Lorentz Transformation, just enough to reach the Earth surface and the \(\alpha \varepsilon\) additional energy is in carried by the horizontal component of the velocity.

\section*{55-022 Maximum Kinetic Energy in a Decay}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|11.21||
If a system of mass \(M\) decays or transforms at rest into a number of final state particles, the sum of whose masses is less than \(M\) by an amount \(\Delta M\), show that the maximum kinetic energy of the \(i\)-th particle (with mass \(m_{i}\) ) is:
\[
\mathscr{K}_{i} \leq \Delta M\left(1-\frac{m_{i}}{M}-\frac{\Delta M}{2 M}\right) .
\]

\subsection*{56.01}

\section*{Introduction}

Read §53-From Galilei Transformation to Lorentz Transformation for introductory remarks.
Read § 19.01 - Some Miscellaneous Topics for recap on continuity equations.
Note that \(c=1\) will be often used except for some of the basic formulas.

\subsection*{56.01.01 EM and Relativity}

ElectroMagnetism is consistent with the principle of relativity from the beginning: all inertial observers describe all physical phenomena, including ElectroMagnetic ones, in the same way.
However the interpretations may be different and what appears to be an Electric|Magnetic phenomenon to one observer may appear as a magnetic/electric phenomenon to another observer. Moreover, the understanding of ElectroMagnetic is greatly increased by the relativistic framework, in particular in all cases when moving observers are present: read § 56.09-ElectroMagnetism and Relativity, § 53.03.01From Galilei Transformation to Lorentz Transformation, § 56.09.08 - ElectroMagnetism and Relativity, § 56.09.03 - ElectroMagnetism and Relativity.
Relativistic invariance of ElectroMagnetism is not demonstrated but, on the other hand as for any physical law, it is an assumption arrived at via a process of induction from the experiments.

\subsection*{56.01.02 Comments on the Relativistic Formulation of EM}

It is easy to be distracted by the mathematical elegance of the relativistic formulation of ElectroMagnetism; however one should not loose the physical meaning of the equations and the complex physical relations underlying the equations and their relativistic invariance.
The importance of the ordinary three-dimensional representation of physical quantities must not be neglected even if complex and compact relativistic invariant relations might embrace different physical concepts. For instance the Maxwell Equations without Charge|Current will be compacted into a single four-dimensional equation, but this single equation embraces, at the same time, the lack of magnetic Monopoles and the Faraday-Neumann-Lenz law of ElectroMagnetic induction.

\section*{Charge and Current}

56.02.01 Invariance Conservation Quantization of the Electric Charge

This § is referenced at pages:
[2440, 2440]
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
The electric charge, in addition to be a Lorentz invariant and a conserved quantity, comes in multiples of the elementary charge of the electron and the proton.
The absolute values of the electric charge of proton and electron are the same as far as we know today, within the current experimental sensitivity.
The electric charge is an intrinsic, Lorentz-Invariance, property of elementary particles, together with the mass, the spin and any other charges (such as baryon charge and lepton charge) which one discovers in fundamental physics.

\subsection*{56.02.01.01 Some Experimental Evidence about charge invariance}

The equality of the absolute values of the electric charge of the electron and the proton is an experimental fact. These experimental facts \({ }^{1}\) can be also used to support the fact that the electrical charge is a Lorentz invariant quantity, or, in other words, the invariance of the charge of the particle from its velocity. In fact neutral atoms at rest with different atomic number have electrons moving with different velocities, depending on the energy levels, which in turn strongly depend on the atomic number. The fact the atoms are neutral provide support for the independence of the electric charge of the electrons from their velocity.
Invariance of the electric charge means that every observer will measure the same value for the flux of the electric field:
\[
\oiint_{\Sigma[t]} \mathbf{E} \cdot \mathrm{d} \mathbf{S}=\oiint_{\Sigma^{\prime}\left[t^{\prime}\right]} \mathbf{E}^{\prime} \cdot \mathrm{d} \mathbf{S}^{\prime} .
\]

One must be very careful that the electric fields, surfaces and times must be taken for the two different observers. In particular the distinction between \(t\) and \(t^{\prime}\) must not be overlooked because one knows that events that are simultaneous in \(\mathcal{J}\) need not be simultaneous in \(\mathcal{J}^{\prime}\). Each of the surface integrals in must be evaluated at one precise instant in its Reference Frame. If charges lie on the boundary one has to be rather careful about ascertaining that the charges within \(\mathcal{J}\) at \(t\) are the same as those within \(\mathcal{J}^{\prime}\) at \(t^{\prime}\). If the charges are well away from the boundary there is no problem in this respect.

\footnotetext{
\({ }^{1}\) J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....
}

\subsection*{56.02.02 Four-Current}

\subsection*{56.02.02.01 Transformation Law of the Charge Density}

As the electric charge is a relativistic invariant the transformation of charge volume density is dictated by the law of transformation of volumes. In particular the relation between the charge volume density in the proper Rest Frame, \(\rho_{0}\), and in any other Reference Frame, \(\rho\), is given by:
\[
\begin{equation*}
\mathrm{d} V=\frac{\mathrm{d} V_{0}}{\gamma} \Longrightarrow \frac{\mathrm{~d} q}{\mathrm{~d} V} \equiv \rho=\rho_{0} \gamma \equiv \frac{\mathrm{~d} q}{\mathrm{~d} V_{0}} \gamma . \tag{56.02.01}
\end{equation*}
\]

\subsection*{56.02.02.02 Transformation Law of the Current Density}

As the electric charge is a relativistic invariant the transformation of current volume density is dictated by the law of transformation of volumes. In particular the relation between the current volume density in the proper Rest Frame, \(\rho_{0}\), and in any other Reference Frame, \(\rho\), is given by:
\[
\begin{equation*}
\mathrm{d} V=\frac{\mathrm{d} V_{0}}{\gamma} \Longrightarrow \mathbf{j} \equiv \rho \mathbf{v}=\frac{\mathrm{d} q}{\mathrm{~d} V} \frac{\mathrm{dx}}{\mathrm{~d} t}=\frac{\mathrm{d} q}{\mathrm{~d} V} \frac{\mathrm{~d} \tau}{\mathrm{~d} t} \frac{\mathrm{~d} \mathbf{x}}{\mathrm{~d} \tau}=\frac{\mathrm{d} q}{\mathrm{~d} V} \frac{1}{\gamma} \frac{\mathrm{dx}}{\mathrm{~d} \tau}=\rho_{0} \frac{\mathrm{dx}}{\mathrm{~d} \tau} \equiv \rho_{0} \mathbf{V} \tag{56.02.02}
\end{equation*}
\]

\subsection*{56.02.02.03 Current Four-Vector}

The two relations (56.02.01), (56.02.02) allows one to define the current four-vector. Consider, to start with, a set of all identical particles moving with the same velocity. The current is a four-vector defined as
\[
j^{\alpha} \equiv \rho_{0} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} \tau}=\rho_{0} \frac{\mathrm{~d} t}{\mathrm{~d} \tau} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} t}=\rho_{0} \gamma \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} t}=\rho \frac{\mathrm{d} x^{\alpha}}{\mathrm{d} t}=\left\{\begin{array}{l}
j^{0} \equiv \rho c=\rho_{0} \gamma c \\
\mathbf{j} \equiv \rho \mathbf{v}=\rho_{0} \gamma \mathbf{v}=\rho_{0} \mathbf{V}
\end{array}\right.
\]
showing explicitly the four-vector character of the four-current, in terms of the Lorentz-invariant volume charge density in the Rest Frame of the charge, \(\rho_{0}\), and the Lorentz-invariant proper time, \(\tau\).
Note that:
\[
\begin{gathered}
j^{\alpha} \equiv \rho_{0} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} \tau} \quad \text { expresses } j^{\alpha} \text { in terms of quantities in the proper Rest Frame only } \\
j^{\alpha} \equiv \rho \frac{\mathrm{d} x^{\alpha}}{\mathrm{d} t} \quad \text { expresses } j^{\alpha} \text { in terms of quantities in the Laboratory only }
\end{gathered}
\]

In the proper Rest Frame the definition reduces to:
\[
j^{\alpha}=\left\{c \rho_{0}, \mathbf{0}\right\} \quad \text { in the proper Rest Frame }
\]

The current four-vector so defined is time-like:
\[
j^{\mu} j_{\mu}=c^{2} \rho_{0}^{2}=\text { invariant } \geq 0 .
\]

In the general case where the current is due to either the motion of different species of charges andor a different sets of charges with different kinematics the Four-Current must be defined as the algebraic sum of the different components, all of them being convective currents:
\[
\begin{equation*}
j^{\alpha} \equiv \sum_{k} j_{k}^{\alpha} \equiv \sum_{k} \rho_{k} \frac{\mathrm{~d} x_{k}^{\alpha}}{\mathrm{d} t} \tag{56.02.03}
\end{equation*}
\]
possibly generating non convective currents, that is conduction currents.

\subsection*{56.02.02.04 Conduction and Convection Currents}

This § is referenced at pages:
[1197, 1197]
The motion of charges produces a current.
- The convection current is the one due to the motion of the Center-Of-Mass of the element of matter. In the simplest case that is a number of all identical particles moving with the same velocity.
- The conduction current is the one due to the motion relative to the Center-Of-Mass. As an example one can quote a plane circular loop of current whose Center-Of-Mass is at rest (no convection current) while it has a conduction current due to the motion of the free charges with respect to the Center-Of-Mass.
Read also § 19.01.03.03 - Some Miscellaneous Topics.

\subsection*{56.02.02.05 Some Comments on the Current Four-Vector}

Note that the definition of \(j^{\mu}\) is totally analogous to the definition of the Four-Momentum, \(p^{\mu}\), of a particle, with the volume charge density, \(\rho\), replacing the energy and the volume charge density in the Rest Frame of the particle, \(\rho_{0}\), replacing the mass of the particle.

One can also write explicitly the definition of current as:
\[
j^{\mu} \equiv\{c \rho, \mathbf{j}\} \equiv\{c \rho, \rho \mathbf{v}\} \quad \text { with } \quad \rho=\gamma_{\mathbf{u}} \rho_{0}
\]
where \(\rho_{0}\) is the volume charge density in the rest frame of the particle.
A stationary charge in the \(\mathcal{J}\) Reference Frame is described by a time-like four-vector. As it is expected when the charge is seen from the \(\mathcal{J}^{\prime}\) Reference Frame, moving with velocity \(\mathbf{V}\) with respect to \(\mathcal{J}\), the four-vector has both a time component and a space component. This is not a surprise as we know that a moving charge possesses both a charge and a current. What is less obvious is the behavior of a space-like current four-vector and the fact that a globally neutral system of currents will show a total net charge when it is seen from a Reference Frame moving with respect to the other system. In general one can say that, as volume charge density and current density are components of a four-vector, they can mix in a Lorentz Transformation.

One consequence, as discussed in \(\S 56.09\) - ElectroMagnetism and Relativity, is that a moving Magnetic Dipole appears as having an Electric Dipole and vice-versa.

\subsection*{56.02.02.06 Charge Conservation and the Current Four-Vector}

The charge continuity equation itself becomes, in terms of the Four-Current:
\[
\partial_{\mu} j^{\mu}=0
\]

\author{
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....|||
}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
It might be thought that the Electric|Magnetic fields are the space part of a four-vector but the situation is actually more complex than that.
It is not unexpected that a stationary charge distribution only produces an electric field while a moving charge distribution produces an electric field plus a magnetic field.
It is less obvious that an electrically neutral steady current, only producing a magnetic field, is seen by a moving observer as a magnetic field plus a electric field. This applies, for instance, to an observer moving with respect to a real magnet.
It is important to stress that when transforming fields, one need to transform:
- both the field quantity;
- and the space-time coordinates describing the event where the filed is calculated and applied.

In fact, a physical field, \(\psi_{k}[x]\), with \(k\) components transforms, under Lorentz Transformation, as:
\[
\psi_{k}\left[x^{\prime}\right]=\mathcal{D}_{k j} \psi_{j}[x] \quad x^{\prime}=\mathbb{L} x+a \quad \text { with } \mathcal{D} \text { any representation of the Poincaré group }
\]

Several arguments in this section are adapted from the references \({ }^{2}\).

\subsection*{56.03.01 Elementary Considerations on the Transformations of Electric Fields}

This § is referenced at pages:
[2458, 2458]

\subsection*{56.03.01.01 An Infinite Ideal Capacitor}

Consider two infinite parallel sheets of charge, perpendicular to the \(z\) axis at \(z= \pm d / 2\), and charged with surface charge density \(\pm \rho_{\mathrm{S}}\left(\rho_{\mathrm{S}}>0\right)\) at rest for the inertial observer \(\mathcal{J}\).
The electric field is zero outside the plates and uniform along the \(z\) axis in between the two plates and the magnetic field is zero:
\[
\mathbf{E}=-\frac{\rho_{\mathrm{S}}}{\varepsilon_{0}} \hat{\mathbf{e}}_{3} \quad \mathbf{B}=0
\]

An inertial observer \(\mathcal{J}^{\prime}\) moving with velocity \(\mathbf{u}\) perpendicularly to the \(z\) axis will see the surface charge density increased by a factor \(\gamma\), as charge is invariant and the distances are contracted by \(\gamma\) along the direction of motion. Any inertial observer moving perpendicularly to the \(z\) axis with velocity \(\mathbf{u}\) will reach the same conclusion.
Therefore, if the electric field is still perpendicular to the \(x y\) plane:
\[
\left\{\hat{\mathbf{e}}_{3}=\hat{\mathbf{e}}_{3}^{\prime} \quad \rho_{\mathrm{S}}^{\prime}=\gamma \rho_{\mathrm{S}}\right\} \Longrightarrow \mathbf{E}_{\perp}^{\prime}=\gamma \mathbf{E}_{\perp} .
\]

Moreover, the moving observer will also see a surface current density \(\propto-\mathbf{u}\). In fact he will see two infinite parallel sheets of currents with surface current:
\[
\mathbf{j}_{\mathrm{S}}^{ \pm^{\prime}}=\mp \rho_{\mathrm{S}}^{\prime} \mathbf{u}=\mp \gamma \rho_{\mathrm{S}} \mathbf{u}
\]

\footnotetext{
\({ }^{2}\) Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., .... D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....
}

He will then see a magnetic field in between the two sheets, given by the sum of the magnetic fields produced by the two sheets:
\[
\mathbf{B}^{\prime}=\mu_{0} \frac{\left(\mathbf{j}_{\mathrm{s}}^{+^{\prime}}\right) \times\left(-\hat{\mathbf{e}}_{3}^{\prime}\right)}{2}+\mu_{0} \frac{\left(\mathbf{j}_{\mathrm{s}}^{-}\right) \times\left(+\hat{\mathbf{e}}_{3}^{\prime}\right)}{2}=\mu_{0} \rho_{\mathrm{S}}^{\prime} \mathbf{u} \times \hat{\mathbf{e}}_{3}^{\prime} .
\]

Note the appropriate signs for \(\hat{\mathbf{e}}_{3}\) in order to pick up the region internal to the two sheets and the factor two in the formula for the magnetic field of one sheet of current removed by summing up the magnetic fields produced by the two sheets. All in all:
\[
\mathbf{j}_{\mathrm{S}}^{ \pm^{\prime}}=\mp \gamma \rho_{\mathrm{S}} \mathbf{u} \quad \hat{\mathbf{e}}_{3}=\hat{\mathbf{e}}_{3}^{\prime} \quad \mathbf{B}^{\prime}=\mu_{0} \rho_{\mathrm{S}} \gamma\left(\mathbf{u} \times \hat{\mathbf{e}}_{3}\right)=-\varepsilon_{0} \mu_{0} \gamma(\mathbf{u} \times \mathbf{E})=-\frac{\gamma}{c^{2}} \mathbf{u} \times \mathbf{E}
\]

Therefore:
\[
\mathbf{B}_{\perp}^{\prime}=-\frac{\gamma}{c^{2}} \mathbf{u} \times \mathbf{E}=-\frac{\gamma}{c^{2}} \mathbf{u} \times \mathbf{E}_{\perp}
\]

It is not strange that charges in motion produce a current and therefore a magnetic field.
An inertial observer \(\mathcal{J}^{\prime}\) moving along the \(z\) axis will see the surface charge density unchanged. She would see the distance between the two plates contracted, but this has no effect on the electric field.
Therefore, if the field is still seen as a field perpendicular to the plane:
\[
\mathbf{E}_{\|}{ }^{\prime}=\mathbf{E}_{\|} .
\]

\subsection*{56.03.02 Elementary Considerations on the Transformations of Magnetic Fields}

\subsection*{56.03.02.01 An Infinite Sheet of Current}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|2-18.4||

Consider one plane infinite neutral sheet of current, perpendicular to the \(z\) axis, located at \(z=0\), and carrying a surface current density \(\mathbf{j}_{\mathbf{S}}\) along the \(x\) axis at rest for the inertial observer \(\mathcal{J}\).
The magnetic field is uniform and directed along the \(y\) axis:
\[
\mathbf{j}_{\mathrm{S}}=\left|\mathbf{j}_{\mathrm{S}}\right| \hat{\mathbf{e}}_{1} \quad \mathbf{B}= \pm \frac{\mu_{0}\left|\mathbf{j}_{\mathrm{S}}\right|}{2} \hat{\mathbf{e}}_{2}=\left\{\begin{array}{l}
z>0 \Longrightarrow \mathbf{B} \cdot \hat{\mathbf{e}}_{2}<0 \\
z<0 \Longrightarrow \mathbf{B} \cdot \hat{\mathbf{e}}_{2}>0
\end{array}\right.
\]

An inertial observer \(\mathcal{J}^{\prime}\) moving along the \(y\) axis will see the current volume density and|or the surface current density unchanged. Moreover, the sheet was electrically neutral and it is still seen as a neutral sheet, as the observer is moving perpendicularly to the current density. In this case the positive ions at rest do not enter as we are moving perpendicularly to the current.
Therefore, if the field is still seen as a field along the \(y\) axis:
\[
\mathbf{B}_{\|}{ }^{\prime}=\mathbf{B}_{\|} .
\]

An inertial observer \(\mathcal{J}^{\prime}\), moving along the \(x\) axis, will see a different surface current density, increased by a factor \(\gamma\), while moving along the current. Moreover, the sheet will also appear electrically charged. In this case the positive ions at rest do enter as we are moving along the current, as for a wire carrying current.
The transformation can be more simply derived from Lorentz Transformation:
\[
\begin{gathered}
j_{x}^{\prime}=\gamma\left(j_{x}-u \rho\right)=\gamma j_{x}, \\
\rho^{\prime}=\gamma\left(\rho-u j_{x} / c^{2}\right) .
\end{gathered}
\]

Therefore, if the field is still seen as a field along the \(y\) axis:
\[
\mathbf{B}_{\perp}{ }^{\prime}=\gamma \mathbf{B}_{\perp} .
\]

An inertial observer \(\mathcal{J}^{\prime}\), moving along the \(z\) axis, will see the thickness of the sheet of current to decrease. Moreover, the time dilatation enters.

\subsection*{56.03.02.02 An Infinite Ideal Solenoid}

Another simple example can be taken from a ideal infinite solenoid, with axis the \(z\) axis, whose \(n_{l}\) (helical windings per unit length) carry a constant current \(I\). The constant and uniform magnetic field at the interior of the solenoid is: \(B_{z}=\mu_{0} n_{l} I\).
An observer in motion along the \(z\) axis, who sees the solonoid moving along the negative \(z\) axis, will see the number of windings per unit length increase by a factor \(\gamma\), as the number of windings does not change but the length of the solenoid decreases by a factor \(\gamma\). Therefore: \(n_{l}{ }^{\prime}=\gamma n_{l}\).
The current \(I\), assumed to be running exactly perpendicularly to the \(z\) axis, is given by the product between the volume current density, which does not change as it runs perpendicular to the relative velocity of the two Reference Frame, and the cross-section of the wire, which shrinks by a factor \(\gamma\), when the solenoid is moving. Therefore the current is reduced, in the judgement of the observer who sees the solenoid moving: \(I^{\prime}=I / \gamma\).
Alternatively, one can reach the same conclusion on the current by observing that the moving observer will see the same charge across any section of the wire in a time longer than the time measured by the stationary observer (who measures the proepr time). Therefore the current measured by the moving observer is reduced by a factor \(\gamma\). Therefore, again: \(I^{\prime}=I / \gamma\).
Therefore, all in all, the magnetic field does not change, as the two factors cancel.

\subsection*{56.03.03 Transformations Mixing-Up Electric|Magnetic Fields}

Read § 56.09.02 - ElectroMagnetism and Relativity for one example of magnetic field transofrming into an electric field.

\subsection*{56.03.04 Relativistic Transformation Laws of ElectroMagnetic Fields}

\section*{This § is referenced at pages:}
[2458, 2458]
In relativity Electric|Magnetic fields have no separate meaning: the single concept of an ElectroMagnetic field exists.
However the Electric|Magnetic field vectors are not the space component of any four-vector. In fact they are members of a four-tensors with two indexes.
The full transformation laws can be derived from the study of other simple situations, as the one described above, as well as from a more general treatment (see section § 56.05.02 - ElectroMagnetism and Relativity). The results are:
\[
\begin{align*}
\mathbf{E}_{\|}^{\prime} & =\mathbf{E}_{\|}  \tag{56.03.01}\\
\mathbf{B}_{\|}^{\prime} & =\mathbf{B}_{\|}  \tag{56.03.02}\\
\mathbf{E}_{\perp}^{\prime} & =\gamma\left(\mathbf{E}+c^{+1} \boldsymbol{\beta} \times \mathbf{B}\right)_{\perp}  \tag{56.03.03}\\
\mathbf{B}_{\perp}^{\prime} & =\gamma\left(\mathbf{B}-c^{-1} \boldsymbol{\beta} \times \mathbf{E}\right)_{\perp}
\end{align*}
\]
56.03.05 Non-Relativistic Transformation Laws of ElectroMagnetic Fields

This § is referenced at pages:
[1300, 1300, 2343, 2343, 2343, 2343]
©|G.Manfredi|Non-relativistic limits of Maxwell's equations| Eur. J. Phys. 34 (2013) 859-871; WEB - URL
© \(\mid\) G.Rousseaux|Forty years of Galilean Electromagnetism (1973-2013)|Eur. Phys. J. Plus 128, 81 (2013); WEB - URL|

Read §53.04.01 - From Galilei Transformation to Lorentz Transformation, § 22.15.03 - Galilei-Newton Mechanics of General Systems.

It is immediate, from equation (56.03.01), (56.03.02), (56.03.03), (56.04), that the limit for \(c \rightarrow \infty\) provides the non relativistic transformation laws, equation (53.04.01).

However, the non-relativistic limit is tricky. The limit for \(c \rightarrow \infty\) is called the instantaneous limit, and other limits are possible.
Note that taking \(\mathbf{u}=0\) is not a sensible way to take the non-relativistic limit, because \(\mathbf{u}=0\) is just the identity transformation, that is no transformation at all, so they have to agree.

This § is referenced at pages:
[1716, 1716]
As discussed in § 33.11 - Basic Laws of ElectroMagnetism the Electric|Magnetic fields do not change under the gauge transformations (equations (33.11.02), (33.11.01)):
\[
\begin{array}{|}
\Phi^{\prime}=\Phi-\partial_{t} \Lambda \\
\mathbf{A}^{\prime}=\mathbf{A}+\operatorname{grad} \Lambda
\end{array}
\]
\[
\partial_{\mu} A^{\mu}=\frac{1}{c^{2}} \partial_{t} \Phi+\operatorname{div} \mathbf{A}=
\]
is normally used in relativistic physics.
Define the four-potential of the ElectroMagnetic field, whose transformation properties are not yet known:
\[
A^{\mu} \equiv\{\Phi / c, \mathbf{A}\}
\]

One can show that the four-potential of the ElectroMagnetic field, \(A^{\mu} \equiv\{\Phi / c, \mathbf{A}\}\), is a four-vector. In fact, in the Lorenz Gauge, it is the solution to the d'Alembert equation:

\[
\ldots \equiv \partial \partial(\ldots) \equiv \partial_{\mu} \partial^{\mu}(\ldots)
\]
\[
\square \Phi=\frac{\rho}{\varepsilon_{0}}=\mu_{0} c^{2} \rho
\]
\[
\square \mathbf{A}=\mu_{0} \mathbf{j}=\frac{1}{\varepsilon_{0} c^{2}} \mathbf{j}
\]
or:
\[
\square A^{\mu}=\frac{j^{\mu}}{\varepsilon_{0} c^{2}}=\mu_{0} j^{\mu} \quad \text { with } \quad \partial_{\mu} A^{\mu}=0
\]

As the four-potential is solution to the covariant d'Alembert equation it must be a four-vector, thanks to the quotient law § 18.03.06-Coordinate Transformations Tensors and Physical Laws and considering the equation in Fourier-transformed space, with arbitrary PW: \(\left(k_{\mu} k^{\mu}\right) A^{\nu}=k^{2} A^{\nu} \propto j^{\nu}\).
In four dimensional notation the gauge transformation (equations (33.11.02), (33.11.01)) becomes:
\[
A^{\mu} \longrightarrow A^{\mu}-\partial^{\mu} \Lambda
\]

Potentials in the Lorenz Gauge are not uniquely defined by the Lorenz Gauge condition any potential
Lorenz Gauge potential. The arbitrariness can be removed, however, by introducing suitable boundary conditions on the potentials.

\subsection*{56.05.01 ElectroMagnetic Field Tensor}

The Electric|Magnetic fields are built from space and time derivatives of the potentials. In order to build a covariant description time and space coordinates (and derivatives) must mix. In fact the magnetic field is given in terms of the spatial derivatives only. Under a Lorentz Transformation of the spatial derivatives the temporal derivative appears and the temporal derivatives uniquely appear in the expression of the Electric field.
Moreover, we know already how to build a four-vector from the potentials. Therefore one might try to build a second-rank tensor from \(A^{\mu}\) and its space and time derivatives, to try to sort out the expressions for the Electric|Magnetic field.
Let us define the (gauge invariant) anti-symmetric ElectroMagnetic field tensor, \(\mathbb{F}\), as the generalisation to four dimensions of the three dimensional rotor: \(\mathbb{F}\) is defined as the four-dimensional rotor of the four-potential (read § ?? - ??).
The anti-symmetric ElectroMagnetic field tensor is thus defined as:
\[
F^{\mu \nu} \equiv \partial^{\mu} A^{\nu}-\partial^{\nu} A^{\mu}=\left(\begin{array}{ccccc}
0 & -E_{x} / c & -E_{y} / c & -E_{z} / c & , \\
+E_{x} / c & 0 & -B_{z} & +B_{y} & , \\
+E_{y} / c & +B_{z} & 0 & -B_{x} & , \\
+F / c & -R & +B & 0
\end{array}\right) \quad \Longrightarrow \quad F^{\mu \nu}+F^{\nu \mu}=0 \quad . \quad \rightarrow 2455
\]

One can verify that:
\[
F_{\mu \nu} \equiv \eta_{\mu \alpha} \eta_{\nu \beta} F_{. .}^{\alpha \beta} \quad \Leftrightarrow \quad \mathbb{F} . . .=\boldsymbol{\eta} \mathbb{F} . . \boldsymbol{\eta}
\]
can be obtained by changing the sign of the electric field vector:
\[
\{\mathbf{B} \longrightarrow+\mathbf{B} \quad \mathbf{E} \longrightarrow-\mathbf{E}\} \quad \Leftrightarrow \quad F^{\mu \nu} \longrightarrow F_{\mu \nu}
\]

By explicit calculation (read §18.05.04 - Coordinate Transformations Tensors and Physical Laws) one can easily verify that the components of the tri-vector fields are:
\[
\begin{gathered}
E^{k}=E_{k}=-c F_{\cdot}^{0 k}=+c F_{.}^{k 0}, \\
B^{k}=B_{k}=\frac{1}{2} \epsilon_{k r s} F_{.}^{s r} .
\end{gathered}
\]

By its very definition, from two four-vectors, \(\mathbb{F}\) is a rank-two Lorentz tensor. The Electric|Magnetic fields, therefore, have no independent existence, but they are parts of the same ElectroMagnetic Field, and transform into each other by Lorentz Transformation.
The dual ElectroMagnetic field tensor is defined, in terms of the totally anti-symmetrical Levi-Civita pseudo-tensor (read § 18.04.02 - Coordinate Transformations Tensors and Physical Laws and comments therein about different conventions)
\[
G_{\mu \nu}^{\because} \equiv \frac{1}{2} \epsilon_{\mu \nu \alpha \dot{\beta}} F_{.}^{\alpha \beta}=\left(\begin{array}{cccc}
0 & +B_{x} & +B_{y} & +B_{z} \\
-B_{x} & 0 & -E_{z} / c & +E_{y} / c \\
-B_{y} & +E_{z} / c & 0 & -E_{x} / c \\
-B_{z} & -E_{y} / c & +E_{x} / c & 0
\end{array}\right) G_{\mu \nu}^{\because}+G_{\nu \mu}^{\cdots}=0
\]

The elements of \(\mathbb{G}\) are obtained from the elements of \(\mathbb{F}\) by applying:
\[
\begin{equation*}
\{\mathbf{E} \longrightarrow-\mathbf{B} \quad \mathbf{B} \longrightarrow+\mathbf{E}\} \quad \Leftrightarrow \quad F^{\mu \nu} \longrightarrow G^{\mu \nu} \tag{56.05.01}
\end{equation*}
\]
56.05.02 Relativistic Transformations of the ElectroMagnetic Fields

This § is referenced at pages:
[2367, 2367, 2431, 2431, 2441, 2441, 2445, 2445]
©|W.K.H.Panoffsky \& M.Phillips, Classical Electricity And Magnetism, 1962, Addison-Wesley, 2ndEd., ....|18.3||
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|26||
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|11||
In order to calculate how the Electric|Magnetic fields transform one just need to do the calculation with the Lorentz Transformation equations. It is just long and tedious. The calculations are done more easily if the transformation law is written in matrix form from \(F^{\mu \nu}\) :
\[
\mathbb{F}^{\prime}=\mathbb{L F \mathbb { L } ^ { T }}
\]

One finds:
\[
\begin{gathered}
\begin{array}{|c|}
\mathbf{E}_{\|}^{\prime}=\mathbf{E}_{\|} \\
\hline \mathbf{B}_{\|}^{\prime}=\mathbf{B}_{\|} \\
\mathbf{E}_{\perp}^{\prime}=\gamma\left(\mathbf{E}+c^{+1} \boldsymbol{\beta} \times \mathbf{B}\right)_{\perp} \\
\mathbf{B}_{\perp}^{\prime}=\gamma\left(\mathbf{B}-c^{-1} \boldsymbol{\beta} \times \mathbf{E}\right)_{\perp}
\end{array}
\end{gathered}
\]

\subsection*{56.05.03 Maxwell Equations in Relativistic Notation}

The two homogeneous Maxwell Equations, equations (33.07.07), (33.07.08), those describing the intrinsic properties of the ElectroMagnetic fields independently from Charge|Current, become, in covariant form:
\[
\partial^{\alpha} F_{.}^{\beta \gamma}+\partial^{\beta} F_{.}^{\gamma \alpha}+\partial^{\gamma} F_{.}^{\alpha \beta}=0
\]

The two homogeneous Maxwell Equations are written most compactly using the dual tensor of the field tensor:
\[
\begin{equation*}
\partial_{\alpha} G^{\alpha \beta}=0 \tag{56.05.03}
\end{equation*}
\]

The two non-homogeneous Maxwell Equations, equations (33.07.01), (33.07.04), those describing how the properties of the ElectroMagnetic fields are related to Charge|Current, become, in covariant form:
\[
\begin{equation*}
\partial_{\alpha} F^{\alpha \beta}=\frac{j^{\beta}}{\varepsilon_{0} c^{2}}=\mu_{0} j^{\beta}, \tag{56.05.04}
\end{equation*}
\]
valid in the Lorenz Gauge and representing the just the wave equation in the Lorenz Gauge.

\section*{Dynamics of Particles in ElectroMagnetic Field}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|11.9||
©|W.K.H.Panoffsky \& M.Phillips, Classical Electricity And Magnetism, 1962, Addison-Wesley, 2ndEd., ....|18||
See the very important comment in § 33.05.03 - Basic Laws of ElectroMagnetism about the modeling of matter with point charges, Dipoles and higher-order Multipoles.
The equations of motion of a charged point particle in an ElectroMagnetic field are:
\[
\frac{\frac{\mathrm{d} \varepsilon}{\mathrm{~d} t}=q \mathbf{u} \cdot \mathbf{E}}{\frac{\mathrm{~d} \mathbf{p}}{\mathrm{~d} t}=q(\mathbf{E}+\mathbf{u} \times \mathbf{B})}
\]

Moreover, if the particle has an intrinsic Electric|Magnetic Dipole moment, in the particle Rest Frame one can write the second Cardinal Equation as:
\[
\frac{\mathrm{ds}}{\mathrm{~d} t}=\mathrm{p} \times \mathbf{E}+\mathrm{m} \times \mathbf{B} \quad \mathbf{j}=\mathbf{s}
\]

In fact, for a mass-point, the orbital angular momentum dynamics is dictated by the first cardinal equation:
\[
\frac{\mathrm{d} \mathbf{p}}{\mathrm{~d} t}=q(\mathbf{E}+\mathbf{u} \times \mathbf{B})+\boldsymbol{\nabla}(\mathrm{p} \cdot \mathbf{E})+\boldsymbol{\nabla}(\mathrm{m} \cdot \mathbf{B}) \quad \text { fixed Dipoles } .
\]

In this case the, in presence of non-uniform Electric|Magnetic fields, the first Cardinal Equation is also modified to account for the force on a Dipole, depending on the gradient of the field (read § 33.05.01 Basic Laws of ElectroMagnetism).
Quantum Physics, however, requires that any intrinsic Electric|Magnetic Dipole moment is parallel to the spin of the particle: \(\mathrm{p}=g_{E} \mathbf{S}\) and \(\mathrm{m}=g_{B} \mathbf{S}\).
Note however that one might limit to consider charged particles only, avoiding introducing explicitly Dipoles and|or higher order Multipoles, when one realizes that any higher order charge or current Multipole can be always described by a suitable combination of charge with a suitable dynamics. Therefore, in principle, one would not need to introduce explicitly the equations for Dipoles and|or higher order Multipoles. However the explicit use of Dipoles and|or higher order Multipoles is often a shortcut allowing a simpler description.
Also note that when one consider a generic continuous distribution of Charge|Current using it for calculations of integrated properties, such as forces/couples, one can always model point charges with a delta charge distribution, Electric|Magnetic Dipoles with a suitable first derivative of a delta charge distribution, and so on.
In terms of the four-velocity and Four-Momentum:
\[
U^{\alpha} \equiv \frac{\mathrm{d} x^{\alpha}}{\mathrm{d} \tau}=\frac{\mathrm{d} t}{\mathrm{~d} \tau} \frac{\mathrm{~d} x^{\alpha}}{\mathrm{d} t}=\gamma_{\mathbf{u}} \frac{\mathrm{d} x^{\alpha}}{\mathrm{d} t} \equiv \gamma_{\mathbf{u}} u^{\alpha} \quad p^{\alpha}=m U^{\alpha}=m \gamma_{\mathbf{u}} u^{\alpha},
\]
one can write:
\[
\begin{aligned}
& \frac{\mathrm{d} p_{0}}{\mathrm{~d} \tau}=q \mathbf{U} \cdot \mathbf{E} \\
& \frac{\mathrm{~d} \mathbf{p}}{\mathrm{~d} \tau}=q\left(U_{0} \mathbf{E}+\mathbf{U} \times \mathbf{B}\right) .
\end{aligned}
\]

The equation of motion can be written in covariant form:
\[
\begin{equation*}
\frac{\mathrm{d} p^{\alpha}}{\mathrm{d} \tau} \equiv m \frac{\mathrm{~d} U^{\alpha}}{\mathrm{d} \tau}=q F^{\alpha \beta} \cdot U_{\beta} \tag{56.06.01}
\end{equation*}
\]

Note that it would be possible to deduce the transformation properties of the EM fields from the equation of motion (56.06.01), as the transformation properties of all other quantities are known.

Read § 19.01 - Some Miscellaneous Topics and § 55.03.01 - Relativistic Dynamics.
Start from equations § 37.01.02 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum, § 37.01.03 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum, § 37.01.04 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum.

In order to build a relativistic covariant expression for the energy and linear momentum, according to section §55.03 - Relativistic Dynamics, one needs to build a suitable covariant expression quadratic in the field tensor \(\mathbb{F}\) as we know that energy density, energy flux and linear momentum density are quadratic in the fields.
Possible components are therefore:
\[
\eta_{\alpha \dot{\beta}}^{\bullet} F^{\mu \alpha} F_{.}^{\beta \nu}=F_{\cdot \delta}^{\mu \cdot} F_{.}^{\delta \nu} \quad \eta_{{ }_{.}^{\mu \nu}} F^{\alpha \beta} F_{\alpha \dot{\beta}}^{\cdot}
\]

Comparing with the known expressions in § 37.01 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum one finds the correct expression:
\[
\begin{equation*}
T_{.}^{\mu \nu}=\varepsilon_{0} c^{2}\left(\eta_{\alpha \dot{\beta}} F_{.}^{\mu \alpha} F_{\ldots}^{\beta \nu}+\frac{1}{4} \eta_{\ldots}^{\mu \nu} F_{\ldots}^{\alpha \beta} F_{\alpha \dot{\beta}}^{.}\right) \tag{56.07.01}
\end{equation*}
\]

\subsection*{56.09.01 Four-Current of a Ohmic Conductor Wire}

Consider the Four-Current in a typical globally neutral Ohmic metallic rectilinear conductor with conduction current four-vector equal to:
\[
j=\left\{c \rho_{+}, \mathbf{0}\right\}+\left\{c \rho_{-}, \rho_{-} \mathbf{v}_{-}\right\}=\left\{0, \rho_{-} \mathbf{v}_{-}\right\},
\]
in terms of the charge density, \(\rho_{-}\), and drift velocity, \(\mathbf{v}_{-}\), of the electrons and of the charge density, \(\rho_{+}\), of the positive ions. All quantities are measured in the Laboratory Rest Frame.
Show that the Current four-vector, \(j\), is space like with
\[
j^{\mu} j_{\mu}=-\left(\rho_{-}\right)^{2} \mathbf{v}_{-}^{2}=-\left(\rho_{+}^{0}\right)^{2} \mathbf{v}_{-}^{2}
\]
in terms of the charge density of the positive ions at rest in the conductor, \(\rho_{+}^{0}\).
\begin{tabular}{cc|}
\hline SOLUTION \\
\hline\(\left|\rho_{+}^{0}\right|=\left|\rho_{-}\right| \quad\), \\
\(j=\left\{0, \rho_{-} \mathbf{v}_{-}\right\}=\left\{c \rho_{+}^{0}, \mathbf{0}\right\}+\left\{c \rho_{-}, \rho_{-} \mathbf{v}_{-}\right\} \quad\), \\
\(\rho_{-}=\rho_{-}^{0} \gamma \quad \rho_{+}=\rho_{+}^{0}\), \\
\(j^{\mu} j_{\mu}=-\left(\rho_{+}^{0}\right)^{2} \mathbf{v}_{-}{ }^{2}=-\left(\rho_{-}\right)^{2} \mathbf{v}_{-}{ }^{2}<0\). \\
\hline
\end{tabular}

\subsection*{56.09.02 EM Fields for an Observer Moving With Respect to Straight Infinite Neutral Current Wire} (1)

This § is referenced at pages:
[2431, 2431]
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....||Alternative detailed demonstratio
Read also § 56.09.03 - ElectroMagnetism and Relativity, for a different solution.
Consider a very long rectilinear electrically neutral current-carrying wire and consider it as an infinite rectilinear electrically neutral current-carrying wire (aligned with the \(z\) axis). Suppose the current \(I>0\) is generated by electrons moving with velocity \(u<0\) inside a lattice of fixed positive ions. Let \(\gamma \equiv \gamma_{u}\).
Let us also consider an observer, \(\mathcal{J}^{\prime}\), moving with the negative electrons.
The wire is neutral, in the Laboratory Reference Frame, with positive ions at rest and negative electrons moving in the negative \(z\) direction. The positive ions are at rest and the free electrons move at constant speed. The system is electrically neutral bacause the measured separation beetween positive ions and electrons are identical.

The Laboratory Reference Frame is the Rest Frame for the positive ions, but it not the Rest Frame for the electrons and therefore:
\[
\rho^{+}=\rho_{0}^{+} \quad \rho^{-}=\gamma \rho_{0}^{-}>\rho_{0}^{-}
\]
\[
\rho^{+}+\rho^{-}=0 \quad \text { as the wire is electrically neutral in the Laboratory Reference Frame }
\]
\[
\rho \equiv \rho_{0}^{+}=\rho^{+}=-\rho^{-}>0 \quad \text { just a definition }
\]

The wire will generate a tangential magnetic field and no electric field:
\[
\mathbf{B}=B[r] \hat{\mathbf{e}}_{\theta} \quad B[r]=\frac{\mu_{0} I}{2 \pi r} \quad \text { and } \quad \mathbf{E}=0
\]

Note that the cross-section of the wire as well as the radial distance do not change, when passing from the Laboratory Reference Frame to \(\mathcal{J}^{\prime}\) :
\[
S^{\prime}=S \quad r^{\prime}=r
\]

We have, in the Laboratory Reference Frame:
\[
I \equiv-\rho u S=-\rho c \beta S>0 \quad j_{z}=\rho^{-} u=-\rho u>0
\]

Lorentz Transformation imply
\[
\begin{gathered}
\rho^{\prime}=-\gamma \beta j_{z} / c=\gamma \rho \beta^{2}>0, \\
j_{z}{ }^{\prime}=\gamma j_{z} \quad I^{\prime}=\gamma I
\end{gathered}
\]

The law of transformation of the charge density can be also derived, with more physical insight, directly as follows. An observer moving with the electrons will see a charge density:
\[
\rho^{\prime}=\rho^{+^{\prime}}+\rho^{-\prime}=\gamma \rho_{0}^{+}+\rho_{0}^{-}=\gamma \rho_{0}^{+}+\rho^{-} / \gamma=\rho(\gamma-1 / \gamma)=\rho \beta^{2} \gamma>0
\]

Therefore he will see a radial electric field (to within the sign, which will be determined later on):
\[
E^{\prime}[r]=\frac{\rho^{\prime} \mathbf{S}^{\prime}}{2 \pi \varepsilon_{0} r}=\frac{\rho \beta^{2} \gamma S}{2 \pi \varepsilon_{0} r}=\gamma \beta c \frac{1}{\varepsilon_{0} \mu_{0} c^{2}} \frac{\mu_{0} \rho c \beta S}{2 \pi r}=\gamma \beta c B
\]

It turns out, introducing vectors (all the fields are perpendicular to \(\mathbf{u}\) ):
\[
\mathbf{E}_{\perp}^{\prime}=\gamma \mathbf{u} \times \mathbf{B}=\gamma \mathbf{u} \times \mathbf{B}_{\perp} \Longrightarrow\left|\mathbf{E}^{\prime}\right|=\left|\mathbf{E}_{\perp}^{\prime}\right|=\frac{\rho \gamma \beta^{2} S}{2 \pi \varepsilon_{0} r}
\]

The moving observer will then Read also an electric force on a point charge, not only a magnetic force.
It is important to stress that the electric field seen by the moving observer is due to the appearance of a real charge density from the point of view of this observer. Compare with the discussion of \(\S 53.03 .01\) - From Galilei Transformation to Lorentz Transformation.

The magnetic field is:
\[
\mathbf{B}_{\perp}^{\prime}=\gamma \mathbf{B}_{\perp}=\frac{\mu_{0} I^{\prime}}{2 \pi r}
\]

Note that the apparent non-invariance of electric charge, due to the fact that the wire appears neutral to one observer and charged to the other one, is an artifact of the idealisation of infinite wire with infinite charge. It might seem to be paradoxical, in view of the invariance of the total electric charge, that the wire appears to be charged to one observed and neutral to another one. Actually there is no problem because the rectilinear infinite wire is an idealisation with charges entering from infinity and exiting to infinity, such that it is not clear what is the total charge (which is, in any case, infinite). Read § 56.09.08 - ElectroMagnetism and Relativity for a more realistic situation.

One should consider a finite loop of current to avoid such kind of problems (read § 56.09.08-ElectroMagnetism and Relativity). In the real case there will be parts of the wire positively charged and parts of the wire negatively charged, thus retaining the overall neutrality of the wire.
However, when considering a finite piece of wire inside a closed finite surface, one might still wonder what happens with the total internal charge, which should be an invariant quantity. In this case one should remember the discussion in section \(\S 56.02 .01\) - ElectroMagnetism and Relativity, about the relativity of simultaneity.

Note that it as been shown not only that an observer in motion with respect to a stationary neutral current distribution will see an electric field but also that the sources of the electric field are real charges (as any real electric field must be traced to specific source charges). This fact was not clear from the discussion in \(\S\) 53.03.01 - From Galilei Transformation to Lorentz Transformation.
56.09.03 EM Fields for an Observer Moving With Respect to Straight Infinite Neutral Current Wire (2)

©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|||
©|Berkeley Physics Course, Vol. 2, E.M.Purcell \& D.J.Morin, Electricity And Magnetism, 2013, CUP, ...Ed., ....||Alternative detailed demonstratio
Consider the central part of a long rectilinear and uniform wire of radius \(r\), section \(S\), carrying a constant current \(I\) and electrically neutral, in global.
Assume that the conduction current is provided by electrons moving inside a lattice of fixed positive ions.
Calculate the ElectroMagnetic fields at a distance \(R\) from the wire according to an observer at rest with respect to the wire (an observer in the Laboratory Frame).
Calculate the ElectroMagnetic fields at a distance \(R\) from the wire according to an observer moving with the same velocity as the average velocity of the (current producing) electrons inside the wire.
Verify that the ElectroMagnetic fields according to the moving observer are produced by the charge density and current as seen from that system.
Verify that the two invariants of the ElectroMagnetic fields (section § 56-004 - ElectroMagnetism and Relativity) are actually invariant in the transformation.
Introduce a cylindrical Coordinate System with the wire on its axis and choose for the \(z\) axis the same orientation as the current flow.
For the stationary observer the electric field is zero, because the wire is electrically neutral. The magnetic field is tangential. It is:
\[
\mathbf{B}[R]=\frac{\mu_{0} I}{2 \pi R} \hat{\mathbf{e}}_{\theta} \quad \mathbf{j} \cdot \mathbf{e}_{z}>0 .
\]

Consider an observer moving with the same velocity as the average velocity of the (current producing) electrons inside the wire. Use the transformation formulas in § 56.05.02-ElectroMagnetism and Relativity, use the fact that for this Lorentz transformation we have
\[
\mathbf{B}[R]=\mathbf{B}_{\perp}=\frac{\mu_{0} I}{2 \pi R} \hat{\mathbf{e}}_{\theta}
\]
use the fact that the observer is moving like the electrons, that is with a negative component of the velocity, \(V_{z}<0\), to find:
\[
\begin{align*}
\mathbf{E}_{\|}^{\prime} & =\mathbf{E}_{\|}=0 \\
\mathbf{B}_{\|}^{\prime} & =\mathbf{B}_{\|}=0 \\
\mathbf{E}_{\perp}^{\prime} & =\gamma_{\mathbf{V}}\left(\mathbf{E}+c^{+1} \boldsymbol{\beta} \times \mathbf{B}\right)_{\perp}=\gamma_{\mathbf{V}} c \boldsymbol{\beta}_{\mathbf{V}} \times \mathbf{B}_{\perp} \\
\mathbf{B}_{\perp}^{\prime} & =\gamma_{\mathbf{V}}\left(\mathbf{B}-c^{-1} \boldsymbol{\beta} \times \mathbf{E}\right)_{\perp}=\gamma_{\mathbf{V}} \mathbf{B}_{\perp} . \tag{tabular}
\end{align*}
\]

A radial electric field has appeared while the perpendicular magnetic field has been modified.
The relation between the charge volume density in the Rest Frame, \(\rho_{0}\), and the one in an arbitrary frame, moving with velocity \(\mathbf{- V}\) with respect to the Rest Frame, is given by:
\[
\begin{equation*}
\rho=\gamma_{\mathbf{V}} \rho_{0} \tag{56.09.05}
\end{equation*}
\]

In the Rest Frame the volume of an element of charge is maximum and the charge density is thus minimum, due to the invariance of the charge.
Let \(\rho_{+}\)and \(\rho_{-}\)be the charge volume density in the Laboratory Frame. Let \(\rho_{+}^{\prime}\) and \(\rho_{-}^{\prime}\) be the charge volume density in the Reference Frame moving with the same velocity as the average velocity of the electrons in the wire. Let \(\rho_{+}^{0}\) and \(\rho_{-}^{0}\) be the charge volume density in the Rest Frame of the corresponding charge.

We have:
\[
\begin{aligned}
\rho_{+}+\rho_{-} & =0 \quad \text { globally neutral in the Laboratory system }, \\
\left|\rho_{+}\right|=\left|\rho_{-}\right| & \equiv \rho>0 \quad \text { definition }, \\
\rho_{-} & =\gamma \rho_{-}^{0} \quad \text { from the transformation of the charge density }, \\
\rho_{+} & =\rho_{+}^{0} \quad \text { from the transformation of the charge density }, \\
\rho_{-}^{\prime} & =\rho_{-}^{0}=\rho_{-} / \gamma, \\
\rho_{+}^{\prime} & =\gamma \rho_{+}^{0}=\gamma \rho_{+}, \\
0 \leq I & =\rho_{-} V_{z} S=-\rho_{-}\left|V_{z}\right| S=\rho\left|V_{z}\right| S \equiv \rho V_{z} S,
\end{aligned}
\]
having used equation (56.09.05).

\subsection*{56.09.03.01 First Method}

From equation (56.09.05) the following relations can be derived:
\[
\begin{equation*}
\rho^{\prime} \equiv \rho_{+}^{\prime}+\rho_{-}^{\prime}=\gamma \rho_{+}+\rho_{-} / \gamma=\rho(\gamma-1 / \gamma)=\rho\left(\frac{\gamma^{2}-1}{\gamma}\right)=\rho \gamma \beta^{2}>0 \tag{56.09.06}
\end{equation*}
\]
\(\rightarrow\) 2443

Note that \(\rho_{-}\)decreases in the transformation, as we are moving onto the Rest Frame, while \(\rho_{+}\)increases, as we are moving away from the Rest Frame. Therefore we expect to see the wire electrically charged with positive charge.
The moving observer will see a positive charge density and thus a radial electric field. Its calculation of the (radial) electric field gives:
\[
\begin{equation*}
E_{r}^{\prime}=\frac{\rho^{\prime} S}{2 \pi \varepsilon_{0} R}=\frac{\rho \gamma \beta^{2} S}{2 \pi \varepsilon_{0} R} \tag{56.09.07}
\end{equation*}
\]

At the same time equation (56.09.03) gives:
\[
\mathbf{E}_{\perp}^{\prime}=\gamma_{\mathbf{v}} c \boldsymbol{\beta}_{\mathbf{V}} \times \mathbf{B}_{\perp}=\gamma \beta c\left(\frac{\mu_{0} I}{2 \pi R}\right)\left(-\hat{\mathbf{e}}_{3} \times \hat{\mathbf{e}}_{\theta}\right)=\frac{\mu_{0} c^{2} \rho \gamma \beta^{2}}{2 \pi R} \hat{\mathbf{e}}_{r}=\frac{\rho \gamma \beta^{2} S}{2 \pi \varepsilon_{0} R} \hat{\mathbf{e}}_{r}
\]
in agreement with (56.09.07). The two methods provide then the same value for the electric field, as it should.

\subsection*{56.09.03.02 Second Method}

It is obvious that the wire appears charged because the current transforms in the Lorentz transformation.
Write the special Lorentz transform, along the \(z\) axis, from the Laboratory Frame to the frame of an observer moving with the same velocity as the average velocity of the (current producing) electrons inside the wire:
\[
\begin{aligned}
\beta & =-V<0, \\
\rho_{+}^{\prime} & =\gamma\left(\rho_{+}-\beta j_{+}\right)=\gamma \rho_{+}, \\
\rho_{-}^{\prime} & =\gamma\left(\rho_{-}-\beta j_{-}\right), \\
j_{+}^{\prime} & =\gamma\left(j_{+}-\beta \rho_{+}\right), \\
j_{-}^{\prime} & =\gamma\left(j_{-}-\beta \rho_{-}\right)=0,
\end{aligned}
\]
where the last passages come from the fact that in this problem:
\[
\begin{gathered}
j_{+}=0 \\
j_{-}^{\prime}=0 \Longrightarrow j_{-}=\beta \rho_{-} .
\end{gathered}
\]

It follows:
\[
\begin{align*}
\rho_{+}^{\prime} & =\gamma \rho_{+}, \\
\rho_{-}^{\prime} & =\gamma\left(\rho_{-}-\beta^{2} \rho_{-}\right)=\gamma \rho_{-}\left(1-\beta^{2}\right)=\rho_{-} / \gamma, \\
\rho^{\prime}=\rho_{+}^{\prime}+\rho_{-}^{\prime} & =\gamma \rho_{+}+\gamma \rho_{-}=\gamma \rho_{+}+\rho_{-} / \gamma=\rho \gamma \beta^{2}>0, \tag{56.09.08}
\end{align*}
\]
where the last passages are the same as in equation (56.09.06).
This second method is actually more general than the first one, as it can be applied to any transformation, not only to the specific one considered in this problem, moving to a Reference Frame where the electrons are at rest. In this case the generalisation requires to distinguish between the velocity of the Lorentz Transformation and the drift velocity of the charges. It is than better to stick to the more general relation \((\rho=0)\) :
\[
\begin{equation*}
\rho^{\prime}=-\gamma \beta j \tag{56.09.09}
\end{equation*}
\]

It might seem to be paradoxical, in view of the invariance of the total electric charge, that the wire appears to be charged to one observed and neutral to another one. Actually there is no problem because the rectilinear infinite wire is an idealisation with charges entering from infinity and exiting to infinity, such that it is not clear what is the total charge (which is, in any case, infinite).

Read \(\S 56.09 .08\) - ElectroMagnetism and Relativity for a more realistic situation.

\subsection*{56.09.04 A Beam of Identical Charged Particles}

This § is referenced at pages:
[2455, 2455]
Consider a cylindrical beam of identical charged particles moving at constant velocity, u, on straight line with uniform charge density and a circular section of radius \(R\). This is often a good approximation for a beam of particles in a particle accelerator.

Show that the repulsive force between particles is damped by a factor \(\gamma^{2}\), as a consequence of the attractive effect of the magnetic field, with respect to the case when the particles are at rest.

Alternatively show that the same effect can be explained by the relativistic time dilatation.

\section*{SOLUTION}

In the Laboratory Frame let the beam density be \(\rho\). Let the \(z\) axis be on the direction of the beam and let the current density along \(z\) be \(\mathbf{j}_{z}=\rho v\). Therefore in the Laboratory Frame:
\[
\begin{aligned}
E_{r}[r] & =\frac{\rho r}{2 \varepsilon_{0}} \quad \text { at an point internal to the beam: } r \leq R \\
B_{\phi}[r] & =\frac{\mu_{0} j_{z} r}{2}=\frac{\mu_{0} \rho v r}{2}, \\
\mathbf{f} & =q(\mathbf{E}+\mathbf{v} \times \mathbf{B})=q\left(E_{r}[r] \hat{\mathbf{e}}_{r}+v \hat{\mathbf{e}}_{3} \times B_{\phi}[r] \hat{\mathbf{e}}_{\psi}\right), \\
f_{r}[r] & =q(\mathbf{E}+\mathbf{v} \times \mathbf{B}) \cdot \hat{\mathbf{e}}_{r}=q \frac{\rho r}{2 \varepsilon_{0}} \frac{1}{\gamma^{2}} .
\end{aligned}
\]

The repulsive force in the Laboratory Frame is trying to scatter away the particles in the beam but in the Laboratory Frame the time evolution is slowed down.
let us look at the situation as it is seen by the Reference Frame where the charged particles are at rest, \(J^{\prime}\). In this system the force is of electrical nature only. The charge density is:
\[
\rho^{\prime}=\rho / \gamma \leq \rho
\]

The perpendicular component of the electric field is:
\(\mathbf{E}_{\perp}^{\prime}=\gamma(\mathbf{E}+c \boldsymbol{\beta} \times \mathbf{B})_{\perp}=\gamma\left(\frac{\rho r}{2 \varepsilon_{0}} \hat{\mathbf{e}}_{r}+\hat{\mathbf{e}}_{3} \times \hat{\mathbf{e}}_{\psi} \frac{\mu_{0} \rho v^{2} r}{2}\right)=\frac{\gamma \rho r}{2 \varepsilon_{0}}\left(1-\frac{v^{2}}{c^{2}}\right) \hat{\mathbf{e}}_{r}=\frac{\rho r}{2 \varepsilon_{0} \gamma} \hat{\mathbf{e}}_{r}=\frac{\rho^{\prime} r}{2 \varepsilon_{0}} \hat{\mathbf{e}}_{r}\).
As the electric charge is invariant the force on one particle in Reference Frame \(\mathcal{J}^{\prime}\) is thus:
\[
\mathbf{f}^{\prime}=\frac{q \rho^{\prime} r}{2 \varepsilon_{0}} \hat{\mathbf{e}}_{r}=\frac{q \rho r}{2 \varepsilon_{0} \gamma} \hat{\mathbf{e}}_{r}=\gamma \mathbf{f}
\]

This can be written as the Minkowski force as:
\[
\mathbf{f}_{\mathrm{M}}^{\prime} \equiv \mathbf{f}^{\prime}=\frac{q \rho^{\prime} r}{2 \varepsilon_{0}} \hat{\mathbf{e}}_{r}
\]
where \(\gamma=1\) in the definition of the Minkowski force because particles are at rest in the \(\mathcal{J}^{\prime}\) Reference Frame.
On the other hand the force on one particle in Reference Frame \(\mathcal{J}\) is:
\[
\mathbf{f}=\frac{q \rho r}{2 \varepsilon_{0} \gamma^{2}} \hat{\mathbf{e}}_{r}=\frac{q \rho^{\prime} r}{2 \varepsilon_{0} \gamma} \hat{\mathbf{e}}_{r}
\]

This can be written as the Minkowski force as:
\[
\mathbf{f}_{\mathrm{M}} \equiv \gamma \mathbf{f}=\frac{q \rho^{\prime} r}{2 \varepsilon_{0}} \hat{\mathbf{e}}_{r}
\]

It is thus evident that:
\[
\mathbf{f}_{\mathrm{M}}=\mathbf{f}^{\prime}{ }_{\mathrm{M}},
\]
as it is required for the transformation of the transverse component of the spatial part of a fourvector as the Minkowski force is.

\subsection*{56.09.05 Force on a Charge Near a Straight Infinite Neutral Current Wire}

Consider the central part of a long rectilinear and uniform cylindrical wire of radius \(R\), cross-sectional area \(S\), carrying a constant current \(I\) and electrically neutral globally.

Consider a positive point charge moving parallel to the wire with speed \(\mathbf{v}\) and determine the force it feels.

Compare the description of the observatory in the Laboratory Frame ( \(\mathcal{J})\) and the observatory moving with the charge \(\left(\mathcal{J}^{\prime}\right)\).

\section*{SOLUTION}

Let the wire be along the \(z\) axis.
The current, charge and current density in the Laboratory Frame are given by:
\[
\rho=0 \quad \mathbf{j} \equiv j \hat{\mathbf{e}}_{3} \quad I=j \pi R^{2}
\]

The charge and current density in the \(\mathcal{J}^{\prime}\) Reference Frame are given by:
\[
\rho^{\prime}=-\gamma \boldsymbol{\beta} \cdot \mathbf{j} / c=-\gamma v j / c^{2} \quad \mathbf{j}^{\prime}=\gamma \mathbf{j}
\]

A positive charge moving equiverse with the current is attracted by the wire by the Lorentz force. In the Laboratory Frame one has:
\[
\begin{gathered}
\mathbf{E}_{\|}=0 \\
\mathbf{E}_{\perp}=0 \\
\mathbf{B}_{\|}=0 \\
\mathbf{B}_{\perp}=\frac{\mu_{0} I}{2 \pi r} \hat{\mathbf{e}}_{\psi}
\end{gathered}
\]

Actually not that \(\mathbf{E}_{\|}=0\) is only approximatively valid at large distance from the central part of a long wire. In fact the conservation of the tangential component of the electric field implies that the electric field just outside the wire is the same as inside it. Moreover, a radial component of the field exists in a real finite wire.
In the \(\mathcal{J}^{\prime}\) Reference Frame one has the transformed fields:
\[
\begin{gathered}
\mathbf{E}_{\|}^{\prime}=\mathbf{E}_{\|}=0, \\
\mathbf{E}_{\perp}^{\prime}=\gamma \mathbf{v} \times \mathbf{B}=\gamma \mathbf{v} \times \mathbf{B}_{\perp} \quad \text { it appears }, \\
\mathbf{B}_{\|}^{\prime}=\mathbf{B}_{\|}=0, \\
\mathbf{B}_{\perp}^{\prime}=\gamma \mathbf{B}_{\perp}=\gamma \frac{\mu_{0} I}{2 \pi r} \hat{\mathbf{e}}_{\psi} \quad \text { it is modified } .
\end{gathered}
\]

The electric field which appears in the \(\mathcal{J}^{\prime}\) Reference Frame requires that the wire appears as charged. In fact:
\[
E_{\perp}^{\prime}=\gamma v B=\gamma v \frac{\mu_{0} I}{2 \pi r}=\frac{\gamma v \mu_{0} \pi R^{2} j}{2 \pi r}=-\frac{c^{2} \rho \mu_{0} R^{2}}{2 r}=-\frac{\rho R^{2}}{2 \varepsilon_{0} r}
\]
as it should be for an attractive electric field due to a circular cylindrical wire of charges.
The Lorentz force in the Laboratory Frame is:
\[
\mathbf{B}=\mathbf{B}_{\perp} \quad \mathbf{f}=q \mathbf{v} \times \mathbf{B}=\frac{\mu_{0} q v I}{2 \pi r} \hat{\mathbf{e}}_{3} \times \hat{\mathbf{e}}_{\psi}=-\frac{\mu_{0} q v I}{2 \pi r} \hat{\mathbf{e}}_{r} \quad \text { attractive }
\]

The Lorentz force in the \(\mathcal{J}^{\prime}\) Reference Frame (the velocity of the charge is zero) is:
\[
\mathbf{E}=\mathbf{E}_{\perp} \quad \mathbf{f}^{\prime}=q\left(\mathbf{E}^{\prime}\right)=q \gamma \mathbf{v} \times \mathbf{B}=\gamma \mathbf{f}
\]

As the Lorentz Transformation is perpendicular to the force the Minkowski force should be unchanged by the transformation. In fact:
\[
\begin{aligned}
& \mathbf{f}_{\mathrm{M}}=\gamma \mathbf{f}, \\
& \mathbf{f}_{\mathrm{M}}^{\prime}=\mathbf{f}^{\prime},
\end{aligned}
\]
which are actually identical, as demonstrated by the previous equations.

\subsection*{56.09.06 ElectroMagnetic Fields of a Point Charge Moving at Constant Velocity}

\section*{This § is referenced at pages:}
[2192, 2192, 2192, 2192, 2209, 2209, 2449, 2449, 2456, 2456, 2456, 2456, 2457, 2457, 2457, 2457,
2458, 2458]
We are going to use Lorentz Transformation and the transformation laws for the ElectroMagnetic fields (section §56.05.02 - ElectroMagnetism and Relativity) to determine the ElectroMagnetic fields produced by a point charge \(q\) moving at constant velocity \(\mathbf{V}\) (with \(\boldsymbol{\beta} \equiv \mathbf{V} / c\) ) in a certain Reference Frame, J.
Let \(\mathcal{J}\) be the inertial Reference Frame where the charge is seen to move at constant velocity V. Let \(\mathcal{J}^{\prime}\) be the inertial Reference Frame where the charge is at rest.

Let the fixed point \(P\), a fixed point in \(\mathcal{J}\), be the point where the ElectroMagnetic fields have to be calculated.

Let \(\mathbf{r}_{\mathrm{P}}\) and \(\mathbf{r}_{\mathrm{C}}\) be the positions, in the Reference Frame \(\mathcal{J}\), respectively, of the point \(P\) and of the moving point charge \(C\).

Let \(\mathbf{r}[t]\) be the vector from the position of the moving point charge to the point \(P\), so that the kinematics of the motion of the point charge is:
\[
\mathbf{r}[t] \equiv \mathbf{r}_{\mathrm{P}}-\mathbf{r}_{\mathrm{C}}[t]=\mathbf{r}_{\mathrm{P}}-\mathbf{V}\left(t-t_{0}\right)-\mathbf{r}_{\mathrm{C}}\left[t=t_{0}\right]
\]

Note that the relation relating the position of \(P\) to the origin of the Coordinate System in \(\mathcal{J}\) and to \(C\) are the same in terms of the coordinates of both \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\) :
\[
\mathbf{r}_{\mathrm{P}}=\mathbf{r}+\mathbf{r}_{\mathrm{C}} \quad \mathbf{r}_{\mathrm{P}}^{\prime}=\mathbf{r}^{\prime}+\mathbf{r}_{\mathrm{C}}^{\prime}
\]
as all the coordinates are related by the linear Lorentz Transformation:
\[
\mathbf{x}^{\prime}=\mathbb{L} \mathbf{x}
\]

Let \(\theta[t]\) be the angle between the velocity vector \(\mathbf{V}\) and the position vector \(\mathbf{r}\) :
\[
\cos \theta[t]=\frac{\mathbf{V} \cdot \mathbf{r}}{|\mathbf{r} \| \mathbf{V}|}
\]

We can show that the (time dependent) electric field is:
\[
\begin{equation*}
\mathbf{E}\left[\mathbf{r}_{\mathrm{P}}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q\left(1-\beta^{2}\right)}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\mathbf{r}}{r^{3}} \tag{56.09.10}
\end{equation*}
\]
while the (time dependent) magnetic field is:
\[
\begin{equation*}
\mathbf{B}=\frac{1}{c} \boldsymbol{\beta} \times \mathbf{E}_{\perp}=\frac{1}{c} \boldsymbol{\beta} \times \mathbf{E}=c \frac{\mu_{0}}{4 \pi} \frac{q\left(1-\beta^{2}\right)}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\boldsymbol{\beta} \times \mathbf{r}}{r^{3}} \tag{56.09.11}
\end{equation*}
\]

Note that the fields are expressed in terms of the instantaneous position of the point charge, that is they are radial with respect to the instantaneous position of the point charge. They are not expressed in terms of the retarded position of the point charge (read § 45 - Radiation of ElectroMagnetic Waves for the precise definition of the retarded position of the point charge, that is its apparent position).
Choose the \(z\) and \(z^{\prime}\) axes parallel to \(\mathbf{V}\) and denote as \(\hat{\mathbf{n}} \equiv \hat{\mathbf{e}}_{3}\) the unit vector associated with this direction.
Let the moving charge be at the origin of the Coordinate System of \(\mathcal{J}^{\prime}\) and let the two origins of the two Coordinate System of \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\) be coincident at the times: \(t=t^{\prime}=0\).
We are going to calculate the ElectroMagnetic fields as a function of the instantaneous position of the point charge, not of the retarded one (read \(\S 45\) - Radiation of ElectroMagnetic Waves for the precise definition of the retarded position of the point charge, that is its apparent position). We will therefore calculate, at a generic time \(t\), the ElectroMagnetic fields at a point \(P\), with coordinates \(\mathbf{r}_{\mathrm{P}}\) and fixed in \(\mathcal{J}\). The point \(P\) is located at a distance \(H\) from the velocity vector \(\mathbf{V}\) and has a distance \(d\) from the origin along the direction of \(\mathbf{V}\), that is:
\[
\hat{\mathbf{n}} \equiv \hat{\mathbf{e}}_{3} \equiv \mathbf{V} / V \quad \mathbf{r}_{\mathrm{P}}=\hat{\mathbf{n}} d+(H /|\mathbf{r}|) \mathbf{n} \times(\mathbf{r} \times \mathbf{n})
\]

The distance \(H\) is the so-called impact parameter of the point particle with respect to the point where the field is being calculated.
Moreover, with our conventions of \(\mathcal{J}\) and \(\mathcal{J}^{\prime}\), we have:
\[
\mathbf{r}_{\mathrm{C}}=\mathbf{V} t \quad \mathbf{r}_{\mathrm{C}}^{\prime}=\mathbf{0}
\]
and
\[
\mathbf{r}_{\mathrm{P}}=\left\{x_{P}, y_{P}, z_{P}=d\right\} \quad H \equiv \sqrt{x_{P}^{2}+y_{P}^{2}}
\]

Let us then transform to the Rest Frame of the moving point charge, the inertial Reference Frame \(\mathcal{J}^{\prime}\) whose \(z^{\prime}\) axis is parallel to the \(z\) axis (and to \(\mathbf{V}\) ).
The Lorentz Transformation of the time-space coordinates of the moving point charge, \(C\), and of the point \(P\) are:
\[
\begin{array}{rlrl}
t^{\prime} & =\gamma\left(t-V z / c^{2}\right) & & , \\
z^{\prime} & =\gamma(z-V t) & z_{C}^{\prime}=0 & z_{P}^{\prime}[t]=\gamma\left(z_{P}-V t\right)=\gamma(d-V t) \equiv z_{C}^{\prime}+z^{\prime}=z^{\prime} \\
r_{\perp}^{\prime} & =r_{\perp}=H & .
\end{array}
\]

We can now calculate, first, and transform to the \(\mathcal{J}\) Reference Frame, later, the ElectroMagnetic fields produced at the point \(P\) in the rest Reference Frame of the point charge, \(\mathcal{J}^{\prime}\).
It must be emphasized that this transformation involves both transformation of the ElectroMagnetic fields and transformation of the time-space coordinates where the fields are to be calculated. In particular equations (56.03.01), (56.03.03), for the electric field, as well as equations (56.03.02), (56.04), are valid provided the ElectroMagnetic fields are those at the same time-space point which, however, has different coordinates in the two different Reference Frame.
The components of the ElectroMagnetic fields parallel to \(\mathbf{V}\) do not change.

\section*{Electric Field}

The components of the Electric field parallel to \(\mathbf{V}\) do not change.
The transformation of component of the Electric field perpendicular to \(\mathbf{V}\) can be calculated by using the inverse transform of equation (56.03.03):
\[
\mathbf{E}_{\perp}=\gamma\left(\mathbf{E}^{\prime}-c^{+1} \boldsymbol{\beta} \times \mathbf{B}^{\prime}\right)_{\perp}
\]
and the fact that \(\mathbf{B}^{\prime}=0\) one finds:
\[
\mathbf{E}^{\prime}\left[\mathbf{r}_{\mathrm{P}}^{\prime}, t^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q \mathbf{r}^{\prime}}{r^{\prime 3}}=\left\{\begin{array}{l}
E_{z}^{\prime}\left[\mathbf{r}_{\mathrm{P}}^{\prime}, t^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}\left(z^{\prime}\right)=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(\gamma(d-V t)) \\
\Longrightarrow E_{z}\left[\mathbf{r}_{\mathrm{P}}, t\right]=E_{z}^{\prime}\left[\mathbf{r}_{\mathrm{P}}^{\prime}, t^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(\gamma(d-V t)) \\
E_{\perp}^{\prime}\left[\mathbf{r}_{\mathrm{P}}^{\prime}, t^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}\left(r_{\perp}^{\prime}\right) \frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(H) \\
\Longrightarrow \mathbf{E}_{\perp}\left[\mathbf{r}_{\mathrm{P}}, t\right]=\gamma \mathbf{E}_{\perp}^{\prime}\left[\mathbf{r}_{\mathrm{P}}^{\prime}, t^{\prime}\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(\gamma H)
\end{array}\right.
\]

Note that in both components a multiplicative factor \(\gamma\) appears, in one case due to the transformation of abscissa in the other case due to the transformation of the electric field.
Moreover, one needs to transform \(r^{\prime}\) :
\[
r^{\prime} \equiv \sqrt{\left(x^{\prime}\right)^{2}+\left(y^{\prime}\right)^{2}+\left(z^{\prime}\right)^{2}}=\sqrt{x^{2}+y^{2}+(\gamma(d-V t))^{2}} .
\]

We observe that all the dependence on \(d\) and \(t\) just happens in the combined variable \(d-V t\). Therefore the ElectroMagnetic fields, for the observer \(\mathcal{J}\), translate rigidly with time. We can therefore limit to calculate the fields at \(t=0\) and generalise the final result for any time by replacing, in the final result, \(d \rightarrow d-V t\).
The expression for \(r^{\prime}\), at \(t=0\), can be written as:
\[
\begin{aligned}
r^{\prime} & =\left(H^{2}+\gamma^{2} d^{2}\right)^{1 / 2}=\gamma\left(d^{2}+\frac{H^{2}}{\gamma^{2}}\right)^{1 / 2}=\gamma\left(d^{2}+H^{2}+H^{2}\left(\frac{1}{\gamma^{2}}-1\right)\right)^{1 / 2}= \\
& \gamma\left(d^{2}+H^{2}\right)^{1 / 2}\left(1-\beta^{2} \frac{H^{2}}{d^{2}+H^{2}}\right)^{1 / 2} \equiv \gamma\left(d^{2}+H^{2}\right)^{1 / 2}\left(1-\beta^{2} \sin ^{2} \theta\right)^{1 / 2} .
\end{aligned}
\]

Finally, letting \(\theta\) be the angle between \(\mathbf{r}\) and \(\mathbf{V}\) in the stationary Rest Frame, one finds, at \(t=0\) :
\[
\begin{gathered}
E_{z}\left[\mathbf{r}_{\mathrm{P}}, t=0\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(\gamma d)=, \\
\frac{1}{4 \pi \varepsilon_{0}} \frac{q \gamma d}{\gamma^{3}\left(d^{2}+H^{2}\right)^{3 / 2}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}}=\frac{1}{4 \pi \varepsilon_{0}} \frac{q d\left(1-\beta^{2}\right)}{\left(d^{2}+H^{2}\right)^{3 / 2}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}}, \\
E_{\perp}\left[\mathbf{r}_{\mathrm{P}}, t=0\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q}{r^{\prime 3}}(\gamma H)=, \\
\frac{1}{4 \pi \varepsilon_{0}} \frac{q \gamma H}{\gamma^{3}\left(d^{2}+H^{2}\right)^{3 / 2}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}}=\frac{1}{4 \pi \varepsilon_{0}} \frac{q H\left(1-\beta^{2}\right)}{\left(d^{2}+H^{2}\right)^{3 / 2}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} .
\end{gathered}
\]

Putting together the above equations and replacing \(d \rightarrow d-V t\) one finds:
\[
\begin{equation*}
\mathbf{E}\left[\mathbf{r}_{\mathrm{P}}, t\right]=\frac{1}{4 \pi \varepsilon_{0}} \frac{q\left(1-\beta^{2}\right)}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\mathbf{r}}{r^{3}} \quad \mathbf{r}[t] \equiv \mathbf{r}_{\mathrm{P}}-\mathbf{r}_{\mathrm{C}}[t]=\mathbf{r}_{\mathrm{P}}-\mathbf{V} t \quad \theta=\theta[t] \tag{56.09.12}
\end{equation*}
\]

Note the electric field is not conservative, because it is a radial field whose module depends on the angle. However as the situation is not a static one this is not a problem and the rotor of the electric field will be compensated by a changing magnetic field.

The result shows that the electric field, when one considers the moving charge at the present position, is still radial, but its module depends on \(\theta\). This is not a violation of the finite velocity of propagation of signals because the point charge has been known to move at constant velocity since an infinite time.
At fixed distance from the charge the \(\theta\) dependence shows that the field is weaker in the forward and backward directions. This anisotropy increases at increasing velocities.
In ultra-relativistic limit, \(\beta \longrightarrow 1\), the electric field becomes basically a field transverse to the velocity of the charge. In fact:
\[
\left\{\begin{array}{l}
\theta=0 \longrightarrow E \sim\left(1-\beta^{2}\right) \quad E \longrightarrow 0 \quad \text { for } \beta \longrightarrow 1 \\
\theta=\pi / 2 \longrightarrow E \sim\left(1-\beta^{2}\right)^{-1 / 2} \quad E \longrightarrow \infty \quad \text { for } \beta \longrightarrow 1
\end{array}\right.
\]

This behavior is not incompatible with Gauss law, because the field increases in the plane perpendicular to the velocity but the region in solid angle where the field increases is decreasing at high speeds.

\section*{Magnetic Field}

The components of the Magnetic field parallel to \(\mathbf{V}\) do not change.
It is therefore zero in each Rest Frame. The transformation of component of the Magnetic field perpendicular to \(\mathbf{V}\) can be calculated by using the inverse transform of equation (56.04):
\[
\begin{equation*}
\mathbf{B}_{\perp}=\gamma\left(\mathbf{B}^{\prime}+c^{-1} \boldsymbol{\beta} \times \mathbf{E}^{\prime}\right)_{\perp} \tag{56.09.13}
\end{equation*}
\]

By using equation (56.09.06) to express \(\mathbf{E}_{\perp}^{\prime}\) and observing that \(\mathbf{E}_{\perp}^{\prime}\) can be replaced with \(\mathbf{E}\) without changing the result of the vector product one finds:
\(\mathbf{B}\left[\mathbf{r}_{\mathrm{P}}, t\right]=\mathbf{B}_{\perp}=\frac{1}{c} \beta \times \mathbf{E}_{\perp}=\frac{1}{c} \boldsymbol{\beta} \times \mathbf{E}=c \frac{\mu_{0}}{4 \pi} \frac{q\left(1-\beta^{2}\right)}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\beta \times \mathbf{r}}{r^{3}} \quad \mathbf{r}[t] \equiv \mathbf{r}_{\mathrm{P}}-\mathbf{r}_{\mathrm{C}}[t]=\mathbf{r}_{\mathrm{P}}-\mathbf{V} t \quad \theta=\theta[t]\)
The result shows that the magnetic field, when one considers the moving charge at the present position, is still radial, but its module depends on \(\theta\). This is not a violation of the finite velocity of propagation of signals because the point charge has been known to move at constant velocity since an infinite time.

At fixed distance from the charge the \(\theta\) dependence shows that the field is weaker in the forward and backward directions. This anisotropy increases at increasing velocities.
In ultra-relativistic limit, \(\beta \longrightarrow 1\), the magnetic field has the same behavior than the electric field, and becomes basically a field transverse to the velocity of the charge. In fact:
\[
\left\{\begin{array}{l}
\theta=0 \longrightarrow B \sim\left(1-\beta^{2}\right) \quad B \longrightarrow 0 \quad \text { for } \beta \longrightarrow 1 \\
\theta=\pi / 2 \longrightarrow B \sim\left(1-\beta^{2}\right)^{-1 / 2} \quad B \longrightarrow \infty \quad \text { for } \beta \longrightarrow 1
\end{array}\right.
\]

\section*{ElectroMagnetic Fields}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
The Electric|Magnetic fields are always perpendicular: E•B.
In ultra-relativistic limit, \(\beta \longrightarrow 1\), the modules tend to become identical, in a system of units where \(c=1\).
The ElectroMagnetic fields produced by a ultra-relativistic charge resembles a impulse of a PW.
Note that the uniformly moving charge is not radiating ElectroMagnetic waves.
The ElectroMagnetic fields move as rigid fields because the charge is supposed to be moving with constant velocity since an infinite time so that any effect of past accelerations has already reached an infinite distance.
56.09.07 Magnetic Field Produced by a Rectilinear Infinite Line of Charges Moving at Constant Velocity

Use the results of §56.09.06 - ElectroMagnetism and Relativity to calculate the magnetic field produced by a rectilinear line of charges moving at constant velocity, like the moving charges in a infinite rectilinear current wire of section \(A\) carrying a current \(I\).
Introduce a cylindrical Coordinate System having as the \(z\) axis the current wire, oriented as the current. Use equation (56.09.11) for an infinitesimal element \(\mathrm{d} z\) of the current wire. Let \(R\) be the distance of the point \(P\) from the wire. Then:
\[
\begin{gathered}
\mathrm{d} \mathbf{B}=\frac{1}{4 \pi \varepsilon_{0}} \frac{\lambda \mathrm{~d} z \beta\left(1-\beta^{2}\right)}{\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \frac{\sin ^{3}[\theta]}{R^{2}} \hat{\mathbf{e}}_{\psi}, \\
z=-R \cot \theta \quad \Longrightarrow \quad \mathrm{~d} z=\frac{R}{\sin ^{2} \theta} \mathrm{~d} \theta \quad, \\
\mathbf{B}=\int_{0}^{\pi} \mathrm{d} \mathbf{B}=\frac{\mu_{0}}{4 \pi} \frac{\lambda \beta}{R} \hat{\mathbf{e}}_{\psi}, \\
\lambda=\rho A \quad \Longrightarrow \quad \mathbf{B}=\frac{\mu_{0}}{4 \pi} \frac{\beta \rho A}{R} \hat{\mathbf{e}}_{\psi}=\frac{\mu_{0}}{4 \pi} \frac{\beta \rho A}{R} \hat{\mathbf{e}}_{\psi}=\frac{\mu_{0}}{4 \pi} \frac{j A}{R} \hat{\mathbf{e}}_{\psi}=\frac{\mu_{0}}{4 \pi} \frac{I}{R} \hat{\mathbf{e}}_{\psi} .
\end{gathered}
\]

The indefinite integral:
\[
\int \frac{\sin \theta}{\left(1-\beta^{2} \sin \theta^{2}\right)^{3 / 2}} \mathrm{~d} \theta=\frac{\sqrt{2} \cos \theta}{\left(-1+\beta^{2}\right) \sqrt{2-\beta^{2}+\beta^{2} \cos [2 \theta]}}
\]
was used.

\subsection*{56.09.08 A Simplified Model for a Moving Magnetic Dipole}

\section*{This § is referenced at pages:}
[2342, 2342, 2342, 2342, 2425, 2425, 2440, 2440, 2440, 2440, 2443, 2443]
According to §56.09.03 - ElectroMagnetism and Relativity a current carrying long rectilinear stationary wire, globally neutral, will appear as charged to an observer moving along the wire. This is an apparent violation of the Lorentz invariance of the charge, as the two different observers will measure a different total charge. The problem lies in the unphysical infinite wire.
In this section a real (possibly super-conducting) closed current loop is modeled. The use of a superconducting loop avoids nuisances such as batteries, external wires and geometrical asymmetries.
Use the results of problem §56.09.03 - ElectroMagnetism and Relativity to cross-check the results of problem (56.09.10) in the simple case of a real Magnetic Dipole made of a plane rectangular current loop, with sides \(a\) and \(b\) and negligible dimensions of its cross-section (of area \(S\) ), where a current \(I\) passes in its own Rest Frame.
Assume that the loop is moving, with respect to an inertial Reference Frame, with constant velocity \(\mathbf{u}\) parallel to its sides of length \(a\) along the axes \(z \equiv z^{\prime}\). Let the sides with length \(a\) be parallel to the axes \(z \equiv z^{\prime}\) and the sides with length \(b\) be perpendicular to the axes \(z \equiv z^{\prime}\). Look at the loop so that the current runs in counterclock-wise direction. Therefore the Magnetic Dipole moment of the loop is directed toward the observer.
The four sides of the rectangle appear neutral in its own Rest Frame: \(\rho^{\prime}=0\). On the other hand: \(\mathbf{j}^{\prime} \neq 0\).
In the upper side of length \(a\) the current goes in the negative \(z \equiv z^{\prime}\) direction, so that it appears negatively charged to the observer who sees the loop moving.
In the lower side of length \(a\) the current goes in the positive \(z \equiv z^{\prime}\) direction, so that it appears positively charged to the observer who sees the loop moving.

Whatever the velocity \(\mathbf{u}\), the two sides of length \(a\) will appear charged to the observer who sees the loop moving. The Lorentz Transformation of the current four-vector allows one to calculate the charge density seen by the moving observer, as discussed in problem § 56.09.03-ElectroMagnetism and Relativity.
In fact:
\[
\begin{array}{ll}
\rho=\gamma\left(\rho^{\prime}+\beta j_{z}^{\prime} / c\right)=\gamma \beta j_{z}^{\prime} / c<0 & \text { in the upper side with } j^{\prime}{ }_{z}<0, \\
\rho=\gamma\left(\rho^{\prime}+\beta j^{\prime} / c\right)=\gamma \beta j^{\prime}{ }_{z} / c>0 & \text { in the lower side with } j_{z}^{\prime}>0 .
\end{array}
\]

Therefore the observer who sees the loop moving will see on the two sides of length \(a\) the charge densities:
\[
\rho= \pm \gamma|\beta|\left|j^{\prime}\right| / c,
\]
the \(\pm\) sign, different for the two sides, being decided by the current being parallel or anti-parallel to \(\mathbf{u}\), according to the above equations.
Note that there is no effect on the charge and currents the other two sides, of length \(b\), because for those sides \(\mathbf{j} \cdot \mathbf{u}=0\), that is the current density is transverse to the velocity of the Lorentz Transformation and there is therefore no transformation at all (it remains neutral). However the cross-section of the other two sides, of length \(b\), is shrinked by a factor \(\gamma\) due to the contraction of the length in the direction of motion.
The loop appears now charged, in its two sides of length \(a\), which appear contracted by a factor \(\gamma\), generating an Electric Dipole moment with absolute value:
\[
|p|=\left(\gamma|\beta|\left|j^{\prime}\right| / c\right)(S a / \gamma)(b)=\left(|\beta|\left(\left|I^{\prime}\right| / S\right) / c\right) S a b=|\beta|\left|I^{\prime}\right| a b / c=|\beta|\left|m^{\prime}\right| / c .
\]

\subsection*{56.09.10 Potentials for a Moving Magnetic Dipole}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|||
Consider an ideal point Magnetic Dipole, with Magnetic Dipole moment, \(\mathrm{m}^{\prime}\), which is moving with respect to the observer with constant velocity V while keeping a constant magnetic Dipole moment vector, \(\mathrm{m}^{\prime}\).
We want to determine the scalar potential as seen by the observer and determine its non relativistic limit. Let \(\mathbf{r}\) be the position of the point where we want to calculate the potentials and the position of the Dipole in the Dipole Rest Frame.
Use \(c=1\). We know the potentials of the Magnetic Dipole in its rest system, \(\mathrm{J}^{\prime}\), (read § 14.13.10Elements of Vector Calculus):
\[
\Phi^{\prime}\left[\mathbf{r}^{\prime}, t^{\prime}\right]=0 \quad \mathbf{A}^{\prime}\left[\mathbf{r}^{\prime}, t^{\prime}\right]=\frac{\mu_{0}}{4 \pi} \frac{\mathrm{~m}^{\prime} \times \mathbf{r}^{\prime}}{r^{\prime 3}},
\]
and we want to calculate the potentials in the \(\mathcal{J}\) Reference Frame of the observer who sees the Magnetic Dipole moving with constant velocity \(\mathbf{V}\) while keeping a constant Magnetic Dipole moment, \(\mathrm{m}^{\prime}\).
Choose a special Lorentz Transformation with \(z=z^{\prime}\) and \(\mathbf{V}\) along the \(z=z^{\prime}\) axis:
\[
\begin{aligned}
z^{\prime} & =\gamma(z-V t), \\
t^{\prime} & =\gamma(t-V z), \\
x^{\prime} & =x, \\
y^{\prime} & =y,
\end{aligned}
\]

We can write ( \(\mathbf{V}\) is the velocity of \(\mathcal{J}^{\prime}\) with respect to \(\mathcal{J}\) ):
\[
\begin{gather*}
\Phi[\mathbf{r}, t]=\gamma\left(\Phi^{\prime}\left[\mathbf{r}^{\prime}, t^{\prime}\right]+\mathbf{V} \cdot A^{\prime}\left[\mathbf{r}^{\prime}, t^{\prime}\right]\right)=\gamma V A_{z}^{\prime}\left[\mathbf{r}^{\prime}, t^{\prime}\right]  \tag{56.09.15}\\
\Phi[\mathbf{r}, t]=\frac{\mu_{0}}{4 \pi} \gamma \frac{\mathbf{V} \cdot\left(\mathbf{m}^{\prime} \times \mathbf{r}^{\prime}\right)}{{r^{\prime 3}}^{\prime}}=\frac{\mu_{0}}{4 \pi} \gamma \frac{\mathbf{r}^{\prime} \cdot\left(\mathbf{V} \times \mathbf{m}^{\prime}\right)}{{r^{\prime 3}}^{3}}=  \tag{56.09.16}\\
\frac{\mu_{0}}{4 \pi} \gamma \frac{\mathbf{r}^{\prime} \cdot\left(V \hat{\mathbf{e}}_{3} \times \mathrm{m}^{\prime}\right)}{{r^{\prime 3}}_{3}}=\frac{\mu_{0}}{4 \pi} \gamma V \frac{y^{\prime} m_{1}^{\prime}-x^{\prime} m_{2}^{\prime}}{\left(\left(x^{\prime}\right)^{2}+\left(y^{\prime}\right)^{2}+\left(z^{\prime}\right)^{2}\right)^{3 / 2}}= \\
\frac{\mu_{0}}{4 \pi} \gamma V \frac{y m_{1}^{\prime}-x m_{2}^{\prime}}{\left(x^{2}+y^{2}+(\gamma(z-V t))^{2}\right)^{3 / 2}}
\end{gather*}
\]

As the potential is not a function of \(z\) and \(t\) separately but only of the combination \(z-V t\), the function moves rigidly with time with speed \(V\). Therefore we can limit to calculate the potential at a specified time \(t=0\), when the Dipole is located at \(\mathbf{r}=\mathbf{0}\) in the J Reference Frame. One thus finds:
\[
\begin{gathered}
\Phi[\mathbf{r}, t=0]=\frac{\mu_{0}}{4 \pi} \gamma V \frac{y m_{1}^{\prime}-x m_{2}^{\prime}}{\left(x^{2}+y^{2}+(\gamma z)^{2}\right)^{3 / 2}}=, \\
\frac{\mu_{0}}{4 \pi} \gamma V \frac{y m_{1}^{\prime}-x m_{2}^{\prime}}{\left(r^{2}+z^{2}\left(\gamma^{2}-1\right)\right)^{3 / 2}}= \\
\frac{\mu_{0}}{4 \pi} \gamma V \frac{y m_{1}^{\prime}-x m_{2}^{\prime}}{r^{3}\left(1+\cos ^{2} \theta\left(\gamma^{2}-1\right)\right)^{3 / 2}}=, \\
\frac{\mu_{0}}{4 \pi} \gamma V \frac{y m_{1}^{\prime}-x m_{2}^{\prime}}{\gamma^{3} r^{3}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}}
\end{gathered}
\]

In order to recover the time dependence in equation (56.09.17) one needs to do the replacement \(z \longrightarrow z-V t\). Finally:
\[
\begin{equation*}
\Phi[\mathbf{r}, t=0]=\frac{\mu_{0}}{4 \pi} \frac{\mathbf{r} \cdot\left(\mathbf{V} \times \mathrm{m}^{\prime}\right)}{r^{3}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}}\left(1-\beta^{2}\right) \quad \mathbf{r}[t] \equiv \mathbf{r}_{\mathrm{P}}-\mathbf{r}_{\mathrm{C}}[t]=\mathbf{r}_{\mathrm{P}}-\mathbf{V}\left(t-t_{0}\right)-\mathbf{r}_{\mathrm{C}}\left[t=t_{0}\right] \tag{56.09.17}
\end{equation*}
\]

The identity
\[
\gamma^{2}-1=v^{2} \gamma^{2},
\]
was used in the derivation.
In the last passage the vector form has been resurrected. That form would have been obtained in case a general boost would be used.
Let us develop to lowest order in the velocity to determine the non-relativistic limit. To do that, it is enough to take the lowest order expression of all the terms. One finds:
\[
\Phi[\mathbf{r}, t=0]=\frac{\mu_{0}}{4 \pi} \gamma \frac{\mathbf{r} \cdot\left(\mathbf{V} \times \mathrm{m}^{\prime}\right)}{\gamma^{3} r^{3}\left(1-\beta^{2} \sin ^{2} \theta\right)^{3 / 2}} \simeq \frac{\mu_{0}}{4 \pi} \frac{\mathbf{r} \cdot\left(\mathbf{V} \times \mathrm{m}^{\prime}\right)}{r^{3}} \equiv \frac{\mu_{0}}{4 \pi} \frac{\mathbf{r} \cdot \mathbf{p}_{\mathrm{E}}}{r^{3}}
\]
where the equivalent Electric Dipole moment has been introduced:
\[
\mathbf{p}_{\mathrm{E}} \equiv \frac{\mathbf{V} \times \mathbf{m}^{\prime}}{c^{2}}
\]

Note that the observer will also see a vector magnetic potential which can be calculated in a similar way. The observer, therefore, will not observe a pure Electric Dipole field but also an additional ElectroMagnetic field.

Note that the identification with an Electric Dipole field is not limited to the non-relativistic limit. In fact inspection of equation (56.09.15) shows that a pure electric Dipole field moving with velocity \(\mathbf{V}\) would give exactly the transformed scalar potential of equation (56.09.16).
Note that the factor \(\mathbf{r}^{\prime} / r^{\prime 3}\) in equation (56.09.16) which need to be transformed, is exactly the same appearing in the ElectroMagnetic fields of the charge moving at constant velocity, and this explains the very similar results and intermediate passages.
Note that when one passes to describe the induced Polarization (that is induced Electric Dipole moment per unit volume) an additional factor \(\gamma\) appears due to the transformation of the volume.

The Poynting-Robertson effect is a consequence of the Head-Light effect, read § ?? - ??. Consider a grain of dust orbiting the Sun in a circular orbit. Assume it is in thermal equilibrium within the solar radiation field, for instance by assuming that it is spinning very fast. Assume, in order to simplify the problem, that for any photon absorbed another photon of the same energy is emitted, in order to maintain thermal equilibrium, within the kinematic constraints imposed by the Head-Light effect.
Neglect the Doppler shift of the emitted radiation on the basis of the fact that the velocity of the grain of dust is assumed to be non relativistic.
Determine the linear momentum loss of the grain of dust by using both the description in the Reference Frame fixed to the Sun (heliocentric Rest Frame) and in the Reference Frame moving with the grain of dust. Verify the compatibility of the two results.
Determine the equation describing the change in the angular momentum of the grain of dust as a function of time and as a function of the photon absorption cross-section, \(\Sigma_{g}\).

\section*{SOLUTION}

Describe the problem in the heliocentric Rest Frame.
The conservation of linear momentum in the radial direction provides the effect of the radiation pressure, which counteracts the effect of the gravitational field of the Sun, see problem § 42.05.02 - ElectroMagnetic Waves.

On the other hand the tangential linear momentum balance give the following equation, where all the components of the momenta must be interpreted as the tangential component of the linear momentum,
\[
p_{\gamma}+P=\hat{p}_{\gamma}+\hat{P} \Longrightarrow P=\hat{p}_{\gamma}+\hat{P} \Longrightarrow \hat{P}=P-\hat{p}_{\gamma}=P-\beta \varepsilon \Longrightarrow \Delta P \equiv \hat{P}-P=-\beta \varepsilon
\]
in terms of the tangential components of the momenta of the grain of dust before and after the absorption-emission process, \(P\) and \(\hat{P}\), the corresponding tangential components of the momenta of the photons, \(p_{\gamma}\) and \(\hat{p}_{\gamma}\) and the last passage follows from equation (??). Note that the energy \(\varepsilon\) appearing in the last equation is the energy of the emitted photon, which is, according to the hypotheses, equal to the energy of a corresponding absorbed photon.
The \(\beta\) factor to use in the previous equation needs some attention. If one considers the real process
where a small but macroscopic grain of dust is immersed, in thermal equilibrium, in the Sun radiation field one actually has a great many absorption and re-emission processes which change almost continuously the speed of the grain of dust. Using the results of § ?? - ?? one can then conclude that the speed to use is the current speed of the grain of dust. On the other hand if one considers a single absorption and re-emission process, possibly not an instantaneous one, and one notes that, according to the results of § ?? - ?? one must use the speed of the grain of dust before the emission, the speed of the grain of dust at the re-emission is slightly changed due to the change in energy following the photon absorption. However the change of speed can be calculated, from the conservation of the tangential components of the momenta, as
\[
V_{1}=\frac{\varepsilon}{\varepsilon+\varepsilon} V_{0} \simeq V_{0}\left(1-\frac{\varepsilon}{\varepsilon}\right)
\]
in terms of the total energy of the grain of dust, \(\varepsilon\), and the total energy of the photon \(\varepsilon\). It is then clear that the use of the exact velocity at emission, \(V_{1}\), would give a correction of the order of \(\varepsilon \mid \mathcal{E}\), which is small under our hypotheses.
When photons traveling in the radial direction are absorbed by the grain of dust the tangential component of the linear momentum of the grain of dust does not change, while the radial component does change. When photons are emitted with a isotropic distribution in the grain of dust rest Rest Frame the grain of dust has a recoil. By hypothesis the energy of the emitted photon, on average, is equal to the energy of the incoming photon.
Every absorption-emission event thus implies a linear momentum loss of the grain of dust approximately equal to \(\Delta P=-\beta \varepsilon / c\) (re-introducing \(c\) for future reference).
Consider all the photons to have the same energy \(\varepsilon\), equal to the average photon energy. The following equations can be derived as a function of the intensity \(I_{0}\) of the Sun light, the number of incoming photons, \(N_{0}\), the Sun Luminosity \(\mathcal{L}_{\odot}\) and the cross section for photon absorption by the dust of grain, \(\Sigma_{g}\), the distance form the Sun, \(r\).
\[
\begin{aligned}
\frac{\mathrm{d} N}{\mathrm{~d} t} & \equiv \Sigma_{g} \frac{\mathrm{~d}^{2} N_{0}}{\mathrm{~d} t \mathrm{~d} A} \\
I_{0} & =\varepsilon \frac{\mathrm{d}^{2} N_{0}}{\mathrm{~d} t \mathrm{~d} A}, \\
\frac{\mathrm{~d} N}{\mathrm{~d} t} & =\Sigma_{g} \frac{I_{0}}{\varepsilon}=\frac{\Sigma_{g}}{\varepsilon} \frac{\mathcal{L}_{\odot}}{4 \pi r^{2}} .
\end{aligned}
\]

The orbital angular momentum loss of the grain of dust, as a function of the orbital angular momentum loss corresponding to a single absorption-emission event, \(\Delta L\), is thus:
\[
\frac{\mathrm{d} L}{\mathrm{~d} t}=\Delta L \frac{\mathrm{~d} N}{\mathrm{~d} t}=r \Delta P \frac{\mathrm{~d} N}{\mathrm{~d} t}=\frac{\Sigma_{g}}{\varepsilon} \frac{\mathcal{L}_{\odot}}{4 \pi r^{2}} \frac{-\beta r \varepsilon}{c}=-\Sigma_{g} \frac{\mathcal{L}_{\odot}}{4 \pi r^{2} m c^{2}} L .
\]

Orbital angular momentum will not be conserved, due to the non-central character of the PoyntingRobertson force, actually also named Poynting-Robertson drag, for this very reason. The linear momentum loss per unit time represents the Poynting-Robertson drag.
In the grain of dust Rest Frame there is no recoil due to the emission of the photons but there is a recoil due to the absorption of the photons, because of the aberration of the light seen by the Rest Frame.
56.09.13 Yarkovsky Effect
©|WEB - URL||A Ph.D. thesis|

The Yarkovsky effect is similar to the Poynting-Robertson effect but it comes into play when the emission of thermal photons is anisotropic in the Rest Frame of the grain of dust, for instance because there is no thermalization of the grain of dust due, for instance, to slow rotation.
If often causes small irregularities on the orbits of small asteroids due to their irregular shape.
The Yarkovsky effect is small in case of very small and very large bodies. In fact the force is approximately proportional to the surface area and the mass to the volume; therefore the resulting acceleration is inversely proportional to the dimensions of the body. On the other hand the conduction of heat across the whole small body effectively diminishes temperature differences on the surface and the corresponding emission is then almost isotropic.

\subsection*{56.09.14 Transformation Law for the Angular Intensity of Light}
©|W.Greiner et al., , ..., ..., ...Ed., ....|||

Consider an isotropic light source at rest in the Reference Frame J. An observer in the Reference Frame \(\mathcal{J}^{\prime}\), moving with velocity \(\mathbf{u}\) with respect to \(\mathcal{J}\), sees a non isotropic light distribution, \(f^{\prime}\left[\theta^{\prime}\right]\).

Determine \(f^{\prime}\left[\theta^{\prime}\right]\).

\section*{Exercises Problems and Physical Applications}

\section*{56-001 Beams of Charged Particles in Particle Accelerators}

The reduction of the repulsive force among identical charged particles forming a straight beam is wellknown in the physics of particle accelerators.
The explanation for this issue has to be found by employing the correct Lorentz transformations for the ElectroMagnetic fields and dynamical quantities, see section § 56.09.04- ElectroMagnetism and Relativity.

\section*{56-002 Invariants of the ElectroMagnetic Field}

Show that the two quantities
\[
\begin{equation*}
\left(c^{2} B^{2}-E^{2}\right) \quad \mathbf{E} \cdot \mathbf{B} \tag{56.10.01}
\end{equation*}
\]
are Lorentz invariant by direct calculation from equations (56.03.01), (56.03.02), (56.03.03), (56.04).

\section*{56-003 Potentials for a Uniform and Constant ElectroMagnetic Field}

This § is referenced at pages:
[Never referenced.]
©|J.P.Pérez et al., Électromagnétisme, ..., DUNOD, ...Ed., WEB - URL.|P16.3||
Read also § 33-018 - Basic Laws of ElectroMagnetism.
Consider a uniform and constant ElectroMagnetic field:
\[
\mathbf{E}=E_{0} \hat{\mathbf{e}}_{2} \quad \mathbf{B}=B_{0} \hat{\mathbf{e}}_{3}
\]
- Show that two possible choices of potentials are the following:
\[
\begin{array}{ll}
\Phi_{1}=-E_{0} y & \mathbf{A}_{1}=\frac{1}{2} \mathbf{B} \times \mathbf{r}, \\
\Phi_{2}=0 & \mathbf{A}_{2}=\left(x B_{0}-t E_{0}\right) \hat{\mathbf{e}}_{2} .
\end{array}
\]
- Determine the scalar field allowing to pass from one set to the other.

\section*{56-004 Some Properties of the ElectroMagnetic Field Tensor}

This § is referenced at pages:
[2441, 2441]
- Verify that the ElectroMagnetic field tensor \(F^{\mu \nu}\) is gauge invariant and that its expression in terms of the Electric|Magnetic fields is the one of equation (56.05.01).
- Verify that the expression of \(G^{\mu \nu}\) in equation (56.05.01) follows from the definition in the same equation (56.05.01) as a function of \(F^{\mu \nu}\).
- Show that the two quantities
\[
\begin{equation*}
F_{\mu \nu} F^{\mu \nu}=2\left(B^{2}-E^{2} / c^{2}\right) \tag{56.10.02}
\end{equation*}
\]
\[
G_{\mu \nu} F^{\mu \nu}=4 \mathbf{E} \cdot \mathbf{B} / c
\]
are Lorentz invariant.
- Show that:
\[
\operatorname{det}[\mathbb{F}]=(\mathbf{E} \cdot \mathbf{B})^{2} / c^{2}
\]

\section*{56-005 Field Equations in Covariant Form}

Verify the equivalence between the four Maxwell Equations ((33.07.01), (33.07.02), (33.07.03), (33.07.04)), and their expression in covariant form ((56.05.02), (56.05.04)).

\section*{56-006 Consistency}

Show that equation (56.05.04) is consistent with charge conservation.

\section*{56-007 Trace of the ElectroMagnetic Energy-LinMomentum Tensor}

Show that the trace of the Energy-LinMomentum tensor in equation (56.07.01) is zero.
56-008 Properties of the ElectroMagnetic Energy-LinMomentum Tensor
Show that equation (56.07.01) gives: \(T_{.}^{00}=\frac{\varepsilon_{0} \mathbf{E}^{2}}{2}+\frac{\mathbf{B}^{2}}{2 \mu_{0}}\).
56-009 EM Energy-LinMomentum Tensor for MPW
Consider ElectroMagnetic MPW and show, from the general expression of the EM EnergyLinMomentum tensor in equation (56.07.01), that the EM Energy-LinMomentum tensor is:
\[
T_{\cdots}^{\mu \nu}=u \frac{c^{2}}{\omega^{2}} k^{\mu} k^{\nu} \quad u \equiv \frac{1}{2}\left(\varepsilon_{0} E^{2}+\frac{B^{2}}{\mu_{0}}\right)=\varepsilon_{0} E^{2}=\frac{B^{2}}{\mu_{0}} .
\]

This result shows that
\[
\frac{E \sqrt{\varepsilon_{0}}}{\omega}=\frac{B}{\omega \sqrt{\mu_{0}}}=\quad \text { Lorentz invariant } .
\]

\section*{56-010 Conduction Current}

Determine the conduction current in the loop seen by the stationary observer.
Verify that the stationary observer sees the same current crossing each section of each side of the loop, coherently with the fact that he is seing a steady situation.
Determine the convection current seen by the stationary observer.

\section*{56-011 Convection and Conduction Currents - Ohm Law}

\section*{56-012 ElectroMagnetic Fields of a Charge Moving at Constant Velocity}

Consider a point charge moving at constant velocity in an inertial Reference Frame. Use the explicit expression of the electric field (section § 56.09.06-ElectroMagnetism and Relativity), with its time dependence, to show that the electric field is divergence-less at any point outside the charge. Use the explicit expression of the magnetic field (section § 56.09.06-ElectroMagnetism and Relativity), with its time dependence, to show that the magnetic field is divergence-less at any point outside the charge.

\section*{56-013 Charge Invariance}

Consider a point charge moving at constant velocity in an inertial Reference Frame. Use the explicit expression of the electric field (section § 56.09.06-ElectroMagnetism and Relativity), with its time dependence, to show that Gauss law is satisfied by calculating the flux on a sphere centered on the charge and with arbitrary radius.

Note that if the sphere is moving along with the charge Gauss law must still apply.

\section*{56-014 Internal Forces of a Pair of Charges Moving at Constant Velocity}

Use the results of this section to calculate the force between two identical charges, such that one charge fixed at the origin of an inertial Reference Frame while the second one is moving with constant velocity V with respect to the same inertial Reference Frame with impact parameter \(b>0\) with respect to the fixed charge. Calculate the sum of the internal forces of the two charges.

\section*{56-015 Transformation Laws for Polarization and Magnetization}

Use the results of section § 56.09.10 - ElectroMagnetism and Relativity as well as charge invariance and volume contraction to write down the relativistic transformation laws of the Polarization and Magnetization vector fields, analogous to equations (56.03.01), (56.03.02), (56.03.03), (56.04).

\section*{56-016 Unipolar Generator}

\section*{56-017 A Cross-Check}

Verify that equations (56.09.01), (56.09.02), (56.09.03), (56.09.04) are consistent with the invariants of the ElectroMagnetic field.

\section*{56-018 A Variation}

Solve the problem §56.09.03 - ElectroMagnetism and Relativity or the case of arbitrary velocity of the observer, parallel to the field, interpreting it in terms of relativistic transformations of charges and currents. Solve the problem using both methods used in section § 56.09.03-ElectroMagnetism and Relativity.

\section*{56-019 Properties of the ElectroMagnetic Fields Produced by a Charge in Motion at Constant Velocity}

Refer to § 56.09.06 - ElectroMagnetism and Relativity.
- Show that Gauss law is satisfied by equation (56.09.12) at fixed time on an arbitrary sphere centered on the charge.
- Show that equation (56.09.12) gives zero flux of the magnetic field at fixed time on an arbitrary sphere centered on the charge.
- Show that for \(\beta \longrightarrow 1\) one finds: \(\boldsymbol{\beta} \cdot \mathbf{E}=\boldsymbol{\beta} \cdot \mathbf{B}=0\) and the ElectroMagnetic fields tend to zero at any point \(\theta \neq \pi / 2\).
- Consider a fixed point and the moving charge. Show that an estimate of the length of time during which a significant field is seen at the fixed point is of the order of:
\[
\Delta t \approx \frac{H}{\beta \gamma}
\]

\section*{56-020 Biot-Savart Law}

Refer to § 56.09.06 - ElectroMagnetism and Relativity.
Show that equation (56.09.11) gives, in the ultra-relativistic limit, the Biot-Savart law.

\section*{56-021 Poynting Vector for a Charge Moving at Constant Velocity}
©|D.J.Griffiths, Introduction To Electrodynamics, 1999, Prentice Hall, 3rdEd., ....|12.43||
Find the Poynting vector for a point charge in uniform motion.

\section*{56-022 Force Between the Armatures of a Plane Capacitor}

Refer to the plane infinite capacitor described in § 56.03.01 - ElectroMagnetism and Relativity.
The observer at rest with respect to the capacitor measures an attractive force between the two armatures. The observer in motion sees a larger electric field, so that he measures a larger attractive force. However he also measures a repulsive force due to the magnetic field. Show that the overall forces is consistent with the force measured by the observer at rest taking into account the law of transformation of the forces.

\section*{56-023 Lorentz Transformation of the ElectroMagnetic Field}
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|11.10||
Use equations (56.03.01), (56.03.03), for the electric field, and equations (56.03.02), (56.04), for the magnetic field and combine each of the two pairs to write in a single vector equation the transformation law for both the electric and the magnetic field.

\section*{SOLUTION}

Use \(c=1\) to simplify the formulae. One finds:
\[
\begin{aligned}
& \mathbf{E}^{\prime}=\gamma(\mathbf{E}+\boldsymbol{\beta} \times \mathbf{B})-\frac{\gamma^{2} \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{E})}{1+\gamma}, \\
& \mathbf{B}^{\prime}=\gamma(\mathbf{B}-\boldsymbol{\beta} \times \mathbf{E})-\frac{\gamma^{2} \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{B})}{1+\gamma} .
\end{aligned}
\]

\section*{56-024 Invariants of the ElectroMagnetic Fields}

Using the relations in §56.03.04 - ElectroMagnetism and Relativity show that the two quantities
\[
\mathbf{E} \cdot \mathbf{B} \quad c^{2} B^{2}-E^{2},
\]
are invariant under Lorentz Transformation.

\section*{56-025 Transformation Laws for a Purely Electric or Purely Magnetic Field}

Use the Lorentz invariants
\[
\mathbf{E} \cdot \mathbf{B} \quad c^{2} B^{2}-E^{2},
\]
to show that a purely electric (magnetic) field in one Reference Frame cannot transform to a purely magnetic (electric) field in another Reference Frame.

The second law of thermodynamics is, without a doubt, one of the most perfect laws in physics. Any reproducible violation of it, however small, would bring the discoverer great riches as well as a trip to Stockholm. The world's energy problems would be solved at one stroke. It is not possible to find any other law (except, perhaps, for super selection rules such as charge conservation) for which a proposed violation would bring more skepticism than this one. Not even Maxwell laws of electricity or Newton law of gravitation are so sacrosanct, for each has measurable corrections coming from quantum effects or general relativity.
Classical thermodynamics of equilibrium states. Classical means that there is no mention of statistical mechanics here and equilibrium means that we deal only with states of systems in equilibrium and do not attempt to define quantities such as entropy and temperature for systems not in equilibrium. This is not to say that we are concerned only with thermostatics because, as will be explained more fully later, arbitrarily violent processes are allowed to occur in the passage from one equilibrium state to another.

\section*{© - QUOTE}

True to his tradition, the primary emphasis is placed on the thermodynamic (macroscopic) study of temperature, energy and entropy, while recognizing that equations of state, temperature variations of specific heats, and valuable insight come from the statistical physics (microscopic) approach.

Thermodynamics, that is classical thermodynamics, should be more properly called thermostatics, as it deals with equilibriums states only.
Thermodynamics (Thermostatics) is a science of the macroscopic world, with, in principle, no reference to the microscopic world.
However, it is out of question that the microscopic view is enlightening and complementary and, in soma cases, necessary to Thermodynamics (Thermostatics).

\section*{© - QUOTE}

Thermodynamics (...) neither claims a unique domain of systems over which it asserts primacy, nor does it introduce a new fundamental law analogue to Newton or Maxwell Equations. In contrast to the speciality of mechanics and electromagnetism, the hallmark of thermodynamics is generality. Generality first in the sense that thermodynamics applies to all types of systems in macroscopic aggregation, and second in the sense that thermodynamics does not predict specific numerical values for observable quantities. Instead thermodynamics sets limits (inequalities) on permissible physical processes, and it establishes relationships among apparently unrelated properties.
Whereas thermodynamics is not based on a new and particular law of nature, it instead reflects a
commonality of universal feature of all laws. In brief, thermodynamics is the study of restrictions on the possible properties of matter that follows from the symmetry properties of the fundamental laws of physics.

Thermodynamics (Thermostatics) is the study of restrictions on the possible properties of matter that follows from the symmetry properties of the fundamental laws of physics.
58.02.01 Systems and Surroundings
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{© - QUOTE}

The study of any special branch of natural science starts with a separation of a restricted region of space or a finite portion of matter from its surroundings by means of a closed surface called the boundary.
The region within the arbitrary boundary and on which the attention is focused is called the system, and everything outside the system that has a direct bearing on the system behavior is known as the surroundings, which could be another system.
If no matter crosses the boundary, then the system is closed; but if there is an exchange of matter between system and surroundings, then the system is open.
When a system has been chosen, the next step is to describe it in terms of quantities related to the behavior of the system or its interactions with the surroundings, or both.
There are, in general, two points of view that may be adopted: the macroscopic point of view and the microscopic point of view.
- The macroscopic point of view considers variables or characteristics of a system at approximately the human scale, or larger.
- The microscopic point of view considers variables or characteristics of a system at approximately the molecular scale, or smaller.

\section*{© - QUOTE}

Vladislav Čápek and Daniel P. Sheehan
There are no truly isolated systems in nature; all are connected by long-range gravitational and perhaps ElectroMagnetic forces; all are likely affected by other uncontrollable interactions, such as by neutrinos, dark matter, dark energy and perhaps local cosmological expansion; and all are inevitably coupled thermally to their surroundings to some degree. Straightforward calculations show, for instance, that the gravitational influence of a minor asteroid in the Asteroid Belt is sufficient to instigate chaotic trajectories of molecules in a parcel of air on Earth in less than a microsecond. Since gravity cannot be screened, the exact molecular dynamics of all realistic systems are constantly affected in essentially unknown and uncontrollable ways. Unless one is able to model the entire universe, one probably cannot exactly model any subset of it. Fortunately, statistical arguments (e.g., molecular chaos, ergodicity) allow thermodynamics to proceed quite well in most cases.

There are no truly isolated systems in nature: not different from modeling in other branches of physics...
58.02.02 Macroscopic Point of View
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{© - QUOTE}

Vladislav Čápek and Daniel P. Sheehan
Macroscopic properties (e.g., temperature, number density, pressure) are ones that exhibit statistically smooth behavior at equilibrium.
Scale lengths are critical; for example, one expects macroscopic properties for typical liquids at scale lengths greater than about \(\mu \mathrm{m}\). At shorter scale lengths statistical fluctuations become important and can undermine the second law.

\section*{© - QUOTE}

Let us take as a system the contents in a cylinder of an automobile engine. A chemical analysis would show a mixture of hydrocarbons and air before being ignited, and after the mixture has been ignited there would be combustion products describable in terms of new chemical compounds. A statement of the amounts of these chemicals describes both the mass and the composition of the system.
At any moment, the system can be described further by specifying the volume, which varies as the piston moves in the cylinder. The volume can be easily measured and, in the laboratory, is recorded automatically by means of a device coupled to the piston.
Another quantity that is indispensable in the description of our system is the pressure of the gases in the cylinder. After ignition of the mixture, the pressure is large; after the expulsion of the combustion products, the pressure is small. In the laboratory, a pressure gauge may be used to measure and record the changes of pressure as the engine operates.
Finally, there is one more quantity without which we should have no adequate description of the operation of the engine. This quantity is the temperature, and, as we shall see, in many instances it can be measured just as simply as the other quantities.
We have described the contents in a cylinder of an automobile engine by specifying the quantities of mass, composition, volume, pressure, and temperature. These quantities refer to the large-scale characteristics, or aggregate properties, of the system and provide a macroscopic description. The quantities are, therefore, called macroscopic coordinates.
For a system other than a gas, such as a paramagnetic salt, the different quantities must be specified to provide a macroscopic description of the system; but macroscopic coordinates, in general, have the following properties in common:
- They involve no special assumptions concerning the structure of matter, fields, or radiation.
- They are few in number needed to describe the system.
- They are fundamental, as suggested more or less directly by our sensory perceptions.
- They can, in general, be directly measured.

In short, a macroscopic description of a system involves the specification of a few fundamental measurable properties of a system.
Thermodynamics, then, is the branch of natural science that deals with the macroscopic properties or characteristics of nature and always includes the macroscopic coordinate of temperature for every system. The presence of temperature distinguishes thermodynamics from other macroscopic branches of science, such as geometrical optics, mechanics, or electricity and magnetism.

In short, a macroscopic description of a system involves the specification of a few fundamental measurable properties of a system.
58.02.03 Microscopic Point of View
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{© - QUOTE}

The microscopic point of view is the result of the tremendous progress of molecular, atomic, and nuclear science during the past hundred years. From this point of view, a system is considered to consist of an enormous number of particles, each of which is capable of existing in a set of states defined by their energy, linear momentum, angular momentum, etc.... The particles are assumed to interact with one another by means of fields. The system of particles may be imagined to be isolated or, in some cases, may be considered to be embedded in a set of similar systems, or ensemble of systems. The mathematics of probability is applied, and the equilibrium state of the system is assumed to be the state of highest probability.
The fundamental problem is to find the number of particles in each of the microscopic states (known as the populations of the states) when equilibrium is reached.
Statistical Physics, then, is the branch of natural science that deals with the microscopic characteristics of nature.
A microscopic description of a system involves the following properties:
- Assumptions are made concerning the structure of matter, fields, or radiation.
- Many quantities must be specified to describe the system.
- These quantities specified are not usually suggested by our sensory perceptions, but rather by our mathematical models.
- They cannot be directly measured, but must be calculated.

In short, a microscopic description of a system involves various assumptions about the internal structure of the system and then calculations of system-wide characteristics.

In short, a microscopic description of a system involves various assumptions about the internal structure of the system and then calculations of system-wide characteristics.

\subsection*{58.02.04 Microscopic Versus Macroscopic}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{© - QUOTE}

Although it might seem that the two points of view are hopelessly different and incompatible, both points of view, applied to the same system, must lead to the same conclusion.
The two points of view are reconciled because the few directly measurable properties whose specification constitutes the macroscopic description are really averages, over a period of time, of a large number of microscopic characteristics. For example, the macroscopic quantity, pressure, is the average rate of change of linear momentum due to the large number of molecular collisions made on a unit of area. Pressure, however, is a property that is perceived by our senses. We feel the effects of pressure. Pressure was experienced, measured, and used long before there was reason to believe in the existence of molecular impacts. If molecular theory is changed, for example, by incorporating the results of chaos, the concept of pressure will still remain and be understood by all normal human beings.
The few measurable macroscopic properties are as sure as our senses. They will remain unchanged as long as our senses remain the same and are not deceived. Herein lies an important distinction between the macroscopic and microscopic points of view.
The microscopic point of view, however, goes much further than our senses and many direct
experiments. It assumes the structure of microscopic particles, their motion, their energy states, their interactions, etc., and then calculates measurable quantities. The microscopic point of view has changed several times, and we can never be sure that the assumptions are justified until we have compared some deduction made on the basis of these assumptions with a similar deduction based on the experimentally proven macroscopic point of view. In other words, when we seek to understand the physical reality of a result of a microscopic calculation, we look to the macroscopic point of view for guidance.
Throughout its history, the study of thermodynamics has always looked for general laws, relationships, and procedures for understanding macroscopic temperature-dependent phenomena. Because it makes no assumptions about the microscopic structure of matter, thermodynamics has not been disproved as the various specific microscopic classical and quantum models of matter have been incorporated into statistical mechanics.

Macroscopic variables are typically averages of microscopic quantities.
© - QUOTE
In thermodynamics, however, the attention is directed to the interior of a system. A macroscopic point of view is adopted, and emphasis is placed on those macroscopic quantities which have a bearing on the internal state of a system.
It is the function of experiment to determine the quantities that are appropriate for a description of such an internal state.
Macroscopic quantities, including temperature, having a bearing on the internal state of a system are called thermodynamic coordinates. Such coordinates serve to determine the internal energy of a system.
It is the purpose of thermodynamics to find, among the thermodynamic coordinates, general relations that are consistent with the fundamental laws of thermodynamics.

\section*{© - QUOTE}
M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....

It has been emphasized that a description of the large-scale characteristics of a system by means of a few of its measurable properties, suggested more or less directly by our sensory perceptions, constitutes a macroscopic description.
Such descriptions are the historic starting point of all investigations in all branches of natural science. For example, in dealing with the mechanics of a rigid body, we adopt the macroscopic point of view in that only the external aspects of the rigid body are considered. The position of its center of mass is specified with reference to coordinate axes at a particular time. Position and time and a combination of both, such as velocity, constitute some of the macroscopic quantities used in classical mechanics and are called mechanical coordinates. The mechanical coordinates serve to determine the potential and the kinetic energy of the rigid body with reference to the coordinate axes, namely, the kinetic and the potential energy of the body as a whole. These two types of energy constitute the external, or mechanical, energy of the rigid body. It is the purpose of mechanics to find such relations between the position coordinates and the time as are consistent with Newton's laws of motion.
In thermodynamics, however, the attention is directed to the interior of a system. A macroscopic point of view is adopted, and emphasis is placed on those macroscopic quantities which have a bearing on the internal state of a system.
It is the function of experiment to determine the quantities that are appropriate for a description of such an internal state.
Macroscopic quantities, including temperature, having a bearing on the internal state of a system are called thermodynamic coordinates. Such coordinates serve to determine the internal energy of a system.
It is the purpose of thermodynamics to find, among the thermodynamic coordinates, general relations that are consistent with the fundamental laws of thermodynamics.
A system that may be described in terms of thermodynamic coordinates is called a thermodynamic system.
In engineering, the important thermodynamic systems are a gas, such as air; a vapor, such as steam; a mixture, such as gasoline vapor and air; and a vapor in contact with its liquid, such as liquid and vaporized freon. Chemical thermodynamics deals with these systems and, in addition, with reactions, surface films, and electric cells. Physical thermodynamics includes, in addition to the above, such systems as wire resistors, electric capacitors, and magnetic substances.

\subsection*{58.03.01 Macroscopic Variables of State}

The choice of the appropriate state variables depends on the system under consideration and on the degree of accuracy that one wishes to achieve. It is ultimately decided by experiment only.
© - QUOTE
Les systèmes physiques considérés en thermodynamique contiennent généralement un très grand nombre de particules (atomes, molécules, etc.), de l'ordre du nombre de Avogadro. L'expérience courante montre que de tels systèmes présentent un comportement que l'on peut décrire et prédire, notre échelle macroscopique, pourvu que l'on puisse maitriser quelques variables caractéristiques de ces systèmes, appelés variables d'état

L'état thermodynamique d'un système est stationnaire si les paramétrés macroscopiques qui définissent son état (volume, pression, nombre de particules par unit de volume, température, etc.) n'évoluent pas au cours du temps.
Un système est en équilibre thermodynamique lorsque son état est stationnaire, en l'absence d'exchange avec le milieu extérieur

\section*{© - QUOTE}

Robert Floyd Sekerka - Thermal Physics: Thermodynamics and Statistical Mechanics
Much of our treatment will be concerned with homogeneous bulk systems in a state of equilibrium.
By bulk systems, we refer to large systems for which surfaces, either external or internal, make negligible contributions
In defining bulk samples, we must be careful to exclude samples such as thin films or thin rods for which one or more dimension is small compared to others. Thus, a thin film ...... which will not be negligible for a sufficiently thin film. We must also exclude samples that are finely subdivided, such as those containing many internal cavities.
From the considerations of the preceding section, atoms of bulk samples can be regarded as being equivalent to one another, independent of location. It follows that certain state variables needed to describe such systems are proportional to the number of atoms.

\subsection*{58.03.02 Intensive and Extensive Macroscopic Properties}

Imagine a system in equilibrium to be divided into two equal parts, each with equal mass. Those properties of each half of the system that remain the same are said to be intensive; those that are halved are called extensive.
The intensive coordinates of a system, such as temperature and pressure, are independent of the mass; the extensive properties are proportional to the mass. Since the intensive variables are ratios or derivatives involving extensive variables the total number of independent intensive variables is one less than the total number of independent extensive variables.
To every extensive variable its intensive variable can be associated. The reverse is not true; temperature and pressure, for instance, have no extensive counterpart.
One has to be careful that examples of properties of already known systems do not necessarily satisfy this property, tat is either intensive or extensive, which is far from trivial. Consider, for instance, a set of \(n\) (an even number) identical point masses: the gravitational interaction energy, as a function of the mass, \(m\), and average distance between all pairs, \(\langle r\rangle\), goes like \(u \sim-\operatorname{Bin}[n, 2] \mathcal{G m} m^{2} /\langle r\rangle\). Therefore, if the system is divided into two equal sets, with the same average distance, the gravitational interaction energy is not halved, because it depends on the quadratic function \(\operatorname{Bin}[n, 2]\). How to deal with it, it will be mentioned later.
At least one extensive variable must be used, else one cannot determine the overall size of the system.

\subsection*{58.03.03 Additive and Extensive Properties}

\section*{©|WEB - URL|||}

Additive quantities: a property is additive whenever, under combination of two independent subsystems, the property of the resulting system is the sum of the the properties of the original systems.

Extensive quantities: a function \(f\) of the variables \(Z_{i}\) is extensive if it satisfies the scaling law
\[
f\left(q Z_{1}, q Z_{2}, \ldots\right)=q f\left(Z_{1}, Z_{2}, \ldots\right) \quad q>0
\]

That is, \(f\) is homogeneous of degree one, and the theorem of Euler applies.

\section*{© - QUOTE}

\section*{GRANDY}

While additivity can readily be shown to imply extensivity, at least for continuous \(f\), the converse is not necessarily true if systems differing in some way are being brought together; for example, even though the two separate systems are extensive, there may be a chemical reaction upon mixing. In any event, the two notions are logically independent.

Additivity implies extensivity; the reverse is not true. For instance, gravitational potential energy is extensive, as it is proportional to the total mass, but it is not additive, as the gravitational potential energy of a system composed of two subsystems, is not the sum of the gravitational potential energies of the subsystems because there is also the interaction energy term (the gravitational force, in fact, is not short-ranged).

(a)

(b)

\subsection*{58.03.04 State Functions and Path Functions}

Any quantity which, in equilibrium, depends only on the state variables is called a state function.

\title{
Thermal Equilibrium and Temperature
}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{© - QUOTE}

For any pure substance, pressure and volume are always state variables, as well as number and type of particles and temperature.
Experiment shows that, for a given composition and for a constant mass and temperature, many different values of pressure and volume are possible for a gas. If the pressure is kept constant, the volume may vary over a wide range of values, and vice versa. In other words, the pressure and the volume are independent coordinates but are related in a simple equation, namely, Boyle law. More recently, experiment has shown that, for a wire of constant mass, the tension and the length are independent coordinates, whereas, in the case of a surface film, the surface tension and the area may be varied independently. Some systems that, at first sight, seem quite complicated, such as an electric cell with two different electrodes and an electrolyte, may still be described with the aid of only two independent coordinates. On the other hand, some thermodynamic systems composed of a number of homogeneous parts require the specification of two independent coordinates for each homogeneous part.
For the present, to simplify our discussion, we shall deal only with systems of constant mass and composition, each requiring only one pair of independent coordinates for its description. This involves no essential loss of generality and results in a considerable saving of words. In referring to any unspecified system, we shall use the symbols \(X\) and \(Y\) for the pair of independent coordinates, where the symbol \(X\) refers to a generalized force (for instance, the pressure of a gas) and \(Y\) refers to a generalized displacement (for instance, the volume of a gas).
A state of a system in which the coordinates \(X\) and \(Y\) have definite values that remain constant so long as the external conditions are unchanged is called an equilibrium state. Experiment shows that the existence of an equilibrium state in one system depends on the proximity of other systems and on the nature of the boundary or wall separating the different systems. Walls are said to be either adiabatic or diathermic in ideal cases. If a wall is adiabatic, an equilibrium state for system A may coexist with any equilibrium state of system B for all attainable values of the four quantities, \(X, Y\) and \(X^{\prime}, Y^{\prime}\) provided only that the wall is able to withstand the stress associated with the difference between the two sets of coordinates. Thick layers of wood, concrete, asbestos, felt, or polystyrene, as well as dewars, are, in this order, increasingly better experimental approximations to ideal adiabatic walls.
If the two systems are separated by a diathermic wall, the values of \(X, Y\) and \(X^{\prime}, Y^{\prime}\) will change spontaneously until an equilibrium state of the combined system is attained. The two systems are then said to be in thermal equilibrium with each other. The most common experimental diathermic wall is a thin metallic sheet. Thermal equilibrium is the state achieved by two (or more) systems, characterized by restricted values of the coordinates of the systems, after they have been in communication with each other through a diathermic wall. Unlike the diathermic wall, an adiabatic wall prevents two systems from communicating with each other and coming to thermal equilibrium with each other. Although we have not yet defined the concept of heat, it may be said that a diathermic wall is a boundary through which heat is communicated from one system to another system, yet remains closed to the transport of matter. An ideal adiabatic wall does not communicate heat.

A state of a system in which the coordinates \(X\) and \(Y\) have definite values that remain constant so long as the external conditions are unchanged is called an equilibrium state.
58.04.01 Principle Zero
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|||

\section*{© - QUOTE}
M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....

These experimental facts may then be stated concisely in the following transitive relation: Two systems in thermal equilibrium with a third are in thermal equilibrium with each other. As suggested by Ralph Fowler, this postulate of transitive thermal equilibrium has been numbered the zeroth law of thermodynamics, which establishes the basis for the concept of temperature and for the use of thermometers.

Two systems in thermal equilibrium with a third system are in thermal equilibrium.
© - QUOTE
All states of corresponding isotherms of all systems have something in common, namely, that they are in thermal equilibrium with one another. The systems themselves, in these states, may be said to possess a property that ensures their being in thermal equilibrium with one another. We call this property temperature.
The temperature of a system is a property that determines whether or not a system is in thermal equilibrium with other systems.

\section*{© - QUOTE}

Questa legge può apparire elementare, ma non è così ovvia come sembra. Possono esistere altre situazioni in cui un sistema C può interagire equivalentemente con due sistemi A e B, senza che A e B presentino uguale interazione tra di loro. Immaginiamo per esempio che A e B siano due chiodi di ferro non Magnetizzati e che C sia una calamita; orbene, C attrae sia A sia B, ma questi ultimi non si attraggono tra di loro.

\section*{© - QUOTE}

Un altro enunciato della legge zero che fa riferimento alla temperatura è il seguente. Esiste una grandezza scalare chiamata temperatura, che è una proprietà di tutti i sistemi termodinamici in equilibrio. Due sistemi sono in equilibrio termico se, e solo se, sono uguali le loro temperature. Questa legge definisce dunque la nozione di temperatura, grazie alla quale abbiamo tratto l'idea di costruire e utilizzare i termometri.

The principle zero defines an equivalence relations partitioning all possible systems into subsets characterized by having the same temperature.
Temperature is the property of a system at thermal equilibrium defining which other systems the system is in equilibrium with.
Note that, it is not necessary to define a temperature scale to define thermal equilibrium.
The time required for a system to come to thermal equilibrium is called the relaxation time. How long the systems need to come into thermal equilibrium is of no concern for thermodynamics (thermostatics).
Time is not a variable in thermostatics.
Isotherm: the locus of states \(X, Y\) which are in thermal equilibrium with a third reference system and among them.

The locii of states \(X, Y\) which are in thermal equilibrium when changing the temperature, provide a generic relation:
\[
f[X, Y, T]=0
\]
which is the equation of state.
The equation of state is assumed to:
- be locally (and only locally) differentiable, as much as required;
- be locally (and only locally) invertible in any of the \(X, Y, T\) variables:
\[
\begin{aligned}
X & =f_{X}[Y, T], \\
Y & =f_{Y}[T, X], \\
T & =f_{T}[X, Y]
\end{aligned},
\]
- depend on pairs of conjugate variables, \(X, Y, X^{\prime}, Y^{\prime}, X^{\prime \prime}, Y^{\prime \prime}, \ldots\), plus the temperature (more on this in §59.02.05 - Work Energy Heat and the First Principle).

\section*{© - QUOTE}

\section*{WHEELER}

Select two systems, \(\mathcal{S}_{1}\) and \(\mathcal{S}_{2}\), and arrange (see the figure) that they be permitted to interact by heat exchange, but in no other way. What happens? One finds that
- either the states of both \(\mathcal{S}_{1}\) and \(\mathcal{S}_{2}\) remain unaltered, which we will record by writing \(\mathcal{S}_{1} \sim \mathcal{S}_{2}\);
- both states change, which we record by writing \(\mathcal{S}_{1} \sim \mathcal{S}_{2}\). One never observes a change in the state of one system which is unaccompanied by a change in the state of the other . . . though "thermostats" ("heat reservoirs"), created by making one system very much more massive than the other, are designed to approximate such behavior. One finds, moreover, that
- if \(\mathcal{S}_{1} \sim \mathcal{S}_{2}\) and \(\mathcal{S}_{1} \sim \mathcal{S}_{3}\) then \(\mathcal{S}_{2} \sim \mathcal{S}_{3}\).

The physical relationship that we have denoted ..... is therefore an equivalence relation. The "diathermal wall test" has served to resolve the set of all systems in all states into disjoint equivalence classes, just as "congruence" serves to resolve into equivalence classes the set of all triangles. There is a lesson to be learned from looking more closely to the set of all triangles inscribed on the Euclidean plane. For it is geometrically evident that
- 3 numbers are required to identify an equivalence class if congruence is the defining relation (angle/side/angle or side/angle/side);
- only 2 numbers are required to identify an equivalence class if similarity is the defining relation (angle/angle);
- only one number is required to identify an equivalence class if isometry is the defining relation (area).
Evidently the resolution of a set into disjoint equivalence classes conveys-in and of itself-no information concerning how many numbers must be specified to identify an equivalence class (the "dimension" of the resolution). The question now before us: What is the dimension of the resolution achieved by the diathermal wall test? How many numbers must be presented to identify one of the resulting equivalence classes, to distinguish it from all others? It is a lesson of simple sense experience that systems which are equivalent in the above sense are invariably adjudged to have, in the most naive tactile sense, the same "temperature." And conversely.
The important implication of the experience thus summarized is formulated in the so-called Zeroth Law of Thermodynamics: The diathermal wall test achieves a one-dimensional resolution of the set \(\{\) states of systems \(\}\) into disjoint equivalence classes. Every such class (to say the same thing another way) can be distinguished from every other such class by specification of a single real number, which we agree to call the "empirical temperature."
However natural it may be to assign larger values to "hotter" system-states, smaller values to cooler ... the 0th law does not by itself obligate us to do so, nor does it provide guidance as to how
we might/should do so: it permits a natural ordering of system-states, but places no constraint on how we might elect to graduate that ordering.

\subsection*{58.04.02 Empirical Concept of Temperature}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|
Useful to have a handy instrument to compare temperatures of different systems.

\section*{© - QUOTE}
M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....

Since temperature is a scalar quantity, the temperature of all systems in thermal equilibrium may be represented by a number. The establishment of a temperature scale is merely the adoption of a set of rules for assigning one number to a set of corresponding isotherms, and a different number to a different set of corresponding isotherms. Once this is done, the necessary and sufficient condition for thermal equilibrium between two systems is that they have the same temperature. Also, when the temperatures are different, we may be sure that the systems are not in thermal equilibrium.

Subjective temperature: common concept of hotness.
Dependence of various physical quantities on temperature: size, electric and Magnetic-Permeability, resistivity, Young/Poisson modules and relatives, ...
Use the dependence on temperature of various physical quantities \((X)\) to build an empirical thermometer, a transducer, for instance mercury/alcohol thermometer or a platinum resistance thermometer.
Define a measurement method for temperature, for instance:
\[
\theta[X] \equiv \alpha_{X} X \quad \text { or } \quad \theta[Y] \equiv \alpha_{Y} Y \quad \text { or } \quad \theta[X, Y] \equiv g[X, Y] .
\]
© - QUOTE
It should be noted further that different empirical temperature scales usually result when this arbitrary relation is applied to different kinds of thermometers and even when it is applied to different systems of the same kind, such as constant volume hydrogen or nitrogen thermometers.

Therefore the detailed knowledge of this law is essential to calibrate the instrument. For instance, if two different thermometers are calibrated at zero and \(100{ }^{\circ} \mathrm{C}\), they do not necessarily measure the same temperature at other temperatures.
Concept of thermal equilibrium: two bodies in thermal contact reach the same temperature, as measured by an empirical thermometer, if the wall is diathermic; the other macroscopic parameters will change as well, in general.
Two bodies in contact via an adiabatic wall will not change their temperature, as measured by an empirical thermometer, nor the other macroscopic parameters.
Thermalization: exchange of internal energy, on the microscopic scale. No macroscopic work is involved.
© - QUOTE
In linea di principio qualsiasi proprietà di una sostanza che dipenda dalla temperatura, detta per questo proprietà termometrica, può servire allo scopo; ne sono esempi il volume di un liquido, come nei termometri a mercurio e ad alcool, la pressione di un gas confinato, la resistenza elettrica di un filo, la lunghezza di una striscia metallica, o il colore di un filamento da lampadina; tutte grandezze che variano al variare della temperatura e tutte utilizzate in comuni termometri. Considerato però che la dipendenza di queste grandezze dalla temperatura non è in generale espressa da una legge lineare, ne consegue che la conoscenza dettagliata di questa legge di dipendenza

\begin{abstract}
diventa un elemento cruciale per la taratura e per l'accuratezza del termometro basato su ognuna di queste grandezze. L'adozione di una semplice dipendenza lineare tra la grandezza misurata e la temperatura da misurare fa sì che ognuno dei citati procedimenti misuri una propria temperatura empirica, che sarà diversa a seconda del tipo di termometro utilizzato. Così facendo, anche ammesso che tutti i tipi siano concordi quando misurano il punto triplo dell'acqua generale non lo saranno più ad altre temperature, sia maggiori sia minori. come illustra il Problema svolto 21.1. Ciononostante i termometri empirici, se tarati opportunamente per confronto con campioni riconosciuti, possono servire utilmente come campioni secondari di misura della temperatura. E difatti quasi tutti i termometri esistenti sono campioni secondari siffatti.
\end{abstract}

58.04.04 Preliminary Microscopic Interpretation of Heat and Temperature

\subsection*{58.04.04.01 Kinetic Temperature}

This § is referenced at pages:
[2673, 2673]
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|Vol. 1, § 39||

Consider a system made of a large number of molecules.
Temperature is a measure of the average internal energy of particles; the kinetic temperature is defined from the random motion of the Center-Of-Mass of the molecule. Also rotations and vibrations, for polyatomic molecules, are related to temperature, via the equipartition theorem, read \(\S\) 63.02.02.01 - Elements of Statistical Physics.

Consider a small part of the large system, large on a microscopic scale and small on a macroscopic scale. The part might have an overall motion, described by the motion of the Center-Of-Mass of all its molecules, with overall linear momentum \(\mathbf{P}=0\). Koënig theorem for kinetic energy may be applied.

Kinetic temperature is defined, locally, in terms of the average squared velocity of the Center-Of-Mass of the single molecules in the Rest Frame of the Center-Of-Mass of the part, \(\mathbf{v}_{\mathrm{CM}}\), as:
\[
\frac{1}{2} m\left\langle v_{\mathrm{CM}}^{2}\right\rangle \equiv \frac{3}{2} k_{\mathrm{B}} T[\mathbf{r}, t] \quad \Leftrightarrow \quad \mathbf{P}=0 \quad \Leftrightarrow \quad\left\langle\mathbf{p}_{i}\right\rangle=0
\]
defining the temperature field, \(T[\mathbf{r}, t]\), whenever there is no net macroscopic motion, \(\mathbf{P}=0\).

\subsection*{58.04.04.02 Collisions and Kinetic Temperature}

This § is referenced at pages:
[2668, 2668]
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|Vol. 1|§ 39.4|
©|Am.J.Phys, , ..., ..., ...Ed., .... 52 (1), January 1984|one-dimensional case||
From the kinematics of classical elastic interactions between any species of molecules, whenever the velocity distribution is isotropic in the laboratory frame, and the angular distribution of the decay products in the CMRF of the pair of particles is isotropic (as it is the case due to the total randomness),
\[
\left\langle\mathbf{v}_{1}\right\rangle=\left\langle\mathbf{v}_{2}\right\rangle=0 \quad\left\langle\mathbf{v}_{1} \cdot \mathbf{v}_{2}\right\rangle=0 \quad\left\langle\mathbf{v}_{1}^{\star_{1}} \cdot \mathbf{v}_{\mathrm{CM}}\right\rangle=\left\langle\mathbf{v}_{2}^{\star_{2}^{\prime}} \cdot \mathbf{v}_{\mathrm{CM}}\right\rangle=0 .
\]

For any two-body collision \(\mathbf{V}_{\mathrm{CM}}\) is the Center-Of-Mass velocity of the pair.ions are derived, for quantities before and after the collision:
\[
\begin{gathered}
\Delta \mathcal{K}_{1} \equiv \mathcal{K}_{1}^{\prime}-\mathcal{K}_{1}=\frac{2 \mu}{M}\left(\mathcal{K}_{2}-\mathcal{K}_{1}\right)+\mu\left(\frac{m_{1}-m_{2}}{M}\right)\left(\mathbf{v}_{1} \cdot \mathbf{v}_{2}\right)+m_{1}\left(\mathbf{v}_{1}^{\star_{1}} \cdot \mathbf{V}_{\mathrm{CM}}\right) \\
V_{\mathrm{CM}}^{2}=\frac{2}{M^{2}}\left(m_{1} \mathcal{K}_{1}+m_{2} \mathcal{K}_{2}+m_{1} m_{2}\left(\mathbf{v}_{1} \cdot \mathbf{v}_{2}\right)\right)
\end{gathered}
\]

Therefore, on average:
\[
\Longrightarrow\left\langle\Delta \mathcal{K}_{1}\right\rangle=\frac{2 \mu}{M}\left(\left\langle\mathcal{K}_{2}\right\rangle-\left\langle\mathcal{K}_{1}\right\rangle\right) \quad\left\langle\Delta \mathcal{K}_{2}\right\rangle=\frac{2 \mu}{M}\left(\left\langle\mathcal{K}_{1}\right\rangle-\left\langle\mathcal{K}_{2}\right\rangle\right),
\]
such that, on average, the kinetic energies tend to become equal (thermalize).
From equation (58.04.04.02) it can be easily shown that, for a fixed particle mass, the maximum average kinetic energy change happens whenever the other particle has the same mass, when \(\mu / M\) is maximum. This is exploited, for instance, for neutron thermalization in nuclear reactors.
Note that, the above results are valid for poly-atomic molecules provided the velocity above of the molecules are taken as the Center-Of-Mass velocities of the single molecules.

\subsection*{58.04.04.03 Heat}

Heat is exchange of energy at the microscopic level, without changing macroscopic parameters.

\subsection*{58.04.04.04 Microscopic Inter-Particle Interactions}

Inter-particle interactions can be described to a first approximation by the Lennard-Jones potential.

\section*{© - QUOTE}

The Lennard-Jones. potential (also referred to as the LJ potential, 6-12 potential, or 12-6 potential) is a mathematically simple model that approximates the interaction between a pair of neutral atoms or molecules.
The form of this inter-atomic potential was first proposed in 1924 by John Lennard-Jones. The most common expressions of the LJ potential are
\[
V_{\mathrm{LJ}}=4 \varepsilon\left[\left(\frac{\sigma}{r}\right)^{12}-\left(\frac{\sigma}{r}\right)^{6}\right]=\varepsilon\left[\left(\frac{r_{m}}{r}\right)^{12}-2\left(\frac{r_{m}}{r}\right)^{6}\right]
\]
where \(\varepsilon\) is the depth of the potential well, \(\sigma\) is the finite distance at which the inter-particle potential is zero, \(r\) is the distance between the particles, and \(r_{m}\) is the distance at which the potential reaches its minimum. At \(r_{m}\), the potential function has the value \(-\varepsilon\). The distances are related as \(r_{m}=2^{1 / 6} \sigma \approx 1.122 \sigma\).

These parameters can be fitted to reproduce experimental data or accurate quantum chemistry calculations. Due to its computational simplicity, the Lennard-Jones. potential is used extensively in computer simulations even though more accurate potentials exist.
The \(r^{-12}\) term, which is the repulsive term, describes Pauli repulsion at short ranges due to overlapping electron orbitals and the \(r^{-6}\) term, which is the attractive long-range term, describes attraction at long ranges (van der Waals force, or dispersion force).

Average energy increase implies, usually, average distance increase, that is thermal dilatation. In some cases the shape of the interaction potential can be such that an average energy increase causes an average distance decrease.
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|
A system in thermodynamic equilibrium is one for which the macroscopic variables \(T,(X, Y),\left(X^{\prime}, Y^{\prime}\right)\), \(\left(X^{\prime \prime}, Y^{\prime \prime}\right), \ldots\) are well defined (meaning that all intensive variables have the same value throughout the whole system) and remain constant over time (provided that external factors do not change); and the same is true for every subsystem.

\subsection*{58.05.01 Thermodynamic Equilibrium States}

\section*{© - QUOTE}

If the state of a thermodynamic system can be fully characterized by the values of the thermodynamic variables, and if these values are invariant over time, one says that it is in a state of thermodynamic equilibrium. Thermodynamic equilibrium, as R. Feynman says, occurs when all fast processes have already occurred, while the slow ones have yet to take place. Clearly the distinction between fast and slow processes is dependent on the observation time that is being considered.
© - QUOTE
When there is no unbalanced force or torque in the interior of a system and also none between the system and its surroundings, the system is said to be in a state of mechanical equilibrium. When these conditions are not satisfied, either the system alone or both the system and its surroundings will undergo a change of state, which will cease only when mechanical equilibrium is restored.
When a system in mechanical equilibrium does not tend to undergo a spontaneous change of internal structure, such as a chemical reaction, or a transfer of matter from one part of the system to another, such as diffusion or solution, however slow, then it is said to be in a state of chemical equilibrium. A system not in chemical equilibrium undergoes a change of state that, in some cases, is exceedingly slow. The change ceases when chemical equilibrium is reached.
Thermal equilibrium exists when there is no spontaneous change in the coordinates of a system in mechanical and chemical equilibrium when it is separated from its surroundings by diathermic walls. In other words, there is no exchange of heat between the system and its surroundings. In thermal equilibrium, all parts of a system are at the same temperature, and this temperature is the same as that of the surroundings. When these conditions are not satisfied, a change of state will take place until thermal equilibrium is reached.
When the conditions for all three types of equilibrium are satisfied, the system is said to be in a state of thermodynamic equilibrium; in this condition, it is apparent that there will be no tendency whatever for any change of state, either of the system or of the surroundings, to occur. States of thermodynamic equilibrium can be described in terms of macroscopic coordinates that do not involve the time, that is, in terms of thermodynamic coordinates. Thermodynamics does not attempt to deal with any problem involving the rate at which a process takes place. The investigation of problems involving the time dependence of changes of state is carried out in other branches of science, as in the kinetic theory of gases, hydrodynamics, and chemical kinetics.
When the conditions for anyone of the three types of equilibrium that constitute thermodynamic equilibrium are not satisfied, the system is said to be in a non-equilibrium state. Thus, when there is an unbalanced force or torque in the interior of a system, or between a system and its

\begin{abstract}
surroundings, the following phenomena may take place: acceleration, turbulence, eddies, waves, etc. While such phenomena are in progress, a system passes through non-equilibrium states. If an attempt is made to give a macroscopic description of anyone of these non-equilibrium states, it is found that the pressure varies from one part of a system to another. There is no single pressure that refers to the system as a whole. Similarly, in the case of a system at a different temperature from its surroundings, a non-uniform temperature distribution is set up and there is no single temperature that refers to the system as a whole.
Therefore, we conclude that when the conditions for mechanical and thermal equilibrium are not satisfied, the states traversed by a system cannot be described in terms of thermodynamic coordinates referring to the system as a whole.
It must not be concluded, however, that we are entirely helpless in dealing with such nonequilibrium states. If we divide the system into a large number of small mass elements, then thermodynamic coordinates may be found in terms of which a macroscopic description of each mass element may be approximated. There are also special methods for dealing with systems in mechanical and thermal equilibrium but not in chemical equilibrium. All these special methods will be considered later. At present, we shall deal exclusively with systems in thermodynamic equilibrium.
\end{abstract}

Thermodynamic equilibrium is established by the exchange of energy, volume or particle number between different systems or subsystems:
- energy exchange \(\rightarrow T=\) constant and uniform \(\rightarrow\) thermal equilibrium, driven by \(\Delta T\);
- volume exchange \(\rightarrow p=\) constant and uniform \(\rightarrow\) mechanical equilibrium, driven by \(\Delta p\);
- particle exchange \(\rightarrow \mu=\) constant and uniform \(\rightarrow\) chemical equilibrium, driven by \(\Delta \mu\).

\subsection*{58.05.02 Thermodynamic Transformations}

A system is in a state of thermodynamic equilibrium at a certain time, and is in a different state of thermodynamic equilibrium at a later time. The act of passing from the first to the second state is a transformation. How long it takes is not a problem of thermostatics.

\subsection*{58.05.02.01 Trasformazioni Quasi Statiche}

Sono trasformazioni ideali che avvengono in modo così graduale che il sistema può essere sempre considerato in equilibrio termodinamico in ogni momento della trasformazione.

\subsection*{58.05.02.02 Types of Thermodynamic Transformations}

Include:
- iso-thermal: quasi-static, with constant temperature;
- iso-bare: quasi-static, with constant pressure;
- iso-core: quasi-static, with constant volume.

Generic, non quasi-static, transformations:
- mono-thermal: non necessarily quasi-static, with equal temperature in the initial and final states;
- mono-bare: non necessarily quasi-static, with equal pressure in the initial and final states;
- mono-core: non necessarily quasi-static, with equal volume in the initial and final states.

\section*{Simple Thermodynamical Systems}

This § is referenced at pages:
[1272, 1272]

\subsection*{58.06.01 pVTN Systems}

A phase is a homogeneous region of matter, separated from other homogeneous regions by a phase boundary with a well defined and smooth geometrical shape enclosing a well-defined volume; the different regions (phases) will have different physical and|or chemical properties; when more than one phase exist, the system is heterogeneous, but the length scale of heterogeneity can vary from nano-meter to macroscopic dimensions.
Polymorphism is the ability of a solid material to exist in more than one form or crystal structure. Fluid polyamorphism is the existence of different condensed amorphous states in a single-component fluid. Polyamorphism of amorphous ice exists!

\section*{© - QUOTE}

\section*{WEB - URL}

Fluid polyamorphism is the existence of different condensed amorphous states in a singlecomponent fluid. It is either found or predicted, usually at extreme conditions, for a broad group of very different substances, including helium, carbon, silicon, phosphorous, sulphur, tellurium, cerium, hydrogen, and tin tetra-iodide. This phenomenon is also hypothesized for metastable and deeply supercooled water, presumably located a few degrees below the experimental limit of homogeneous ice formation. We present a generic phenomenological approach to describe polyamorphism in a single-component fluid, which is completely independent of the molecular origin of the phenomenon. We show that fluid polyamorphism may occur either in the presence or in the absence of fluid phase separation depending on the symmetry of the order parameter. In the latter case, it is associated with a second-order transition, such as in liquid helium or liquid sulphur. To specify the phenomenology, we consider a fluid with thermodynamic equilibrium between two distinct interconvertible states or molecular structures. A fundamental signature of this concept is the identification of the equilibrium fraction of molecules involved in each of these alternative states. However, the existence of the alternative structures may result in polyamorphic fluid phase separation only if mixing of these structures is not ideal. The two-state thermodynamics unifies all the debated scenarios of fluid polyamorphism in different areas of condensed-matter physics, with or without phase separation, and even goes beyond the phenomenon of polyamorphism by generically describing the anomalous properties of fluids exhibiting interconversion of alternative molecular states.

It is a matter of experience that the thermodynamic properties of a homogeneous phase depend on temperature, pressure, volume, mass and composition. It is found, experimentally, that many thermodynamic systems of fixed composition can be described in terms of pressure and volume only as macroscopic thermodynamical variables (plus composition).
For closed systems, \(N\) is fixed parameter. For open systems \(N\) becomes a thermodynamic variable.
Moreover, pressure and volume, a priori, are macroscopic variables which, a priori, should enter the description of any thermodynamical system, even if in some cases they can be neglected as non relevant with respect to the interesting aspects of the problem.
In all cases temperature is a macroscopic thermodynamical variable.

Similarly the number of molecules (or moles) of every kind of molecule is always a relevant macroscopic variable (for open systems) or fixed parameter (for closed systems).
Examples include:
- a pure substance (gas, liquid, solid);
- a homogeneous mixture of pure substances;
- a heterogeneous mixture of homogeneous phases;
- an ideal solution (read § 61.11.06 - Thermodynamics in Action);
- any composite system made of a number of the previous subsystems.

Note that negative pressures are not forbidden in themselves: they simply characterize a system under extension and not under compression. By pulling a solid, one subjects it to such a negative pressure.

Pressure, by convention in thermodynamics, is defied as the pressure exerted by the system on the walls, as opposed to the stresses on a elastic medium, which is exerted and positive in the opposite direction. This is the origin of the negative sign that accompanies hydrostatic work.

\subsection*{58.06.01.01 Thermo-Elastic Coefficients}

\section*{Coefficienti Di Dilatazione Termica Lineare E Volumico}

Il coefficiente di dilatazione termica lineare a pressione costante è definito come
\[
\begin{equation*}
\alpha \equiv \frac{1}{L}\left(\frac{\partial L}{\partial T}\right)_{p}=\alpha[T, p] \tag{58.06.01}
\end{equation*}
\]
\(\rightarrow\)
2504
See table 7.7 and 7.8 of WEB - URL for values.
Il coefficiente di espansione termica volumetrica a pressione costante è definito come
\[
\begin{equation*}
\beta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{p}=\beta[T, p] \tag{58.06.02}
\end{equation*}
\]

Nelle definizioni si assume che le eventuali altre variabili, da cui dipende lo stato del sistema, oltre alla temperatura, siano tenute fisse. In generale i coefficienti così definiti dipendono quindi anche da tali altre variabili, se significative.

Per una sostanza isotropa il coefficiente di dilatazione termica lineare non dipende dalla direzione. In tal caso si ha
\[
\beta=3 \alpha
\]

In generale per una sostanza non isotropa, detti \(\alpha_{1}, \alpha_{2}\) ed \(\alpha_{3}\) i coefficienti di dilatazione lineare lungo tre assi ortogonali si ha:
\[
\begin{equation*}
\beta=\alpha_{1}+\alpha_{2}+\alpha_{3} \tag{58.06.03}
\end{equation*}
\]

All the thermal dilatation coefficients are often positive, but it is not forbidden for them to be negative (for instance, liquid water below \(4{ }^{\circ} \mathrm{C}\) at atmospheric pressure).

\section*{Coefficiente Di Compressibilità Isoterma}

This § is referenced at pages:
[Never referenced.]
Il coefficiente di compressibilità isoterma è definito come
\[
\begin{equation*}
\kappa_{\mathrm{T}} \equiv-\frac{1}{V}\left(\frac{\partial V}{\partial p}\right)_{T} \equiv \kappa_{\mathrm{T}}[T, p] \tag{58.06.04}
\end{equation*}
\]

See table 7.4, 7.5 and 7.6 of WEB - URL for values.

Si può dimostrare, come i metodi della termodinamica, che per un sistema in equilibrio stabile, il modulo di compressibilità isoterma è sempre maggiore o uguale di zero:
\[
\begin{equation*}
\kappa_{\mathrm{T}} \geq 0 \tag{58.06.05}
\end{equation*}
\]

La plausibilità si può dedurre dal seguente ragionamento. Supponiamo che un oggetto abbia \(\kappa_{\mathrm{T}}<0\). Si consideri l'oggetto rinchiuso in un recipiente rigido. Si aumenti la pressione entro il recipiente (ad esempio iniettando del gas). Essendo \(\kappa_{\mathrm{T}}<0\) il volume dell'oggetto aumenta. Ma questo causerebbe un ulteriore aumento della pressione circostante. Qualunque aumento della pressione causerebbe dunque un ulteriore aumento della stessa. Analogamente si deduce che qualunque diminuzione di pressione causerebbe un'ulteriore diminuzione della stessa. Il sistema sarebbe instabile per fluttuazioni di pressione.

\section*{Isochore Pressure Variation}

Equation (58.08.02) shows the, for a general \(p V T\) system:
\[
\left(\frac{\partial p}{\partial T}\right)_{V}=\frac{\beta}{\kappa_{\mathrm{T}}} \text {. }
\]

\subsection*{58.06.01.02 Pure Substances as pVTN Systems}

A pure substance viewed as a \(p V T N\) system is described by the equation of state, \(f[p, V, T]=0\), which can be represented as a 3D graph as well as via its three 2D projections: \(p V, p T\) and \(T V\).

\section*{pV Diagram}

It is useful for visualizing work. In fact work is the signed integral of \(p[V, T]\). Read § 59.02.05.01 - Work Energy Heat and the First Principle.

\section*{pT Diagram}

It is useful to discuss phase transitions and equilibrium among phases. Read § 61.08-Thermodynamics in Action.

\section*{Triple Points of Water}

Triple points is any combination of \((p, V, T)\) values such that three different phases can co-exist. The gas-liquid-solid triple point of water corresponds to the minimum pressure at which liquid water can exist. At pressures below the triple point (as in outer space), solid ice when heated at constant pressure is converted directly into water vapor in a process known as sublimation.
Super-cooling is the process of lowering the temperature of either a liquid or a gas below its freezing point without solidification; this can happen in the absence of a seed crystals or nuclei around which a crystal structure can form.
The term sub-cooling refers to a liquid existing at a temperature below its normal boiling point.
Triple point of gaseous-liquid-solid water: \(T_{t p}=273.16 \mathrm{~K}\) and \(p_{t p}=0.00604 \mathrm{~atm}\).

\subsection*{58.06.02 Wires Under Tension as 1D Thermodynamical Systems}

Consider an elastic wire under tension, that is a rectilinear wire, whose cross-sectional area, \(A\), is much smaller than its length, \(L\), and such that the changes of its cross-sectional area are negligible. Note that, when dealing with Hooke law in mechanics, all processes are usually considered to be iso-thermal processes; in particular, Young modulus is the iso-thermal one.
Let the stretched elastic wire with fixed cross-sectional area \(A\), be defined by its thermodynamic variables:
- length, \(L\); it is an extensive macroscopic variable.
- tension per unit area, \(\tau \equiv F_{\perp} / A\), the normal stress, where \(F_{\perp}\) is the normal force at the two ends of the wire, positive when attempting to extend the wire; it is an intensive macroscopic variable.
It is, therefore, considered as a one-dimensional system. Define:
\[
\begin{aligned}
\alpha & \equiv \frac{1}{L}\left(\frac{\partial L}{\partial T}\right)_{\tau} \equiv \alpha_{\tau} \\
Y & \equiv L\left(\frac{\partial \tau}{\partial L}\right)_{T} \equiv Y_{T}
\end{aligned}
\]
\[
\left(\frac{\partial \tau}{\partial T}\right)_{L}=-\alpha_{\tau} Y_{T} \quad \text { from the mathematical relations on mixed derivatives }
\]
having used equation (58.08.02). The Young modulus, as defined in elementary mechanics, is the isothermal Young modulus.
The linear expansivity at fixed tension is most often a positive number, with rubber as a notable exception. In general, for any change of temperature, at fixed length, the change of tension will be opposite to the sign of the linear expansivity coefficient.
It is assumed, as for every thermodynamic system, that there exists an equation of state, relating \(L, \tau\) and \(T\) :
\[
G[L, \tau, T]=0 \Longrightarrow \mathrm{~d} L=\left(\frac{\partial L}{\partial T}\right)_{\tau} \mathrm{d} T+\left(\frac{\partial L}{\partial \tau}\right)_{T} \mathrm{~d} \tau=L \alpha_{\tau} \mathrm{d} T+\frac{L}{Y_{T}} \mathrm{~d} \tau \Longrightarrow \frac{\mathrm{~d} L}{L}=\alpha_{\tau} \mathrm{d} T+\frac{1}{Y_{T}} \mathrm{~d} \tau
\]

At constant tension, whenever \(\alpha_{\tau}\) does not depend on temperature, the equation can be integrated to get:
\[
L[T]=L_{0} \exp \left[\alpha_{\tau}\left[\tau_{0}\right]\left(T-T_{0}\right)\right] \quad \text { at constant } \tau=\tau_{0} .
\]

At constant temperature, whenever \(Y_{T}\) does not depend on tension, the equation can be integrated to get:
\[
L[\tau]=L_{0} \exp \left[\left(\tau-\tau_{0}\right) / Y_{T}\left[T_{0}\right]\right] \quad \text { at constant } T=T_{0} .
\]

Examples include:
- a Hooke spring;
- an ideal elastic wire;
- a non-elastic wire;
- a rubber band.
58.06.03 Surfaces Under Surface Tension as 2D Thermodynamical Systems

\subsection*{58.06.04 Non-Isotropic Solids}

The mechanical behavior of a anisotropic region, such as a volume element of a non-cubic crystal, cannot be described by two variables only, such as volume and pressure.
In general the state of deformation is given by a set of six variables, the strain components, and the state of stress is given by another set of six variables, the stress components.
The quantities analogous to the volume of an isotropic region are the six extensive properties giving the volume of the reference state. The stress components correspond to the negative pressure and are intensive properties.

\subsection*{58.06.05 Polarizable Materials in External Electric Field}

It is made complex by the fact that ElectroMagnetic interactions are long-range interaction, and therefore the problem does not directly fit the framework of elementary classical thermodynamics.
Read § 61.12.02 - Thermodynamics in Action.

\subsection*{58.06.06 Magnetizable Materials in External Magnetic Field}

It is made complex by the fact that ElectroMagnetic interactions are long-range interaction, and therefore the problem does not directly fit the framework of elementary classical thermodynamics.
Read § 61.12.03-Thermodynamics in Action

\subsection*{58.06.07 ElectroMagnetic Radiation}

It is actually a \(p V T N\) system, but in this case \(N\) is not fixed.

© - QUOTE
An equation of state expresses the individual peculiarities of one system as compared with another system and must, therefore, be determined either by experiment or by molecular theory. A general theory like thermodynamics, based on general laws of nature, is incapable of generating an equation of state of any system. An equation of state, therefore, is not a theoretical deduction from thermodynamics, but is usually an experimental addition to thermodynamics. It expresses the results of experiments in which the thermodynamic
It is obvious that no equation of state exists for the states traversed by a system that is not in mechanical and thermal equilibrium, since such states cannot be described in terms of thermodynamic coordinates referring to the system as a whole. For example, if a gas in a cylinder were to expand and to impart to a piston an accelerated motion, the gas might have, at any moment, a definite volume and temperature, but the corresponding pressure, calculated from an equation of state, would not apply to the system as a whole. The pressure would not be a thermodynamic coordinate, because it would depend not only on the velocity and the acceleration of the piston but would also vary from point to point.

Macroscopic thermodynamic variables always come in pairs, the two variables being the conjugate variables appearing in the expression of the work done on the system.
Moreover, from the expression of the first principle for an infinitesimal quasi-static transformation, as the internal energy is an extensive variable, the work term must be extensive as well, and therefore one of the two conjugate variables must be intensive, while the second one must be extensive.

An equation of state is the (either empirical of theoretical) relation among one pair of conjugate variables plus temperature. For each pair of conjugate variables, \(\{Y, X\}\) there exist one equation of state: \(G[X, Y, T]=0\). The number of equations of state is therefore equal to the number of pairs of conjugate variables.
The equation of state so defined, is often called the thermal equation of state, or just equation of state, in short.

\subsection*{58.07.01 pVTN Systems}

\subsection*{58.07.01.01 Ideal Gas}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|Chapter 5||
The molecular ideal gas - ideal gas in short - is the ideal gas of massive particles (molecules, ...).
The ideal gas is made of non-interacting particles; thermalization is assumed to happen thanks to the interactions with the walls.
1. Boyle law:
\[
p V=\text { constant }
\]
2. Dalton law: In a mixture of non-reacting ideal gases, the total pressure is equal to the sum of the partial pressures of the individual gases:
\[
p_{i}=p x_{i} \quad p=\sum_{i}^{n} p_{i}
\]
where \(x_{i}\) is the mole fraction of the \(i\)-th component in the total mixture of \(n\) components.
3. Charles law (also known as the law of volumes): At constant pressure on gas, the temperature and the volume are proportional.
\[
V \propto T \quad \text { at constant pressure }
\]
4. Ideal gas state equation:
\[
p V=n R T=N k_{\mathrm{B}} T
\]

Clearly, the ideal gas state equation summarizes Boyle, Dalton and Charles laws.

\subsection*{58.07.01.02 Non Ideal Gases}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|problem 5.6||
1. Clausius state equation (first type) for a hard core gas:
\[
\begin{equation*}
p(V-n b)=n R T \tag{58.07.01}
\end{equation*}
\]
2. Van der Waals state equation:
\[
\begin{equation*}
\left(p+\frac{a n^{2}}{V^{2}}\right)(V-n b)=n R T \tag{58.07.02}
\end{equation*}
\]
3. The empirical algebraic Redlich-Kwong equation of state:
\[
\begin{equation*}
p=\frac{n R T}{v-n b}-\frac{a n^{2}}{\sqrt{T} v(v+n b)} \tag{58.07.03}
\end{equation*}
\]
4. Dieterici equation of state:
\[
\begin{equation*}
p=\left(\frac{R T}{v-b}\right) \exp \left[-\frac{a}{R T v}\right] \tag{58.07.04}
\end{equation*}
\]
\(\vec{~}\)
2645
At low pressures the Dieterici equation becomes identical to Van der Waals equation.
5. Berthelot equation of state:
\[
\begin{equation*}
\left(p+\frac{a n^{2}}{T V^{2}}\right)(V-n b)=n R T \tag{58.07.05}
\end{equation*}
\]
6. Clausius state equation (second type):
\[
\begin{equation*}
\left(p+\frac{a n^{2}}{T(c+V)^{2}}\right)(V-n b)=n R T \tag{58.07.06}
\end{equation*}
\]

\subsection*{58.07.01.03 Incompressible Solid/liquid}

Dal punto di vista della termodinamica un liquido o un solido ideale è un sistema \(p V T\) caratterizzato dalla proprietà di incompressibilità assoluta. L'equazione di stato di una liquido o un solido ideale è dunque
\[
\begin{equation*}
V=V_{0} \tag{58.07.07}
\end{equation*}
\]

Clearly, the above relation is nothing but the zero-order development of the state function \(V(T, p)\).
For many phenomena liquids and solids can essentially be regarded as incompressible under changes of pressure, but still changing when temperature changes, so that their equation of state reduces to
\[
\begin{equation*}
V=V[T] \tag{58.07.08}
\end{equation*}
\]

\subsection*{58.07.01.04 Elastic Solid/liquid}

Una approssimazione migliore rispetto all'equazione di stato di solido e liquido incomprimibile, consiste nello sviluppare il volume al primo ordine della serie di Taylor in pressione e temperatura:
\[
V[p, T] \simeq V\left[p_{0}, T_{0}\right]+\left.\left(\frac{\partial V}{\partial p}\right)_{T}\right|_{0}\left(p-p_{0}\right)+\left.\left(\frac{\partial V}{\partial T}\right)_{p}\right|_{0}\left(T-T_{0}\right)
\]
where the derivatives must be evaluated at the starting point of the Taylor series development.
Dal punto di vista della termodinamica un liquido oppure un solido reale possono essere caratterizzati come sostanze elastiche ideali. stato di un sistema elastico ideale fornisce per il volume una variazione lineare in funzione della pressione e temperatura attorno ad un punto a temperatura \(T_{0}\) e pressione \(p_{0}\)
\[
\begin{equation*}
V=V_{0}+\beta V_{0}\left(T-T_{0}\right)-\kappa_{\mathrm{T}} V_{0}\left(p-p_{0}\right) \tag{58.07.09}
\end{equation*}
\]
dove \(V_{0}\) è il volume alla pressione \(p_{0}\) e temperatura \(T_{0}\) mentre \(\beta\) e \(\kappa_{\mathrm{T}}\) sono considerati costanti. Quest'ultima assunzione è ben verificata normalmente per un liquido o un solido pur di considerare variazioni di temperatura e pressione non troppo estese. Si noti che non è necessario che il solido sia isotropo.

Clearly, the above relation is nothing but the first-order development of the state function \(V(T, p)\).
58.07.01.05 Carnahan-Starling Equation of State
©|WEB - URL|||

The Carnahan-Starling equation of state is a good equation of state for a fluid made of hard spheres:
\[
\begin{equation*}
\frac{p V}{N k_{\mathrm{B}} T}=\frac{1+\eta+\eta^{2}-\eta^{3}}{(1-\eta)^{3}} \quad \eta \equiv \frac{\pi N d^{3}}{6 V} \quad d \text { is the hard sphere diameter } \tag{58.07.10}
\end{equation*}
\]
58.07.01.06 ElectroMagnetic Radiation - the Photon Gas
© |R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|Vol. 1|§ 39.3|

The photon gas is the ideal gas of massless particles (photons).
Read § 59.09.01.06 - Work Energy Heat and the First Principle for the discussion.

\subsection*{58.07.01.07 Stiffened Equation of State}
©|WEB - URL|||

When considering water under very high pressures (typical applications are underwater nuclear explosions, sonic shock lithotripsy, and sonoluminescence) the stiffened equation of state is often used:
\[
p=\rho(\gamma-1) e-\gamma p^{0}
\]
where \(e\) is the internal energy per unit mass, \(\gamma\) is an empirically determined constant typically taken to be about 6.1 , and \(p^{0}\) is another constant, representing the molecular attraction between water molecules. The magnitude of the correction is about 2 GPa. For a ideal gas, \(p_{0}=0\).

\subsection*{58.07.02 Wires Under Tension}

\subsection*{58.07.02.01 Hooke Ideal Wire/spring}

It satisfies Hooke law:
\[
\tau=(a-b T)\left(L-L_{0}\right)
\]
where \(a\) and \(b\) are constants.

\subsection*{58.07.02.02 Ideal Elastic Wire}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|problem 2.7, 3.8, 3.9||
Read §58.11.13 - Framework of Thermodynamics and Temperature.

\subsection*{58.07.02.03 Rubber Band}

Read § 61.11.03 - Thermodynamics in Action.

\subsection*{58.07.03 Surfaces of a Pure Liquid in Equilibrium With Their Vapor}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 2.6|Adapted from|
The surface of a pure liquid in equilibrium with its vapor has a particularly simple equation of state. Experiment shows that the surface tension of such a surface does not depend on the area but is a function of the temperature only. For most pure liquids in equilibrium with their vapor phase, the surface tension has an equation of state of the form originated by Van der Waals, but further developed by Guggenheim:
\[
\gamma[T]=\gamma_{0}\left(1-\frac{T}{T_{\mathrm{c}}}\right)^{\alpha}
\]
where \(\gamma_{0}\) is the surface tension at a standard temperature, \(T_{\mathrm{c}}\) is the critical temperature, that is the temperature above which no amount of pressure will condense vapor into liquid, and \(\alpha\) is a constant that lies between 1 and 2. It is clear from this equation that the surface tension decreases as \(T\) increases, becoming zero when \(T=T_{\mathrm{c}}\).

\subsection*{58.07.04 Materials in External ElectroMagnetic Fields}

\subsection*{58.07.04.01 Curie and Curie-Weiss Laws for Linear Polarizable|Magnetizable Substances}

A linear Polarizable|Magnetizable substance material in an external Electric|Magnetic field assumes a Polarization/Magnetization approximately directly proportional to the applied field.
If the temperature of the material is changed, this proportionality is changed as well: for a fixed value of the field, the Polarization/Magnetization is (approximately) inversely proportional to temperature (Curie law). For a simple homogeneous, isotropic and linear material:
\[
\chi_{\mathrm{E}} \propto C_{e} / T \quad \chi_{\mathrm{M}} \propto C_{m} / T
\]

A more general law is the Curie-Weiss law: For a simple homogeneous, isotropic and linear material:
\[
\chi_{\mathrm{E}} \propto C_{e} /\left(T+\theta_{e}\right) \quad \chi_{\mathrm{M}} \propto C_{m} /\left(T+\theta_{m}\right) .
\]

The Curie constants \(C_{e}, C_{m}, \theta_{e}, \theta_{m}\) depend on the material.

\subsection*{58.07.04.02 Other Equations of State for Polarizable|Magnetizable Substances}

Include, non homogeneous and|or non isotropic materials, ferro-magnetic and ferro-electric, general non linear equation of state.

\subsection*{58.07.05 Non-Isotropic Solids}

The full stress-tensor and strain tensor must be used to write the expression of work
There exists a stress-strain relation which is the equation of state. The simplest relation of this kind is the generalized Hooke law which holds for small deformations.

©|ocw.mit.edu||WEB - URL
Let \(f[x, y, z]=0\) that is, only two out of the three variables \(x, y, z\) are independent. Let \(w\) a fourth variable, with \(x=x[w], y=y[w], z=z[w]\). Then:
\[
\begin{equation*}
\left(\frac{\partial y}{\partial x}\right)_{z}\left(\frac{\partial x}{\partial y}\right)_{z}=+1 \quad \text { reciprocal rule } \tag{58.08.01}
\end{equation*}
\]
\[
\left(\frac{\partial x}{\partial y}\right)_{z}\left(\frac{\partial y}{\partial z}\right)_{x}\left(\frac{\partial z}{\partial x}\right)_{y}=-1 \Longrightarrow\left(\frac{\partial x}{\partial y}\right)_{z}=-\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial y}\right)_{x} \quad \text { cyclic rule } \quad, \quad \text { (58.08.02) } \underset{\substack{2489 \\ 2427}}{\rightarrow}
\]
\[
\begin{gather*}
\left(\frac{\partial x}{\partial y}\right)_{w}\left(\frac{\partial y}{\partial z}\right)_{w}\left(\frac{\partial z}{\partial x}\right)_{w}=+1  \tag{58.08.03}\\
\text { chain rule }  \tag{58.08.04}\\
\left(\frac{\partial x}{\partial w}\right)_{z}=\left(\frac{\partial x}{\partial w}\right)_{y}+\left(\frac{\partial x}{\partial y}\right)_{w}\left(\frac{\partial y}{\partial w}\right)_{z} \\
\text { Jacobian rule }
\end{gather*}
\]
58.08.02 Second Mean Value Theorem for Integrals

If \(f\) is continuous on \([a, b], a<b\), show that there exists \(c \in[a, b]\) such that we have \(\int_{a}^{b} f=\) \(f(c)(b-a)\). This result is sometimes called the Mean Value Theorem for Integrals.
If \(f\) and \(g\) are continuous on \([a, b]\) and \(g(x)>0\) for all \(x \in[a, b]\), show that there exists \(c \in[a, b]\) such that \(\int_{a}^{b} f g=f(c) \int_{a}^{b} g\). Show that this conclusion fails if we do not have \(g(x)>0\). (Note that this result is an extension of the preceding exercise.)

\subsection*{58.09.01 Legge Del Raffreddamento Di Newton}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.9 22.10||
È esperienza comune che gli oggetti caldi tendono a raffreddarsi e quelli freddi a riscaldarsi alla temperatura dell'ambiente circostante. Se la differenza di temperatura tra l'oggetto e l'ambiente, \(\Delta T \equiv T_{\mathrm{ogg}}-T_{\mathrm{amb}}\), non è troppo elevata la velocità di raffreddamento o riscaldamento è proporzionale, in prima approssimazione, alla differenza di temperatura
\[
\frac{\mathrm{d}(\Delta T)}{\mathrm{d} t}=-A(\Delta T)
\]
dove \(A\) è una costante.
1. Da quali fattori dipende la costante \(A\) e quali sono le sue dimensioni?
2. Se all'istante \(t=0\) si ha \(\Delta T=\Delta T_{0}\) mostrare che l'andamento previsto della differenza di temperatura è
\[
\Delta T=\Delta T_{0} \exp -A t
\]

\title{
Summary of the Framework of Thermodynamics
}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|

\section*{Definitions}
- System: the portion of universe one is interested in.
- Surroundings: the complement to the system; also, often, known as ambient.
- Universe: system plus surroundings.
- Boundary: the frontier between the system and surroundings, a closed surface; usually a well-defined geometrical shape enclosing a definite volume.
- Isolated System: no exchange of matter with surroundings; no exchange of energy with surroundings; no exchange of any other dynamical quantities with surroundings (linear momentum, angular momentum,...); no exchange of work nor heat.
- Closed system: no exchange of matter with surroundings; can exchange energy and|or any other dynamical quantities with surroundings, including work and heat.
- Open system: can exchange matter with surroundings as well as energy and|or other dynamical quantities, including work and heat
- Adiabatic wall: two systems put in contact across an adiabatic wall will keep the same macroscopic parameters; when an adiabatic wall is used to separate two systems, the macroscopic properties of one system are found to be uninfluenced by those of the other.
- Diathermic wall: two systems put in contact across a diathermic wall will change their macroscopic parameters until thermodynamic equilibrium is reached; the two systems will undergo changes until thermal equilibrium is reached.
- An isotherm is the locus of all points representing states in which a system is in thermal equilibrium with one state of another reference system; we make no assumption as to the continuity of the isotherm, although experiments on simple systems indicate usually that at least a portion of an isotherm is a continuous curve.
- A phase is a homogeneous region of matter, separated from other homogeneous regions by a phase boundary with a well defined and smooth geometrical shape enclosing a well-defined volume; the different regions (phases) will have different physical and|or chemical properties; when more than one phase exist, the system is heterogeneous, but the length scale of heterogeneity can vary from nano-meter to macroscopic dimensions. Usually, three kind of phases are identified: solid, liquid, gas.
- A fluid phase: liquid and gas.
- A condensed phase: solid and liquid.
- System in steady state: the state variables do not change with time.
- System in thermodynamic equilibrium: given a system in steady state, if furthermore there are no macroscopic currents of energy (work and|or heat) or particle number flowing through the system, the system is said to be in equilibrium.
- A thermodynamic path: a continuous succession of equilibrium states; it can be represented as a smooth curve in a multidimensional space whose axes are labeled by the state variables.
- A thermodynamic process/transformation: any change or succession of changes which results in a change of the state variables.
- A cyclic process: the initial and final states are the same.
- A quasi-static process: the system passes through a continuous succession of equilibria.
- A reversible process: the external conditions and the thermodynamic path of the system can be time-reversed and the initial state ba be reached again leaving both the system and the environment in exactly the same state as before. It is both quasi-static and non-dissipative. To reverse the process, infinitesimal changes in the opposite direction must be applied.
- A quasi-static process which is not reversible: slow drag a mass on a floor; slow leak of air from a tire; slow thermal transfer between two objects at different temperatures across a wall with very little thermal conductivity.
- Irreversible processes, as a rule, are dissipative.
- Thermal contact: heat conduction by direct physical contact, heat convection via some moving heated fluid, heat exchange via radiation.

\section*{Conceptual Bases}
- Objective of thermodynamics.
- In thermodynamics, systems of many-many bodies are studied (many-many: number of Avogadro).
- Macroscopic approach.
- Here, we limit to thermostatics.
- Define the system.
- Define with precision what belongs to the system and what does not: in thermodynamics, it may be tricky.
- Define the boundary between system and surroundings (assume it is a geometrically smooth surface).
- Define the surroundings (the complement of the system).
- Universe: the system plus the surroundings.
- Define how the system interacts with the surroundings.
- As in mechanics, but with emphasis on exchanges of energy.
- Exchanges of energy.
- But also: exchanges of linear and|or angular momentum, and|or whatever else
- Here, we only study exchanges of energy (work and|or heat).
- Define the macroscopic variables.
- Select the macroscopic variables relevant to the proper description of the system, that is relevant to the scope, within the empirical/experimental/phenomenological accuracy desired/required and within the known constraints, limits, capabilities.
- The selection of the macroscopic variables is an empirical/experimental/phenomenological step.
- Do not forget anything relevant to the problem
- Do not overdo, by including less relevant quantities
- You decide what is relevant to the scope and what is not relevant to the scope: to do this you must know what you want to achieve.
- You should know the physics, to decide what you can/must ignore and you will not ignore.
- The macroscopic variables must be able to describe the exchanges of energy: pairs of macroscopic variables, a generalized force and a generalized displacement, to describe macroscopic work.
- The generalized force and generalized displacement depend on the type of system.
- Work is energy exchange due to some change of the macroscopic parameters.
- Work is opposed to heat: energy exchange without changes in macroscopic parameters (that is at a microscopic level).
- The pairs of macroscopic variables shall be independent variables; name them \((X, Y),\left(X^{\prime}, Y^{\prime}\right)\), \(\left(X^{\prime \prime}, Y^{\prime \prime}\right), \ldots\)
- If the set of pairs of macroscopic variables have been chosen in a correct way, that is all and only the variables relevant to the scope, then they describe in a unambiguous way the state of the system.
- Here we will mainly describe the formalism for systems defined by one single pair of macroscopic variables, \((X, Y)\), to avoid a cumbersome notation; the extension of the formalism to systems described by more than one pair of macroscopic variables is straightforward.
- Walls.
- Experience shows that there exist materials such that two systems, A and B, put in contact via a material wall will keep the same values of their macroscopic variables (the same state) for a very long time;
\[
\left(X_{A}, Y_{A}\right) \rightarrow\left(X_{A}^{\prime}, Y_{A}^{\prime}\right)=\left(X_{A}, Y_{A}\right),
\]
and
\[
\left(X_{B}, Y_{B}\right) \rightarrow\left(X_{B}^{\prime}, Y_{B}^{\prime}\right)=\left(X_{B}, Y_{B}\right),
\]
this is named an adiabatic wall.
- Experience shows that there exist materials such that two systems, A and B, put in contact via a material wall will change the values of their macroscopic variables (they change their state) in a short time, reaching new values which will be then kept for very long times:
\[
\left(X_{A}, Y_{A}\right) \rightarrow\left(X_{A}^{\prime}, Y_{A}^{\prime}\right) \neq\left(X_{A}, Y_{A}\right),
\]
and
\[
\left(X_{B}, Y_{B}\right) \rightarrow\left(X_{B}^{\prime}, Y_{B}^{\prime}\right) \neq\left(X_{B}, Y_{B}\right)
\]
this is named a diathermic wall.
- In the case of contact via a diathermic wall, the two systems (better, the states of the two systems), at the end, are said to be in thermal equilibrium.
- Whenever two systems are in thermal equilibrium, not all the values of the macroscopic variables \(\left(X_{A}, Y_{A}\right)\) and \(\left(X_{B}, Y_{B}\right)\) are allowed but only a restricted subset, namely those corresponding to thermal equilibrium between the two systems.
- Adiabatic wall and diathermic walls are limiting concepts (limiting models).
- Note that contact does not necessarily mean physical contact; one speaks of thermal contact, which means to let heat flow, that is to let energy exchanges on a microscopic scale, which can happen via physical contact (conduction), via mass in contact flow (convection) or via radiation.
- Thermal equilibrium.
- Principle zero: if the states of two systems are in thermal equilibrium with the state of a third system, then they are in thermal equilibrium.
- The locus of states, in the \(X Y\) plane, of any one system which are in thermal equilibrium with a well-defined state of a third (reference) system, is called an isothermal curve; the reference system is named thermometer.
- Any isothermal curve is assume to be, locally, differentiable just enough.
- Empirical temperature scale.
- An empirical temperature scale can be defined by associating a numerical value and unit of measure to any function of the macroscopic variables of the thermometer, for instance: \(\Theta[X, Y]=g[X, Y]\); it is often used in a simplified form of \(\Theta_{X}[X]=g_{X}[X]\) or \(\Theta_{Y}[Y]=g_{Y}[Y]\).
- Equations of state.
- As the pair of macroscopic variable is assumed to describe unambiguously the macroscopic state of the system, the empirical temperature is uniquely defined, and there is therefore a well-defined relations among \(X, Y, T\) which can be written in the most general way in implicit form as \(G[X, Y, T]=0\) and it is called equation for state.
- It is assumed that, locally, the equation of state is invertible in any of the variables:
\[
X=f_{X}[Y, T] \quad Y=f_{Y}[T, X] \quad T=f_{T}[X, Y]
\]

\section*{Examples and Physical Applications}

\subsection*{58.11.01 Applications of Thermal Expansion}

\section*{© - QUOTE}

Per aprire il coperchio troppo stretto di un vaso di conserva si può sovente riuscire nell'intento ponendolo sotto un getto di acqua calda. Al crescere della temperatura il coperchio metallico si espande un po' di più rispetto al vetro.
La dilatazione termica non è però sempre desiderabile. Conosciamo tutti le fessure che devono essere lasciate nei giunti delle rotaie e dei ponti per consentirne la dilatazione.
Nell'industria aerea i bulloni e gli altri agganci sono raffreddati con ghiaccio secco prima dell'inserzione e quindi lasciati espandere una volta che si sono correttamente adattati.
Esistono termometri e termostati che fondano il loro funzionamento sulla differenza di dilatazione tra le componenti di un bimetallo.

\subsection*{58.11.02 Lo Specchio Del Telescopio Di Monte Palomar}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.15||
Lo specchio in vetro Pyrex del telescopio di Monte Palomar (il telescopio Hale) misura \(D=200\) pollici di diametro. Le temperature più estreme misurate a Monte Palomar sono \(T_{\min }=-10^{\circ} \mathrm{C}\) e \(T_{\max }=+50^{\circ} \mathrm{C}\). Determinare la massima variazione possibile del diametro \(D\) e della superficie \(A\) dello specchio causata dalle variazioni di temperatura. Si assuma per il coefficiente di dilatazione lineare medio del Pyrex, nell'intervallo di temperatura considerato, il valore \(\alpha=3.2 \cdot 10^{-6}{ }^{\circ} \mathrm{C}^{-1}\).

\section*{SOLUTION}

Dalla relazione (58.06.01), valida per variazioni a tensione costante in approssimazione di solido elastico e per piccoli intervalli di temperatura cosicché \(\alpha\) possa essere considerato costante, si ha
\[
\Delta L=L_{0} \alpha \Delta T
\]

Nel caso di solidi isotropi (o liquidi) il coefficiente di espansione lineare non dipende dalla direzione per cui per una variazione piccola di temperatura si può valutare la variazione di una piccola superficie rettangolare \(A\) come
\[
A \equiv X Y=X_{0} Y_{0}(1+\alpha \Delta T)(1+\alpha \Delta T)=A_{0}(1+2 \alpha \Delta T)+\mathcal{O}\left(\Delta T^{2}\right)
\]
fa cui si deduce che il coefficiente di dilatazione superficiale vale \(2 \alpha\). Il coefficiente di espansione volumetrica è definito dalla
\[
\beta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{p}
\]
mantenendo costante la pressione (nel caso di un sistema \(p V T\) ) oppure lo sforzo normale (nel caso di un sistema elastico \(\tau X \mathcal{T}\) ). Analogamente si trova che vale \(\beta=3 \alpha\) nel caso di sistemi isotropi oppure in generale \(\beta=\alpha_{1}+\alpha_{2}+\alpha_{3}\) nel caso di un sistema anisotropo con coefficienti di dilatazione lineare \(\alpha_{1}, \alpha_{2}\) ed \(\alpha_{3}\) lungo i tre assi. Infatti dalla definizione di \(\beta\) e ponendo \(V=x y z\) e derivando si ha \(\beta=3 \alpha\).
Con i dati del problema si ottiene la variazione del diametro \(\Delta D=0.98 \mathrm{~mm}\) e una variazione di superficie \(\Delta \mathbf{S}=78 \mathrm{~cm}^{2}\). In questo caso la variazione della superficie dello specchio può essere
ottenuta anche dalla relazione tra \(\Delta \mathbf{S}\) ed il diametro \(d\)
\[
\Delta \mathbf{S}=\frac{\pi d}{2} \Delta d=\frac{\pi d^{2}}{2} \alpha \Delta T=A_{0} 2 \alpha \Delta T
\]
valida per piccole variazioni di diametro.

\section*{SOLUTION}
\[
\Delta D=0.98 \mathrm{~mm} ; \Delta \mathbf{S}=78 \mathrm{~cm}^{2} .
\]

\subsection*{58.11.03 Effetto Delle Variazioni Di Temperatura Su Un Barometro}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.21||

Dimostrare che quando la temperatura del liquido di un barometro varia delle quantità \(\Delta T\) e la pressione resta costante, l'altezza del liquido nel barometro varia di \(\Delta h=\beta h \Delta T\) dove \(\beta\) è il coefficiente di espansione volumetrica del liquido definito dalla (58.06.02). Si supponga di poter trascurare la variazione di dimensioni del bulbo di vetro del barometro.

\subsection*{58.11.04 Espansione Termica in Un Termometro a Mercurio}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.26||
Si consideri un termometro a mercurio con bulbo e capillare di vetro. Si supponga che la sezione del capillare sia \(A\) costante e che \(V\) sia il volume del bulbo a temperatura \(T_{0}=0{ }^{\circ} \mathrm{C}\). Si supponga che il mercurio riempia esattamente il bulbo alla temperatura \(T_{0}=0^{\circ} \mathrm{C}\).

Dimostrare che la lunghezza \(L\) della colonna di mercurio nel capillare a temperatura \(T\) (espressa in gradi centigradi) vale \(L=V(\beta-3 \alpha) T / A\) ed è dunque proporzionale alla temperatura con \(\beta\) il coefficiente di espansione volumica del mercurio e \(\alpha\) il coefficiente di espansione lineare del vetro.

\subsection*{58.11.05 Movimento a Micro-Velocità}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.22||

In un certo esperimento occorre muovere un sorgente radioattiva ad un velocità assegnata estremamente piccola. Questo può essere ottenuto fissando la sorgente radioattiva ad un estremo di una sbarra di alluminio e riscaldando la parte centrale della sbarra in modo controllato tramite un avvolgimento elettrico. Se la sezione della sbarra effettivamente riscaldata è lunga \(z=1.8 \mathrm{~cm}\) a quale ritmo costante deve essere variata la temperatura della sbarra se la sorgente radioattiva deve muoversi alla velocità costante \(v_{0}=96 \cdot 10^{-9} \mathrm{~ms}\)

\section*{© - QUOTE}

If a system as a whole exerts a force on its surroundings and a displacement takes place, the work that is done, either by the system or on the system, is called external work. Thus, a gas, confined in a cylinder and at uniform pressure, while expanding and imparting motion to a piston does external work on its surroundings. The work done, however, by one part of a system on another part is called internal work. The interactions of molecules, atoms, or electrons on one another constitute internal work.
Internal work cannot be discussed in macroscopic thermodynamics. Only the work that involves an interaction between a system and its surroundings is analysed. When a system does external work, the changes that take place can be described by means of macroscopic quantities referring to the system as a whole, in which case the changes may be imagined to accompany the raising or lowering of a suspended weight, the winding or unwinding of a spring, or, in general, the alteration of the position or configuration of some external mechanical device. This may be regarded as the ultimate criterion as to whether external work is done or not. It will often be found convenient throughout the remainder of this book to describe the performance of external work in terms of, or in conjunction with, the operation of a mechanical device, such as a suspended weight or deformed spring. Unless otherwise indicated, the word work, unmodified by any adjective, will mean external work.
In mechanics, we are concerned with the behavior of systems acted on by external forces. When the total force exerted on a mechanical system is in the same direction as the displacement of the system, the work of the force is positive, work is said to be done on the system, and the energy of the system increases. For thermodynamics to be consistent with mechanics, we adopt the same sign convention for work. Thus, when work is done on the system, the work is regarded as positive. Conversely, when work is done by the system, the work is regarded as negative. This sign convention disagrees with engineering practice, in which positive work is done by the system on an external object.
A process performed in this ideal way is said to be quasi-static. During a quasi-static process, the system is at all times infinitesimally near a state of thermodynamic equilibrium, and all the states through which the system passes can be described by means of thermodynamic coordinates referring to the system as a whole. An equation of state is valid, therefore, for all these states. A quasi-static process is an idealization that is applicable to all thermodynamic systems, including Electric|Magnetic systems. The conditions for such a process can never be rigorously satisfied in the laboratory, but they can be approached with almost any degree of accuracy.
The expression
\[
\delta \mathcal{W} \equiv-p \mathrm{~d} V
\]
is an infinitesimal amount of work and has been. There is, however, an important distinction between an infinitesimal amount of work and the other infinitesimals, such as \(\mathrm{d} p\) or \(\mathrm{d} V\). An infinitesimal amount of hydrostatic work is an inexact differential; that is, it is a quantity but it is not the differential, that is the infinitesimal change, of an actual function of the thermodynamic coordinates. To indicate that an infinitesimal amount of work is not a mathematical differential of a function and to emphasize at all times that it is an inexact differential, the symbol used is \(\delta \mathcal{W}\). Another explanation of the symbolism is that \(\mathrm{d} V\) is a very small change in the value of the volume, whereas \(\delta \mathcal{W}\) is a very small value of work, not a change of something.

There are various interpretations of the fact that thermodynamic work is an inexact differential. Already it has been shown that work is a path-dependent integral; in other words, work is not a state function. There is no function of the thermodynamic coordinates representing the work in a body. The physical interpretation of thermodynamic work is that the performance of work is an external activity or process that leads to a change in the state of the body, namely, to increase or decrease the energy. The phrase work in a body has no meaning. Notice that work is not a quantity that itself moves, but is a process that moves another quantity, namely, energy of some type.

\subsection*{59.02.01 Thermodynamic Work}

Work is always defined as the work done by the surroundings on the system (positive work).
Unless otherwise indicated, the word work, unmodified by any adjective, will mean external work.
It is postulated that work done on a system can be always calculated, at least in principle, in terms of physical quantities of the universe.
Consider a composite system made by two subsystems \(A\) and \(B\).
By definition, the total work done on the composite system is the sum of the works done on the two sub-systems:
\[
\mathcal{W}_{A+B} \equiv \mathcal{W}_{A}+\mathcal{W}_{B}
\]

It is postulated that contact Force|Torque (that is short-range Force|Torque) are only allowed. This implies:
\[
\mathcal{W}_{A \rightarrow B}+\mathcal{W}_{B \rightarrow A}=0
\]

If this does not apply, some of the conclusions of classical thermodynamics might not work and the appropriate thermodynamics framework must be re-built from the start.
Clearly, the postulate is false, in general, but it applies straightforwardly to many common thermodynamic systems, whenever only contact forces, that is short-range forces, are responsible for the work, in such a way that two small parts of the two systems are in contact and therefore always have the same displacement.
Notable exceptions are long-range gravitational and ElectroMagnetic interactions.
However, gravitational forces are very weak on the every-day scale, and negligible. On astrophysical scales, the thermodynamic treatment of gravitating systems must take into account its long-range character.
On the every-day scale, physics is dominated by ElectroMagnetic interactions. However, free charges tend to redistribute in such a way to self-shield, so that neutral systems are obtained, which only exert Van-der-Walls type, short ranges, forces.
Read §27.06.23 - Introduction to Central Force Fields and Gravitation for the characterization of long-range interactions.

\subsection*{59.02.02 Quasi Static Work}

If, and only if, the transformation is a quasi-static one, that is it proceeds very slowly and gradually so that system and surroundings are always in thermodynamic equilibrium, the work can be calculated in terms of the state variables of the system, thanks to the thermodynamic equilibrium.
Consider a system defined by the set of pairs of macroscopic variables:
\[
(X, Y) \quad\left(X^{\prime}, Y^{\prime}\right) \quad\left(X^{\prime \prime}, Y^{\prime \prime}\right) \quad \ldots
\]
the expression of work, for a quasi-static transformation, in terms of variables of the system:
\[
\delta \mathcal{W}=Y \mathrm{~d} X+Y^{\prime} \mathrm{d} X^{\prime}+Y^{\prime \prime} \mathrm{d} X^{\prime \prime}+\ldots
\]

As quasi-static transformations are idealized transformations, calculating the work in terms of the state variables of the system must be considered, conceptually, the exception to the general rule.

\subsection*{59.02.03 Work Depends on the Transformation}

Work done on a system between two arbitrary states depends, in general, on the path followed, for a quasi-static transformation, and in general on the transformation details.
Consider, for instance, two transformations of a \(p V T\) systems from state \(A\) and \(A^{\prime}\), with the same initial and final temperatures, \(T_{0}\), with the same initial, \(V_{1}\), and final volumes, \(V_{2}\), assuming, for the sake of clarity, \(V_{2}<V_{1}\), and the same initial and final pressures, \(p_{1}\) and \(p_{2}\).
1. For the (unique) iso-thermal transformation, the work is: \(\mathcal{W}=-\int_{V_{1}}^{V_{2}} p\left[V, T_{0}\right] \mathrm{d} V\).
2. For the unique sequence of isocore followed by isobare transformations, via the intermediate state \(B=\left(p_{2}, V_{1}, T^{\prime}\right): \mathcal{W} \equiv \mathcal{W}_{A B}+\mathcal{W}_{B A^{\prime}}=0-p_{2}\left(V_{2}-V_{1}\right)>0\)
3. For the unique sequence of isobare followed by isocore transformations, via the intermediate state \(C=\left(p_{1}, V_{2}, T^{\prime \prime}\right): \mathcal{W} \equiv \mathcal{W}_{A C}+\mathcal{W}_{C A^{\prime}}=-p_{1}\left(V_{2}-V_{1}\right)+0>0\)
The microscopic interpretation helps to understand the difference between slow quasi-static transformations and non quasi-static transformations, such as a sudden expansion/compression of the gas. Imagine the gas inside the typical piston-cylinder, with the piston initially clamped in a fixed position with a weight resting on it exerting a pressure on the piston. Depending on the weight, the pressure on the piston may be either smaller or larger than the initial gas pressure. If friction is negligible and the volume of gas decreases then the work done by the weight on the system is larger than it would be for a quasi-static transformation, because the external pressure is larger. The local compression of the gas near the piston generates a larger resistance which must be overcome by the external force. The reverse happens in case of a sudden expansion.

\subsection*{59.02.04 Adiabatic Work}

If a closed system is caused to change from an initial state to a final state by adiabatic means only, then the work done on the system is the same over all adiabatic paths connecting the two states: work done adiabatically on a system is a state function.
© - QUOTE
Consider a system enclosed by a thermally isolated (adiabatic), impermeable wall, so that the sole interaction with the external world will appear under the form of a mechanical work \(\mathcal{W}\), for instance by expansion of its volume or by stirring. Referring to the famous experience of Joule, the work can be measured by the decrease in potential energy of a slowly falling weight. During the evolution of the system between the two given equilibrium states A and B , it is checked experimentally that the work \(\mathcal{W}\) is determined exclusively by the initial and the final states A and B , independently of the transformation paths. This observation allows us to identify \(\mathcal{W}\) with the difference \(\Delta \mathcal{U}=\mathcal{U}(B)-\mathcal{U}(A)\) of a state variable \(\mathcal{U}\) which will be given the name of internal energy.

\subsection*{59.02.05 Work on Various Systems}

This § is referenced at pages:
[2480, 2480]
Un sistema termodinamico è descritto da un insieme di variabili macroscopiche. Tali variabili intervengono sempre a coppie (variabili coniugate) nell'espressione del lavoro fatto sul sistema
\[
\delta \mathcal{W}=\sum_{i} Y_{i} \mathrm{~d} X_{i}
\]
dove \(Y_{i}\) è una forza generalizzata (ad esempio la pressione per un sistema \(p V T\) ) ed \(\mathrm{d} X_{i}\) è uno spostamento generalizzato (ad esempio il volume per un sistema \(p V T\) ).

\subsection*{59.02.05.01 Work on the Generalized Force-Displacement Diagram}

This § is referenced at pages:
[2489, 2489, 2515, 2515]
It is useful for visualizing work. In fact work is the signed integral of \(p[V, T]\). Read \(\S\) 59.02.05.01- Work Energy Heat and the First Principle.

For a system described by the variables \(X\) and \(Y\), with work \(\delta \mathcal{W}=Y \mathrm{~d} X\), the work in a quasi-static transformation from \(A\) to \(B\) is the signed definite integral
\[
\mathcal{W}=\int_{X_{A}}^{X_{B}} Y[X, T] \mathrm{d} X>0 \quad \Leftrightarrow \quad Y>0 \quad \& \& \quad X_{B}>X_{A}
\]
59.02.05.02 Sistema pVT

\subsection*{59.02.05.03 Solido Elastico}

Il lavoro fatto su una sbarra elastica di sezione \(A\), definita dalle variabili termodinamiche lunghezza, \(L\), e sforzo normale, tensione per unità di area, \(\tau\), vale
\[
\delta \mathcal{W}=+\tau A \mathrm{~d} L
\]

Si adotta la convenzione che lo sforzo \(\tau\) è positivo per una sbarra in tensione e negativo per una sbarra in compressione.

\subsection*{59.02.05.04 Superfici}

Il lavoro fatto per variare una superficie, dovuto alla presenza della tensione superficiale \(\gamma(\operatorname{Read} \S 26.06\)
- Introduction to Mechanics of Fluids), vale
\[
\delta \mathcal{W}=+\gamma \mathrm{d} \mathbf{S}
\]

\subsection*{59.02.05.05 Polarizable Materials in External Electric Field}
© - QUOTE
S.Bobbio, Electrodynamics of Materials, 2000, Academic Press, 1stEd., ....

The definition of the energy of an ElectroStatic field is borrowed from that of potential energy in mechanics, and is grounded upon the irrotational character of the ElectroStatic field. Basing ourselves on this important property, we are able to introduce the ElectroStatic energy of a continuous distribution of charges: it is, by definition, the work "we" should spend in order to "build" the given distribution (in an arbitrary way), by counterbalancing only the forces due to the long-range ElectroStatic interactions between charges.

This work is independent of the way in which the given distribution of charge is built (as the ElectroStatic field is irrotational), we conclude that the ElectroStatic energy of the distribution is expressed, by definition, as...

It is made complex by the fact that ElectroMagnetic interactions are long-range interaction, and therefore the problem does not directly fit the framework of elementary classical thermodynamics.

Read § 61.12.02 - Thermodynamics in Action.
For the sake of illustration, it is anticipated that the work done when changing the external electric field, with no work done by the generators, and considering as a system an infinitesimal volume of matter, \(\mathrm{d} V\), including the ElectroMagnetic field interaction energy, is:
\[
\delta \mathcal{W}=-\left(\mathbf{P} \cdot \Delta \mathbf{E}_{0}\right) \quad \text { for a path in the plane } \mathbf{P}-\mathbf{E}_{0} .
\]
59.02.05.06 Magnetizable Materials in External Magnetic Field
© - QUOTE
S.Bobbio, Electrodynamics of Materials, 2000, Academic Press, 1stEd.,

In this section we intend to evaluate the work that we have to spend on "building" a steady, continuous current distribution.

It is made complex by the fact that ElectroMagnetic interactions are long-range interaction, and therefore the problem does not directly fit the framework of elementary classical thermodynamics.
Read § 61.12.03 - Thermodynamics in Action
For the sake of illustration, it is anticipated that the work done when changing the external magnetic field, with no work done by the generators, and considering as a system an infinitesimal volume of matter, \(\mathrm{d} V\), including the ElectroMagnetic field interaction energy, is:
\[
\delta \mathcal{W}=-\left(\mathbf{M} \cdot \Delta \mathbf{B}_{0}\right) \quad \text { for a path in the plane } \mathbf{M}-\mathbf{B}_{0}
\]

\section*{Internal Energy}

For every system, there is a scalar extensive state function called energy. When the system is isolated, the energy is conserved.
The change in internal energy of a system when changing from state 1 to state 2 , is defined as the adiabatic work done:
\[
\begin{equation*}
\Delta \mathcal{U}_{1 \rightarrow 2} \equiv \int_{1}^{2} \delta \mathcal{W}^{\mathcal{A}} \equiv \mathcal{W}_{1 \rightarrow 2}^{\mathcal{A}} \tag{59.03.01}
\end{equation*}
\]

Internal energy is assumed to be additive over subsystems:
\[
u_{A+B}=u_{A}+u_{B}
\]
and extensive:
\[
u_{=}=M u
\]

In fact, the former implies the latter.
Additivity follows from the hypothesis of weak-coupling of the systems.

The heat system when changing from state \(A\) to state \(B\), is defined as:
\[
\begin{equation*}
Q_{1 \rightarrow 2} \equiv \Delta \mathcal{U}_{1 \rightarrow 2}-\mathcal{W}_{1 \rightarrow 2}^{\mathcal{A}} \tag{59.04.01}
\end{equation*}
\]
© - QUOTE
Microscopically, mechanical work is related to coherent correlated motions of the particles while heat represents that part of motion, which is uncorrelated, say incoherent.

\subsection*{59.05.01 Statement of the First Principle of ThermoDynamics for Closed Systems}
© \(\mid\) On the notion of internal energy - M.Alonso and E.J.Finn, Phys. Educ. 32 (1997) 256|WEB - URL|Excellent.| ©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|||

The first principle of ThermoDynamics states the energy balance for a generic system and the conservation of energy for isolated systems (energy is never created nor destroyed).

In a very general form it states that, for any closed system, having, possibly, an overall linear momentum \(\mathbf{P} \neq 0\) but an overall angular momentum \(\mathbf{J}=0^{1}\), the change of total energy, \(\mathcal{E}\), due to energy transfers across the boundaries, is:
\[
\begin{equation*}
\Delta \mathcal{E} \equiv \Delta \mathcal{K}+\Delta \Phi+\Delta \mathcal{U}=\mathcal{W}+Q \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+\mathrm{Q}_{\mathrm{rad}}\right) \tag{59.05.01}
\end{equation*}
\]
where:
- \(\mathcal{K}\) is the macroscopic kinetic energy of the system, that is the kinetic energy associated with the motion of the Center-Of-Mass, according to Koënig theorem for kinetic energy (section § 22.16.03 - Galilei-Newton Mechanics of General Systems); for complex continuous systems this must be thought as the macroscopic kinetic energy of any macroscopically small but microscopically large part of the system \({ }^{\text {a }}\);
- \(\Phi\) is the potential energy associated to external forces/fields (the macroscopic potential energy); for complex continuous systems this must be thought as the macroscopic potential energy of any macroscopically small but microscopically large part of the system;
- the sum \(\mathcal{K}+\Phi\) is normally called the macroscopic energy of any part of the system;
- \(U\) is the internal energy of the system (see section \(\S 59.05 .04\) - Work Energy Heat and the First Principle); it includes the potential energy of all internal forces and normally it cannot be attributed to individual particles, while the kinetic and intrinsic energy can; internal energy is invariant for Galilei Transformation;
- \(\mathcal{W}\) is the work done by the surroundings on the system, counted as positive if the work done on the system; it shall include the work of all Force|Torque which is not accounted for as potential energy; whenever any force is conservative one might choose between including it into the potential energy or counting it as work in the right-hand side of the expression; it is assumed that any contribution to the work \(\mathcal{W}\) can be always be calculated from macroscopic parameters;
- \(Q \equiv\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+Q_{\mathrm{rad}}\right)\) is the heat exchanged between the system and the surroundings, counted as positive if it is given to the system; heat is a way to transfer energy from/to a system without changing the macroscopic parameters of the system;
- \(Q_{\text {cnd }}\) is the heat exchanged between the system and the surroundings via thermal conduction, counted as positive if it is given to the system; heat is a way to transfer energy from/to a system without changing the macroscopic parameters of the system; \(Q_{\text {cnd }}\) is an exchange of energy with physical

\footnotetext{
\({ }^{1}\) The case of \(\mathbf{J} \neq 0\) is slightly more complex and has some subtleties, see the references.
}
contact;
- \(Q_{\text {cnv }}\) is the heat exchanged between the system and the surroundings via thermal convection, counted as positive if it is given to the system; heat is a way to transfer energy from/to a system without changing the macroscopic parameters of the system; \(Q_{\text {cnv }}\) is an exchange of energy with physical contact;
- \(Q_{\text {rad }}\) is the energy given by radiation to the system from the surroundings, counted as positive if it is given to the system; \(Q_{\mathrm{rad}}\) refers to exchange of energy without physical contact.
\({ }^{\text {a }}\) In case \(\mathbf{J} \neq 0\) the overall macroscopic kinetic rotational energy must be included in the macroscopic kinetic energy. However, when the volume tends to zero, the kinetic rotational energy goes to zero faster than the translational kinetic pnergy.
The right-hand terms (work, heat and radiation), are actually energy in transfer: they are the three possible ways any system can exchange energy with the external world.
It is assumed that one always knows how to calculate the work done by the surroundings on the system, by means of parameters external to the system. In case of quasi-static transformations, that is transformations so slow that the system is always in equilibrium, and only in this case, the work can be also calculated via parameters of the system.
The work term, \(\mathcal{W}\), must include all and only the interactions with the surroundings which are not included in the external macroscopic potential energy term \(\Delta \Phi\) : in fact one should make sure both to include all the interactions and avoid double-counting them.
The work of internal forces is usually included in the internal energy, ans internal forces are normally conservative.
It is worth emphasizing once more the following. In classical elementary thermodynamics it is assumed that, given two arbitrary systems, \(A\) and \(B\), the work \(A\) does on \(B\) is equal and opposite to the work that \(B\) does on \(A\) :
\(\mathcal{W}_{A \rightarrow B}+\mathcal{W}_{B \rightarrow A}=0 \quad\) basic assumption of classical elementary thermodynamics \(\quad\) (59.05.02)
This results, which is obviously totally false in general, comes from the assumption of classical elementary thermodynamics that the external forces included in \(\mathcal{W}\) are contact forces. Therefore the action-reaction principle, coupled to the fact that for contact forces the application points of the action-reaction pair move by the same amount gives the desired result. This hypothesis ignores the systems where long-range forces are acting, as for these systems the additivity of energies do not apply (this is the case of gravitational and ElectroMagnetic interactions).
In addition to the assumption that internal energy is additive,
\[
u_{A+B}=u_{A}+u_{B}
\]
equation (59.05.02) immediately leads to the conclusion that, if the system \(A+B\) is isolated, then
\[
Q_{A \rightarrow B}+Q_{B \rightarrow A}=0 \quad \text { heat conservation for isolated systems } .
\]

Isolated System means: no work, that is no change in the macroscopic parameters of the system; no heat nor radiation exchange, as enforced by adiabatic walls \({ }^{2}\). Adiabatic walls therefore refers to walls which do not allow passage to heat nor radiation, that is totally radiation absorbing walls.
When, as it is often the case, there is no changes in macroscopic mechanical energies, \(\mathcal{K}+\Phi\), one has the simplified form of the first principle of thermodynamics:
\[
\begin{equation*}
\Delta \mathcal{U}=\mathcal{W}+Q \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+Q_{\mathrm{rad}}\right) \tag{59.05.03}
\end{equation*}
\]

It is important to emphasize that, in general, the internal energy, \(\mathcal{U}\), of an isolated system is not necessarily conserved; only the total energy is.

}

\section*{© - QUOTE}

Thermodynamics of Natural Systems
G. M. Anderson

Note that we have not "proved" the first law. It is a principle that has been deduced from the way things work in our experience, but the fact that it has never been known to fail does not constitute a proof. Neither does the fact that the sun has never failed to rise in the east constitute a proof that it will rise in the east tomorrow, but I wouldn't bet against it.

\subsection*{59.05.02 Isolated Systems and Energy Conservation}

The first principle of thermodynamics is a balance law for energy accounting for the change of energy due to heat and work.
For an isolated system, there is no heat and no work, and therefore the balance law becomes a conservation law, the law of energy conservation. As in other branches of physics, because the strength of interactions decrease with distance and therefore any system sufficiently far-away from sources of interactions can be considered as an isolated system.

\subsection*{59.05.03 Local Balance and Conservation of the Total Energy}

The principle of conservation of energy is a local conservation law (see section § 19.01-Some Miscellaneous Topics), that is a balance equation for a quantity, energy, which is not created nor destroyed. The total energy of a system can change if and only if energy flows across the boundaries as work, heat or radiation. The change of energy in side an arbitrary volume of space, that is, can only be due to energy flow through the boundary of the volume. Two separate regions of space cannot exchange energy except through a flow of energy through a region of space that connects them. This is required by the theory of relativity.
See, for instance § 37.01 - ElectroMagnetic Field - Energy Linear Momentum and Angular Momentum for the ElectroMagnetic field.

Physical systems we observe in nature (such as gases, liquids, solids and plasmas as well as molecules, atoms, nuclei hadrons and other particles), are typically composed of interacting particles.
Particles are the recognisable units composing the system at any time. Particles might have an internal structure, that is, the particles themselves may be systems and are not always strictly geometrical points (an erroneous idea that often appears in some textbooks). Some particles may be stable, but others may change in time as a result of processes occurring in the system (such as chemical and particle reactions) or related to the internal structure of the particles themselves (such as decays).

The internal kinetic energy of the system is defined as the sum of the kinetic energies of the particles, \(k_{i}\), measured relative to the Center-Of-Mass of the system, by using Koënig theorem. The internal kinetic energy of a system does not depend on the Reference Frame used to measure the velocities of the particles: it is a property of the system, independent of its motion relative to the observer.

In classical physics the translational part of the internal kinetic energy can be expressed in terms of the translational velocity of the Center-Of-Mass of each particle, \(\mathbf{v}_{i}\), thanks to the classical theorem of equipartition of energy, as:
\[
\sum_{i} \frac{1}{2} m_{i} v_{i}^{2}=\frac{3}{2} N k_{\mathrm{B}} T
\]

The absolute temperature \(T\) in the equation above is called the kinetic temperature.
Note that the theorem of equipartition of energy implies that the total internal kinetic energy is shared among the internal degrees of freedom in such a way that to any quadratic term in the Hamiltonian is associated a mean kinetic energy of \(k_{\mathrm{B}} T / 2\). That is to say: the theorem of equipartition of energy implies that the system thermalizes among all its internal degrees of freedom. In Quantum Physics thermalization still holds but to a different extent such that the different degrees of freedom do not always have the same energy but share it according to well-defined rules. In fact in Quantum Physics the equipartition of energy holds among the so called accessible degrees of freedom.
Internal forces can do work on the particles as a consequence of their relative motion, and therefore one may associate an interaction energy with these internal forces. The internal interaction energy of the system, associated with the internal forces, is defined as the sum of the interaction energies, of the particles, which, in many cases, may be assumed to be expressible as interactions between pairs of particles, \(u_{i j}\). In many cases the interaction energy can be expressed as a potential energy depending on the relative dynamical coordinates of the particles:
\[
\delta \mathcal{W}_{\mathrm{I}}=-\mathrm{d} \Phi_{\mathrm{I}} .
\]

In this case one speaks about an internal potential energy. When that is not possible, other descriptions of the interaction might be necessary.
In case three-body or \(n\)-body forces are significant the extension is straightforward.
Since the particles in a system may have an internal structure, which can be modified either as a result of inelastic collisions and other interactions among the particles or by external agents, one must take into account the energy associated with that structure. This energy is called the intrinsic particle energy, \(\varepsilon_{i}\).
Therefore, the internal energy \(U\) of a system is defined as the sum of the three energies we have just considered, kinetic, interaction and intrinsic particle energies:
\[
\begin{equation*}
\mathcal{U}=\sum_{i} \mathrm{k}_{i}+\frac{1}{2} \sum_{a \neq b} \Phi_{a b}+\sum_{i} \varepsilon_{i} \tag{59.05.04}
\end{equation*}
\]

Note that the interaction energy \(u_{i \ddot{ }}\) corresponds to a coupling between particles, individual particle energies are not well defined and therefore the internal energy of a system is not the sum of individual particle energies. Only the internal kinetic energies and the intrinsic energies are additive. Only the total internal energy of the system is well defined.
The internal structure of particles may sometimes be ignored, as long as it does not affect the overall physical properties and one is not interested in the internal details. Moreover, Quantum Physics ensures that only energy exchanges larger than a minimum quantum jump in energy are required to change the quantum state of a particles/system. When the involved energies are smaller than the minimum possible energy changes of the internal state of the particle/system, energy changes are not actually possible. Of course, some particles are assumed to be really structure-less, such as, as far as we know today, the leptons and quarks, and thus have only the mass-energy \(m \gamma c^{2}\) contributing to their intrinsic energy.
The way one treats the particles of a system depends on the relative values of the three terms in equation (59.05.04) and the type of process involved. That is: models must be considered as flexible tools and must be adapted to each specific situation.
One should note that a system may be composed of several kinds of different particles, each kind with a different internal structure, and the number and kind of particles do not always remain constant \({ }^{3}\).

There may also be more than one kind of interaction, Most often only one interaction is dominant and the others can be neglected to a first approximation: the dominant interaction determines the physics of the system.

\footnotetext{
\({ }^{3}\) For instance for a gas of photons.
}

Also note that that we consider particles in a system may themselves be systems composed of other particles. For instance molecules can be considered as the particles in certain problems but the must be considered as composite systems, made of atoms, in other problems: the intrinsic energy of the molecules then becomes the internal energy of the molecule, with atoms having kinetic, interaction and intrinsic energies.
Changes in the internal energy of a system, which generally consist in changes of the three terms in equation (59.05.04), must be related to energy exchanges with other systems, such as the environment.

When the system is just one particle, so that there is no interaction energy with external fields (because external fields do not exist), and the notion of heat does not apply, equation (59.05.03) reduces to a simplified form which is the logical generalisation of the standard kinetic energy theorem for the dynamics of a single particle:
\[
\Delta \mathcal{E} \equiv \Delta \mathcal{K}+\Delta \mathcal{U}=\mathcal{W} .
\]

For an isolated system, that is, a system not subject to any external action/interaction, the three terms on the right-hand side of equation (59.05.01) are zero, so that the total energy of the system remains constant.
One may point out that the real and interesting physics is contained in the interaction energy and in the intrinsic particle energy. These two terms are essential to explain those processes that may occur or what structures may appear in a physical system.
In most of the processes traditionally considered in classical thermodynamics one may ignore the intrinsic energy, because thermodynamics deals only with relatively low energy processes during which the intrinsic energy stays, most often, constant.

\subsection*{59.05.05 From Mechanics to ThermoDynamics}
© \(\mid\) On the notion of internal energy - M.Alonso and E.J.Finn, Phys. Educ. 32 (1997) 256|WEB - URL \(\mid\) Excellent.|
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|||
The work-energy theorem for a general system in mechanics states that the change in total kinetic energy of any system is equal to the total work done on the system, by both external and internal interactions:
\[
\Delta \mathcal{K}_{\mathrm{tot}}=\mathcal{W}^{\prime} \equiv \mathcal{W}_{\mathrm{ext}}^{\prime}+\mathcal{W}_{\mathrm{int}}^{\prime}
\]

When some of the interactions are conservative one can account for them either as work or as potential energy, obtaining the balance (not conservation, in the general case) of mechanical energy:
\[
\Delta E_{\mathrm{mech}} \equiv \Delta \mathcal{K}_{\mathrm{tot}}+\Delta \Phi_{\mathrm{int}}+\Delta \Phi_{\mathrm{ext}}=\mathcal{W}
\]
describing some (or all) conservative interactions as potential energy, and letting the other conservative interactions non described as potential energy as \(\mathcal{W}\). Obviously non conservative interactions cannot be described as potential energy and are necessarily described by the work \(\mathcal{W}\) term.
The mechanical energy \(E_{\text {mech }}\) is made of the sum of the total kinetic energy and the total potential energy, both of internal and external interactions.
In the most general case mechanical energy is not a conserved quantity, unless non conservative interactions are absent, as it is well known from mechanics.
It is however possible to extend the principle of energy conservation in such a way to obtain a conserved quantity for isolated systems: the total energy.

Consider an isolated system, that is a system which cannot exchange energy nor matter with its surroundings. The general case of an open system can be deduced later from this case by the usual procedure to consider a larger global system made of the actual non isolated system plus the matter and energy exchanged so that the larger system is an isolated one.

The total kinetic energy can be separated in two contributions according to Koënig theorem.
For any isolated system it is possible to define a state function \(\mathcal{U}\), the internal energy, a function of the extensive variables, such that the total energy is conserved, that is the term of energy creation is zero:
\(\Delta \varepsilon=0 \quad \Leftrightarrow\)
\(\mathcal{E}=\mathcal{K}+\Phi+\mathcal{U} \quad\) with \(\Phi \equiv \Phi_{\text {ext }}\)
and \(\mathcal{K}_{\text {tot }} \equiv \mathcal{K}+\mathcal{K}_{\text {int }}\)
(59.05.05)

For a general system, not isolated, one has the first principle of thermodynamics, equation (59.05.01).
Note that the extensivity character is a working hypothesis, satisfied in many cases, but not necessarily in all cases (for instance in systems with long-range interactions).
It follows that any change of the total energy of a system must come from exchanges of energy with the surroundings (energy balance).
The potential energy is separated into its internal and external parts according to whether the interaction is either an internal or an external interaction.
The internal energy is made of the sum of the microscopic kinetic energy (that is the kinetic energy with respect to the Center-Of-Mass of the system, according to Koënig theorem) plus the potential energy due to all internal interactions plus any other possible intrinsic contribution (intrinsic particle energy) such as the rest energy of the particles.
The separation between macroscopic and microscopic kinetic energy is easily made by means of the Koënig theorem. Consider, in fact, for any macroscopically small but microscopically large piece of the system its Center-Of-Mass and decompose the kinetic energy accordingly. Note that as the internal energy is defined in terms of the internal kinetic energy it does not depend on the Reference Frame.
The internal energy is basically defined by equation (59.05.05), as the total energy minus the macroscopic kinetic energy and minus the potential energy due to external fields.
The intrinsic particle energy depends on the internal structure of the particles.

\subsection*{59.05.06 Summary - the First Principle of ThermoDynamics for Closed Systems}

Il primo principio della termodinamica per un generico sistema si scrive
\[
\begin{equation*}
\Delta \mathcal{K}+\Delta \Phi+\Delta \mathcal{U}=\Delta E^{\text {macro }}+\Delta \mathcal{U}=\Delta \mathcal{E}=\mathcal{Q}+\mathcal{W} \tag{59.05.06}
\end{equation*}
\]
dove \(\mathcal{K}\) indica l'energia cinetica macroscopica del sistema, \(\Phi\) l'energia potenziale associata a campi di forza macroscopici esterni al sistema, \(E^{\text {macro }}\) l'energia totale macroscopica del sistema, \(\mathcal{E}\) l'energia totale del sistema, \(\mathcal{U}\) l'energia interna del sistema, \(Q\) il calore assorbito dal sistema (contatto, convezione o irraggiamnto), \(\mathcal{W}\) il lavoro fatto sul sistema dalle forze esterne che non sono descritte dal termine di energia potenziale \(\Phi\).
Nel caso l'energia cinetica e potenziale macroscopica non cambino il primo principio si riduce alla forma semplificata
\[
\begin{equation*}
\Delta \mathcal{U}=\mathcal{W}+Q \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+Q_{\mathrm{rad}}\right) \tag{59.05.07}
\end{equation*}
\]

Si assume che il lavoro fatto su un sistema possa essere sempre espresso in termini dei parametri esterni al sistema. Solo in caso di trasformazioni quasi statiche il lavoro può anche essere espresso in termini delle variabili di stato del sistema. In tal caso infatti il sistema è sempre in equilibrio termodinamico e quindi le variabili di stato del sistema sono ben definite.

\subsection*{59.05.07 First Principle of ThermoDynamics for Open Steady Systems}

L'equazione del bilancio energetico per un sistema aperto in moto stazionario è
\[
\begin{equation*}
\Delta \mathrm{k}+\Delta \phi+\Delta \mathrm{h}=\mathrm{w}^{\prime}+\mathrm{q} \tag{59.05.08}
\end{equation*}
\]
dove h è l'entalpia per unità di massa, k l'energia cinetica macroscopica per unità di massa, \(\phi\) l'energia potenziale macroscopica per unità di massa, q il calore ricevuto per unità di massa e w' il lavoro utile effettivo per unità di massa fatto sul sistema, ad esclusione cioè del lavoro fatto dalle forze di pressione del fluido, che è quello che realmente interessa in problemi di ingegneria.
59.05.08 First Principle of ThermoDynamics for Open Generic Systems

This § is referenced at pages:
[1312, 1312]
In general, energy can change due to transfer of matter across the boundary of the system. In this case:
\[
\begin{equation*}
\mathrm{d} \mathcal{K}+\mathrm{d} \Phi+\mathrm{d} \cup=\delta Q+\delta \mathcal{W}+\mu \mathrm{d} N \tag{59.05.09}
\end{equation*}
\]
in terms of the change in number of particles, \(N\), and the chemical potential.
59.05.09 First Principle in Terms of Power for Generic Open Systems
\[
\begin{equation*}
\dot{\mathcal{K}}+\dot{\Phi}+\dot{U}=\dot{Q}+\dot{W}+\mu \dot{N} \tag{59.05.10}
\end{equation*}
\]

\subsection*{59.05.10 Dissipative Phenomena}

Dissipative phenomena convert some form of energy into some other form of energy such that the capacity of the final form to do mechanical work is less than that of the initial form.
One such example is when macroscopic energy is transformed into internal energy.
Another example is heat transfer which is dissipative because it is a transfer of internal energy from a hotter body to a colder one.
Dissipative phenomena include: mechanical solid friction, viscosity, turbulence, heat transport, electrical resistance, free expansion, particle diffusion, hysteresis, chemical reactions....

\section*{Internal Energy for Some Thermodynamic Systems}

The equation providing the internal energy for a particular system is often called the caloric equation of state.

Some of the results of this section require the use of the equations of internal energy, read § 61.04.01Thermodynamics in Action

\subsection*{59.06.01 Incompressible Solid/Liquid}

The equation of state implies:
\[
V=V_{0} \quad\left(\frac{\partial V}{\partial p}\right)_{T}=0 \quad\left(\frac{\partial V}{\partial T}\right)_{p}=0 \quad\left(\frac{\partial p}{\partial T}\right)_{V}=\text { undetermined }
\]

The internal energy can be considered as a function of any pair of the three variables \(p V T\), for instance \(V\) and \(T\). But, as \(V=V_{0}\) it is only a function of temperature.

Alternatively and more formally, equation (61.04.01) implies:
\[
\left(\frac{\partial u}{\partial p}\right)_{T}=0
\]

Therefore, l'energia interna dipende solo dalla temperatura (as volume does not change):
\[
\mathrm{d} \mathcal{U}=C_{\mathrm{v}}[T] \mathrm{d} T
\]

In fact, equation (61.04.01) implies that the internal energy does not depend on the pressure whenever the volume is constant.

\subsection*{59.06.02 Elastic Solid/Liquid}

La capacità termica a volume costante e quella a pressione costante di un liquido o solido descritti dall'equazione di stato (58.07.09) non dipendono, rispettivamente, dal volume e dalla pressione, come si deduce dalla relazione (61.03.05), (61.03.05). Equation (61.03.02) implies
\[
C_{\mathrm{p}}-C_{\mathrm{V}}=\frac{\beta^{2} V_{0} T}{\kappa_{\mathrm{T}}}
\]
and therefore, as \(C_{\mathrm{V}}\) does not depend on \(V\) and \(C_{\mathrm{p}}-C_{\mathrm{V}}\) only depends on \(T\), and as \(C_{\mathrm{p}}\) does not depend on \(p\) and \(C_{\mathrm{p}}-C_{\mathrm{V}}\) only depends on \(T\), both \(C_{\mathrm{p}}\) and \(C_{\mathrm{V}}\) only depend on temperature.

Si ha:
\[
\left(\frac{\partial \mathfrak{u}}{\partial V}\right)_{T}=\left(\frac{V-V_{0}}{\kappa_{\mathrm{T}} V_{0}}-p_{0}+\frac{\beta T_{0}}{\kappa_{\mathrm{T}}}\right) \quad\left(\frac{\partial \mathfrak{u}}{\partial p}\right)_{T}=V_{0}\left(p \kappa_{\mathrm{T}}-T \beta\right) .
\]

L'energia interna di un liquido o solido descritti dall'equazione di stato (58.07.09) vale dunque
\[
\mathcal{U}[T, V]=\left(\frac{V-V_{0}}{2 \kappa_{\mathrm{T}} V_{0}}-p_{0}+\frac{\beta}{\kappa_{\mathrm{T}}} T_{0}\right)\left(V-V_{0}\right)+\int_{T_{0}}^{T} C_{\mathrm{V}}[T] \mathrm{d} T
\]
59.06.03 Ideal Gas
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|Chapt. 5||

Experimentally, it is found, via experiments of free expansion inside a rigid and adiabatic container, \(\mathcal{W}=\mathcal{Q}=0\), that all gases at sufficiently low densities, do not change their temperature.

Considering \(\mathcal{U}=\mathcal{U}[T, V]\), if no temperature change takes place in a free expansion, \(\Delta \mathcal{U}=0\) then
\[
\left(\frac{\partial u}{\partial V}\right)_{T}=0
\]
that is, \(\mathcal{U}\) does not depend on \(V\).
Considering \(\mathcal{U}=\mathcal{U}[T, p]\), if no temperature change takes place in a free expansion, \(\Delta \mathcal{U}=0\) then
\[
\left(\frac{\partial u}{\partial p}\right)_{T}=0
\]
that is, \(\mathcal{U}\) does not depend on \(p\).
Therefore, \(\mathcal{U}\) is a function of temperature only.
An ideal (molecular) gas is defined as a system following the equation of state of ideal gases and whose internal energy only depends on temperature:
\[
p V=n R T \quad \mathcal{U}=\mathcal{U}[T]
\]

Note that, given equation (58.08.02), and the equation of state of a ideal gas, the equality to zero of the partial derivatives of the internal energy with respect to volume and pressure, at constant temperature, are equivalent:
\[
\left(\frac{\partial \mathfrak{u}}{\partial V}\right)_{T}=0 \quad \Leftrightarrow \quad\left(\frac{\partial \mathfrak{u}}{\partial p}\right)_{T}=0 \quad \text { for an ideal molecular gas } .
\]

Note that, the specific heats at constant volume/pressure can depend on temperature, in general.
59.06.04 ElectroMagnetic Field

This § is referenced at pages:
[2531, 2531, 2538, 2538]
Poynting theorem is the first principle (energy balance) for the ElectroMagnetic field.
Poynting theorem is the energy balance applied to the system made of the EM fields (the system). When comparing with the first principle of thermodynamics §59.05-Work Energy Heat and the First Principle one identifies the expression (37.01.02) of the energy density \(u[\mathbf{x}]\) with the total energy density of the ElectroMagnetic fields, the term \(\mathbf{j} \cdot \mathbf{E}\) as the work per unit volume done by the ElectroMagnetic fields on matter and the flux of Poynting vector as a radiation term, for exchanging ElectroMagnetic energy across the boundaries of the system.

Note that when writing the first principle of thermodynamics to some piece of matter (now the system) the term \(\mathbf{j} \cdot \mathbf{E}\) becomes the work per unit volume done by the ElectroMagnetic fields on the system.

Heat is radiation, here, given by the Poynting vector.
In fact, Heat only exists in a macroscopic approach.

\subsection*{59.07}

\section*{Enthalpy}
©|D.V.Schroeder, Thermal Physics, 1999, Addison-Wesley, ...Ed., ....|Introduction to thermal physics|§ 1|
By definition:
\[
\mathcal{H} \equiv \mathcal{U}+p V
\]

Enthalpy, therefore, can increase for two reasons: either because the energy increases or because the system expands doing work on the external pressure to make room for it.
During constant pressure transformations, any change of the enthalpy of a system is caused only by heat and, possibly, other forms of work except compression-expansion work. That is, compression-expansion work can be ignored, because it is automatically accounted for by enthalpy. In fact, the symbols \(\mathscr{H}\) is used, because, whenever no other types of work are being done, except compression-expansion work the change in enthalpy provides the heat added to the system.
Clearly, enthalpy is very important for chemical reactions, which very often happen at constant external pressure.

\section*{Capacità Termica Calore Specifico/Molare E Calore Latente}

This § is referenced at pages:
[2610, 2610]
La definizione generale di capacità termica di un sistema lungo una trasformazione quasi-statica, arbitraria ma completamente definita, \(\Gamma\) è definita da
\[
C_{C} \equiv\left(\frac{\delta \mathbb{Q}}{\delta T}\right)_{C}
\]

Occorre specificare la trasformazione in quanto il calore non è una funzione di stato e il calore scambiato dipende quindi dalla trasformazione.
Per un sistema \(p V T\) si utilizzano frequentemente le capacità termiche a volume e pressione costante
\[
\begin{aligned}
C_{\mathrm{V}} & \equiv\left(\frac{\delta Q}{\delta T}\right)_{V} \\
C_{\mathrm{p}} & \equiv\left(\frac{\delta Q}{\delta T}\right)_{p}
\end{aligned}
\]

Il calore specifico è la capacità termica per unità di massa.
Il calore molare è la capacità termica per unità di mole.
\[
c_{C}^{(m)} \equiv \frac{1}{m}\left(\frac{\delta Q}{\delta T}\right)_{C} \quad, c_{C}^{(n)} \equiv \frac{1}{n}\left(\frac{\delta Q}{\delta T}\right)_{C}
\]

\subsection*{59.08.01 Capacità Termica a Volume Costante}

This § is referenced at pages:
[Never referenced.]
Si consideri un sistema \(p V T\) chiuso a composizione costante.
Data una qualunque trasformazione a volume invariato, isocora, cioè una qualunque trasformazione tra due stati di equilibrio termodinamico, tale che il volume del sistema, è uguale all'inizio e alla fine della trasformazione, il lavoro fatto sul sistema è nullo. Allora si ha:
\[
\Delta \mathcal{U}=Q=\text { funzione di stato } \quad \Leftrightarrow \quad V=\text { constant }
\]

Si noti che il volume deve restare invariato, isocora e non monocora, e non è in generale sufficiente che il volume iniziale sia uguale a quello finale per garantire che il lavoro totale fatto sul sistema sia nullo, ad esempio nel caso siano presenti forze di attrito.

Nel caso il lavoro sia nullo comunque il calore risulta essere una funzione di stato.
\(C_{\mathrm{v}}\) might be called energy capacity. Moreover, there doesn't have to be any heat involved at all, since the energy could just as well enter as other work.

\subsection*{59.08.02 Capacità Termica a Pressione Costante}

This § is referenced at pages:
[2627, 2627]
Si consideri un sistema \(p V T\) chiuso a composizione costante.
Data una qualunque trasformazione tra due stati di equilibrio termodinamico, tale che la pressione del sistema, \(p\), è uguale all'inizio e alla fine della trasformazione, e quindi ugulae alla presisone esterna, si ha:
\[
\Delta \mathcal{H}=\Delta U+\Delta(p V)=\Delta U \mathcal{U}+p\left(V_{\mathrm{F}}-V_{\mathrm{I}}\right)=\Delta \mathcal{U}+p^{\text {ext }}\left(V_{\mathrm{F}}-V_{\mathrm{I}}\right)
\]

Negli stati iniziale e finale, essendo in equilibrio termodinamico, la pressione esterna coincide con quella del sistema: \(p=p^{\mathrm{ext}}\).
Se la pressione esterna, che per ipotesi è la stessa all'inizio e alla fine della trasformazione, è costante durante la trasformazione, cioè la trasformazione è isobara non monobara con riferimento alla pressione esterna, in modo che il lavoro è:
\[
\mathcal{W}=-p^{\mathrm{ext}}\left(V_{\mathrm{F}}-V_{\mathrm{I}}\right)
\]
allora si ha
\[
\Delta \mathcal{H}=Q=\text { funzione di stato } \quad \Leftrightarrow \quad p^{\text {ext }}=\text { constant } .
\]
\(C_{\mathrm{p}}\) might be called enthalpy capacity. Moreover, there doesn't have to be any heat involved at all, since the enthalpy could just as well enter as other work.

\subsection*{59.08.03 Latent Heats}

In certain situations it is possible to put heat into a system without increasing its temperature. This happens at a phase transformation. Technically, the heat capacity is infinite in these conditions.
It is an experimental fact that phase transitions happen at constant pressure and temperature.
The latent heat of transformation is the amount of heat necessary to induce, reversibley, the phase transformation of a certain amount of matter. However, this simple definition is ambiguous, since any amount of work could also be done during the process. By convention, it is assumed that pressure and temperature are constant, and that no other work is done. Therefore lantent heats are entalpies.
The specific/molar latent heat of transformation is a characteristic of the substance:
\[
Q \equiv m \lambda^{(s p e)}=n \lambda^{(m o l)} \Longrightarrow \lambda^{(m o l)}=\mathcal{M}_{0} \lambda^{(s p e)}
\]

Whether the latent heat of transformation is either specific or molar is clear from the units of measure.

\subsection*{59.08.04 Heat Reservoirs}

Heat reservoirs (aka: heat baths, heat sources) are bodies which such a large mass that that can exchange any amount of heat without changing their temperature. That is, ideally:
\[
C \rightarrow+\infty .
\]

Clearly, it is an abstraction, well approximated by bodies with large thermal capacity.
On practical grounds a mixture of two (or more) phases of a pure substance, represent a system, such that its temperature does not change, until more than one phase is present.

Read § 59.06.04 - Work Energy Heat and the First Principle.
Thermal (heat) radiation, is the ElectroMagnetic radiation emitted by any body of temperature \(T>0 \mathrm{~K}\).

Whenever a surface is mentioned, the surface can be either real or imaginary (that is, a mathematical surface, not a real interface between different things).

\subsection*{59.09.01.01 Kinematics of Particle/Radiation Transport}

This § is referenced at pages:
[1197, 1197, 1197, 1197]
Consider the transport of a generic physical quantity, \(Q\), such as mass, energy, linear momentum, particles, electric charge...

Two cases can be envisaged:
- sources: the transported quantity is emitted by some source and we are describing the properties of the matter;
- receiver: the transported quantity is directed onto some detector of any kind, describing the properties of the incoming flux.

\section*{One-Dimensional Flow}

All particles have velocity along a fixed direction in space: \(\mathbf{v}=v_{n} \hat{\mathbf{n}}\).
To quantify the flow of any quantity it is useful to introduce the flux, defined as the amount of quantity crossing a fixed surface, perpendicular to the velocity, per unit surface perpendicular area per unit time:
\[
\frac{\mathrm{d}^{2} Q}{\mathrm{~d} A_{\perp} \mathrm{d} t} \equiv \frac{\mathrm{~d} Q}{\mathrm{~d} V} v_{n} \equiv \mathcal{J}[\mathbf{x}]
\]

The quantity \(\mathcal{J}[\mathbf{x}]\) is often called irradiance.

\section*{Omni-Dimensional General Flow}

Particles have velocities along any direction in space.
In this case, to quantify the flow, one needs also to take into account the direction. The differential flux in solid angle is defined as the amount of quantity crossing a fixed surface, perpendicular to the velocity, per unit surface perpendicular area per unit time per unit solid angle around the normal to the surface:
\[
\frac{d^{3} Q}{\mathrm{~d} A_{\perp} \mathrm{d} t \mathrm{~d} \Omega} \equiv \frac{1}{\cos [\theta]} \frac{d^{3} Q}{\mathrm{~d} A \mathrm{~d} t \mathrm{~d} \Omega} \equiv \mathcal{R}[\mathbf{x}, \theta, \phi]
\]

The quantity \(\mathcal{R}[\mathbf{x}, \theta, \phi]\) is often called radiance.
The flux across a fixed surface, regardless of the angle inside the solid angle \(\Omega_{0}\), is:
\[
\frac{\mathrm{d}^{2} Q}{\mathrm{~d} A \mathrm{~d} t}[\mathbf{x}]=\mathcal{J}[\mathbf{x}]=\iint_{\Omega_{0}} \mathcal{R}[\mathbf{x}, \theta, \phi] \cos \theta \mathrm{d} \Omega
\]

In case the \(\mathfrak{R o f}\) a source is independent from the angles, the source is called a Lambertian source (read § 42-031 - ElectroMagnetic Waves).
In the important case of fixed \(\mathcal{R}\), that is homogeneous and isotropic flow:
\[
\frac{\mathrm{d}^{2} Q}{\mathrm{~d} A \mathrm{~d} t}=\pi \mathcal{R}
\]

\section*{Radiance Differential in Energy}

It is often useful, for instance in the case of ElectroMagnetic energy transport, to introduce the spectral quantities, in terms of \(\lambda\) and or \(\nu\) :
\[
\mathcal{R}_{\lambda} \equiv \frac{\mathrm{d} \mathcal{R}}{\mathrm{~d} \lambda}[\mathbf{x}, \theta, \phi, \lambda] \equiv \frac{d^{4} Q}{\mathrm{~d} A_{\perp} \mathrm{d} t \mathrm{~d} \Omega \mathrm{~d} \lambda} \quad \mathcal{R}_{\nu} \equiv \frac{\mathrm{d} \mathcal{R}}{\mathrm{~d} \nu}[\mathbf{x}, \theta, \phi, \nu] \equiv \frac{d^{4} Q}{\mathrm{~d} A_{\perp} \mathrm{d} t \mathrm{~d} \Omega \mathrm{~d} \nu}
\]

\subsection*{59.09.01.02 Deposition of Radiation}

When ElectroMagnetic radiation impinges upon the surface of a substance, three processes may occur:
- Absorption: the ElectroMagnetic power is deposited into the substance and converted to another type of energy, typically internal energy.
- Transmission: the ElectroMagnetic radiation passes through the substance unhindered.
- Reflection: the radiation is reflected at the surface of the substance.

In general, the three processes do not occur separately but simultaneously:
\[
\alpha+\tau+\varrho=1 \quad \text { absorptance } \quad+\quad \text { transmittance } \quad+\text { reflectance }=1
\]

\subsection*{59.09.01.03 Radiometry - Transport of ElectroMagnetic Energy}

Is the science of measurement of radiant energy (including light) in terms of absolute power.
Classical radiometric nomenclature is as follows \({ }^{4}\).
- Radiant energy, measured in joules.
- Radiant power, measured in watts.
- Radiant flux: Energy per unit Time per unit normal Area (also called Intensity); it is the flux of energy. The flux can leave/reach the surface in any direction.
There are two possible cases:

\footnotetext{
\({ }^{4}\) Beware that radiometric nomenclature is quite confusing and varying; here we try to avoid names which are misleading with respect to their use in other branches of physics.
}
- the flux can be arriving at the surface, in which case the radiant flux is referred to as irradiance, J;
- the flux can be leaving the surface, due to emission and|or reflection, in which case the radiant flux is referred to as radiant exitance, \(\mathcal{E}\).
The importance of either real or imaginary surface cannot be overstated: the radiant flux can be measured anywhere including on the surface of physical objects, in the space between them and inside transparent media.
Radiant flux is measured in watts per square meter.
- Spectral radiant flux: Energy per unit Time per unit normal Area per unit frequency/wavelength; it is the radiant flux differential in frequency/wavelength.
There are two possible cases:
- the flux can be arriving at the surface, in which case the spectral radiant flux is referred to as spectral irradiance;
- the flux can be leaving the surface, due to emission and|or reflection, in which case the spectral radiant flux is referred to as spectral radiant exitance.
- Radiant flux differential in solid angle: Energy per unit Time per unit normal Area per unit solid angle; it is the irradiance differential in solid angle.
Unlike the radiant flux, the definition of radiance does not distinguish between flux arriving at or leaving a surface. In fact, the formal definition of radiance (ANSI/IES 1986) states that it can be leaving, passing through or arriving at the surface.
Radiance is measured in watts per square meter per steradian.
- Spectral Radiance: radiance differential in frequency/wavelength.

\subsection*{59.09.01.04 Photometry - ElectroMagnetic Radiation as Perceived by the Human Eye}

Photometry is the science of the measurement of light, in terms of its perceived brightness to the human eye.
To pass from radiometric to photometric units: replace the prefix rad- with the lum- prefix.

- Consider an enclosure which has an arbitrary shape and which may contain several bodies within it. Its walls, which may consist of any material, are maintained at a fixed absolute temperature. The enclosure thus acts as a heat reservoir.
- All the enclosure is assumed to be at thermodynamic equilibrium.
- Let \(f_{\alpha}[\mathbf{x}, \mathbf{k}]\) be the mean number of photons per unit volume at the point \(\mathbf{x}\), with wave-vector \(\mathbf{k}\) and with Polarization specified by the index \(\alpha\).
- It turns out that \(f_{\alpha}[\mathbf{x}, \mathbf{k}]\) is independent of \(\mathbf{x}\) : the radiation field is homogeneous. Consider, in fact, what would happen if two identical small bodies at temperature \(T\) were placed at two different positions inside the cavity. Imagine these to be surrounded by filters which transmit only frequencies in a specified range and which transmit only radiation of a specified Polarization. Then, if the values of \(f_{\alpha}[\mathbf{x}, \mathbf{k}]\) were different at the different points, the temperature would increase, at one place, and would decrease at the other place, contrary to thermodynamics equilibrium.
- It turns out that \(f_{\alpha}[\mathbf{k}]\) is independent of the direction of \(\mathbf{k}\), but depends only on \(|\mathbf{k}|\) : the radiation field is isotropic. Suppose, in fact, that \(f_{\alpha}[\mathbf{k}]\) did depend on the direction \(\mathbf{k}\), for instance that is greater if \(\mathbf{k}\) points north than if it points east. We could again imagine that two identical small bodies at temperature \(T\) (and surrounded by the same filters as before) are introduced into the enclosure. Then the body on the north side would have more radiation incident on it and thus absorb more power than the body on the east side. This would again lead to a non permissible temperature difference being produced between these bodies.
- It turns out that \(f_{\alpha}[|\mathbf{k}|]\) is independent of the Polarization of the radiation, that is: the radiation field is un-Polarized. Suppose, in fact, that \(f_{\alpha}[|\mathbf{k}|]\) did depend on the Polarization. Then we could imagine that two identical small bodies at the temperature \(T\) are introduced side by side into the enclosure and are surrounded by filters which transmit different directions of Polarization. Hence different amounts of radiation would be incident upon these bodies, and a temperature difference would be developed between them in contradiction to the equilibrium condition.
- It turns out that \(f[|\mathbf{k}|]\) does not depend on the shape nor volume of the enclosure, nor on the material of which it is made, nor on the bodies it may contain. Consider, in fact, two different enclosures, both at the temperature \(T\), and suppose that the two functions \(f[|\mathbf{k}|]\) describing their radiation fields were different. Imagine that we connect the two enclosures through a small hole (containing a filter which transmits only radiation in a narrow frequency range about and of the specified Polarization). This would represent an equilibrium situation if both enclosures are at the same temperature. If the two functions \(f[|\mathbf{k}|]\) are different more radiation per unit time would pass from one enclosure to the other than in the opposite direction. A temperature difference would then develop between the two enclosures, in contradiction to the equilibrium condition of uniform temperature.
- At thermodynamic equilibrium, consider a closed cavity with a small body inside. The body emits radiation and radiation is continually incident upon the body which absorbs a certain fraction of it. To keep equilibrium, the absorbed power must be equal to the emitted power: Kirchhoff law.
- Imagine that the body is surrounded by a filter which absorbs completely all radiation except that, in one small element of area, it is completely transparent to radiation of one specific Polarization and of one narrow frequency range. The presence of this shield cannot affect such intrinsic parameters of the body as its emissivity or absorptivity. Nor can it, by the arguments of the preceding section, affect the nature of the radiation in the enclosure. Since the equilibrium situation can equally well exist in the presence of the shield, it follows that the energy balance must hold for this particular element of area, Polarization, and frequency range.

\section*{© - QUOTE}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....||Adapted from.|
Thermal radiation is important in thermometry, since it is the basis of precisely measured high temperatures above the range of gas thermometers. As an example of the effects of thermal radiation, consider placing your hand near a hot object and experiencing the warming that occurs before the object is touched. Evidently, heat is transmitted across the space between the object and the hand. That this can occur without the intervention of matter is proved by the fact that heat comes to us from the Sun across 150 million km of empty space. By conduction and convection, the transfer of heat is accomplished through the medium of matter, and heat can be transferred in this way only as far as matter extends or can itself be transported. By the process of radiation, however, heat is separated from its association with matter and can travel as radiation as far as empty space extends.
A substance may be stimulated to emit ElectroMagnetic radiation in a number of ways, including:
1. An electric conductor carrying a high-frequency alternating current emits radio waves.
2. Electrons oscillating in a magnetron-type tube emit microwaves.
3. A hot solid or liquid emits thermal radiation, that is, infrared radiation.
4. A gas experiencing an electric discharge may emit visible or ultraviolet radiation.
5. A substance exposed to ultraviolet radiation from an external source may emit fluorescent light.
6. A metal target bombarded by high-speed electrons emits x-rays.
7. A substance whose atoms are radioactive may emit gamma rays.

All these radiations are ElectroMagnetic waves, differing only in frequency (or wavelength) in vacuum.
We shall be concerned in this section only with thermal radiation, namely, the radiation emitted by a solid or a liquid by virtue of its temperature. In these cases, the close-packing of the atoms generate a continuous ElectroMagnetic spectrum.
The radiation characteristics of gases require special treatment. In fact, for gases, the spectrum is typically the emission/absorption discrete spectrum of the gas molecules. In this section, we shall assume that gases are transparent to thermal radiation.
When thermal radiation is dispersed by a prism or Interference|Diffraction Grating, one obtains a continuous spectrum of the visible spectrum and the invisible infrared radiation. The distribution of energy among the various wavelengths is such that, at temperatures below about \(500^{\circ} \mathrm{C}\), the energy is infrared radiation; at higher temperatures, increasingly more visible light is emitted. In general, the higher the temperature of a body, the greater the total energy emitted. The loss of energy due to the emission of thermal radiation may be compensated in a variety of ways. The emitting body may be a source of energy itself, such as the sun; or, there may be a constant supply of electrical energy from the surroundings, as in the case of a lamp. Energy may be supplied also by heat conduction or by the performance of work on the emitting body. In the absence of these sources of supply, the only other way in which a body may receive energy is by the absorption of radiation from its surroundings. In the case of a body that is immersed in radiation, the internal energy of the body will remain constant when the rate at which radiant energy is emitted equals the rate at which radiant energy is absorbed; in other words, the exiting radiant power equals the incident radiant power.
Experiment shows that the radiant power leaving a body as thermal radiation depends on the temperature, on the area of the surface, and on the nature of the surface of the body. The total radiant power exiting an infinitesimal element of surface, divided by the area of that surface, is called the radiant exitance, \(\mathcal{E}\), of the body. For example, the radiant exitance of tungsten at 1000 K is \(6.46 \mathrm{~kW} / \mathrm{m}^{2}\), at 2000 K is \(236 \mathrm{~kW} / \mathrm{m}^{2}\), and at 3000 K is \(1534 \mathrm{~kW} / \mathrm{m}^{2}\).
In general, some of the radiation may be absorbed, some reflected, and some transmitted.
In general, the incident isotropic radiation of all wavelengths that is absorbed depends on the
temperature and the nature of the surface of the absorbing body.
The fraction of the total incident radiant power that is absorbed is called the absorptivity.
In thermal equilibrium, the processes of absorption and emission of radiant power are equal and opposite. So, the emissivity, equal to the absorptivity, is defined as the fraction of the power provided to a real body that is emitted through a material surface as thermal radiation, where the word total includes all wavelengths of ElectroMagnetic radiation. As a practical matter, it is easier to measure emissivity than absorptivity.
To summarize:
- radiant exitance \(\mathcal{E}\) : total radiant power emitted per unit area;
- emissivity \(\varepsilon\) : fraction of the total radiant power that is emitted as thermal radiation, equal to the absorptivity.
The emissivity depends on both the temperature and the nature of the emitting surface. The emissive nature of surfaces is revealed by comparing emissivities at the same temperature. At 300 K , when all bodies emit only infrared radiation, the emissivity of polished steel is 0.09 , rough oxidized steel is 0.81 , and ocean water is 0.96 . There are some substances, such as lampblack or carbon soot, whose emissivity is very nearly unity, that is, almost an ideal emitter.
For theoretical purposes, it is useful to conceive of an ideal substance capable either of absorbing all the thermal radiation falling on it or of emitting all the energy provided to it in the form of thermal radiation. Such a substance is called a blackbody. If a blackbody is indicated by the subscript \(b b\), we have, for the emissivity:
\[
\varepsilon_{b b}=1
\]

A very good experimental approximation to a blackbody is provided by a cavity enclosed by hightemperature opaque walls. The interior walls, which are maintained at a uniform temperature, permit thermal radiation to pass through a hole small in comparison with the dimensions of the cavity. Any radiation entering the hole is completely absorbed by the walls after repeated reflections at the walls, with only a negligible amount eventually finding its way out the hole. This is true regardless of the composition of the materials of the interior walls. The radiation emitted by the interior walls is similarly absorbed or diffusely reflected a large number of times, so that the cavity is filled with isotropic blackbody radiation.
Let us define the irradiance, \(\mathcal{J}\), as the radiant power per unit area incident upon a surface within the cavity.
Suppose a blackbody whose temperature is the same as that of the walls is introduced into the cavity. Since the temperature of the blackbody remains constant, the radiant power per unit area that is absorbed must equal the radiant power per unit area that is leaving; whence the irradiance within a cavity whose walls are at the temperature \(T\) is equal to the radiant exitance of a blackbody at the same temperature. For this reason, the radiation enclosed within a cavity is called blackbody radiation.
Such radiation, which provides standard radiation in terms of wavelengths and intensities, is a function only of temperature and is studied by allowing a small amount to escape from a small hole in the cavity. Since \(\mathcal{J}\) is independent of the materials of which the interior walls are composed, it follows that the radiant exitance of a blackbody is a function of the temperature only.
The radiant exitance of a non-blackbody depends as much on the nature of the surface as on the temperature, according to a simple law that we may derive as follows.
Suppose that a non-blackbody at the temperature \(T\), with radiant exitance \(\mathcal{E}\), and emissivity \(\varepsilon\), is introduced into a cavity whose interior walls are at the same temperature and where the irradiance is \(\mathcal{J}\) :
\[
\mathcal{E}=\varepsilon \mathcal{E}_{b b} .
\]

The radiant exitance of any body at any temperature is equal to a fraction of the radiant exitance of a blackbody at that temperature, this fraction being the emissivity at that temperature. This equation, known as Kirchhoff law and named after the German physicist, shows that the emissivity
of a body may be determined experimentally by measuring the radiant exitance of the body and dividing it by the radiant exitance of a blackbody at the same temperature.
It should be emphasized that the tabulated values of emissivity refer to the thermal radiation appropriate to the temperature listed in the temperature- range column. Thus, the emissivity of ice is 0.97 not for visible radiation, but for the long infrared waves associated with matter at \(0^{\circ} \mathrm{C}(273 \mathrm{~K})\). It should be noticed that the word "heat" has not appeared as yet. If there is a temperature difference between a body and its surroundings, then, in a given interval of time, the body loses an amount of internal energy equal to the energy radiated minus the energy absorbed, whereas the surroundings gain an amount of internal energy equal to the energy absorbed minus the energy radiated. The gain of the surroundings equals the loss of the body. The gain or loss of internal energy of the body, equal to the difference between the energy of the thermal radiation which is absorbed and that which is radiated, is called heat. This statement is in agreement with the original definition of heat, since a gain or loss of internal energy by radiation and absorption will take place only if there is a difference in temperature between a body and its surroundings. If the two temperatures are the same, there is no net gain or loss of internal energy of either the body or its surroundings, and there is, therefore, no transfer of heat.
The rate at which heat is transferred by radiation is proportional to the difference between the radiant exitance of a black-body at the two temperatures in question.
The first measurements of the heat transferred by radiation between a body and its surroundings were made by Tyndall. On the basis of these experiments, it was concluded by Stefan in 1879 that the heat radiated was proportional to the difference of the fourth powers of the absolute temperatures. This purely experimental result was later derived thermodynamically by Boltzmann, who showed that the radiant exitance of a black-body at any temperature \(T\) is equal to:
\[
\varepsilon_{b b}[T]=\sigma_{\mathrm{SB}} T^{4}
\]

This law is now known as the Stefan-Boltzmann law, and \(\sigma_{\mathrm{SB}}\) is called the Stefan-Boltzmann constant.
\[
\sigma_{\mathrm{SB}}=5.67 \cdot 10^{-8} \mathrm{Wm}^{2} \mathrm{~K}^{-4}
\]

\section*{© - QUOTE}
©|Y.A.Cengel, Introduction To Thermodynamics And Heat Transfer, 2008, McGraw-Hill, 2ndEd., ....|||
A blackbody is defined as a perfect emitter and absorber of radiation. At a specified temperature and wavelength, no surface can emit more energy than a blackbody. A blackbody absorbs all incident radiation, regardless of wavelength and direction. Also, a blackbody emits radiation energy uniformly in all directions per unit area normal to direction of emission. That is, a blackbody is a diffuse emitter. The term diffuse means independent of direction.
For a blackbody: \(\varrho=\tau=0\) and \(\alpha=1\).
The emissivity of a surface represents the ratio of the radiation emitted by the surface at a given temperature to the radiation emitted by a black-body at the same temperature.
The fraction of irradiation absorbed by the surface is called the absorptivity; the fraction reflected by the surface is called the reflectivity; and the fraction transmitted is called the transmissivity.
For opaque surfaces, \(\tau=0\). This is an important property relation since it enables us to determine both the absorptivity and reflectivity of an opaque surface by measuring either of these properties. The total hemispherical emissivity of a surface at temperature \(T\) is equal to its total hemispherical absorptivity for radiation coming from a blackbody at the same temperature. This relation, which greatly simplifies the radiation analysis, was first developed by Gustav Kirchhoff in 1860 and is now called Kirchhoff law. Note that this relation is derived under the condition that the surface temperature is equal to the temperature of the source of irradiation, and the reader is cautioned against using it when considerable difference (more than a few hundred degrees) exists between
the surface temperature and the temperature of the source of irradiation.
The form of Kirchhoff law that involves no restrictions is the spectral directional form, that is, the emissivity of a surface at a specified wavelength, direction, and temperature is always equal to its absorptivity at the same wavelength, direction, and temperature.
It is very tempting to use Kirchhoff law in radiation analysis since it enables us to determine all three properties of an opaque surface from a knowledge of only one property.
Surfaces emit radiation as well as reflect it, and thus the radiation leaving a surface consists of emitted and reflected parts. The calculation of radiation heat transfer between surfaces involves the total radiation energy streaming away from a surface, with no regard for its origin. The total radiation energy leaving a surface per unit time and per unit area is called radiosity and is denoted by \(J\).
For an opaque surface:
\[
\alpha=\varepsilon \quad \alpha+\varrho=1 \quad J=\varepsilon \mathcal{E}_{b b}+\varrho \mathcal{J}=\varepsilon \mathcal{E}_{b b}+(1-\varepsilon) \mathcal{J}
\]
where \(\varepsilon_{b b}\) is the blackbody radiant exitance of the surface and \(\mathcal{J}\) is the irradiation, the radiation energy incident on the surface per unit time per unit area.
During a radiation interaction, a surface loses energy by emitting radiation and gains energy by absorbing radiation emitted by other surfaces. A surface experiences a net gain or a net loss of energy, depending on which quantity is larger. The net rate of radiation heat transfer from a surface of surface area \(A\) is expressed as:
\[
\dot{Q}=A(\mathcal{J}-J)
\]

Consider two diffuse, grey, and opaque surfaces of arbitrary shape maintained at uniform temperatures. Recognizing that the radiosity \(J_{k}\) represents the rate of radiation leaving surface \(k\) per unit surface area and that the view factor \(F_{i j}^{*}\) represents the fraction of radiation leaving surface \(i\) that strikes surface \(j\), the net rate of radiation heat transfer from surface \(i\) to surface \(j\) can be expressed as
\[
\dot{Q}_{i j}=A_{i} F_{i j}^{\because} J_{i}-A_{j} F_{j i}^{\ddot{ }} J_{j}=A_{i} F_{i j} \ddot{ }\left(J_{i}-J_{j}\right) \quad A_{i} F_{i j}^{\ddot{ }}=A_{j} F_{j i}^{\ddot{ }}
\]

Recall Poynting theorem in § 59.06.04 - Work Energy Heat and the First Principle.

\section*{© - QUOTE}

Adapted from....?
Consider a container of volume \(V\), whose walls are maintained at temperature \(T\). The walls of the cavity, are diathermic, meaning they are in thermal contact with their surroundings, so that the temperature within the cavity may be controlled.
Suppose it has been emptied of matter by a vacuum pump. It cannot be entirely empty because the walls radiate photons into the container. Some photons scatter off the walls, with some being absorbed and new ones being emitted continually. A dynamic equilibrium exists when the average absorption and emission rates are equal. Thus, an apparently empty container actually is filled with a photon gas.

Consider an open molecular ideal gas system: in this case \(N\) is not a fixed parameter, but an additional variable: one has three independent variable and one equation of state. Unlike the molecular ideal gas, for which there are three independent variables among \(p, T, V\) and \(N\), if the number of particles is not fixed, the photon gas has just two independent, controllable variables, among \(p, T, V\) and \(N\); that is, there is a second relation linking the four variables, and \(N\) is not a parameter, but a variable.
We can envisage building a photon gas from energy stored in the container walls. Consider a container. Imagine purging it of all atoms with a vacuum pump, and then moving the piston to the left until it touches the left wall. The volume is then zero and the walls, including the piston, have temperature \(T\). Now slowly move the piston to the right, keeping the wall temperature constant using a reservoir. Photons will pour out of the walls as the volume increases, until the dynamic equilibrium described above occurs.
In this way, we mentally construct a photon gas of volume \(V\) and temperature \(T\), with average photon number \(N[T, V]\). Building the photon gas using this thought experiment can help develop an understanding of the nature of the variable particle photon gas.
- Either ElectroMagnetic waves or photons.
- EM radiation in thermal equilibrium inside a closed cavity with rigid walls kept at a fixed temperature \(T\). The photons inside the cavity are in thermal equilibrium with the cavity walls, and form ElectroMagnetic standing waves.
- The ElectroMagnetic energy density is known from Maxwell. This is the internal energy of the ElectroMagnetic field.
- Photons are continuously absorbed and emitted by/from the walls. It is by virtue of these mechanisms that the ElectroMagnetic radiation inside the container depends on the temperature of the walls.
- A key feature of the photon gas is that it has a variable particle number, \(N\). For photons, \(N\) is not conserved! The total number of photons inside the enclosure is not fixed, but depends on the temperature \(T\) of the walls.

\section*{© - QUOTE}

This observation calls our attention to the fact that in the empty cavity there exist no conserved particles to be counted by a parameter \(N\), but \(N\) is a variable.
The ElectroMagnetic radiation within the cavity is governed by a fundamental equation of the form \(\mathcal{S}=\mathcal{S}[U, V, N] \rightarrow \mathcal{S}[\ldots, \ldots]\) in which there are only two rather than three independent extensive parameters!

The equation of state depends on the energy momentum relation for the gas particle. It is different for
non-relativistic particles / relativistic particles / photons.
\[
\begin{gathered}
m=0 \Longrightarrow \varepsilon=p c \quad \varepsilon=\hbar \omega \equiv h \nu \\
u=\frac{U}{V}=\eta_{\mathrm{N}} \varepsilon \quad, \quad, \\
p V=\frac{\mathcal{U}}{3} \quad \text { internal energy for a photon gas }, \\
p V=\frac{2 U}{3} \quad \text { internal energy for a molecular mono-atomic gas }, \\
u \equiv \frac{U}{V} \propto T^{4} \Longrightarrow \mathcal{U}=\alpha V T^{4} \quad \text { internal energy (photons) }, \\
\eta_{\mathrm{N}} \propto T^{3} \Longrightarrow N=\beta V T^{3} \quad \text { number of particles (photons) }, \\
p V=\frac{\alpha}{3 \beta} N[V, T] T \quad, \\
p=\frac{\alpha T^{4}}{3} \quad \text { independent variables are: } V \text { and }(p \text { or } T),
\end{gathered}
\]
\[
\text { Energy Flux }=u c=\sigma_{\mathrm{SB}} T^{4} \quad \text { jet-like, collinear distribution }
\]
\[
\text { Energy Flux }=\frac{1}{4} u c=\sigma_{\mathrm{SB}} T^{4} \quad \text { isotropic distribution }
\]

The two equations of state are:
\[
\mathcal{U}=\frac{6 \zeta[4] \hbar c}{\pi^{2}} V\left(\frac{k_{\mathrm{B}} T}{\hbar c}\right)^{4}=\frac{\pi^{2} \hbar c}{15} V\left(\frac{k_{\mathrm{B}} T}{\hbar c}\right)^{4}
\]
and:
\[
N=\frac{2 \zeta[3]}{\pi^{2}} V\left(\frac{k_{\mathrm{B}} T}{\hbar c}\right)^{3}
\]
where:
- \(\zeta[3] \simeq 1.202\),
- \(\zeta[4]=\frac{\pi^{4}}{90}\),
are values of the zeta function.
The mean photon energy is:
\[
\begin{equation*}
\frac{U}{N}=\frac{\pi^{4}}{30 \zeta[3]} k_{\mathrm{B}} T \simeq 2.70118 k_{\mathrm{B}} T \tag{59.09.01}
\end{equation*}
\]

Notice that \(N\) is strictly a function of \(T\) and \(V\) and must not be considered an independent parameter. In fact the above relations show that everything is known as soon as one knows, for instance, \(V\) and \(T\), which are perhaps the most natural variables for an ElectroMagnetic cavity, or any other pair of variables. In other words, \(N\) cannot be chosen independently from \(V\) and \(T\). While for a molecular ideal gas you can choose \(N\) as you like, for photons, given \(T\) and \(V\), then \(N\) is given.

That is, we're dealing with an open system where the number of particles is not conserved.

\section*{© - QUOTE}
© |?|?|Adapted|

The ElectroMagnetic energy density is known from Maxwell. This is the internal energy of the ElectroMagnetic field.
A priori it depends on the position inside the cavity and linear momentum of the photons: \(\mathbf{x}\) and \(\mathbf{p}=\hbar \mathbf{k}\). The cavity dimension is assumed to be much larger than the longest wavelength of
significance in the discussion.
The energy density
\[
u \equiv u[\mathbf{x}, \mathbf{k}, \lambda, \alpha, \text { MAT, shapes, } \ldots]
\]
of ElectroMagnetic radiation is a quantity that tells you how many Joules are stored in a cubic meter of cavity. What we want to do now is to specify in which frequency ranges that energy is stored.
... but we want to continue to apply a classical thermodynamic treatment to see how far we can get. To do this, consider two containers, each in contact with thermal reservoirs at temperature \(T\) and joined to one another by a tube... Two cavities at temperature \(T\) : one is lined with soot and the other with a mirror coating. The system is allowed to come to equilibrium.
The thermal reservoirs are at the same temperature \(T\) and so we know from the second law of thermodynamics that there can be no net heat flow from either one of the bodies to the other.
- Therefore there can be no net energy flux along the tube, so that the energy flux from the soot-lined cavity along the tube from left to right must be balanced by the energy flux from the mirror-lined cavity along the tube from right to left. Equation (59.09.01.06) thus tells us that each cavity must have the same energy density. This argument can be repeated for cavities of different shape and size as well as different coatings. Hence we conclude that \(u\) is independent of shape, size, or material of the cavity.
- But maybe one cavity might have more energy density than the other at certain wavelengths, even if it has to have the same energy density overall? This is not the case, as we shall now prove.
The spectral energy density \(u_{\lambda}\) is defined as follows:
\[
\mathrm{d} E \equiv u_{\lambda} \mathrm{d} \lambda
\]
is the energy density due to those photons which have wavelengths between \(\lambda\) and \(\lambda+\mathrm{d} \lambda\). Now imagine that a filter, which only allows a narrow band of radiation at wavelength to pass, is inserted at \(\qquad\) and the system is left to come to equilibrium. The same arguments listed above apply in this case: there is no net energy flux from one cavity to the other and hence the specific internal energy within a narrow wavelength range is the same for each case. This demonstrates that the spectral internal energy density has no dependence on the material, shape, size, or nature of a cavity.
- Suppose that \(u\) were different at two positions in the enclosure, in equilibrium at temperature \(T\). Consider what would happen if two identical small bodies at temperature \(T\) were placed at these positions. Imagine these to be surrounded by filters which transmit only frequencies in the specified range and which transmit only radiation of the specified Polarization. Since different amounts of radiation would be incident on the two bodies, they would absorb different amounts of energy per unit time and their temperatures would therefore become different. This would contradict the equilibrium condition.
- The energy density is independent of the direction of \(\mathbf{k}\), but depends only its module, that is wavelength; the radiation field is therefore isotropic. Suppose that \(u\) did depend on the direction of \(\mathbf{k}\), for instance that is greater if \(\mathbf{k}\) points north than if it points east. We could again imagine that two identical small bodies at temperature \(T\) (and surrounded by the same filters as before) are introduced into the enclosure. Then the body on the north side would have more radiation incident on it and would become hotter, contradicting the equilibrium condition.
- The energy density is independent of the direction of Polarization of the radiation, that is the radiation field in the enclosure is un-Polarized. Suppose that \(u\) did depend on the direction of Polarization. Then we could imagine that two identical small bodies at the temperature \(T\) are introduced side by side into the enclosure and are surrounded by filters which transmit different directions of Polarization. Hence different amounts of radiation would be incident upon these bodies, and a temperature difference would be developed between them in contradiction to the equilibrium condition. Hence, \(u\) is independent of the Polarization.
There exists, therefore, a very close connection between the emissivity and the absorptivity a of a body. A good emitter of radiation is also a good absorber of radiation, and vice versa. This is a qualitative statement of Kirchhoff law.
Note that this statement refers only to properties of the body and is thus generally valid, even if the body is not in equilibrium; but we arrived at this conclusion by investigating the conditions which must be fulfilled to make the properties of the body consistent with a possible equilibrium situation.

The ElectroMagnetic energy density inside the cavity only depends on \(T\) and \(\lambda\).
The spectral energy density inside the cavity is thus a universal function of \(\lambda\) and \(T\) only.

Kirchhoff law,
\(\alpha_{\lambda}[T]\) specral absorpitity, dimensionless; ratio between the absorbed enery and the incident energy , , \(e_{\lambda}[T]\) spectral emissive power, \(\mathrm{Wm}^{-2} \mathrm{~m}^{-1}\); power emitted per uit area per unit wavelenght ,
\[
\frac{e_{\lambda}[T]}{\alpha_{\lambda}[T]}=\frac{c}{4 \pi} u_{\lambda}[T]
\]
states that the ratio \(e_{\lambda} / \alpha_{\lambda}\) is a universal function of \(\lambda\) and \(T\).
Therefore, if you fix \(\lambda\) and \(T\), the ratio \(e_{\lambda} / \alpha_{\lambda}\) is fixed and hence
\[
e_{\lambda} \propto \alpha_{\lambda}
\]

In other words good absorbers are good emitters and bad absorbers are bad emitters.
A better statement of Kirchhoff laws would be good absorbers at one wavelength are good emitters at the same wavelength.
A black body is an object that is defined to have \(\alpha_{\lambda}=1\) for all \(\lambda\). Kirchhoff law tells us that for this maximum value, a black body is the best possible emitter.

\section*{Planck Law}

The spectral radiance and spectral energy density of Black-Body radiation are given by the Planck function.
Spectral radiance:
\begin{tabular}{|ll|}
\(\frac{d^{4} E}{\mathrm{~d} A_{\perp} \mathrm{d} t \mathrm{~d} \Omega \mathrm{~d} \lambda} \equiv \mathcal{R}_{\lambda}^{b b}[T]=\frac{2 h c^{2}}{\lambda^{5}}\left(\frac{1}{\left(\exp \left[(h c) /\left(\lambda k_{\mathrm{B}} T\right)\right]-1\right)}\right)\) & spectral radiance; physical dimensions \(\mathrm{W} \cdot \mathrm{m}^{-2} \mathrm{~m}^{-1} \mathrm{sr}^{-1}\) \\
\(\frac{d^{4} E}{\mathrm{~d} A_{\perp} \mathrm{d} t \mathrm{~d} \Omega \mathrm{~d} \nu} \equiv \mathcal{R}_{\nu}^{b b}[T]=\frac{2 h \nu^{3}}{c^{2}}\left(\frac{1}{\left(\exp \left[(h \nu) /\left(k_{\mathrm{B}} T\right)\right]-1\right)}\right)\) & spectral radiance; physical dimensions \(\mathrm{W} \cdot \mathrm{m}^{-2} \mathrm{~Hz}^{-1} \mathrm{sr}^{-1}\) \\
\hline
\end{tabular}
The spectral energy density is:
\[
u_{\lambda}^{b b}[T]=\frac{4 \pi}{c} \mathcal{R}_{\lambda}^{b b}[T] \quad \text { spectral energy (volume) density; physical dimensions } \mathrm{J} \cdot \mathrm{~m}^{-3} \mathrm{~m}^{-1}
\]
\[
u_{\nu}^{b b}[T]=\frac{4 \pi}{c} \mathcal{R}_{\nu}^{b b}[T] \quad \text { spectral energy (volume) density; physical dimensions } \mathrm{J} \cdot \mathrm{~m}^{-3} \mathrm{~Hz}^{-1}
\]

\section*{Wien Displacement Law}

Wien displacement law gives the maximum of the Planck distribution:
\[
\begin{array}{|l|l|}
\hline \lambda_{\max } T=2.9 \cdot 10^{-3} \mathrm{~m} \cdot \mathrm{~K} & \text { for } \mathcal{R}_{\lambda}^{b b}[T] \\
\hline \nu_{\max } / T=5.9 \cdot 10^{+10} \mathrm{~Hz} / \mathrm{K} & \text { for } \mathcal{R}_{\nu}^{b b}[T] \\
\hline
\end{array},
\]

\section*{Stefan-Boltzmann Law}

Stefan-Boltzmann law provides the total energy per unit area per unit time emitted by a piece of plane surface in all directions:
\[
\frac{\mathrm{d}^{2} E}{\mathrm{~d} A \mathrm{~d} t}=\mathcal{I}_{b b}[T]=\pi \int_{0}^{+\infty} \mathcal{R}_{\lambda}^{b b}[T] \mathrm{d} \lambda=\pi \int_{0}^{+\infty} \mathcal{R}_{\nu}^{b b}[T] \mathrm{d} \nu \equiv \sigma_{\mathrm{SB}} T^{4}
\]
\[
\sigma_{\mathrm{SB}}=\frac{2 \pi^{5} k_{\mathrm{B}}^{4}}{15 c^{2} h^{3}}=5.67 \cdot 10^{-8} \mathrm{~W} \cdot \mathrm{~m}^{-2} \mathrm{~K}^{-4} \quad \text { Stefan-Boltzmann constant }
\]

\section*{One Directional Flow}
\[
\begin{gathered}
c u=\sigma_{\mathrm{SB}} T^{4} \quad \text { power per unit area }, \\
u=\frac{\sigma_{\mathrm{SB}}}{c} T^{4} \quad \text { energy density }, \\
p=u \quad \text { pressure on the cavity walls } .
\end{gathered}
\]

\section*{Omni-Directional Flow}
\[
\begin{gathered}
\frac{1}{4} c u=\sigma_{\mathrm{SB}} T^{4} \quad \text { power per unit area }, \\
u=\frac{4 \sigma_{\mathrm{SB}}}{c} T^{4} \quad \text { energy density }, \\
p=\frac{u}{3} \quad \text { pressure on the cavity walls . }
\end{gathered}
\]

\section*{Radiant Energy Emitted/received From/to a Plane Surface}
\[
E=\iiint \mathcal{R}[\mathbf{x}, \theta, \phi] \cos \theta \mathrm{d} \Omega \mathrm{~d} \mathbf{S} \mathrm{~d} t \quad \text { energy }
\]

In case \(\mathcal{R}\) is independent of direction: \(\Delta E=\pi \mathcal{R}[\mathbf{x}] \Delta \mathbf{S} \Delta t\).
Note that, in all definitions above, the area is the area perpendicular to the velocity, that is to the specific direction considered; it is the area projected along the direction, that is:
\[
\mathrm{d} \mathbf{S}_{\perp} \equiv \mathrm{d} \mathbf{S} \cos \theta \quad \theta:=\text { angle between the direction and the normal to the surface } .
\]

Read § 62.05.06 - Elements of Kinetic Theory and Transport Phenomena
59.09.03 Heat Convection

This § is referenced at pages:
[Never referenced.]
Convection is energy exchange by means of exchange of matter. Actually, while conduction and radiation can be considered fundamental processes, convection is made by conduction and radiation with moving matter as transport medium.

\section*{© - QUOTE}

A flow of liquid or gas that absorbs heat at one place and then moves to another place, where it mixes with a cooler portion of the fluid and rejects heat, is called a convection current. If the motion of the fluid is caused by a difference in density that accompanies a temperature difference, the phenomenon is called natural convection. If the fluid is made to move by the action of a pump or a fan, it is called forced convection.
Consider a fluid in contact with a flat or curved wall whose temperature is higher than that of the main body of the fluid. Although the fluid may be in notion, there is a relatively thin layer of stagnant fluid next to the wall, the thickness of the layer depending upon the character of the motion of the main body of fluid. The more turbulent the motion, the thinner the layer. Heat is transferred from the wall to the fluid by a combination of conduction through the layer and convection in the fluid.

\section*{Examples and Physical Applications}

\subsection*{59.10.01 Compression Work on a Solid/liquid}

\subsection*{59.10.02 Urto Anaelastico Di Un Contenitore Con Gas}
©|I.E.Irodov, Problems In General Physics, 1988, MIR publishers Moscow, ...Ed., ....|2.27||
Un recipiente a pareti rigide e adiabatiche contiene \(n\) moli di un gas ideale di capacità termica \(c_{V}\) e massa molecolare \(\mathcal{M}_{0}\) ed è in moto a velocità costante \(\mathbf{v}_{0}\), orizzontale. Il recipiente urta in modo totalmente anaelastico un muro rigido fermandosi.
- Determinare l'aumento di temperatura del gas contenuto nel recipiente. Si trascuri la capacità termica del recipiente.
- Determinare l'aumento di temperatura del gas contenuto nel recipiente se la capacotà termica del recipiente vale \(C_{0}\).

\section*{SOLUTION}

Essendo le pareti del recipiente rigide si ha \(\mathcal{W}=0\), ed essendo adiabatiche si ha \(Q=0\). Inoltre \(\Delta \Phi=0\). Ne segue
\[
\Delta u=-\Delta \mathcal{K}=n c_{V} \Delta T=\frac{1}{2} n \mathcal{M}_{0} v_{0}^{2}
\]

Da cui si ricava
\[
\Delta T=\frac{\mathcal{M}_{0} v_{0}^{2}}{2 c_{\mathrm{V}}}
\]

\subsection*{59.10.03 II Proiettile Che Si Conficca Nel Muro}

Un proiettile di piombo di massa \(m\) e temperatura \(T_{0}=30^{\circ} \mathrm{C}\) che viaggia orizzontalmente a velocità \(v_{0}=346 \mathrm{~ms}\) incontra una parete in cui penetra fermandosi. Supponendo che tutta l'energia meccanica dissipata vada in energia interna del proiettile determinare la temperatura finale del proiettile, \(T_{\mathrm{F}}\), e l'eventuale frazione della massa del proiettile, \(x\), che fonde in conseguenza dell'urto. Per il piombo si usino i seguenti dati: \(T_{\text {fus }}=601 \mathrm{~K}, c_{\mathrm{V}}^{\text {sol }}=0.129 \cdot 10^{3} \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}, c_{\mathrm{V}}^{\text {1iq }}=x x \cdot 10^{y y} \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1} \mathrm{e}\) \(\lambda_{\text {fus }}=24.7 \cdot 10^{3} \mathrm{~J} \mathrm{~kg}^{-1}\). Si consideri il proiettile puntiforme.

\section*{SOLUTION}

Si consideri come sistema l'insieme formato dal proiettile e dal muro. Il primo principio della termodinamica, equazione (59.05.06), si scrive
\[
\Delta \mathscr{K}+\Delta \Phi+\Delta \mathcal{U}=\mathcal{W}+Q \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+Q_{\mathrm{rad}}\right)
\]

Considerando il sistema proiettile-muro isolato termicamente \((\mathbb{Q}=0)\) ed energeticamente \((\mathcal{W}=0)\), si ha
\[
\begin{equation*}
\Delta \mathcal{K}+\Delta \mathcal{U}_{p}+\Delta \mathcal{U}_{m}=0 \tag{59.10.01}
\end{equation*}
\]

Si denoti con \(T\) la temperatura finale del piombo incognita e con \(x\) la eventuale frazione della massa del proiettile che liquefa ( \(0 \leq x \leq 1\) ). Assumendo che tutta l'energia meccanica (in questo caso
l'energia cinetica macroscopica) vada tutta in energia interna del proiettile, cioè \(\Delta \mathcal{U}_{m}=0\), si ha, a seconda del valore di \(\Delta \mathcal{U}_{p}\), l'equazione
\[
\begin{aligned}
& \Delta \mathcal{U}_{p}=-\Delta \mathcal{K}=m c_{\mathrm{V}}^{\text {sol }}\left(T-T_{0}\right) \quad \text { se } T \leq T_{\text {fus }} \quad, \\
& \Delta \mathcal{U}_{p}=-\Delta \mathcal{K}=m c_{\mathrm{V}}^{\text {sol }}\left(T_{\text {fus }}-T_{0}\right)+m x \lambda_{\text {fus }} \quad \text { se } 0 \leq x \leq 1 \quad, \\
& \Delta \mathcal{U}_{p}=-\Delta \mathcal{K}=m c_{\mathrm{V}}^{\text {sol }}\left(T_{\text {fus }}-T_{0}\right)+m \lambda_{\text {fus }}+m c_{\mathrm{V}}^{\text {liq }}\left(T-T_{\text {fus }}\right) \quad \text { se } T \leq T_{\text {ebol }} \quad,
\end{aligned}
\]

Nel primo caso si determina la temperatura finale del proiettile nel caso l'energia meccanica dissipata non sia sufficiente a far salire la temperatura fino alla temperatura di fusione. Nel secondo caso si determina la frazione della massa del proiettile che fonde, nel caso l'energia meccanica dissipata non sia sufficiente a farlo fondere tutto. Nel terzo caso si determina la temperatura finale del piombo liquido. Con i dati del problema si ha, usando la prima equazione,
\[
T-T_{0}=-\frac{\Delta \mathcal{K}}{m c_{\mathrm{V}}^{\text {sol }}}=464^{\circ} \mathrm{C}
\]
cui corrisponde una temperatura superiore a quella di fusione del piombo per cui occorre usare la seconda equazione. Dalla seconda equazione si ricava allora
\[
x=\frac{-\Delta \mathscr{K}-m c_{\mathrm{v}}^{\text {sol }}\left(T_{\text {fus }}-T_{0}\right)}{m \lambda_{\text {fus }}}=0.86
\]
che fornisce la frazione della massa del proiettile che fonde.
L'assunzione che tutta l'energia cinetica vada in energia interna del solo proiettile fornisce in ogni caso un lmiite superiiore allatemperatura finale del proiettile.

\subsection*{59.10.04 Blocco Trascinato a Velocità Costante Su Un Piano Scabro}

Un blocco rigido è trascinato a velocità costante su un piano rigido e scabro da una forza costante \(F\) parallela al piano. Determinare il bilancio energetico del blocco, del piano e del sistema complessivo. Si consideri il sistema blocco più piano isolato termicamente e che non scambi lavoro con l'esterno (eccetto quello relativo alla forza \(F\) ).

\subsection*{59.10.05 Bilancio Energetico Di Un'auto in Discesa}
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|1.15||
©|H.C.Ohanian, , ..., ..., ...Ed., ....|21.34||

Un'auto di massa \(m\) scende a motore spento lungo una discesa a pendenza costante.
1. Scrivere il bilancio energetico dell'auto se il guidatore aziona i freni in modo che la velocità dell'auto sia costante e uguale a \(v_{0}\) e supponendo che si sia raggiunta una situazione stazionaria in cui l'energia interna dell'auto è costante.
2. Scrivere il bilancio energetico dell'auto se il guidatore, partendo da uan situazione in cui l'auto scende in discesa libera, vede un semaforo in fondo alla discesa, e frena fino a fermarsi, iniziando a frenare dalla velocità \(v_{0}\) alla quota \(z_{0}\).
Si supponga che in ogni caso le ruote ruotino senza strisciare sull'asfalto.

\section*{SOLUTION}

Consideriamo come sistema l'auto nella sua intrerezza.
1. L'energia cinetica e interna sono costanti per ipotesi. Inoltre le forze esterne che agiscono sull'auto, la reazione normale della strada e la forza di attrito statico del terreno, non compiono lavoro mentre l'effetto della forza peso viene incluso nel termini di energia potenziale del sistema nei campi esterni. L'attrito dell'aria è trascurato.
Indicando con \(z\) la quota dell'auto, il primo principio della termodinamica (59.05.01) per l'auto, in condizioni stazionarie, si scrive allora:
\[
\Delta \mathcal{U}=0 \Longrightarrow \Delta \mathcal{E}=m g \Delta z=Q<0
\]

L'energia potenziale gravitazionale dell'auto viene in questo caso ceduta all'ambiente esterno sotto forma di calore in quanto, per ipotesi, l'energia interna dell'auto resta costante. Infatti il calore 2 risulta negativo.
2. Nel caso in cui il guidatore frena rallentando non è più accettabile l'ipotesi di costanza dell'energia interna. Il primo principio della termodinamica (59.05.01) per l'auto tra l'istante di inizio della frenata e lo stop completo si scrive allora
\(\Delta \mathcal{E} \equiv \Delta \mathcal{K}+\Delta \mathcal{U}+\Delta \mathcal{U}=-\frac{m v_{0}^{2}}{2}+m g \Delta z+\Delta \mathcal{U}=\mathcal{Q} \Longrightarrow \Delta \mathcal{U}-\mathcal{Q}=-\Delta \mathcal{K}-\Delta \mathcal{U}=\frac{m v_{0}^{2}}{2}+m g z_{0} \quad\),
da cui si deduce che la variazione di energia interna dell'auto più il calore \(-\mathbb{Q}\) che l'auto cede all'ambiente eguagliano l'energia meccanica totale che l'auto aveva all'inizio della frenata e che viene dunque dissipata, nel linguaggio della meccanica, in parte sotto forma di calore ceduto all'ambiente e in parte come aumento di energia interna. Non è possibile sulla sola base del primo principio della termodinamica determinare come si ripartisce tra energia interna e calore ceduto all'ambiente l'energia meccanica dissipiata. Qualitativamente si può però affermare quanto segue. Inizialmente, a freni freddi, non può esserci cessione di calore all'ambiente in quanto l temperatura è uniforme. Allora inizialmente l'energia meccanica si trasforma in energia interna dell'auto (di fatto dei freni dell'auto). Questo ha per conseguenza un aumento della temperatura dei freni che rende possibile una cessione di calore verso l'esterno. La temperatura aumenta finché la cessione di calore diventa sufficiente a dissipare l'energia meccanica che va dissipata. A questo punto si instaura una situazione stazionaria in cui l'energia interna dell'auto non varia. Si osservi che la forza di attrito statico, pur essendo quella che effettivamente decelera l'auto non compie però lavoro.
Notare che il segno di \(\mathcal{Q}\), in generale, dipende dalle condizioni: se siamo all'equatore e l'auto è appena uscita da un frigorifero inizialmente si ha comunque \(\mathcal{Q}>0\). In generale il motore di un'auto è tipicamente a temperature maggiore di quella ambiente, per cui si ha sempre una cessione di calore dal motore all'ambiente.

\subsection*{59.10.06 Bilancio Energetico Di Un Paracadutista}

Scrivere il bilancio energetico di un paracadutista in discesa.

\subsection*{59.10.07 Bilancio Energetico Di Un Fluido in Moto Stazionario}
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|§???||
Si deduca l'espressione del primo principio della termodinamica per il moto stazionario di un fluido (sistema aperto in moto stazionario). Si consideri un volume di controllo e il fluido che entra ed esce dal volume.

\section*{SOLUTION}

L'equazione del bilancio energetico per un fluido in moto stazionario (sistema aperto) è la (59.05.08):
\[
\Delta \mathrm{k}+\Delta \phi+\Delta \mathrm{h}=\mathrm{w}^{\prime}+\mathrm{q}
\]
dove h è l'entalpia per unità di massa, k l'energia cinetica macroscopica per unità di massa, \(\phi\) l'energia potenziale macroscopica per unità di massa, q il calore ricevuto per unità di massa ed w' il lavoro utile effettivo per unità di massa fatto sul sistema, ad esclusione cioè del lavoro fatto dalle forze di pressione del fluido, che è quello che realmente interessa in problemi di ingegneria. La variazione riguarda le proprietà del fluido tra due punti del condotto di flusso mentre per l'ipotesi di stazionarietà le proprietà del fluido in ogni punto non cambiano.
L'equazione fondamentale del bilancio energetico si ricava considerando il moto stazionario di un fluido in un volume di controllo fissato in cui entra il calore 2 su cui viene compiuto il lavoro totale \(\mathcal{W}\), e con variazione, tra l'uscita e l'ingresso del volume di controllo, di energia cinetica \(\Delta \mathcal{K}\), di energia potenziale associata ai campi esterni \(\Delta \Phi\), di energia interna \(\Delta \mathcal{U}\). Si consideri la massa di fluido contenuta nel volume di controllo più la massa di fluido che entrerà nel volume di controllo in un certo intervallo di tempo arbitrario fissato \(\Delta t\). Nello stesso intevallo di tempo un'uguale massa di fluido uscirà dal volume di controllo. Essendo il moto stazionario tutte le proprietà del fluido entro il volume di controllo non cambiano per cui il bilancio energetico coinvolgerà solo la differenza delle proprietà della massa di fluido che esce rispetto alla massa di fluido che entra nel volume di controllo, per la conservazione della massa. Dal primo principio della termodinamica si ha dunque
\(\Delta \mathcal{K}+\Delta \Phi+\Delta \mathcal{U}=\mathcal{W}+Q \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+Q_{\mathrm{rad}}\right) \Longrightarrow \mathcal{K}_{2}-\mathcal{K}_{1}+\Phi_{2}-\Phi_{1}+\mathcal{U}_{2}-\mathcal{U}_{1}=Q+p_{1} V_{1}-p_{2} V_{2}+\mathcal{W}^{\prime}\) avendo indicato con l'indice 1 le grandezze relative alla massa di fluido che entra nel volume di controllo in \(\Delta t\) e con l'indice 2 le grandezze relative alla massa di fluido che esce dal volume di controllo in \(\Delta t\). Si è poi indicato con \(V_{1}\) e \(V_{2}\), rispettivamente, il volume di fluido che entra e quello che esce dal volume di controllo nell'intervallo di tempo \(\Delta t\) e si è separato il lavoro fatto dalle forze di pressione sul fluido del volume di controllo dal restante lavoro \(\mathcal{W}^{\prime}\). Si ha poi
\[
\mathcal{W}^{\prime}-\mathcal{W}=p_{2} V_{2}-p_{1} V_{1}=\Delta m\left(p_{2} v_{2}-p_{1} v_{1}\right)
\]
dove si è tenuto conto che, per la conservazione della massa, la massa che entra nel volume di controllo è pari a quella che esce e avendo indicato con \(v\) i volumi specifici del fluido. Riarrangiando i termini e semplificnado la massa si perviene alla (59.05.08).

\subsection*{59.10.08 Ebollizione Dell'acqua per Agitazione}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|25.11||

Un fisico si sveglia un mattino e trova la stufa guasta. Decide allora di far bollire l'acqua per il caffè agitandola dentro un thermos. Si supponga che usi \(560 \mathrm{~cm}^{3}\) di acqua alla temperatura di \(59^{\circ} \mathrm{F}\), che capovolga ripetutamente il thermos, che ad ogni capovolgimento l'acqua cada di 35 cm e che il fisico capovolga il thermos 30 volte al minuto.
1. Trascurando ogni perdita di energia si stimi per quanto tempo il fisico deve agitare il thermos per portare ad ebollizione l'acqua.

\section*{SOLUTION}
1. 2.4 giorni

\subsection*{59.10.09 Riscaldatore Ad Energia Solare}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|25.12||
In un riscaldatore ad energia solare l'energia solare è raccolta da un collettore sul tetto di un edificio entro il quale si trovano i tubi in cui circola l'acqua. La radiazione solare entra nel collettore tramite una finestra trasparente e riscalda l'acqua nei tubi. L'acqua è poi pompata entro un serbatoio. Assumendo che l'efficienza globale del sistema sia \(20 \%\), cioè che \(80 \%\) dell'energia solare non sia utilizzata per riscaldare l'acqua, quale superficie deve avere il collettore per riscaldare 200 l di acqua da \(20^{\circ} \mathrm{C}\) a \(40^{\circ} \mathrm{C}\) in un'ora? L'intensità della luce incidente è \(700 \mathrm{~W} / \mathrm{m}^{2}\).

\subsection*{59.10.10 II Calorimetro a Flusso}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|22.14||
Un calorimetro a flusso è utilizzato per misurare il calore specifico di un liquido. Si cede calore al liquido ad un tasso noto e costante mentre questo passa entro il calorimetro e si misura la differenza di temperatura del liquido tra l'uscita e l'ingresso. Un liquido di densità \(\rho=0.85 \mathrm{~g} / \mathrm{cm}^{3}\) scorre nel calorimetro ad un flusso di \(8.2 \mathrm{~cm}^{3} / \mathrm{s}\), si cedono 250 W al fluido e la differenza di temperatura che si stabilisce in situazione stazionaria tra uscita ed ingresso vale \(15^{\circ} \mathrm{C}\).
1. Determinare il calore specifico del liquido.

\subsection*{59.10.11 Calore Specifico Dell'argento}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|25.22||
La capacità termica molare dell'argento, misurata a pressione atmosferica, varia con la temperatura, nell'intervallo tra 50 K e 100 K , secondo la relazione empirica
\[
C=0.318 T-0.00109 T^{2}-0.628
\]
dove \(C\) è espressa in \(\mathrm{J} / \mathrm{mol} \mathrm{K}\) e la temperatura \(T\) in K . Calcolare la quantità di calore necessaria ad alzare la temperatura di 316 g di argento da 50 K a 90 K . La massa molare dell'argento vale \(M=107.87 \mathrm{~g} / \mathrm{mol}\).

\subsection*{59.10.12 Adiabatic Transformations and Thermal Capacities for Ideal Gas}

Consider a quasi-static adiabatic transformation of an ideal gas. One can show that:
\[
\frac{\mathrm{d} p}{p}+\gamma[T] \frac{\mathrm{d} V}{V}=\text { constant } \quad \gamma[T] \equiv \frac{C_{\mathrm{p}}[T]}{C_{\mathrm{v}}[T]}
\]

If \(\gamma[T]\) does not depend on temperature, the equation can be integrated:
\[
p V^{\gamma}=\text { constant }
\]

In fact, for a ideal gas (and only for a ideal gas):
\[
\begin{gathered}
\mathcal{U}=\mathcal{U}[T] \quad \mathcal{H} \equiv \mathcal{U}[T]+p V=\mathcal{U}[T]+n R T, \\
\mathrm{~d} \mathfrak{U}=C_{\mathrm{v}}[T] \mathrm{d} T \quad \mathrm{~d} \mathcal{H}=C_{\mathrm{p}}[T] \mathrm{d} T, \\
C_{\mathrm{p}}[T]=C_{\mathrm{v}}[T]+n R .
\end{gathered}
\]

\subsection*{59.10.13 Heat Capacity for a Generic Polytropic Transformation for Ideal Gas}

Consider a generic polytropic transformation, \(\Gamma\), for an ideal gas.
\[
\delta Q=C_{\mathrm{v}}[T] \mathrm{d} T+p \mathrm{~d} V,
\]
\(p V^{\alpha}=\) constant \(\Longrightarrow T V^{\alpha-1}=\) constant \(\Longrightarrow \mathrm{d} T V^{\alpha-1}+(\alpha-1) T V^{\alpha-2} \mathrm{~d} V=0 \Longrightarrow-\frac{\mathrm{d} T V}{T(\alpha-1)}=\mathrm{d} V \quad\),
\[
\begin{gathered}
\delta Q=C_{\mathrm{v}}[T] \mathrm{d} T-p V \mathrm{~d} T \frac{1}{T(\alpha-1)}=C_{\mathrm{v}}[T] \mathrm{d} T-n R \mathrm{~d} T \frac{1}{(\alpha-1)}, \\
C_{C}[T]=C_{\mathrm{V}}[T]-\frac{n R}{(\alpha-1)}=n R\left(\frac{1}{(\gamma[T])}-\frac{1}{(\alpha-1)}\right) .
\end{gathered}
\]

Note that, for some transformations \((0<\alpha<\gamma)\) the thermal capacity is negative. This means that the change of temperature due to work overcomes the one due to heat.

\subsection*{59.10.14 Ciclo Termodinamico Di Un Gas Ideale}
©|I.E.Irodov, Problems In General Physics, 1988, MIR publishers Moscow, ...Ed., ....|2.32||
Un cilindro contiene \(n=2\) moli di un gas ideale a temperatura \(T_{0}=300 \mathrm{~K}\) e pressione \(p_{0}\). Il sistema viene sottoposto ad una compressione quasi-statica che riduce la pressione a \(p=p_{0} / \alpha\), con \(\alpha>1\), mantenendo il volume costante. Successivamente il sistema è sottoposto ad una espansione quasi-statica in cui la pressione esterna resta costante mentre la temperatura viene riportata al valore iniziale \(T_{0}\). Determinare il calore complessivo ceduto al sistema. Determinare il calore ceduto al sistema in ciascuna delle due trasformazioni. Discutere cosa cambia se le due trasformazioni non sono quasi-statiche

\subsection*{59.10.15 Free Expansion of Different Model Gases}

A gas, \(n\) moles, is initially in equilibrium at temperature \(T_{0}\) and volume \(V_{0}\). The gas undergoes a free expansion to a total final volume \(V\), while it is contained in a rigid and adiabatic container.

Determine the final temperature for:
1. an ideal gas;
2. a Clausius gas, explaining the energy changes;
3. a Van der Waals gas, explaining the energy changes;
4. a Dieterici gas (can you answer?);
5. a Berthelot gas(can you answer?).

If the equation for the internal energy is not known, try to assume \(\mathcal{U}[T, V, N] \propto V^{\alpha} T^{\beta} N^{\gamma}\) For the expression to be extensive one needs \(\alpha+\gamma=1\). Therefore:
\[
\begin{gathered}
\mathcal{U}[T, V, N] \propto V^{\alpha} T^{\beta} N^{\gamma} \quad \alpha+\gamma=1 \\
\Longrightarrow \Delta \mathcal{U}=0 \Longrightarrow V_{1}^{\alpha} T_{1}^{\beta} N^{\gamma}=V_{1}^{\alpha} T_{1}^{\beta} N^{\gamma} .
\end{gathered}
\]

If the equation for the internal energy is not known, we do not know the final pressure. However the pressure must decrease because the isothermal compressibility is always positive.
Note that the free expansion of a gas is a spontaneous process and irreversible process.

\subsection*{59.10.16 Stima Della Temperatura Di Equilibrio Di Un Pianeta}
©|B.W.Carroll \& D.A.Ostlie, An Introduction To Modern Astrophysics, ..., ..., 1stEd., ....|???||
In prima approssimazione si può supporre che la temperatura di un pianeta dipenda dal bilancio energetico dell'energia che riceve per irraggiamento dal Sole e di quella che emette verso lo spazio, supponendo di considerare sia il pianeta che il Sole due corpi neri. Si consideri il caso della Terra. L'energia irradiata dal Sole vale \(P_{S}=3.846 \cdot 10^{26} \mathrm{~W}\), il raggio equatoriale medio del Sole vale \(R=6.96 \cdot 10^{8} \mathrm{~m}\) e la distanza media tra la Terra e il Sole vale \(d=1.496 \cdot 10^{11} \mathrm{~m}\). Si supponga che una frazione \(a=30 \%\) (l'albedo della Terra) dell'energia che arriva sulla Terra venga riflessa e la restante assorbita.
1. Supponendo che la temperatura del pianeta sia uniforme, determinare l'espressione del valore della temperatura di equilibrio \(T\) nel caso il pianeta ruoti così velocemente che si possa considerare uniforme la temperatura su tutta la sua superficie.
2. Determinare l'espressione del valore della temperatura di equilibrio \(T\) nel caso il pianeta ruoti in modo da rivolgere sempre la stessa faccia verso il Sole.
3. Si commentino i risultati nel caso della Terra.

\subsection*{59.10.17 Scudo Termico}

Si supponga di avere due piani paralleli a piccola distanza, che si comportano come un corpo nero, a temperature \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\), con \(T_{\mathrm{H}}>T_{\mathrm{C}}\). Il flusso di energia tra i due piani è \(J=\sigma\left(T_{\mathrm{H}}^{4}-T_{\mathrm{C}}^{4}\right)\).
1. Se si inserisce un terzo piano parallelamente ai due (schermo), anche esso schematizzabile con un corpo nero, la temperatura di questo raggiungerà un valore intermedio, \(T_{x}\). Determinare \(T_{x}\) in funzione di \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\) e dimostrare che il flusso di energia viene dimezzato dall'inserimento del terzo piano.
2. Si generalizzi il risultato al caso in cui si inseriscono \(N\) piani indipendenti.
3. Si supponga che lo schermo sia opaco \((\tau=0)\) e abbia riflettività \(\varrho\). Determinare \(T_{x}\) in funzione di \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\) calcolare il flusso di energia dopo l'inserimento del terzo piano.
Quello descritto è il principio dello scudo termico usato per ridurre la trasmissione di calore per irraggiamento.

\section*{SOLUTION}

Il piano intermedio riceve un flusso \(J=\sigma\left(T_{\mathrm{H}}^{4}\right)\) da parte del piano più caldo e un flusso \(J=\sigma\left(T_{\mathrm{C}}^{4}\right)\) da parte del piano più freddo. E cederà due flussi \(J=\sigma\left(T_{x}^{4}\right)\) verso entrambi i piani. La condizione di equilibrio termico del piano intermedio fornisce dunque
\[
T_{x}^{4}=\frac{T_{\mathrm{H}}^{4}+T_{\mathrm{C}}^{4}}{2}
\]

Da questo si deduce che il flusso netto di calore risulta dimezzato.
\[
J=\sigma\left(T_{\mathrm{H}}^{4}-T_{x}^{4}\right)=\sigma\left(T_{x}^{4}-T_{\mathrm{C}}^{4}\right)=\sigma \frac{T_{\mathrm{H}}^{4}-T_{\mathrm{C}}^{4}}{2}
\]

Nel caso di inserimento di \(N\) scudi termici (corpi neri) il flusso risulta ridotto di un fattore \(N+1\)
\[
J^{\prime}=J /(N+1)
\]

Se lo scudo ha reflectivity \(\varrho\), la temperatura di equilibrio non cambia, mentre il flusso di calore viene moltplicato per un fattore \(1-\varrho\).

\subsection*{59.10.18 Cooling of the Earth}

A material made of radioactive nuclides may increase its temperature due to conversion of intrinsic particle energy (where particles are nuclei) into internal kinetic energy.
It is though that the cooling of the Earth is slowed down by this process of conversion of intrinsic unstable nuclei energy into internal kinetic energy which tends to increase the temperature.

\subsection*{59.10.19 Greenhouse Effect}

The greenhouse effect is presented as an example of the consequences of the wavelength dependence of radiation properties.

\subsection*{59.10.20 Flusso Di Calore Tra Due Sfere Concentriche}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|25.61||

Si consideri un oggetto sferico a simmetria sferica. Assumendo il coefficiente di conduzione termica \(k\) costante si dimostri che il flusso di calore in direzione radiale tra due sfere concentriche di raggio rispettivamente \(r_{1}, r_{2}\) con \(r_{1}<r_{2}\) e temperatura \(T_{1}, T_{2}\) è dato da
\[
\begin{equation*}
J=\frac{4 \pi k r_{1} r_{2}\left(T_{1}-T_{2}\right)}{r_{2}-r_{1}} \tag{59.10.02}
\end{equation*}
\]

\subsection*{59.10.21 Espansioni Quasi-Statica E Non Di Un Gas Ideale}

Un cilindro con pistone senza attrito contiene \(V_{0}=1 \mathrm{ft}^{3}\) di un gas perfetto alla pressione di 200psia \(\left(1 \mathrm{psia}=1 \mathrm{lbf} / \mathrm{in}^{2}=6.895 \cdot 10^{3} a\right)\). Il pistone è tenuto fermo da una forza esterna. Il fondo del cilindro ha la parete diatermica ed è a contatto con un serbatoio di temperatura.
- Si calcoli il lavoro fatto nel caso la forza esterna sia diminuita gradualmente (trasformaizone quasistatica) fino a che il volume aumenta di un fattore \(\alpha>1\).
- Si calcoli il lavoro fatto nel caso il modulo della forza esterna sia bruscamente diminuito dello stesso fattore \(\alpha\) (trasformaizone non quasi-statica).

\section*{SOLUTION}

Si definisca il gas come sistema.
- Nel caso la forza esterna venga diminuita gradualmente (trasformazione quasi-statica) il lavoro fatto sul sistema dall'ambiente vale
\[
\mathcal{W}^{\prime}=-\mathcal{W}_{g}^{\prime}=-\int_{V_{0}}^{V} p \mathrm{~d} V=-p_{0} V_{0} \log \left[\frac{V}{V_{0}}\right]=-p_{0} V_{0} \log [\alpha]<0
\]

Il lavoro fatto dall'ambiente sul gas è negativo cioè il gas fa lavoro espandendosi. Si noti che, essendo la trasformazione quasi-statica, il lavoro può essere calcolato indifferentemente usando le variabili di stato del sistema o le variabili relative all'ambiente. Si ha poi \(V=\alpha V_{0}\) e quindi, essendo la temperatura costante, \(\alpha p=p_{0}\).
- Se il modulo della forza esterna viene diminuito bruscamente di un fattore \(\alpha\) il processo non è quasi-statico e il lavoro può solo essere calcolato usando le variabili relative all'ambiente. Lo stato finale, raggiunto dopo una fase transitoria più o meno lunga che non sappiamo descrivere, è lo stesso che se la trasformazione è quasi-statica in quanto la temperatura finale è la stessa (per il contatto termico con il serbatoio di temperatura) e la pressione finale anche. Dopo una fase transitoria il sistema si porterà nello stesso stato finale del caso precedente. La forza esterna applicata al pistone durante l'espansione è costante e vale \(A p_{0} / \alpha\) dove \(A\) è l'area del pistone. Ne segue
\[
\mathcal{W}^{\prime \prime}=-p_{0} V_{0}\left(\frac{\alpha-1}{\alpha}\right)<0
\]

Si noti che è sempre
\[
\left|w^{\prime \prime}\right|<\left|w^{\prime}\right|
\]
cioè il lavoro fatto dall'ambiente sul sistema nel caso non quasi-statico, in valore asoluto, è minore di quello nel caso quasi-statico; ovvero, il lavoro fatto dal sistema nel caso non quasi-statico, in valore asoluto,è minore che nel caso quasi-statico.

\subsection*{59.10.22 Flusso Di Calore Attraverso Un Muro}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|25.46||
Si stimi la quantità di calore che viene ceduta all'ambiente esterno in un freddo giorno d'inverno attraverso un muro di mattoni di lunghezza 6.2 m e altezza 3.8 m e spessore 32 cm se la temperatura interna vale \(26^{\circ} \mathrm{C}\) e quella esterna vale \(-18^{\circ} \mathrm{C}\). Si assuma per la conduttività termica del muro il valore \(0.74 \mathrm{~W} / \mathrm{m}\) K.

\subsection*{59.10.23 Flusso Di Calore Attraverso Una Parete Composta}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|§ 25.7E6 25.52||
Si consideri una parete composta formata da due lastre di materiale differente poste a contatto. Le lastre hanno sezione \(A\), spessore \(L_{1}\) ed \(L_{2}\) e conduttività termica \(k_{1}\) e \(k_{2}\). Le temperature delle due pareti esterne sono \(T_{1}\) e \(T_{2}\) con \(T_{2}>T_{1}\).
1. Determinare il flusso di calore \(H\) che si instaura in regime stazionario attraverso la parete composta.
2. Determinare la temperatura \(T_{x}\) che si determina alla superficie di contatto delle due lastre.
3. Generalizzare il risultato la caso di \(n\) lastre di spessore \(L_{j}\) e conducibilità termica \(k_{j}\) con \(j=1, \ldots n\).

\section*{SOLUTION}
1. \(H=A\left(T_{2}-T_{1}\right) /\left(L_{1} / k_{1}+L_{2} / k_{2}\right)\);
2. \(T_{x}=\left(R_{1} T_{1}+R_{2} T_{2}\right) /\left(T_{1}+T_{2}\right)\) con \(R_{j} \equiv L_{j} / k_{j}\);
3. \(H=A\left(T_{2}-T_{1}\right) /\left(\sum_{j} R_{j}\right)\).

\subsection*{59.10.24 Finestre a Doppio Vetro}

Si consideri una rotaia d'acciaio di sezione uniforme \(A=20 \mathrm{~cm}^{2}\) che a riposo e alla temperatura ambiente \(T_{0}=20^{\circ} \mathrm{C}\) ha lunghezza \(L_{0}=12 \mathrm{~m}\).
1. Di quanto varia la lunghezza della rotaia per variazioni stagionali di temperatura \(\Delta T \simeq 50^{\circ} \mathrm{C}\) ?
2. Quale è la forza che esercita la rotaia se la temperatura varia di \(\Delta T=25^{\circ} \mathrm{C}\) e la rotaia è mantenuta a lunghezza costante \(L_{0}\). Si consideri la rotaia come una sbarra elastica ideale e si assuma per l'acciaio \(\alpha=11 \cdot 10^{-6 \circ} \mathrm{C}^{-1}\) ed \(Y=2 \cdot 10^{11} \mathrm{~N} / \mathrm{m}^{2}\).
3. The tension in a wire is increased quasi-statically and isothermally. If the length, cross-sectional area, and isothermal Young modulus of the wire remain practically constant, calculate the work.
59.10.27 Enthalpy of Formation of Water
©|D.V.Schroeder, Thermal Physics, 1999, Addison-Wesley, ...Ed., ....|Introduction to thermal physics - § \(1 \mid\) Adapted from|
Consider the chemical reaction in which hydrogen and oxygen gas combine to form liquid water. For each mole of water produced, \(\Delta \mathcal{H}=-286 \mathrm{~kJ}\), referred to as the enthalpy of formation of water, because water is being formed out of elemental constituents in their most stable states. The numerical values provided by data tables usually assume that both the reactants and the product are at room temperature and atmospheric pressure. If one mole of hydrogen burns, then \(-\Delta \mathcal{H}\) is the amount of heat produced. Nearly all of this energy comes from the thermal and chemical energy of the molecules themselves, but a small amount comes from work done by the atmosphere as it collapses to fill the space left behind by the consumed gases.

\section*{Introduction}

The main goal of this section is to relate the path functions \(d Q\) and \(d \mathcal{W}\) to state functions, in order to exploit the path-independence of state functions; this is accomplished by introducing entropy.

\section*{© - QUOTE}
J.P.Ansermet et al.

We realise now that temperature (and pressure) cannot be the only thermodynamic variable that characterises thermal processes. The melting process of an ice cube suggests the need to introduce a thermodynamic quantity that is different from temperature (and pressure). It is indeed clear that an ice cube needs heat for it to melt. However, the melting occurs at a fixed temperature (and pressure).
Thus, a variable different than temperature needs to be used to characterise this process.
The first principle alone does not explain why some phenomena conserve the energy and can happen, while others conserve the energy but do not happen, such as:
- when two bodies at different temperatures are put in contact, the temperatures are equalized and never happens that the temperature difference increase (thermal irreversibility);
- free expansion of a gas in vacuum is never seen to go backward, even if the laws of mechanics are time-reversible and no mechanical law forbids it (mechanical irreversibility);
- a piece of paper can burn, but paper is never seen to be recreated from its ashes (chemical irreversibility), that is no Phoenix.
We need something more than the first principle to understand why such processes only appear to be unidirectional in time, while all fundamental laws of macroscopic physics (basically ElectroMagnetism and gravitation) are invariant under time-reversal.

\section*{© - QUOTE}

Vladislav Ĉápek and Daniel P. Sheehan
The second law has more common formulations than any other physical law.
Despite, or perhaps because of, its fundamental importance, no single formulation has risen to dominance. This is a reflection of its many facets and applications, its protean nature, its colorful and confused history, but also its many unresolved foundational issues.
Formulations can be categorized roughly into five categories, depending on whether they involve: device and process impossibilities; engines; equilibrium; entropy; or mathematical sets and spaces. We will now consider twenty-one standard (and non-standard) formulations of the second law. This survey is by no means exhaustive.
Carnot theorem is occasionally but not widely cited as the second law. Usually it is deduced from the Kelvin-Planck or Clausius statements.
All natural processes are irreversible. Irreversibility is an essential feature of natural processes and it is the essential thermodynamic characteristic defining the direction of time; e.g., omelettes do not spontaneously unscramble; redwood trees do not un-grow; broken Ming vases do not reassemble; the dead do not come back to life. An irreversible process is, by definition, not quasi-static (reversible); it cannot be undone without additional irreversible changes to the universe. Irreversibility is so undeniably observed as an essential behavior of the physical world that it is put forward by numerous authors in second law statements.
In many thermodynamic texts, natural and irreversible are equated, in which case this formulation is tautological; however, as a reminder of the essential content of the law, it is unsurpassed. In fact, it is so deeply understood by most scientists as to be superfluous.

The macroscopic properties of an isolated non-static system eventually assume static values.
Gyftopolous and Beretta - Among all the states of a system with given values of energy, the amounts of constituents and the parameters, there is one and only one stable equilibrium state. Moreover, starting from any state of a system it is always possible to reach a stable equilibrium state with arbitrary specified values of amounts of constituents and parameters by means of a reversible weight process.
One can distinguish between stable and unstable static (or equilibrium) states, depending on whether they persist over time intervals significant for some particular purpose in hand. For instance, to say "Diamonds are forever" is to assume much. Diamond is a metastable state of carbon under everyday conditions; at elevated temperatures it reverts to graphite. In a large enough vacuum, graphite will evaporate into a vapor of carbon atoms and they, in turn, will thermally ionize into a plasma of electrons and ions. After \(\approx 10^{33}\) years, the protons might decay, leaving a tenuous soup of electrons, positrons, photons, and neutrinos. Which of these is a stable equilibrium? None or each, depending on the time scale and environment of interest. By definition, a stable static state is one that can change only if its surroundings change, but still, time is a consideration. To a large degree, equilibrium is a matter of taste, time, and convenience. Gyftopoulos and Beretta emphasise one and only one stable equilibrium state. This is echoed by others, notably by Mackey who reserves this caveat for his strong form of the second law.
Gibbs - For the equilibrium of an isolated system, it is necessary and sufficient that in all possible variations of the state of the system which do not alter its energy, the variation of its entropy shall either vanish or be negative. In other words, thermodynamic equilibrium for an isolated system is the state of maximum entropy. Although Gibbs does not refer to this as a statement of the second law, per se, this maximum entropy principle conveys its essential content.
Entropy Properties - Every thermodynamic system has two properties (and perhaps others): an intensive one, absolute temperature \(T\), that may vary spatially and temporally in the system; and an extensive one, entropy \(S\). Together they satisfy the following three conditions:
1. The entropy change \(\mathrm{d} \delta\) during time interval \(\mathrm{d} t\) is the sum of: entropy flow through the boundary of the system \(\mathrm{d} \delta_{e}\) and entropy production within the system, \(\mathrm{d} \delta_{i}\); that is, \(\mathrm{d} \delta=\mathrm{d} \delta_{e}+\mathrm{d} \delta_{i}\).
2. Heat flux (not matter flux) through a boundary at uniform temperature \(T\) results in entropy change \(\mathrm{d} \delta_{e}=\delta Q / T\).
3. For reversible processes within the system, \(\mathrm{d} \delta_{i}=0\), while for irreversible processes, \(\mathrm{d} \delta_{i}>0\). This version is a starting point for some approaches to irreversible thermodynamics.
In addition to academic formulations there are also many folksy aphorisms that capture aspects of the law. Many are catchphrases for more formal statements. Although loathe to admit it, most of these are used as primary rules of thumb by working scientists. Most are anonymous; when possible, we try to identify them with academic forms. Among these are:
- Disorder tends to increase, (Clausius, Planck).
- Heat goes from hot to cold, (Clausius).
- There are no perfect heat engines, (Carnot).
- There are no perfect refrigerators, (Clausius).
- Murphy Law (and corollary), (Murphy 1947).

I- If anything can go wrong it will.
- Situations tend to progress from bad to worse.
- A mess expands to fill the space available.
- The only way to deal with a can of worms is to find a bigger can.
- Laws of Poker in Hell:
- Poker exists in Hell. (Zeroth Law)
- You can't win. (First Law)
- You can't break even. (Second Law)
- You can't leave the game. (Third Law)
- Messes don't go away by themselves. (Mom)
- Perpetual motion machines are impossible. (Nearly everyone)

The discovery of thermodynamic entropy as a state function is one of the triumphs of nineteenthcentury theoretical physics. Inasmuch as the second law is one of the central laws of nature, its handmaiden - entropy - is one of the most central physical concepts. It can pertain to almost any system with more than a few particles, thereby subsuming nearly everything in the universe from nuclei to super-clusters of galaxies.
Roughly, entropy is a quantitative macroscopic measure of microscopic disorder. It is the only major physical quantity predicated and reliant upon wholesale ignorance of the system it describes. This approach is simultaneously its greatest strength and its Achilles heel.
A working-man summary of standard properties can be extracted from Gyftopoulous and Beretta. Classical entropy must:
- be well defined for every system and state;
- be invariant for any reversible adiabatic process and increase for any irreversible adiabatic process;
- be additive and sub-additive for all systems, subsystems and states;
- be non-negative, and vanish for all states described by classical mechanics;
- have one and only one state corresponding to the largest value of entropy;
- be such that graphs of entropy versus energy for stable equilibria are smooth and concave; and
- reduce to relations that have been established experimentally.

There is no completely satisfactory definition of entropy. To some degree, every definition is predicated on physical ignorance of the system it describes and, therefore, must rely on powerful ad-hoc assumptions to close the explanatory gap. These limit their scopes of validity. Let us review a few examples. The Boltzmann-Gibbs entropy assumes equal a priori probability either of phase space or ensemble space. While this is a reasonable assumption for simple equilibrium systems like the ideal gas and Lorentz gas, it is known to fail for large classes of systems, especially at disequilibrium; the molecular chaos ansatz is similarly suspect. It is not known what the necessary conditions are for ergodicity. The thermodynamic limit, which is presumed or necessary for most quantum and classical thermodynamic formalisms, on its face cannot be completely realistic, particularly since it ignores boundary conditions that are known to be pivotal for many thermodynamic behaviors. Extensivity, also presumed for most entropies, is ostensibly violated by systems that exhibit long-range order and fields. These include systems from nuclei up to the largest scale structures of the universe. Information entropies are hobbled by lack of general definitions of order, disorder and complexity. Finally, as it is deduced from thermodynamics, the notion of entropy is critically dependent of the presumed validity of the second law. Among
the many foundational issues thwarting a general definition of physical entropy, none is more urgent than extending entropy into the non-equilibrium regime. After all, changes in the world are primarily irreversible nonequilibrium processes, but even the most basic nonequilibrium properties, like transport coefficients, cannot be reliably predicted in general.

The first principle, among other things, has provided unification of the concepts of work and heat, showing they are both a mean to exchange energy. However, there was an important difference between work and heat: work is an exchange of energy related to the macroscopic Force|Torque exerted on the system, while heat is an energy exchange that can exist in the absence of any macroscopic Force|Torque. The second principle emphasizes and clarifies precisely this difference.
So, let us ask whether there is a way to directly relate the path functions, work and heat, to some other state functions, in addition to combining the two through the first law. In fact, we have two path functions, but so far, only one relation to a state function: a second one is needed.
For the quasi-static work caused by a volume change, we know that, although the work depends on path, division of the work by the pressure gives a change in a state function, the volume. In other words, the reciprocal pressure is an integrating factor that converts work into an exact differential.
We should look for a similar integrating factor for heat.

The second law of thermodynamics. First is the definition of the entropy, which relates a path function to a new state function. For closed systems:
\[
\mathrm{d} \delta \equiv \frac{\delta Q_{R}}{T} \quad \text { with } \Omega_{R} \text { the heat receive on any reversible path } .
\]

The second part prescribes the observed limits on the directions of adiabatic processes in closed systems (i.e., it identifies those states that are accessible and inaccessible by adiabatic processes):
- \(\mathrm{d} S>0\), for irreversible adiabatic changes of state;
- \(\mathrm{d} \delta=0\), for reversible adiabatic changes of state;
- dS \(<0\), for changes of state that cannot be realized adiabatically.

The second part of the second law divides a state diagram into three parts (a line and two areas), as illustrated on the \(T S\) diagram in Figure 2.9. We emphasize that the second law (2.3.7) does not preclude the system entropy from decreasing; in fact, the entropy must decrease whenever heat is removed from a system during a work-free process. Let us compare the second law (2.3.7) with the first law (2.2.4): the first law asserts that energy is a conserved quantity, but in contrast, the second law asserts that entropy may not be conserved.
Entropy is created during irreversible processes.

Conservation of mass and energy, by themselves, admit as possibilities phenomena which are not observed in nature: we need another axiom.
In fact, a variety of phenomena which may satisfy mass and energy conservation, but are not observed in nature. Some include:
- water running uphill without an external assist;
- \(\mathrm{CO}_{2}\) and \(\mathrm{H}_{2} \mathrm{O}\) reacting spontaneously to form \(\mathrm{CH}_{4}\) and \(\mathrm{O}_{2}\);
- air separating into its constituents spontaneously.

Let us summarize some more reasons for studying the second law:
- it predicts the direction in time of processes;
- it aids in determining equilibrium conditions;
- it allows one to determine peak performance of practical devices;
- it enables one to frame analysis of the factors which inhibit the realization of peak performance;
- it allows a rational definition of the absolute temperature scale;
- it has implications beyond engineering in physics, philosophy, economics, computer science, etc..
Second law of thermodynamics: The entropy of an isolated system can never decrease with time. This definition begs the question, what is entropy? Let us loosely define it here as a measure of the so-called randomness (or disorder) of a system, with high randomness corresponding to high entropy. Low randomness or low disorder often corresponds to low entropy.
Interpreted in another way, structure or order requires energy input to be realized, while over time, without continued maintenance, structure and order decay. The formulation of the second law we adopt will be robust enough to prevent us from predicting water to run uphill, methane to spontaneously form from carbon dioxide and water, or air to separate into its constituents. It will also be seen to be an important principle for predicting the optimal behavior of a wide variety of engineering devices. All that said, it should be noted that the equivalence of entropy with disorder, while useful and common, is likely not universal. Certainly Wright characterizes it as "a highly contentious opinion" and discusses counter-examples, especially as related to molecular level phenomena. Wright arguments are reinforced by Styer, who concludes that the notion of "entropy as disorder" be used only in conjunction with the notion of "entropy as freedom." Freedom here is to be interpreted as the ability to acquire a variety of states: if only one state is available, freedom is severely restricted, and entropy is low; if many states are available, freedom is widespread, and entropy is high. Both terms, "disorder" and "freedom" are shown by Styer to have alternate interpretations which render both imperfect metaphors for entropy.
Second law of thermodynamics: "Heat cannot, of itself, pass from a colder to a hotter body."
Second law of thermodynamics: It is impossible for any system to operate in a thermodynamic cycle and deliver a net amount of work to its surroundings while receiving an energy transfer by heat from a single thermal reservoir.
In informal language, the Kelvin-Planck statement says: you can turn all the work into heat, but you cannot turn all the heat into work.
We shall find it useful to have in hand definitions for so-called reversible and irreversible processes. Let us take
- Reversible process: A process in which it is possible to return both the system and surroundings to their original states.
- Irreversible process: a process in which it is impossible to return both the system and surroundings to their original states.
Now, it may be possible to restore the system to its original state but not the surroundings (or the surroundings to its original state but not the system). Such a process is irreversible. We shall often study reversible processes as they represent an ideal of the most we can ever hope to achieve. Some common engineering idealizations of reversible processes include frictionless motion and ideal inviscid flow. Now, everything in the real world deviates from the ideal.
The informal statement of the Kelvin-Planck version of the second law is that you cannot turn all the heat into work. Now, an engineer often wants to harvest as much as possible of the thermal energy of combustion and convert it into mechanical energy. Kelvin-Planck simply says we cannot have it all. But it lets us have some! In fact if we only harvest a portion of the thermal energy for work and reject the rest in the form of thermal energy, we can satisfy the second law.

Now, recall we previewed the idea of thermal efficiency, \(\eta\) :
\[
\eta \equiv \frac{\text { what you want }}{\text { what you pay for }}
\]

It is possible to prove the following corollary to the Kelvin-Planck statement:
\[
\eta_{\text {irreversible }} \leq \eta_{\text {reversible }}
\]
for cycles operating between the same thermal reservoirs.
And there is a second corollary, applicable for two different cycles, both reversible, and both operating between the same thermal reservoirs:
\[
\eta_{\text {reversible;1 }}=\eta_{\text {reversible;2 }}
\]

The second corollary to the Kelvin-Planck statement holds that all reversible engines operating between the same thermal reservoirs have the same efficiency. This is independent of any details of the cycle or the materials involved. This implies that the thermal efficiency, should depend only on the character of the reservoirs involved But, a thermal reservoir is uniquely defined by its temperature. - Editor's note. Specifically, we will define \(\eta\) in terms of what we will call the temperature of the reservoir. This is the classical macroscopic interpretation of temperature. Later statistical theories give it the additional interpretation as a measure of the average translational kinetic energy of molecules of the system. But that is not our approach here! Now, we might suppose that this new thermodynamic property, temperature, should somehow be a measure of how much heat is transferred from one reservoir to another. Moreover, each reservoir will have its own temperature. The hot reservoir will have temperature \(T_{\mathrm{H}}\); the cold reservoir will have temperature \(T_{\mathrm{C}}\). So we are then saying that
\[
\eta \equiv f\left[T_{\mathrm{H}}, T_{\mathrm{C}}\right]
\]

As of yet, this functional form is unspecified. Substituting this form into our earlier equation we get
\[
f\left[T_{\mathrm{H}}, T_{\mathrm{C}}\right]=1-\frac{\left|Q_{\mathrm{L}}\right|}{\left|Q_{\mathrm{H}}\right|}
\]

This can only be true if \(\left|\mathfrak{Q}_{\mathrm{L}}\right|\) and \(\left|\mathfrak{Q}_{\mathrm{H}}\right|\) have some relation to \(T_{\mathrm{C}}\) and \(T_{\mathrm{H}}\). So let us propose a useful definition. We insist that our temperatures take the form of that for a Carnot cycle
\[
\frac{T_{\mathrm{H}}}{T_{\mathrm{C}}} \equiv \frac{\left|Q_{\mathrm{L}}\right|}{\left|Q_{\mathrm{H}}\right|}
\]

This is just a definition that cannot be argued. Its utility will be seen as its justification, but nothing more. It is valid only in the context of a Carnot cycle, and not for other cycles. Our logic train is that we observe heat engines, such as steam engines seen by Carnot in the early 1800s, doing work as a result of heat transfers. That effect, work, must have a cause. And we are going to assert that the cause is affiliated with a temperature difference.

Conversion of Work Into Heat and Vice-Versa
}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 6.1||

\section*{© - QUOTE}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 6.1||
When two stones are rubbed together under water, the work done against the force of friction is transformed into internal energy tending to produce a rise of temperature of the stones. As soon as the temperature of the stones rises above that of the surrounding water, however, there is heating of the water. If the mass of water is large enough, then there will be no appreciable rise of temperature, and the water can be regarded as a heat reservoir, as discussed in Sec. 4.10.
Since the state of the stones is the same at the end of the process as at the beginning, the net result of the process is merely the conversion of mechanical work into heat. Similarly, when an electric current is maintained in a resistor immersed either in running water or in a very large mass of water, there is also a conversion of electrical work into heat, without any change in the thermodynamic coordinates of the wire.
In general, work of any kind may be done on a system in contact with a reservoir, causing heat to leave the system without altering the state of the system. The system acts merely as an intermediary. It is apparent from the first law that the work is equal to the heat; in other words, the transformation of work into heat is accomplished with 100 percent efficiency. Moreover, this transformation can be continued indefinitely.
To study the opposite process, namely, the conversion of heat into work, we must also have at hand a process, or series of processes, by means of which such a conversion may continue indefinitely without involving any resulting changes in the state of the system. At first thought, it might appear that the isothermal expansion of an ideal gas might be a suitable process to consider in discussing the conversion of heat into work. In this case, there is no change of internal energy, since the temperature remains constant, and, therefore, heat has been converted completely into work. This process, however, involves a change of state of the gas. The volume increases and the pressure decreases until atmospheric pressure is reached, at which point the process stops. Therefore, the process of isothermal expansion cannot be used indefinitely.
Beware, the word heat is used in a sloppy way, as it would be more precise to use internal energy. - Editor's note.

\title{
Entropy and the Second Law of Thermodynamics
}
©|D.Kondepudi \& I.Prigogine, Modern Thermodynamics, 2015, J.Wiley \& Sons, 2ndEd., ....|Preface, 3.4||
Historically, several statements of the second principle of thermodynamics exist. Many of them are related to the functioning of thermal machines, as they date back to the beginning of the industrial era.
Here we use a more recent and more general approach, which immediately introduces an extensive and additive, but not conservative, state quantity, entropy.
© - QUOTE
D.Kondepudi \& I.Prigogine, Modern Thermodynamics, 2015, J.Wiley \& Sons, 2ndEd., ....

The usefulness of the concept of entropy and the Second Law depends on our ability to define entropy for a physical system in a calculable way. If the entropy of a reference or standard state is defined, then the entropy of an arbitrary state can be obtained through any reversible process that transforms the reference/standard state to the desired state. In practice \(\delta Q\) is measured with the knowledge of the heat capacity.
In a real system, the transformation from the reference/standard state to the desired state occurs in a finite time and involves irreversible processes along the path. In this process, the entropy of the system, and hence of the universe, increases. In classical thermodynamics it is assumed that every irreversible transformation that a system undergoes can also be achieved through a reversible transformation for which the equation defining the change of entropy is valid. In other words, it is assumed that every irreversible transformation that results in a certain change in the entropy of the system can be exactly reproduced through a reversible process in which the entropy change is solely due to the exchange of heat. Since the change in entropy of the system depends only on the initial and final states, the change in entropy calculated using a reversible path will be equal to the entropy change produced by the irreversible processes.
However, it must be noted that a reversible transformation from an initial state to the final state may give the right value for the change in entropy of the system, but it leaves the entropy of the universe unchanged. In a reversible process, the change in entropy of the system is compensated by the opposite change in the entropy of the exterior, leaving the entropy of the universe unchanged. On the other hand, the naturally occurring irreversible transformation increases the entropy of the universe. Some authors restrict the above assumption to transformations between equilibrium states: this restriction excludes chemical reactions, in which the transformations are often from a non-equilibrium state to an equilibrium state.

In the classical formulation of entropy it is often stated that, along the irreversible path, the entropy may not be a function of the total energy and the total volume and hence it is not defined. However, for a large class of systems, the notion of local equilibrium makes entropy a well-defined quantity, even if it is not a function of the total energy and volume.

The basis of the modern approach is the notion of local equilibrium. For a very large class of systems that are not in thermodynamic equilibrium, thermodynamic quantities such as temperature, concentration, pressure and internal energy, remain well-defined concepts locally, that is, one could meaningfully formulate a thermodynamic description of a system in which intensive variables such as temperature and pressure are well defined in each elemental volume, and extensive variables such as entropy and internal energy are replaced by their corresponding densities. Thermodynamic variables can thus be functions of position and time. This is the assumption of local equilibrium. There are, of course, systems in which this assumption is not a good approximation, but such systems are exceptional. In most hydrodynamic and chemical systems, local equilibrium is an
excellent approximation. Modern computer simulations of molecular dynamics have shown that if initially the system is in such a state that temperature is not well defined, then in a very short time (few molecular collisions) the system relaxes to a state in which temperature is a well-defined quantity.

The modern approach bridges classical thermodynamics to the modern thermodynamics of irreversible processes.
The entropy of a system can vary:
- by external operations (transfers across the border of either heat or matter);
- by internal phenomena (creation of entropy).

For any closed system, an extensive, additive and not conserved function of the thermodynamic state exists, called entropy, \(\mathcal{S}=\delta[X, Y, T]\), such that, for every transformation between two states, (1) and (2), corresponding to times \(t_{1}\) and \(t_{2}\), with \(t_{2}>t_{1}\) :
\[
\Delta \mathcal{S}=\mathcal{S}_{i}+\mathcal{S}_{e} \quad \mathcal{S}_{e} \equiv \int_{t_{1}}^{t_{2}} \frac{\delta \mathcal{Q}}{T} \quad \mathcal{S}_{i} \geq 0 \quad \text { for each subsystem: } \quad \Delta \mathcal{S}_{i} \geq 0
\]
with the following meaning.
- The received entropy, \(\mathcal{S}_{e}\), is the variation of entropy due to exchange of heat with the environment, which may be either positive or negative, and calculated by dividing each exchanged heat, \(\delta Q\), by the external temperature of the external heat reservoirs at the point of the closed surface delimiting the system where the heat enters/exits the system.
- The intensive state function \(T\) depending on the system temperature, measured as any empirical temperature, is called absolute thermodynamic temperature and it is always positive. It is a universal function of the empirical temperature of the system as recorded by measuring some arbitrary property. It constitutes a particular temperature scale, still to be defined. We can assume the system small enough that the temperature on the border can be considered uniform; otherwise, integration relates to both duration and the set of points forming the border. The thermodynamic temperature is given here without any other specification. It will be seen that it identifies with the temperature defined from the ideal gas equation \({ }^{a}\).
- The entropy created inside the system, \(\mathcal{S}_{i}\), is due to irreversible processes, with \(\mathcal{S}_{i} \geq 0\) and \(\mathcal{S}_{i}=0\) if and only if all processes internal to the systems are reversible. The term has the same sign as the time interval and therefore it physically determines the arrow of time, makes it possible to qualify real phenomena as irreversible and provides a macroscopic interpretation of the concept of entropy directly related to time.
- It is also postulated that the internal entropy production in non-negative for every subsystem, \(\Delta S_{i} \geq 0\), so that it is not allowed that a negative entropy change is compensated by a larger positive change somewhere else.
- Whenever an infinitesimal piece of system is considered, it must be remembered that it has to be small, on a macroscopic scale, but large on the microscopic scale, in such a way that the properties of infinitesimal piece can be obtained by sensible averaging over its microscopic properties.
\({ }^{\text {a }}\) Logical path. 1) Empirical arbitrary temperature. 2) Constant volume ideal gas thermometer, as a reference thernometer. 3) ideal gas thermometer as an abstraction. 4) Discovery that absolute temperature is the same as the ideal gas femperature.
The equality \(\mathcal{S}_{i}=0\) corresponds to so-called reversible limit transformations, for which the meaning of the passage of time has no influence. In these unreal cases, for which time does not exist, the balance is reduced to:
\[
\Delta \mathcal{S}=\mathcal{S}_{e} \equiv \int_{t_{1}}^{t_{2}} \frac{\delta Q_{R}}{T}
\]

However, the interest of reversible evolutions is considerable, because they make it possible to carry out the calculations of entropy changes for any real transformation in a path-independent way. In fact, experimental observations have indicated that by dividing \(\delta Q_{R}\) by a uniform and continuous function \(T[\theta]\) of an empirical temperature \(\theta\), called the absolute thermodynamic temperature, one obtains an integral which is independent of the path and may therefore be identified with a state function, entropy.
Note that, as for state functions, only differences of entropy are defined.
It is also worth emphasizing, that d \(\delta\), is the exact differential of the entropy, while \(\delta S_{i}\) and \(\delta S_{e}\) are not exact differential; only for reversible transformations \(\delta \S_{e}\) is an exact differential.
Some special cases.
- Isolated System (thermally Isolated System): \(\Delta \mathcal{S}=S_{i} \geq 0\). The principle of increase of entropy for Isolated Systems. Note that every system can be extended to a larger Isolated System by including in the definition of system all the surroundings interacting with the system.
- steady system: \(0=\Delta \mathcal{S}=\mathcal{S}_{i}+\mathcal{S}_{e}\). The entropy created is given off to the surroundings.

It is important to point-out that the inequality \(S_{i} \geq 0\) does not prevent that the entropy of open or closed systems may decrease. This happens for processes for which the change of \(S_{e}\) decreases with a larger rate, in absolute value than the rate \(S_{i}\) increases.
If the system is open the additional contribution due to matter exchange should be included.
\[
\frac{\mathrm{d} \Delta \mathcal{S}}{\mathrm{~d} t}=\frac{\mathrm{d} \delta_{e}}{\mathrm{~d} t}+\frac{\mathrm{d} \delta_{i}}{\mathrm{~d} t}=-\oiiint_{\partial \Omega} \mathbf{J}_{\mathbf{s}} \cdot \mathrm{d} \mathbf{S}+\iiint_{\Omega} \sigma_{\mathbf{s}} \cdot \mathrm{d} V
\]
with
- \(\mathbf{J}_{\mathbf{s}}\) : entropy flux, that is entropy per unit time per unit area perpendicular to the direction of \(\mathbf{J}_{\mathbf{s}}\);
- \(\sigma_{\mathrm{s}} \geq 0\) : entropy produced per unit time per unit volume.
© - QUOTE
©|D.Kondepudi \& I.Prigogine, Modern Thermodynamics, 2015, J.Wiley \& Sons, 2ndEd., ....|||
Thermodynamics as formulated in the twentieth century, what we chose to call Modern Thermodynamics is a theory of irreversible processes in contrast to nineteenth century thermodynamics, which is a theory of states (thermostatics). In the latter, thermodynamics is confined to initial and final states, the processes that transform a state are not central to the theory; they are treated as another subject, kinetics. In Modern Thermodynamics, however, entropy-increasing irreversible processes are central to the theory. In it, we find additional tools, such as the rate of entropy production, to characterize and analyse non-equilibrium systems, and new results, such as the Onsager reciprocal relations, that are applicable to the thermoelectric effect, thermal diffusion and other cross-effects. The context in which thermodynamics is being taught is rapidly changing.

The First Principle considers all transformations as equally possible, provided energy is conserved. It does not take into account the irreversibility of a process and does not not say anything on the stability of equilibriums states.

The Second Principle defines the privileged sense in which the transformations can take place and specify the equilibrium conditions of the thermodynamic state of the system. It is an empirical law established by experimental observations. It is promoted to a postulate which can be approached in different ways and give place to various statements.
60.04.01 Measuring the Entropy

Entropy cannot be measured directly. However, it can be measured indirectly from the heat capacity. The zero temperature entropy is provided by the third law of thermodynamics.
60.04.02 Thermodynamic Equilibrium From Maximum Entropy

Read § 60.13.17 - Entropy and the Second Principle, § 60.13.18 - Entropy and the Second Principle.
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 6.9||

There is irreversibility if and only if there is production of entropy.
There are several causes of irreversibility, that is production of entropy.
The first of these causes is constituted by all of the viscous or solid friction forces, whose work is systematically transformed into internal energy or heat. The second is, in the absence of external field strength, the non-uniformity of the quantities intensive in the system, for example particle density, temperature or pressure

A transformation between two states of thermodynamic equilibrium is said to be quasi-static if it occurs in such a way that the system can always be considered in thermodynamic equilibrium with the external environment during the whole transformation. In this case the macroscopic parameters of the system are always well-defined during the transformation, and temperature, pressure, chemical potential coincide with those of the external environment; moreover they are uniform across the system, as all subsystems must be in equilibrium among each other as well.
A quasi-static transformation is reversible if it can be traced back in the reverse direction so that, at the end, the system status and the status of the whole universe are unchanged. A transformation is only reversible if it is quasi-static. A quasi-static transformation is reversible if dissipative effects are missing: any form of friction/viscosity, effects of hysteresis, diffusion, deformations, etc.

\section*{Local Equilibrium for Extended Systems}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.10||
The definitions given for internal (and total) energy and enthalpy, as well as for entropy and for any other thermodynamic state function, can be extended to states of non-equilibrium. In fact, as long as temperature changes, density changes, pressure changes and changes in any other intensive thermodynamic variables, are small enough in space and slow enough over time, these can be defined and measured locally, in space and in the time.
In this case all the intensive variables (such as temperature, pressure, density ....) become functions of position and time, while extensive variables (such as internal energy, parental and entropy) are replaced by density functions (either per volume unit or mass unit) which depend on position and time.
These states are called local thermodynamic equilibrium states.
For these states, entropy is defined as the volume integral of the entropies of individual infinitesimal parts, a priori dependent on time:
\[
\mathcal{U}[t] \equiv \iiint \mathrm{u}[\mathbf{x}, t] \mathrm{d} V \quad \mathcal{H}[t] \equiv \iiint \mathrm{h}[\mathbf{x}, t] \mathrm{d} V \quad \delta[t] \equiv \iiint \mathrm{s}[\mathbf{x}, t] \mathrm{d} V
\]

The equation of state still applies, but locally, in space and time.
At the local thermodynamic equilibrium, all the intensive thermodynamic variables are homogeneous, and each arbitrary subset is in thermodynamic equilibrium with the adjacent parts.

\section*{Entropy Outside Equilibrium}

Dal primo principio della termodinamica (59.05.06) e dal secondo principio della termodinamica (60.11.08) si ricava, per una trasformazione infinitesima reversibile di un sistema \(p V T\) :
\[
\begin{equation*}
\mathrm{d} \mathfrak{U}=T \mathrm{~d} \mathcal{S}-p \mathrm{~d} V \tag{60.09.01}
\end{equation*}
\]

Essendo una relazione tra variabili di stato questa vale per una qualunque trasformazione tra due stati assegnati. Solo nel caso di trasformazione reversibile però si può interpretare \(T \mathrm{~d} S\) come il calore assorbito dal sistema \(\mathrm{e}-p \mathrm{~d} V\) come il lavoro fatto sul sistema. In generale infatti il calore e il lavoro dipendono dalla trasformazione e solo la somma del calore assorbito e del lavoro fatto ne è indipendente.
The identification of \(-p \mathrm{~d} V\) as the mechanical work and of \(T \mathrm{~d} \delta\) as the heat transfer is valid only for reversible processes.
© - QUOTE
Note that this equation was derived by assuming a reversible process. This equation can therefore be integrated for any reversible process, for during such a process the state of the substance can be identified at any point during the process. We also note that Eq. (60.09.01) deals only with state properties. Suppose we have an irreversible process taking place between the given initial and final states. The properties of a substance depend only on the state, and therefore the changes in the properties during a given change of state are the same for an irreversible process as for a reversible process. Therefore, Eq. (60.09.01) is often applied to an irreversible process between two given states, but the integration of Eq. (60.09.01) is performed along a reversible path between the same two states.

For isochoric/isobaric reversible processes:
\[
\mathrm{d} \mathcal{U}=\delta \mathrm{Q}_{\mathrm{R}}=C_{\mathrm{v}} \mathrm{~d} T \quad \text { isochoric processes } \quad, \quad \mathrm{d} \mathcal{H}=\delta \mathfrak{Q}_{\mathrm{R}}=C_{\mathrm{p}} \mathrm{~d} T \quad \text { isobaric processes }
\]

Thermal Engines - Refrigerators - Heat-Pumps
}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 6.2, 6.3, 6.4||
A thermal engine is a device which uses the heat taken from a high-temperature reservoir to let a thermodynamic system generate work while rejecting some heat into a cooler reservoir. The thermodynamic system repeatedly transforms in a thermodynamic cycle, that is any closed path with the final state coincident with the initial state.
For any system such that work is given by the generalized macroscopic coordinates \((Y, X)\) the work is represented, in the generalized work plane, \(Y-X\), by the area of the region surrounded by the path of the cycle. It is important to take into account the sign of the work, to define whether positive/negative work on the system is given by a path in the clockwise/counter-clockwise direction. For a \(p V T\) system, work on the system during a quasi-static transformation is \(\delta \mathcal{W}=-p \mathrm{~d} V\), that is, positive/negative for compression/expansion. Therefore, for a simple counter-clockwise path, the work on the system is positive. For a thermal engine to do work, therefore, the path must be clockwise.
A thermal engine working with only one thermal reservoir, that is, an engine producing work while extracting heat from only one thermal reservoir, cannot exist due to the second law, Kelvin-Planck statement.
On the contrary, it is possible to fully convert work into heat.
The next simplest thermal engine uses two thermal reservoirs at different temperatures. If the engine is a reversible one, it is a Carnot engine. By definition, a Carnot engine is a reversible engine operating between only two thermal reservoirs.

Not Everything is a Heat Engine
It must be emphasized that the discussion applies to heat engines and not otherwise. In particular, consider an electrochemical fuel cell. If it's done right, the efficiency of such a thing vastly exceeds \(1-T_{\mathrm{C}} / T_{\mathrm{H}}\). That's OK, because it's not a heat engine. Even though it takes in fuel and puts out work, it is not a heat engine. As an even more familiar example, consider a plain old electrochemical battery driving an electric motor. If it's done right, the efficiency of such a thing vastly exceeds \(1-T_{\mathrm{C}} / T_{\mathrm{H}}\).
It is not worth the trouble to try to understand such things in terms of heat, or in terms of classical thermodynamics generally. I doubt it is even possible. It is however straightforward to understand such things in terms of modern (post-1898) thermodynamics, i.e. statistical mechanics. Rather than getting bogged down trying to define heat, formalize everything in terms of energy and entropy instead. Entropy is defined in terms of probability, as a sum over states. In a battery, the state that stores the energy doesn't even have a temperature, and it isn't in equilibrium with your thermometer. Let us be clear: For a heat reservoir, its entropy is proportional to its energy, and the constant of proportionality is the inverse temperature. For a battery, that's just not true. You can stick a lot of energy into a battery without changing its temperature.

\subsection*{60.10.01 Efficiency and Coefficients of Performance}

In general:
\[
\text { efficiency } \equiv \frac{(\text { what you want })}{(\text { what you pay for })}
\]

When working with two thermal reservoirs, there are three possibilities:
- one wants to produce work: thermal engine;
- one wants to cool something, by taking heat away: refrigerator;
- one wants to heat something, by injecting heat: heater (a heat-pump).

\subsection*{60.10.02 Efficiency of a Thermal Engine}

Il rendimento di un ciclo di una macchina termica che opera tra due sorgenti di calore a temperatura \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\left(T_{\mathrm{C}}<T_{\mathrm{H}}\right)\), è definito dalla relazione
\[
\begin{equation*}
\eta \equiv \frac{|\mathcal{W}|}{\left|Q_{\mathrm{H}}\right|}=1-\frac{\left|Q_{\mathrm{C}}\right|}{\left|Q_{\mathrm{H}}\right|} \leq 1 \tag{60.10.01}
\end{equation*}
\]
dove \(\left|Q_{H}\right|>0\) è il calore assorbito dalla sorgente calda, \(\left|Q_{C}\right|>0\) è il calore ceduto alla sorgente fredda, mentre \(|\mathcal{W}|>0\) è il lavoro fatto dalla macchina termica.

Tale definizione è motivata dal fatto che in una macchina termica si cerca di massimizzare il lavoro ottenuto minimizzando il calore estratto alla sorgente calda.

Note that only two of the three \(Q_{C}, Q_{\mathrm{H}}\) and \(\mathcal{W}\) are independent quantities.
Il massimo rendimento di una macchina termica che opera tra due sorgenti a temperature \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\) \(\left(T_{\mathrm{C}}<T_{\mathrm{H}}\right)\) è quello di una macchina di Carnot ed è dato dal teorema di Carnot
\[
\eta_{\max }=1-\frac{T_{\mathrm{C}}}{T_{\mathrm{H}}}
\]

\subsection*{60.10.03 Coefficient of Performance of a Refrigerator}

Il rendimento di un ciclo di una macchina frigorifera è definito dalla relazione
\[
\begin{equation*}
\omega_{\mathrm{C}} \equiv \frac{\left|Q_{\mathrm{C}}\right|}{|\mathcal{W}|}=\frac{\left|Q_{\mathrm{H}}\right|-|\mathcal{W}|}{|\mathcal{W}|} \tag{60.10.02}
\end{equation*}
\]
dove \(\left|Q_{C}\right|>0\) è il calore assorbito dalla sorgente fredda, \(\left|Q_{H}\right|>0\) è il calore ceduto alla sorgente calda e \(|\mathcal{W}|>0\) il lavoro che occorre fare sul frigorifero. Tale definizione è basata sul fatto che in un frigorifero si cerca di minimizzare il lavoro che è necessario compiere per sottrarre una certa quantità di calore alla sorgente fredda (raffreddamento).

Note that only two of the three \(Q_{C}, Q_{\mathrm{H}}\) and \(\mathcal{W}\) are independent.
Il massimo rendimento di una macchina frigorifera che opera tra due sorgenti di calore a temperature \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\left(T_{\mathrm{C}}<T_{\mathrm{H}}\right)\) è quello di una macchina di Carnot ed è dato dal teorema di Carnot
\[
\max \left\{\omega_{\mathrm{C}}\right\}=\frac{T_{\mathrm{C}}}{T_{\mathrm{H}}-T_{\mathrm{C}}}
\]

Il rendimento di una macchina frigorifera può essere un numero maggiore o minore di uno.

\subsection*{60.10.04 Coefficient of Performance of a Heat-Pump}

Il rendimento di un ciclo di una pompa di calore è definito dalla relazione
\[
\begin{equation*}
\omega_{\mathrm{H}} \equiv \frac{\left|Q_{\mathrm{H}}\right|}{|\mathcal{W}|}=\frac{\left|Q_{\mathrm{C}}\right|+|\mathcal{W}|}{|\mathcal{W}|} \tag{60.10.03}
\end{equation*}
\]
dove \(\left|Q_{C}\right|>0\) è il calore assorbito dalla sorgente fredda, \(\left|Q_{H}\right|>0\) è il calore ceduto alla sorgente calda e \(|\mathcal{W}|>0\) il lavoro che occorre fare sulla pompa di calore. Tale definizione è basata sul fatto che in una pomap di calore si cerca di minimizzare il lavoro che è necessario compiere per fornire una certa quantità di calore alla sorgente calda (riscaldamento).
Note that only two of the three \(Q_{\mathrm{C}}, \mathrm{Q}_{\mathrm{H}}\) and \(\mathcal{W}\) are independent.
Il massimo rendimento di una pompa di calore che opera tra due sorgenti di calore a temperature \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\left(T_{\mathrm{C}}<T_{\mathrm{H}}\right)\) è quello di una macchina di Carnot ed è dato dal teorema di Carnot
\[
\max \left\{\omega_{\mathrm{H}}\right\}=\frac{T_{\mathrm{H}}}{T_{\mathrm{H}}-T_{\mathrm{C}}} .
\]

\subsection*{60.11.01 Carnot Cycle and Theorems}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 7.1, 7.2, 7.3, 7.4||
What is the maximum thermal efficiency that can be achieved by an engine operating between reservoirs, inasmuch as efficiency 1 is not allowed by the second law? What are the characteristics of such an engine? Of what effect is the nature of the working substance?

\subsection*{60.11.01.01 Single-Reservoir Thermal Engine}

A thermal engine working with a single reservoir does not exists thanks to Kelvin-Planck formulation of the first law. This can be formalized as:
\(\mathcal{W} \geq 0 \quad \Leftrightarrow \quad \mathrm{Q} \leq 0 \quad \Leftrightarrow \quad \frac{\mathrm{Q}}{\mathrm{T}} \leq 0\).

In preparation for the forthcoming generalization, for one heat reservoirs and arbitrary cycle, one has:
\[
\frac{\Omega_{1}}{T_{1}} \leq 0 \quad \text { Kelvin-Planck statement }
\]

\subsection*{60.11.01.02 Thermal Engine Operating Between Two Reservoirs}

A reversible thermal engine that works between two heat reservoirs only is said a Carnot machine. The cycle of a Carnot machine necessarily consists of two isothermal and two adiabatic transformations.
© - QUOTE
A Carnot engine operates between two reservoirs in a particularly simple way. All the absorbed heat enters the system at a constant high temperature, namely, that of the hotter reservoir. Also, all the rejected heat leaves the system at a constant low temperature, that of the cooler reservoir. Notice that the exchange of heat in the Carnot cycle is unlike the situation for idealized real engines, which need a series of reservoirs to exchange heat during the constant-volume or constant-pressure processes in order to achieve reversibility.
In the Carnot cycle, a single reservoir exchanges heat during a constant-temperature process.
Since all four processes are reversible, the Carnot engine is a reversible engine.
A Carnot machine can be based on any kind of thermodynamic system, for instance a gas, a liquid, liquid-vapor in equilibrium. Carnot discovery that the reversible engine produces maximum work amounts to the statement that its efficiency is maximum. This efficiency is independent of the properties of the engine and is a function only of the temperatures of the hot and the cold reservoirs.
Examples of Carnot cycles include:
- a gas, not necessarily and ideal gas;
- any pure substance;
- a two-phase system, such as steam and water in equilibrium;
- an photon gas.

A Carnot cycle consists of reversible processes only, and therefore it may be performed in either direction. When it is performed in a direction opposite to the one needed to produce work, the cycle is a refrigeration cycle.

\section*{Carnot Theorems}

The Carnot engine has the maximum possible efficiency but it is totally useless; in fact the isothermal processes must take place quasi-statically, that is infinitely slowly in order for the working material to remain in thermal equilibrium with the reservoirs. Therefore, the work done per cycle is finite but the cycle duration is infinite so that the engine power is zero.
Carnot theorem states that: a Carnot engine operating between two reservoirs has an efficiency, \(\eta_{\mathrm{R}}\), larger or equal than any other engine operating between the same two reservoirs, \(\eta_{\mathrm{I}}\),
\[
\eta_{\mathrm{I}} \leq \eta_{\mathrm{R}}
\]

Imagine a Carnot engine, R , and any other engine, I , which might be irreversible, working between the same two reservoirs and adjusted so that they both extract the same heat from the hot reservoir. Assume, by absurd, that \(\eta_{\mathrm{I}}>\eta_{\mathrm{R}}\) : the work produced by the engine I is therefore larger than the work produced by engine R. Now, let the engine I drive the Carnot engine R backward as a Carnot refrigerator. The engine and the refrigerator coupled together in this way constitute a self-contained machine, since all the work needed to operate the refrigerator is supplied by the engine. Actually, not all the work produced by the machine I is needed to run the Carnot engine backward, and the remaining work is free for use. Moreover, the hot reservoir is actually irrelevant, as it gives the same heat it receives. Therefore the coupled machine produces a net work by only extracting heat from the single cold reservoir, this violating Kelvin-Planck statement and the hypothesis is false. Therefore:
\[
\eta_{\mathrm{I}} \leq \eta_{\mathrm{R}}
\]

Carnot corollary to Carnot theorem states that: all Carnot engines operating between two reservoirs have the same efficiency,
\[
\eta_{\mathrm{R} 1}=\eta_{\mathrm{R} 2} \text {. }
\]

In fact, it is sufficient to do twice the reasoning used to demonstrate the theorem, by reverting the two reversible engines in turn, to obtain the result.
Carnot theorems translate into:
\[
\frac{Q_{\mathrm{H}}}{T_{\mathrm{H}}}+\frac{Q_{\mathrm{C}}}{T_{\mathrm{C}}} \leq 0
\]
with the equality that applies to reversible Carnot engines only.
In preparation for the forthcoming generalization, for two heat reservoirs and a Carnot cycle, one has:
\[
\frac{Q_{1}}{T_{1}}+\frac{Q_{2}}{T_{2}} \leq 0
\]
60.11.01.03 Thermal Engine Operating With Many Reservoirs (Discrete Set)
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.1||
It can be shown that:
\[
\sum_{i} \frac{Q_{i}}{T_{i}} \leq 0
\]

\subsection*{60.11.01.04 Thermal Engine Operating With Many Reservoirs (Continuous Set)}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.1||
© - QUOTE
©|ABejan|arg2|arg3|
The final step in this line of generalization is to consider the possibility of a continuous variation of system boundary temperature as the cycle is executed in contact with an infinite sequence of temperature reservoirs, each contributing a heat interaction of size \(\delta Q\).
© - QUOTE
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|arg2|arg3|
If we are given an arbitrary reversible process, between two states, it is always possible to find a reversible zig-zag path process between the same two states, consisting of an adiabatic process followed by an isothermal process followed by an adiabatic process, such that the heat transferred during the isothermal segment is the same as that transferred during the original process and the work done is the same as that of the original process.

It can be shown that:
\[
\oint \frac{\delta Q}{T} \leq 0
\]

\subsection*{60.11.02 Reversible Part of the Second Law and Entropy}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.1, 8.2, 8.5, 8.6||
For every reversible cyclic process during which a system reversibly absorbs the amount of heat \(\mathrm{d}_{R}\) from the environment via temperature sources with temperature \(T\) :
\[
\begin{equation*}
\oint \frac{\delta Q_{R}}{T}=0 \tag{60.11.01}
\end{equation*}
\]
\(\rightarrow\) 2584
It follows that there exists a function of the thermodynamic coordinates of a system whose value at the final state minus its value at the initial state equals
\[
\int_{1}^{2} \frac{\delta Q_{R}}{T}
\]

Si può allora introdurre la funzione di stato entropia come segue. La variazione di entropia tra due stati (1) e (2) di un sistema è definita da
\[
\begin{equation*}
\Delta \mathcal{S}_{1 \rightarrow 2} \equiv \int_{1}^{2} \frac{\delta \mathfrak{Q}_{R}}{T} \tag{60.11.02}
\end{equation*}
\]
dove l'integrale va valutato lungo una qualunque trasformazione reversibile che connette i due stati.
It must be emphasized that: any process is isoentropic if and only if it is both adiabatic and reversible. Entropy is an additive quantity.

\subsection*{60.11.02.01 TS Diagram}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.5||

\subsection*{60.11.03 Irreversible Part of the Second Law}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.6, 8.7, 8.8, 8.9||
Per ogni processo ciclico reversibile durante il quale un sistema assorbe le quantità di calore \(\delta_{R}\) dall'ambiente tramite sorgenti a temperatura \(T\) si ha
\[
\oint \frac{\delta Q_{R}}{T}=0
\]

Per ogni processo ciclico irreversibile durante il quale un sistema assorbe le quantità di calore \(\delta Q\) dall'ambiente tramite sorgenti a temperatura \(T\) si ha
\[
\begin{equation*}
{ }_{I} \oint^{\delta Q} \frac{}{T}<0 \tag{60.11.03}
\end{equation*}
\]
\(\rightarrow\) 2584
This notation of equation (60.11.03) is a symbolic one, since an irreversible path is not a succession of states of equilibrium and cannot be indicated on, say, a \(p V\) diagram.
© - QUOTE
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.8|Demonstration of (6

Per ogni processo ciclico durante il quale un sistema assorbe le quantità di calore \(\delta Q\) dall'ambiente tramite sorgenti a temperatura \(T\) si ha
\[
\begin{equation*}
\oint \frac{\delta Q}{T} \leq 0 \tag{60.11.04}
\end{equation*}
\]
dove il segno di uguaglianza vale se e solo se la trasformazione è reversibile. In equation (60.11.04):
- for a reversible transformation all the quantities refer to the system (and are equal to those of the surrounding) and the equality sign applies;
- for an irreversible cycle all the quantities refer to the auxiliary reservoirs and the inequality sign applies.

\section*{© - QUOTE}

In order to avoid misunderstandings, as to the meaning of equation (60.11.01), the equality for reversible cycles, and equation (60.11.03), the inequality for irreversible cycles, we must point out that \(T\) represents the temperature of the reservoir or auxiliary reversible engine that provides the small quantity of heat \(\delta Q\), and is not necessarily equal to the temperature \(T^{\prime}\) of the system (or part of the system) that receives the heat \(\delta Q\).
Indeed, if the cycle is irreversible, then \(T^{\prime}<T\) when \(\delta Q\) is positive, because heat cannot flow spontaneously from a cooler to a hotter body. Similarly, \(T^{\prime}>T\) when \(\delta Q\) is negative.
On the other hand, if the cycle is reversible, then we must always have \(T=T^{\prime}\), because an exchange of heat between two bodies at different temperatures is not reversible. In equation (60.11.01), we may take \(T\) to be the temperature of the reservoir or auxiliary surroundings and also the temperature of the part of the system that absorbs the heat \(\delta Q\). In equation (60.11.01), all quantities refer to the system itself, and the integral is evaluated for a closed path taken by the reversible system. In equation (60.11.04), everything refers to the auxiliary reservoirs, and the integral is evaluated for a closed range of reservoir temperatures through which, incidentally, the
irreversible system is brought back to its initial state.

\section*{© - QUOTE}

Note that reversible isoentropic implies adiabatic, and isoentropic adiabatic implies reversible. But, irreversible isoentropic is not adiabatic \(\delta Q<0\) and implies that heat flows out of the system. Of course, if the process is irreversible adiabatic, then it is not isoentropic ( \(T\) not constant) and implies that the temperature increases. Finally, if the process is isoentropic adiabatic, then it is not irreversible \(\delta Q_{R}=0\) and implies that the process is reversible.

La diseguaglianza di Clausius si può riscrivere, in termini della variazione di entropia, come
\[
\begin{equation*}
\Delta s_{1 \rightarrow 2} \geq \int_{1}^{2} \frac{\delta \mathcal{Q}}{T} \tag{60.11.05}
\end{equation*}
\]
\[
\overrightarrow{2585}
\]

The Second Law states that the change of the entropy of a system is always greater or equal to the entropy supplied to a system in heat form.
Questa fornisce il valore minimo della variazione di entropia di un sistema per una trasformazione qualunque tra due stati di equilibrio (1) e (2), \(\Delta \delta_{1 \rightarrow 2}\). La temperatura che appare nella diseguaglianza è la temperatura delle sorgenti con cui il sistema scambia le quantità di calore \(\delta Q\), atrraveros una parte della supercie chiusa che racchiude il sistema.
Equation (60.11.05) shows that, in an irreversible process, the entropy absorbed from the surroundings is less than the increase of entropy of the system: some entropy is created by the irreversible process. Therefore, the entropy of an isolated system is always increased by the occurrence of an irreversible process. Or, the total entropy of the universe is always increased when an irreversible process takes place.
Dalla diseguaglianza di Clausius (60.11.05) si può riscrivere la variazione di entropia di un sistema in una trasformazione generica tra due stati di equilibrio (1) e (2), come
\[
\begin{equation*}
\Delta \mathcal{S}_{1 \rightarrow 2}=\int_{1}^{2} \frac{\delta Q}{T}+\Delta \mathcal{S}_{0} \tag{60.11.06}
\end{equation*}
\]
che esprime la variazione di entropia come una parte dovuta allo scambio di calore con l'ambiente esterno ed una parte, \(\Delta \Omega_{0}\), che ne è indipendente con
\[
\begin{equation*}
\Delta s_{0} \geq 0 \tag{60.11.07}
\end{equation*}
\]

Si osservi che, benché il calore non sia una funzione di stato, il calore diviso la temperatura termodinamica assoluta a cui viene scambiato in una trasformazione reversibile è una funzione di stato. Di conseguenza la capacità termica divisa per la temperatura termodinamica assoluta a cui viene scambiato il calore è una funzione di stato e può perciò essere espressa in termini di funzioni di stato nella relazione (??).

\subsection*{60.11.03.01 Principle of Increase of Entropy}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.11||
Per una trasformazione reversibile:
\[
\begin{equation*}
\delta \Omega_{R}=T \mathrm{~d} \delta . \tag{60.11.08}
\end{equation*}
\]

Ne segue che l'entropia di un sistema termicamente isolato non può diminuire. Quindi l'equilibrio termodinamico di un sistema isolato è caratterizzato da entropia massima.
Il caso in cui l'entropia di un sistema termicamente isolato abbia un massimo relativo ma non assoluto in una certa configurazione è detto stato metastabile. Lo stato è stabile per piccole variazioni della configurazione ma la stabilità non è assoluta.
Un sistema termicamente isolato può esistere in uno stato di quasi-equilibrio quando il sistema non è in equilibrio termodinamico ma la trasformazione di evoluzione verso lo stato di equilibrio termodinamico è così lenta che il sistema appare in equilibrio nella scala dei tempi considerata.
© - QUOTE
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.11|Demonstration|
The entropy change of the universe was found to be positive for each of the irreversible processes treated so far. We are led to believe, therefore, that whenever an irreversible process occurs, the entropy of the universe increases. To establish this proposition, known as the entropy principle, in a general manner, it is sufficient to confine our attention to adiabatic processes only, since we have already seen that the entropy principle is true for all processes involving the irreversible transfer of heat.

\subsection*{60.11.04 Thermodynamic Temperature and Absolute Zero}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 7.5, 7.6, 7.7||
Read § 60.13.29 - Entropy and the Second Principle for the calculation of the efficiency of A Carnot engine by using a ideal gas.
The efficiency of a Carnot engine only depends od the temperature of the two reservoirs and therefore, in general:
\[
\frac{\mathfrak{Q}_{\mathrm{H}}}{\mathcal{Q}_{\mathrm{C}}}=\psi\left[T_{\mathrm{H}}, T_{\mathrm{C}}\right] \Longrightarrow \psi\left[T_{\mathrm{H}}, T_{\mathrm{C}}\right] \psi\left[T_{\mathrm{C}}, T_{\mathrm{H}}\right]=1
\]

Given three thermal reservoirs at temperatures, \(T_{1}, T_{2}, T_{3}\), with \(T_{1}<T_{2}<T_{3}\) and three Carnot engine operating between the three pairs of reservoirs, one has:
\[
\begin{gathered}
\frac{Q_{1}}{\Omega_{2}}=\psi\left[T_{1}, T_{2}\right] \\
\frac{Q_{2}}{Q_{3}}=\psi\left[T_{2}, T_{3}\right] \\
\frac{Q_{1}}{Q_{3}}=\psi\left[T_{1}, T_{3}\right] \\
\frac{Q_{1}}{Q_{3}}=\frac{Q_{1} Q_{2}}{Q_{3} Q_{2}}=\psi\left[T_{1}, T_{3}\right]=\psi\left[T_{1}, T_{2}\right] \psi\left[T_{2}, T_{3}\right] \\
\psi\left[T_{1}, T_{2}\right]=\frac{\psi\left[T_{1}, T_{3}\right]}{\psi\left[T_{2}, T_{3}\right]} \\
\psi\left[T_{1}, T_{2}\right]=\frac{\phi\left[T_{1}\right]}{\phi\left[T_{2}\right]}
\end{gathered}
\]

\subsection*{60.11.04.01 Absolute Zero and Carnot Efficiency}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 7.8||
© - QUOTE
If any system undergoes a reversible isothermal process without transfer of heat, the temperature at which this process takes place is called absolute zero. In other words, at absolute zero, an isotherm and an adiabatic are identical. It should be noticed that the definition of absolute zero holds for all substances and is, therefore, independent of the specific properties of any arbitrarily chosen substance. Furthermore, the definition is in terms of purely macroscopic concepts. No reference is made to atoms or molecules. Whether absolute zero may be achieved is a question that is left to experiment.

For a Carnot engine to have an efficiency of 1 , it is clear that the temperature of the cold reservoirs must be zero. Only when the lower reservoir is at absolute zero will all the heat be converted into work. Since nature does not provide us with a reservoir at absolute zero, a heat engine with efficiency 1 is a practical impossibility.

\section*{Examples and Physical Applications}
60.13.01 Identification of the Absolute Thermodynamic Temperature With the Ideal Gas One

Ideal gas:
\[
p V=n R T^{\star} \quad \mathcal{U}=\mathcal{U}\left[T^{\star}\right]
\]
where \(T^{\star}\) is by definition the ideal gas temperature. The ideal gas temperature has been used so far, but called simply \(T\), anticipating what will be shown here, that it is coincident with the thermodynamic absolute temperature.
Reversible transformation:
\[
\begin{gathered}
T=T\left[T^{\star}\right], \\
\mathrm{d} u=T \mathrm{~d} \mathcal{S}-\frac{n R T^{\star}}{V} \mathrm{~d} V=C_{\mathrm{V}}\left[T^{\star}\right] \mathrm{d} T^{\star}, \\
\mathrm{d} \mathcal{S}=\frac{n R T^{\star}}{V T} \mathrm{~d} V+\frac{C_{\mathrm{v}}\left[T^{\star}\right]}{T} \mathrm{~d} T^{\star}, \\
\Longrightarrow 0=\left(\frac{\partial}{\partial V}\right)_{T^{\star}} \frac{C_{\mathrm{v}}\left[T^{\star}\right]}{T}=\left(\frac{\partial}{\partial T^{\star}}\right)_{V} \frac{n R T^{\star}}{V T}, \\
\Longrightarrow T \propto T^{\star} \quad \text { and we can choose: } \quad T=T^{\star}
\end{gathered}
\]

\subsection*{60.13.02 Internal Energy and Entropy of Ideal Gases}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.4||
Equazione di stato di un gas ideale:
\[
p V=N k_{\mathrm{B}} T=n R T=\frac{m}{\mathcal{M}_{0}} R T
\]

Energia di un gas ideale:
\[
\left(\frac{\partial u}{\partial V}\right)_{T}=\left(\frac{\partial u}{\partial p}\right)_{T}=0 \Longrightarrow u=u[T] \Longrightarrow\left\{c_{\mathrm{v}}=c_{\mathrm{V}}[T] \quad c_{\mathrm{p}}=c_{\mathrm{p}}[T]\right\}
\]

La variazione di energia interna di un gas ideale è data dalla relazione
\[
\begin{equation*}
\Delta \mathcal{U}=n \int_{T_{0}}^{T} c_{\mathrm{V}}[T] \mathrm{d} T=n c_{\mathrm{V}}[\widetilde{T}]\left(T-T_{0}\right) \quad \text { for a suitable } \widetilde{T} \text { such that } T_{0} \leq \widetilde{T} \leq T \tag{60.13.01}
\end{equation*}
\]

If \(c_{\mathrm{V}}\) does not depend on temperature:
\[
\begin{equation*}
\Delta U=n c_{\mathrm{v}}\left(T-T_{0}\right) \tag{60.13.02}
\end{equation*}
\]

La variazione di entropia di un gas ideale vale: vale:
\[
\begin{equation*}
\Delta \mathcal{S}=n c_{\mathrm{V}}[\widetilde{T}] \log \left[\frac{T}{T_{0}}\right]+n R \log \left[\frac{V}{V_{0}}\right]=n c_{\mathrm{p}}[\widetilde{T}] \log \left[\frac{T}{T_{0}}\right]-n R \log \left[\frac{p}{p_{0}}\right] \quad \text { for a } \widetilde{T} \text { such that } T_{0} \leq \widetilde{T} \leq T \tag{60.13.03}
\end{equation*}
\]

\subsection*{60.13.03 Internal Energy and Entropy of Incompressible Solid or Liquid}
©|J.M.Powers, Lecture Notes On Thermodynamics, ..., ..., ...Ed., WEB - URL.|par 8.5||
Note that under most conditions encountered by in the laboratory, the internal energy can be regarded as a function of \(T\) alone for all substances.
\[
\begin{gathered}
V[p, T]=V_{0}=\text { constant } \quad \mathrm{d} V=0, \\
\mathcal{U}_{=} \mathcal{U}[T] \\
\mathrm{d} \cup=C_{\mathrm{v}}[T] \mathrm{d} T \\
\mathrm{~d} S=\frac{C_{\mathrm{v}}[T]}{T} \mathrm{~d} T
\end{gathered}
\]

Note the expression is the same as for a ideal gas at costt volume, because in both cases the internla enegy does not depedn on volume.

\subsection*{60.13.04 Compressione Reversibile E Non Di Un Gas Ideale}
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|2.12||
Un kg-mole ( \(=1 \cdot 10^{3} \mathrm{~mol}\) ) di gas ideale viene compressa da una pressione \(p_{0}=1 \mathrm{~atm}\) alla pressione \(p=10 \mathrm{~atm}\) in un sistema cilindro-pistone in modo che la temperatura iniziale e finale del gas sia la stessa, pari a \(T=127^{\circ} \mathrm{C}\). Calcolare la variazione di entropia del gas, dell'ambiente esterno e la variazione totale di entropia dell'universo se il processo è meccanicamente reversibile e l'ambiente esterno è costituito da una sorgente di calore a temperatura \(T\); se il processo è meccanicamente reversibile e l'ambiente esterno è costituito da una sorgente di calore a temperatura \(T^{\prime}=27^{\circ} \mathrm{C}\); se il processo è meccanicamente irreversibile e richiede \(\alpha=20 \%\) di lavoro in più rispetto alla compressione reversibile e l'esterno è costituito da una sorgente di calore a temperatura \(T^{\prime}\).

\section*{SOLUTION}

La variazione di entropia di un gas ideale le cui capacità termiche sono indipendenti dalla temperatura (nell'intervallo di temperatura di interesse) vale
\[
\Delta \mathcal{S}=n c_{\mathrm{V}} \log \left[\frac{T_{2}}{T_{1}}\right]+n R \log \left[\frac{V_{2}}{V_{1}}\right]
\]

Ne segue per il gas
\[
\Delta S_{g}=n R \log \left[\frac{V_{2}}{V_{1}}\right]=n R \log \left[\frac{p_{1}}{p_{2}}\right]=-19.1 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}
\]

Il gas cede calore alla sorgente esterna alla stessa temperatura del gas. La quantità di calore ricevuta dal gas vale
\[
Q=\Delta u+\mathcal{W}
\]
ma essendo la temperatura finale e iniziale del gas ideale uguali fra loro si ha \(\Delta \mathcal{U}=0\) e quindi
\[
Q=\mathcal{W}=n R T \log \left[\frac{V_{2}}{V_{1}}\right]
\]

La variazione di entropia della sorgente vale dunque
\[
\Delta \delta_{s}=\frac{-Q}{T}=-n R \log \left[\frac{V_{2}}{V_{1}}\right]=19.1 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}
\]
e
\[
\Delta S_{g}+\Delta S_{s}=0
\]
come deve essendo il processo reversibile sia dal punto di vista meccanico che termico.

Nel caso in cui la sorgente esterna sia a temperatura diversa ma la compressione ancora meccanicamente reversibile la variazione di entropia del gas non cambia essendo gli stati iniziale e finale del gas gli stessi che nel caso precedente. La stessa quantità di calore però è ora ceduta ad una sorgente a temperatura \(T^{\prime}\) la cui variazione di entropia vale dunque
\[
\Delta S_{s}^{\prime}=\frac{-Q}{T^{\prime}}=-n R \frac{T}{T^{\prime}} \log \left[\frac{V_{2}}{V_{1}}\right]=25.5 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}
\]

Ne segue
\[
\begin{equation*}
\Delta S_{g}^{\prime}+\Delta S_{s}^{\prime}=\Delta S_{g}+\Delta S_{s}^{\prime}=6.38 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}>0 \tag{60.13.04}
\end{equation*}
\]

In tale caso la variazione totale di entropia è positiva essendo lo scambio di calore con il serbatoio esterno irreversibile.
La diseguaglianza di Clausius può essere applicata al sistema gas ottenendo
\[
\Delta s_{g}=n R \log \left[\frac{V_{2}}{V_{1}}\right] \geq n R \frac{T}{T^{\prime}} \log \left[\frac{V_{2}}{V_{1}}\right]=\frac{\mathbb{Q}}{T^{\prime}}=-\Delta S_{s}^{\prime}
\]
che è soddisfatta essendo di fatto equivalente alla (60.13.04). Si noti che in questo caso la variazione di entropia del gas è sempre data da \(Q / T\).
Nel caso la compressione meccanica sia irreversibile e richieda \(\alpha=20 \%\) di lavoro in più che il caso reversibile la quantità di calore che il gas cede alla sorgente di calore vale
\[
Q=\mathcal{W}(1+\alpha)
\]

La variazione di entropia del gas è la stessa calcolata nei due casi precedenti in quanto lo stato iniziale e finale del gas sono gli stessi. La variazione di entropia della sorgente vale però ora
\[
\Delta S_{s}^{\prime}=\frac{-Q}{T^{\prime}}=-n R \frac{T}{T^{\prime}}(1+\alpha) \log \left[\frac{V_{2}}{V_{1}}\right]=30.6 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}
\]
e la variazione totale di entropia dell'universo vale
\[
\begin{equation*}
\Delta \mathrm{S}_{g}^{\prime \prime}+\Delta \mathrm{S}_{s}^{\prime \prime}=\Delta \mathrm{S}_{g}+\Delta \mathrm{S}_{s}^{\prime \prime}=11.5 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}>0 \tag{60.13.05}
\end{equation*}
\]

Si noti in questo caso che la variazione di entropia del gas non è data da \(Q / T\) perché il processo è meccanicamente irreversibile e ciò significa che è internamente irreversibile. La sorgente termica non subisce invece alcuna irreversibilità interna. L'irreversibilità connessa con lo scambio termico è infatti esterna sia al gas che al serbatoio di temperatura. Calcolando \(Q / T\) per il gas si ottiene
\[
\frac{Q}{T}=-23.0 \cdot 10^{3} \mathrm{~J} / \mathrm{kg}
\]
che rappresenta la variazione di entropia del sistema causata dallo scambio termico. Tuttavia questa non è la variazione totale di entropia del sistema gas in quanto questo subisce anche un aumento di entropia dovuto alla irreversibilità meccanica interna, che non sappiamo calcolare direttamente e che parzialmente compensa la diminuzione di entropia dovuta alla cessione di calore ed è tale che la variazione totale di entropia è quella calcolata sopra utilizzando il fatto che l'entropia è una funzione di stato. Anche in questo caso si può applicare la diseguaglianza di Clausius al sistema gas ottenendo
\[
\Delta \mathrm{S}_{g}=n R \log \left[\frac{V_{2}}{V_{1}}\right] \geq n R \frac{T}{T^{\prime}}(1+\alpha) \log \left[\frac{V_{2}}{V_{1}}\right]=\frac{Q}{T^{\prime}}=-\Delta \delta_{s}^{\prime \prime}
\]
che è soddisfatta essendo di fatto equivalente alla (60.13.05).
Il grado di irreversibilità dei processi è misurato dal valore di \(\Delta \mathcal{S}_{\text {tot }}\) ed è maggiore nel terzo caso rispetto la secondo in quanto nel terzo caso esiste, oltre alla fonte di irreversibilità del secondo processo, una fonte di irreversibilità addizionale.
60.13.05 Unit of Entropy - Entropy Generator
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|§ 8.2||

\section*{© - QUOTE}

It is instructive to calculate a unit of entropy, one joule per kelvin, in order to gain a feeling for this new variable. Consider the Joule paddle wheel apparatus. The system is one kilogram of water at room temperature, \(T\). The surroundings are the adiabatic cylindrical wall and top, the diathermic bottom in contact with a heat reservoir, also at temperature \(T\), and the paddle wheels. A slowly falling mass \(m=29.9 \mathrm{~kg}\) causes the paddle wheels to turn, so the portion of the boundary formed by the paddle wheels moves. The falling mass does work on the system, which tends to experience an increase in the temperature of the water. However, the diathermic bottom prevents the temperature from rising by removing energy from the system in the form of heat. What is the change of entropy of the water and reservoir?

If the system is water: entropy is produced by converting mechanical energy into heat given to the heat reservoir. The system water does not change its status.
If the system includes the Joule paddle wheel apparatus and the heat reservoir and anything else involved, then the system is adiabatically isolated and it is an entropy generator.

\subsection*{60.13.06 Thermalisation of Two Blocks}

\subsection*{60.13.07 Mono-Thermal Expansion of a Ideal Gas}
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|IV.2.a, IV.2.b||
A ideal gas in thermal contact with a thermal reservoir at temperature \(T_{0}\) changes its volume from \(V_{1}\) to \(V_{2}\), moving from one equilibrium state to another one. Except for the contact with the thermal reservoir, the gas is surrounded by adiabatic walls.
Whatever the process, the entropy change of the gas is determined by the initial and final states.
\[
\begin{gathered}
\Delta \mathcal{U}=0=\mathcal{W}+\mathfrak{Q} \equiv \mathcal{W}+\left(Q_{\mathrm{cnd}}+Q_{\mathrm{cnv}}+\mathfrak{Q}_{\mathrm{rad}}\right) \\
0 \leq \Delta \mathcal{S}_{\mathrm{U}}=\Delta \mathcal{S}+\Delta \mathcal{S}_{\mathrm{T}}=n R \log \left[\frac{V_{2}}{V_{1}}\right]+\frac{-Q}{T_{0}}, \\
\Longrightarrow \\
\mathcal{Q} \leq n R T_{0} \log \left[\frac{V_{2}}{V_{1}}\right] \Longrightarrow(-\mathcal{W}) \leq n R T_{0} \log \left[\frac{V_{2}}{V_{1}}\right] .
\end{gathered}
\]

Maximum work (and heat) happens for a reversible transformation. In this case, and only in this case, work can be calculated from the properties of the gas:
\[
-Q=\mathcal{W}=-n R T_{0} \log \left[\frac{V_{2}}{V_{1}}\right] \Longrightarrow \Delta s_{\mathrm{U}}=0
\]

\subsection*{60.13.08 Entropy of Mixing Between Two Ideal Gases at the Same Temperature}
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|V.2.b||

\subsection*{60.13.09 Entropy Production by a Ohmic Conductor With Steady Current}
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|V.2.g||
Consider a resistor \(R\) where a steady current \(I\) flows and heat transfers energy to the atmosphere, considered as a thermal reservoir at temperature \(T_{0}\).
\(\Delta \mathcal{S}=0 \quad\) steady state \(\Longrightarrow\) the thermodynamic state of the resistor does not change ,
\[
\begin{gather*}
\Delta \delta_{\mathrm{T}}=\frac{R I^{2} \Delta t}{T_{0}}, \\
\Delta \delta_{\mathrm{U}}=0+\frac{R I^{2} \Delta t}{T_{0}} \geq 0 \tag{60.13.06}
\end{gather*}
\]

The system resistor is a entropy producer: entropy is produced by converting electric energy into heat given to the heat reservoir atmosphere. The system resistor does not change its status.
Note that, the ambient temperature is different (smaller) than the temperature of the resistor.
Show that, in case of two resistors in parallel, instead of one, the current is divided between the resistors in such a way that the entropy production is minimum, for a fixed \(I\) from the battery.

In una giornata invernale calore viene ceduto all'ambiente esterno da un appartamento tramite le pareti ad un ritmo di \(2.5 \cdot 10^{4}\) calor/ ora. La temperatura interna alla casa è \(T_{\mathrm{I}}=21^{\circ} \mathrm{C}\) e la temperatura esterna è \(T_{e}=-5^{\circ} \mathrm{C}\).
1. Determinare la produzione di entropia per unità di tempo causata da questo processo.
60.13.16 Maximum Entropy for Isolated Systems

\subsection*{60.13.17 Entropy Maxima}

This § is referenced at pages:
[2573, 2573]
A rigid adiabatic cylindrical container has a moving diathermic wall dividing its volume into two parts of volume \(V_{1}\) and \(V_{2}\) with \(V_{0}=V_{1}+V_{2}=\) constant, with the two parts containing \(n_{1}\) and \(n_{2}\) moles at initial temperatures \(T_{1}\) and \(T_{2}\). Assume the molar heats at constant volume of the two gases, \(c_{1}\) and \(c_{2}\), are independent of the temperature.
1. The wall is left free: determine the equilibrium condition and entropy.
2. The wall is removed: determine the final state and its entropy.
3. Compare the entropies in the two cases.

Constraints:
\[
\begin{aligned}
& V_{0}=V_{1}+V_{2}=\mathrm{constant} \\
& \mathcal{U}_{0}=\mathcal{U}_{1}+\mathcal{U}_{2}=\mathrm{constant}
\end{aligned}
\]
1. Equilibrium state:
\[
\begin{gathered}
T_{1}^{\prime}=T_{2}^{\prime} \equiv T^{\star}=\frac{c_{1} n_{1} T_{1}+c_{2} n_{2} T_{2}}{c_{1} n_{1}+c_{2} n_{2}} \\
p_{1}=p_{2} \quad, \\
\frac{V_{1}^{\prime}}{n_{1}}=\frac{V_{2}^{\prime}}{n_{2}} \quad V_{1}^{\prime}=\frac{V_{0} n_{1}}{n_{1}+n_{2}} \quad V_{2}^{\prime}=\frac{V_{0} n_{2}}{n_{1}+n_{2}} \quad, \\
\Delta \mathcal{S}=n_{1} c_{1} \log \left[\frac{T^{\star}}{T_{1}}\right]+n_{2} c_{2} \log \left[\frac{T^{\star}}{T_{2}}\right]+n_{1} R \log \left[\frac{V_{1}^{\prime}}{V_{1}}\right]+n_{2} R \log \left[\frac{V_{2}^{\prime}}{V_{2}}\right] .
\end{gathered}
\]
2. Equilibrium state:
\[
\begin{gathered}
T_{1}^{\prime}=T_{2}^{\prime} \equiv T^{\star}=\frac{c_{1} n_{1} T_{1}+c_{2} n_{2} T_{2}}{c_{1} n_{1}+c_{2} n_{2}}, \\
\frac{p_{1}}{n_{1}}=\frac{p_{2}}{n_{2}} \quad, \\
V_{1}^{\prime}=V_{0} \quad V_{2}^{\prime}=V_{0} \\
\Delta \mathcal{S}=n_{1} c_{1} \log \left[\frac{T^{\star}}{T_{1}}\right]+n_{2} c_{2} \log \left[\frac{T^{\star}}{T_{2}}\right]+n_{1} R \log \left[\frac{V_{0}}{V_{1}}\right]+n_{2} R \log \left[\frac{V_{0}}{V_{2}}\right] .
\end{gathered}
\]
3. Clearly the entropy is larger in the second case as it is easy to see by comparing the two expressions. In fact, one might imagine the two operations in sequence: by removing the constraint wall, the system proceeds towards a more stable state with larger entropy.

\subsection*{60.13.18 Thermal Mechanical Chemical Balance of an Isolated System}

This § is referenced at pages:
[2573, 2573]
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|E2.8|| ©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|§ 2.5||

Un cilindro chiuso a pareti rigide e adiabatiche contiene un pistone mobile, conduttore di calore e permeabile, che divide il volume in due parti. Le due parti sono occupate rispettivamente da \(n_{1}\) ed \(n_{2}\) moli di un fluido comprimibile.

Si noti che il fluido non deve necessariamente essere un gas perfetto in quanto nessuna proprietà specifica dell'equazione di stato dei due sotto-sistemi deve essere utilizzata.
1. Determinare la relazione che esiste all'equilibrio tra le temperature \(T_{1}, T_{2}\) nei due vani del cilindro nel caso in cui il pistone sia fisso e impermeabile.
2. Determinare la relazione che esiste all'equilibrio tra le pressioni \(p_{1}, p_{2}\) e le temperature \(T_{1}, T_{2}\) nei due vani del cilindro nel caso in cui il pistone è libero di muoversi senza attrito e impermeabile.
3. Determinare la relazione che esiste all'equilibrio tra le pressioni i potenziali chimici, \(\mu_{1}, \mu_{2}\), le pressioni \(p_{1}, p_{2}\) e le temperature \(T_{1}, T_{2}\) nei due vani del cilindro nel caso in cui il pistone è libero di muoversi senza attrito ed è permeabile alle molecole dei due gas.

\section*{SOLUTION}

Il sistema complessivo è isolato termicamente (pareti adiabatiche) e meccanicamente (non scambia lavoro con l'esterno) ed è chiuso.
All'equilibrio l'entropia di un sistema termicamente isolato è massima.
Si ricava allora
\[
\mathrm{d} \mathcal{S}=\frac{\mathrm{d} \mathfrak{U}}{T}+\frac{p}{T} \mathrm{~d} V
\]

L'entropia del sistema complessivo è data dalla somma delle entropie dei due sotto-sistemi essendo l'additività dell'entropia un assunto fondamentale della termodinamica. Il differenziale dell'entropia del sistema totale vale allora
\[
\begin{equation*}
\mathrm{d} S=\mathrm{d} S_{1}+\mathrm{d} S_{2}=\frac{\mathrm{d} \mathcal{U}_{1}}{T_{1}}+\frac{p_{1}}{T_{1}} \mathrm{~d} V_{1}+\frac{\mathrm{d} \mathcal{U}_{2}}{T_{2}}+\frac{p_{2}}{T_{2}} \mathrm{~d} V_{2} \tag{60.13.07}
\end{equation*}
\]
e all'equilibrio vale zero (entropia massima).
1. Essendo i volumi dei due vani fissati i due sotto-sistemi non compiono lavoro l'uno sull'altro (se la trasformazine è reversibile si può dire: \(\mathrm{d} V_{1}=\mathrm{d} V_{2}=0\); in generale, volume fissato implica zero lavoro contro le forze di pressione). Poiché il sistema è isolato l'energia totale è costante.
\[
\mathcal{U}_{1}+\mathcal{U}_{2}=\text { constant } \Longrightarrow \mathrm{d} \mathcal{U}_{1}+\mathrm{d} \mathcal{U}_{2}=0
\]

Sostituendo nell'espressione (60.13.07) si trova
\[
\mathrm{d} \mathcal{S}=\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \mathrm{d} \mathcal{U}_{1}
\]

L'uguaglianza a zero di dS deve valere per variazioni arbitrarie di \(\mathrm{d}_{1}\). Ne segue che all'equilibrio termodinamico si ha
\[
T_{1}=T_{2}
\]

E si è ricavata la condizione di equilibrio termico dei due sotto-sistemi.
Supponendo che i due vani siano soggetti ad una differenza di temperatura piccola ma finita il sistema non è in equilibrio. Per l'evoluzione del sistema si può scrivere allora l'espressione
della variazione di entropia della trasformazione che segue
\[
\Delta \mathcal{S} \simeq\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \Delta \mathcal{U}_{1}
\]

Allora ne segue, affinche una trasfomrazione spontanea possa avvenire:
\(\Delta \mathcal{S} \geq 0 \Longrightarrow\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \Delta \mathfrak{U}_{1} \geq 0 \Longrightarrow \quad \Delta \mathcal{U}_{1}<0\) e \(\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right)\) devono avere lo stesso segno . cioè l'energia interna del sistema a temperatura maggiore diminuisce e fluisce sotto forma di calore verso il sistema a temperatura minore la cui temperatura quindi cresce. Il sistema evolve dunque verso lo stato di equilibrio termodinamico.
2. Nel caso in cui il pistone sia mobile i volumi dei due vani non sono più fissi ma lo è la somma dei due volumi \(V_{1}\) e \(V_{2}\). Ne segue che ora i vincoli al sistema sono ora due. Assumendo che la trasformazione verso l'equilibrio sia reversibile:
\[
\begin{aligned}
U_{1}+\mathfrak{U}_{2} & =\text { constant } \Longrightarrow \mathrm{d} U_{1}+\mathrm{d} \mathfrak{U}_{2}=0 \\
V_{1}+V_{2} & =\text { constant } \Longrightarrow \mathrm{d} V_{1}+\mathrm{d} V_{2}=0
\end{aligned}
\]

Sostituendo nell'espressione (60.13.07) si trova ora
\[
\mathrm{d} \delta=\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \mathrm{d} \chi_{1}+\left(\frac{p_{1}}{T_{1}}-\frac{p_{2}}{T_{2}}\right) \mathrm{d} V_{1}=0
\]

L'uguaglianza a zero di d \(\delta\) deve valere per variazioni arbitrarie di \(\mathrm{d} V_{1}\) e \(\mathrm{d} \varkappa_{1}\). Ne segue che all'equilibrio termodinamico si ha
\[
T_{1}=T_{2} \quad p_{1}=p_{2}
\]

In questo secondo caso oltre alla condizione di equilibrio termico si è ricavata pure la condizione di equilibrio meccanico tra i due sotto-sistemi.
La risposta era evidente dall'inizio essendo le due condizioni trovate le condizioni di equilibrio termico e meccanico del sistema. Tuttavia il problema mostra come tali condizioni possano essere ricavate in modo del tutto generale a partire dal Secondo Principio della Termodinamica.
3. Nel caso generale in cui i due sotto-sistemi possano scambiare pure materia
\[
\begin{aligned}
U_{1}+\mathfrak{U}_{2} & =\text { constant } \Longrightarrow \mathrm{d} U_{1}+\mathrm{d} \mathfrak{U}_{2}=0 \\
V_{1}+V_{2} & =\text { constant } \Longrightarrow \mathrm{d} V_{1}+\mathrm{d} V_{2}=0 \\
N_{1}+N_{2} & =\text { constant } \Longrightarrow \mathrm{d} N_{1}+\mathrm{d} N_{2}=0
\end{aligned}
\]
tra loro si ottiene all'equilibrio termodinamico la condizioni aggiuntiva dell'equilibrio chimico di uguaglianza dei potenziali chimici di tutte le spece \((k)\) presenti
\[
T_{1}=T_{2} \quad p_{1}=p_{2} \quad \mu_{1}^{(k)}=\mu_{2}^{(k)}
\]

Occorre sottolineare che la condizione \(\mathrm{d} \delta=0\) è solo necessaria e non sufficiente per il massimo dell'entropia e che quello che si è determinato è solo la condizione di stazionarietà dell'entropia. Occorrerebbe verificare anche che la soluzione trovata corrisponde effettivamente ad un massimo. In generale per un sistema complesso potranno esistere anche configurazioni di massimo relativo corrispondenti a stati metastabili. In tali stati il sistema è in equilibrio stabile purché non intervengano perturbazioni troppo grosse.

©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|2.13||
One mole of an ideal gas expands isothermally from \(p_{1}=2\) bar to \(p_{2}=1\) bar in the piston-and-cylinder device shown in Fig. 2-10. The device is surrounded by the atmosphere, which exerts a constant pressure of \(p_{A}=1\) bar on the outer face of the piston. Moreover, the device is always in thermal equilibrium with the atmosphere, which constitutes a heat reservoir at \(T=300 \mathrm{~K}\). During the expansion process, a frictional force is exerted on the piston and this force varies in such a way that it always almost balances the net pressure forces on the piston. Thus the piston moves very slowly and experiences negligible acceleration. The piston and cylinder are good heat conductors. Determine the entropy change of the gas, the entropy change of the atmosphere, and the total entropy change brought about by the process.

1. Mostrare come l'efficienza \(\eta\) di una macchina termica reversibile ideale che opera tra due sorgenti è legata al coefficiente di prestazione \(\omega_{\mathrm{C}}\) del frigorifero ideale ottenuto eseguendo il ciclo nel verso opposto.
2. Mostrare come l'efficienza \(\eta\) di una macchina termica reversibile ideale che opera tra due sorgenti è legata al coefficiente di prestazione \(\omega_{\mathrm{H}}\) della pomap di calore ideale ottenuta eseguendo il ciclo nel verso opposto.

\section*{SOLUTION}
1. \(\eta=1 /\left(1+\omega_{\mathrm{C}}\right)\).
2. \(\eta=\ldots\).

\subsection*{60.13.23 Macchina Di Carnot Composta}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|26.22||
In una macchina di Carnot a due stadi la quantità di calore \(\left|Q_{1}\right|\) è assorbita a temperatura \(T_{1}\), viene fatto un lavoro \(\mathcal{W}_{1}\) e si cede la quantità di calore \(\left|Q_{2}\right|\) ad un serbatoio a temperatura \(T_{2}\). Il secondo stadio assorbe il calore ceduto dal primo stadio, fa un lavoro \(\mathcal{W}_{2}\) e cede la quantità di calore \(\left|\mathfrak{Q}_{3}\right|\) ad un serbatoio a temperatura più bassa \(T_{3}\).
1. Dimostrare che l'efficienza della macchina composta è \(\eta=\left(T_{1}-T_{3}\right) / T_{1}\).

\subsection*{60.13.24 Pompa Di Calore per Riscaldamento}
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|§ 26.3E2 § 26.4E4 26.19||
Una pompa di calore è una macchina termica che, fungendo da frigorifero, sottrae calore da un serbatoio a bassa temperatura e fornisce calore ad un serbatoio a temperatura più elevata. Una pompa di calore può essere usata per riscaldare l'interno di un edificio sottraendo calore all'ambiente esterno. Si supponga che la temperatura esterna sia \(T_{e}=-10^{\circ} \mathrm{C}\), che la temperatura sia da mantenere a \(T_{\mathrm{I}}=22^{\circ} \mathrm{C}\) all'interno dell'edificio e che sia necessario fornire calore all'ambiente interno ad una potenza di 16 kW per compensare le normali dispersioni di calore. Qual'è la potenza minima che bisogna fornire alla pompa di calore per ottenere il risultato desiderato?

\section*{SOLUTION}

Il rendimento di un frigorifero è definito dalla relazione
\[
\omega_{\mathrm{C}} \equiv \frac{Q_{\mathrm{C}}}{\mathcal{W}}=\frac{Q_{\mathrm{H}}-\mathcal{W}}{\mathcal{W}}
\]
dove \(Q_{C}>0\) è il calore assorbito dalla sorgente fredda, \(Q_{\mathrm{H}}>0\) è il calore ceduto alla sorgente calda ed \(\mathcal{W}>0\) il lavoro che occorre fare sul frigorifero. Tale definizione è basata sul fatto che in un frigorifero si cerca di minimizzare il lavoro che è necessario compiere per sottrarre una certa quantità di calore al serbatoio freddo. Il massimo rendimento di una macchina frigorifera che opera tra due serbatoi a temperature \(T_{\mathrm{H}}\) e \(T_{\mathrm{C}}\left(T_{\mathrm{C}}<T_{\mathrm{H}}\right)\) è dato dal teorema di Carnot
\[
\max \omega_{\mathrm{C}}=\frac{T_{\mathrm{C}}}{T_{\mathrm{H}}-T_{\mathrm{C}}}
\]

Si noti che il rendimento di un frigorifero ideale tende all'infinito se le temperature dei due serbatoi di calore tendono a diventare uguali per cui è facile trasferire calore da un sistema freddo ad uno più caldo se la differenza di temperatura è piccola. Viceversa se, a parità di \(T_{\mathrm{H}}\), la temperatura del sistema freddo a cui si deve sottrarre calore tende allo zero assoluto il rendimento tende a zero per cui è sempre più difficile raffreddare un corpo freddo verso lo zero assoluto.
Ne segue il lavoro minimo che occorre fornire
\[
\omega=\frac{Q_{\mathrm{H}}-\mathcal{W}}{\mathcal{W}} \leq \omega_{\max } \Longrightarrow \mathcal{W} \geq \frac{Q_{\mathrm{H}}}{\omega_{\max }+1} \Longrightarrow \frac{\mathcal{W}}{\Delta t} \geq \frac{Q_{\mathrm{H}}}{\Delta t}\left(\frac{1}{\omega_{\max }+1}\right)=1.7 \mathrm{~kW}
\]
è dunque possibile fornire calore all'interno di un edificio usando un lavoro \(\left(\omega_{\max }+1\right)\) volte inferiore. Il minimo teorico calcolato sarà certamente inferiore alla richiesta di un frigorifero reale per il quale si ha tipicamente \(\omega \approx 5\). In ogni caso la pompa di calore permette di riscaldare la casa con una potenza molto inferiore a quella necessaria a fornire lo stesso calore alla casa trasformando in calore tutto il lavoro fatto su una macchina termica, ad esempio un riscaldatore elettrico. In questo caso infatti il calore fornito all'ambiente va pagato tutto in termini di lavoro speso. Un frigorifero è dunque un'ottimo riscaldatore di ambiente, in quanto fornendo un certo lavoro si cede all'ambiente una quantità di calore superiore. La stessa pompa di calore può poi essere usata
come condizionatore quando la temperatura esterna è superiore a quella interna a differenza di un riscaldatore elettrico.

\subsection*{60.13.25 Otto Cycle}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|2.6||
©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|26.6||
Il ciclo di un motore a quattro tempi a benzina può essere idealizzato con il ciclo Otto standard. Questo è un ciclo reversibile consistente in due trasformazioni isocore e due adiabatiche di aria, in quanto l'aria è il componente predominante della miscela combustibile e combusta. L'aria è assunta come gas perfetto e tutti gli scambi di calore avvengono con serbatoi a temperatura fissata.
1. Determinare il rendimento del ciclo.

\section*{SOLUTION}

Il ciclo Otto consiste di sei passi.
- Ingresso della miscela \((0 \rightarrow 1)\) : la miscela aria-benzina entra nel cilindro a pressione atmosferica e occupa tutto il volume \(V_{1}\).
- Compressione \((1 \rightarrow 2)\) : la miscela aria-benzina viene compressa adiabaticamente (perché la compressione è rapida) fino al volume della camera di combustione \(V_{2}\) e relativa pressione \(p_{2}\) con relativo aumento della temperatura.
- Scoppio \((2 \rightarrow 3)\) : la miscela è soggetta a combustione che causa un repentino aumento di pressione e temperatura a volume essenzialmente costante, \(V_{3}=V_{2}\), data la rapidità della combustione. In questa schematizzazione di ciclo reversibile l'aumento di temperatura è causato da cessione di calore \(\Omega_{1}\) da parte di opportuni serbatoi di calore esterni.
- Espansione \((3 \rightarrow 4)\) : la miscela combusta calda si espande adiabaticamente finché si raggiunge il volume \(V_{4}=V_{1}\).
- Scarico \((4 \rightarrow 1)\) : La valvola di scarico si apre e la miscela combusta si espande alla pressione atmosferica in un processo rapido che è supposto isocoro e con la caduta di temperatura schematizzata da cessione di calore ad una serie di serbatoi opportuni.
- Eliminazione della miscela ( \(1 \rightarrow 0\) ): il pistone ora spinge la maggior parte del gas combusto restante fuori dal cilindro in un processo isobaro a pressione atmosferica.
Il primo e l'ultimo passo del ciclo sono supposti coincidenti e percorsi in senso opposto cosicché si cancellano lasciando solo il ciclo \(1-2-3-4-5\). Durante la fase \(2-3\) la miscela riceve calore da una serie di serbatoi opportuni a temperatura superiore a quelle della miscela mentre durante la fase 4-1 cede calore ad una serie di serbatoi opportuni a temperatura inferiore a quella della miscela. In entrambi i casi non compie lavoro. Viceversa nei due tratti adiabatici \(1-2\) e \(3-4\) viene scambiato lavoro con l'ambiente. Definendo il rapporto di compressione del ciclo
\[
r \equiv \frac{V_{1}}{V_{2}}=\frac{V_{4}}{V_{3}}
\]
l'adiabaticità e reversibilità delle trasformazioni \(1-2 \mathrm{e} 3-4\) fornisce
\[
\begin{aligned}
& T_{1} V_{1}^{\gamma-1}=T_{2} V_{2}^{\gamma-1} \Longrightarrow T_{2}=T_{1} r^{\gamma-1}, \\
& T_{3} V_{3}^{\gamma-1}=T_{4} V_{4}^{\gamma-1} \Longrightarrow T_{3}=T_{4} r^{\gamma-1}
\end{aligned}
\]

Si ha allora
\[
\begin{aligned}
& \mathfrak{Q}_{2-3}=\mathfrak{u}_{3}-\mathfrak{u}_{2}=C_{\mathrm{V}}\left(T_{3}-T_{2}\right)=C_{\mathrm{V}}\left(T_{4}-T_{1}\right) r^{\gamma-1}, \\
& \mathfrak{Q}_{4-1}=\mathfrak{u}_{1}-\mathfrak{u}_{4}=C_{\mathrm{V}}\left(T_{1}-T_{4}\right)
\end{aligned}
\]

Si ha inoltre
\[
\begin{aligned}
& \mathcal{W}_{1-2}=\int_{1}^{2} p \mathrm{~d} V=p_{1} V_{1}^{\gamma} \int_{1}^{2} \frac{\mathrm{~d} V}{V^{\gamma}}=\frac{p_{1} V_{1}^{\gamma}}{1-\gamma}\left(V_{2}^{1-\gamma}-V_{1}^{1-\gamma}\right)=\frac{p_{1} V_{1}}{1-\gamma}\left(r^{\gamma-1}-1\right) \\
& \mathcal{W}_{3-4}=\int_{3}^{4} p \mathrm{~d} V=p_{4} V_{4}^{\gamma} \int_{3}^{4} \frac{\mathrm{~d} V}{V^{\gamma}}=\frac{p_{4} V_{4}^{\gamma}}{1-\gamma}\left(V_{4}^{1-\gamma}-V_{3}^{1-\gamma}\right)=\frac{p_{4} V_{4}}{1-\gamma}\left(1-r^{\gamma-1}\right)
\end{aligned}
\]

Dalla definizione di rendimento di un ciclo di una macchina termica
\[
\eta \equiv \frac{\mathcal{W}}{\mathcal{Q}_{\mathrm{H}}}
\]
dove \(\mathcal{Q}_{\mathrm{H}}>0\) è il calore assorbito dalla sorgente calda mentre \(\mathcal{W}>0\) è il lavoro fatto dalla macchina termica. si ha allora
\[
\eta=\frac{\mathcal{W}_{1-2}+L_{3-4}}{\mathcal{Q}_{2-3}}=\frac{p_{1} V_{1}\left(r^{\gamma-1}-1\right)+p_{4} V_{4}\left(1-r^{\gamma-1}\right)}{C_{\mathrm{V}}(1-\gamma)\left(T_{4}-T_{1}\right) r^{\gamma-1}}=1-\frac{1}{r^{\gamma-1}}
\]

Il rendimento del ciclo cresce al crescere del rapporto di compressione. In pratica però il rapporto di compressione non può essere aumentato oltre un certo limite per evitare pre-combustione della miscela, cioè combustione prima del punto 2 , fenomeno che può danneggiare il motore e diminuisce la potenza sviluppata. Usando un valore tipico di \(r=5\) e per l'aria \(\gamma=1.4\) si ha \(\eta=0.48\). Questo è solo un valore limite superiore teorico che non è ottenibile da alcun motore reale. Per \(r=5\) l'efficienza reale di un motore può essere dell'ordine di 0.25 . Nel caso reale infatti entreranno in gioco tutta un a serie di fenomeni che rendono il ciclo irreversibile quali attriti, turbolenze, cadute di pressione, effetti dinamici relativi ad accelerazioni e decelerazioni flussi di calore attraverso differenze finite di temperatura, e altro.

Physical quantities such as internal energy, enthalpy and entropy are not directly measurable. It is therefore important that numerical values of properties that are not directly measurable can often be calculated from the numerical values of other properties that are easily measurable, at least in principle, such as pressure, volume and temperature.
Many of such relations are presented in this section. Unless stated otherwise, energy, in short, will always mean: internal energy.

\title{
Thermodynamics Potentials
}

\author{

}

One can build a number of of other functions of state, starting from internal energy and enthalpy, simply by adding various other combinations of the functions of state in such a way as to give the resulting quantity the dimensions of energy. Technically, this is a Legendre transformation, read § 61.13 - Thermodynamics in Action. potential. The result is a plethora of thermodynamic functions. All these thermodynamic potentials carry the same information but the information is encoded in different ways in the different potentials.

Basic state functions (all energies):
\begin{tabular}{rl}
\(\mathcal{U} \equiv \mathcal{H}-p V \Longrightarrow\) & \(\mathrm{~d} \mathfrak{U}=+T \mathrm{~d} \mathcal{S}-p \mathrm{~d} V\) \\
\(\mathcal{H} \equiv \mathcal{U}+p V \Longrightarrow \mathrm{~d} \mathcal{H}=+T \mathrm{~d} \mathcal{S}+V \mathrm{~d} p\) \\
\(\mathcal{F} \equiv \mathcal{U}-T \mathcal{S} \Longrightarrow \mathrm{~d} \mathcal{F}=-\mathcal{S} \mathrm{d} T-p \mathrm{~d} V\) \\
\(\mathcal{G} \equiv \mathcal{H}-T \mathcal{S} \Longrightarrow \mathrm{~d} \mathcal{G}=-\mathcal{S} \mathrm{d} T+V \mathrm{~d} p\) \\
&
\end{tabular}

Gibbs free entalpy (Gibbs function) .
(61.01.04)

\section*{© - QUOTE}

Poirer 14.2 Helmholtz and Gibbs Free Energies
The two new free energy/enthalpy quantities, serve as practical tools. They enable the Second Law to be applied directly to the system, rather than the total system-thus making it possible to forget about the surroundings entirely.
The free energies also describe the extent to which the internal energy can be transformed into useful work.
Note also that the free energies are obtained by subtracting the conjugate variable product \(T S\) from \(\mathcal{U}\) and \(\mathcal{H}\) (respectively), rather than adding it. This is a critical point: since all four functions are positive, free energy/enthalpy values are always less than the corresponding energy/enthalpy. To some extent, this reflects the Second Law fact that only some of the energy can be converted into useful work.
Since the independent variables \(T\) and \(p\) are generally preferred to \(T\) and \(V, \mathcal{G}\) is more important than \(\mathcal{F}\), in practice. This is especially true for thermodynamic processes that occur at constant \(T\) and \(p\) such as phase transitions and chemical reactions. Therefore we will often single out \(\mathcal{G}\) for special treatment even though similar analyses might hold for \(\mathcal{F}\), or even \(\mathcal{U}\) and \(\mathcal{H}\).

\subsection*{61.01.01 Fundamental Relations and Natural Variables}

This § is referenced at pages:
[Never referenced.]
If the thermodynamic potentials are known as a function of their natural variables, all the thermodynamic functions can be deduced by making suitable derivatives. On the other hand, if the thermodynamic potentials are known as a function of other variables, it is necessary to do also some integral and therefore arbitrary functions appear from determine otherwise.

The natural variables of thermodynamic potentials are the variables in terms of which the fundamental relationships are expressed, as in equations (61.01.01), (61.01.02), (61.01.03), (61.01.04):
\begin{tabular}{|c|}
\hline \(\mathcal{U}=\mathcal{U}[\mathcal{S}, V]\) \\
\hline \(\mathcal{H}=\mathcal{H}[\mathrm{S}, p]\) \\
\hline \(\mathcal{F}=\mathcal{F}[T, V]\) \\
\hline \(\mathcal{Y}=\mathcal{G}[T, p]\) \\
\hline
\end{tabular},

In addition:
\[
\mathrm{d} \mathfrak{U}=+T \mathrm{~d} \delta-p \mathrm{~d} V \Longrightarrow \mathcal{U}=\bigcup[\delta, V] \Longrightarrow T=\left(\frac{\partial u}{\partial \delta}\right)_{V}
\]
\[
\mathrm{d} \delta=\frac{\mathrm{d} \mathfrak{U}}{T}+\frac{p \mathrm{~d} V}{T} \Longrightarrow \mathcal{S}=\delta[\mathcal{U}, V]
\]
61.01.02 (Internal) Energy

\subsection*{61.01.03 Enthalpy}

\subsection*{61.01.04 Helmholtz Free Energy}
61.01.05 Gibbs Free Enthalpy

\subsection*{61.01.06 Maxwell Relations}

From equations (61.01.01), (61.01.02), (61.01.03), (61.01.04), one has:
\(T=+\left(\frac{\partial U}{\partial S}\right)_{V}\)
\(T=+\left(\frac{\partial \mathcal{H}}{\partial \mathcal{S}}\right)_{p}\)
\(S=-\left(\frac{\partial \mathcal{F}}{\partial T}\right)_{V}\)
\(\mathcal{S}=-\left(\frac{\partial \mathcal{G}}{\partial T}\right)_{p}\)
\(p=-\left(\frac{\partial \bigcup}{\partial V}\right)_{s}\)
\(V=+\left(\frac{\partial \mathcal{H}}{\partial p}\right)_{\delta}\)
\(p=-\left(\frac{\partial \mathcal{F}}{\partial V}\right)_{T}\)
\[
\begin{equation*}
V=+\left(\frac{\partial \mathcal{G}}{\partial p}\right)_{T} \tag{61.01.08}
\end{equation*}
\]
(61.01.05)

Da queste si derivano le relazioni di Maxwell (come conseguenza dell'uguaglianza delle derivate miste di una funzione di due variabili differenziabile due volte) la cui importanza sta nel fatto che legano grandezza
misurabili \((p, V, T)\) con l'entropia che non è direttamente misurabile.
\[
\begin{gather*}
+\left(\frac{\partial T}{\partial V}\right)_{S}=-\left(\frac{\partial p}{\partial S}\right)_{V} \\
+\left(\frac{\partial T}{\partial p}\right)_{S}=+\left(\frac{\partial V}{\partial S}\right)_{p}  \tag{61.01.09}\\
+\left(\frac{\partial S}{\partial V}\right)_{T}=+\left(\frac{\partial p}{\partial T}\right)_{V} \\
-\left(\frac{\partial S}{\partial p}\right)_{T}=+\left(\frac{\partial V}{\partial T}\right)_{p}
\end{gather*}
\]
(61.01.10) \(\rightarrow\)
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
Write the fundamental relation both with energy and enthalpy and then consider iso-core and iso-bare transformations:
\[
\begin{aligned}
\mathrm{d} \mathcal{U} & =T \mathrm{~d} \mathcal{S} \quad \text { fundamental relation with } \mathcal{U} \text { at constant volume }, \\
\mathrm{d} \mathcal{H} & =T \mathrm{~d} \mathcal{S}
\end{aligned} \quad \text { fundamental relation with } \mathcal{H} \text { at constant pressure } .
\]

It follows:
\[
C_{\mathrm{v}}=\left(\frac{\partial u}{\partial T}\right)_{V}=T\left(\frac{\partial \delta}{\partial T}\right)_{V}
\]
\[
C_{\mathrm{p}}=\left(\frac{\partial \mathcal{H}}{\partial T}\right)_{p}=T\left(\frac{\partial \mathcal{S}}{\partial T}\right)_{p}
\]

Write the differential of entropy first as a function of \(T\) and \(V\), after as a function of \(T\) and \(p\), multiply by \(T\), use equations (61.02), (61.02), and finally use Maxwell Equations to obtain the first and second TdS equations:
\[
\begin{gathered}
T \mathrm{~d} \delta=C_{\mathrm{V}} \mathrm{~d} T+T\left(\frac{\partial p}{\partial T}\right)_{V} \mathrm{~d} V \\
T \mathrm{~d} \delta=C_{\mathrm{p}} \mathrm{~d} T-T\left(\frac{\partial V}{\partial T}\right)_{p} \mathrm{~d} p \\
T \mathrm{~d} \delta=C_{\mathrm{V}}\left(\frac{\partial T}{\partial p}\right)_{V} \mathrm{~d} p+C_{\mathrm{p}}\left(\frac{\partial T}{\partial V}\right)_{p} \mathrm{~d} V \\
\hline
\end{gathered}
\]
dette equazioni per l'entropia o equazioni \(T \mathrm{~d} \delta\).

\subsection*{61.03}

\section*{Equations for Thermal Capacities}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||

\subsection*{61.03.01 Constant Volume Thermal Capacity and Stability of Thermal Equilibrium}

It can be shown that
\[
\begin{equation*}
C_{\mathrm{V}} \geq 0 \tag{61.03.01}
\end{equation*}
\]

Actually, it can be shown that \(C_{\mathrm{V}} \geq 0\) is the condition for thermal stability of a \(p V T\) system. Read \(\S\) 61.06.04 - Thermodynamics in Action.

\subsection*{61.03.02 Constant Volume and Constant Pressure Thermal Capacities}

Read §59.08 - Work Energy Heat and the First Principle.

\subsection*{61.03.03 Difference Between Constant Pressure and Constant Volume Thermal Capacities}

La relazione generale tra le capacità termiche a pressione e volume costante di un sistema \(p V T\) a composizione costante si ricava dalle relazioni (61.02), (61.02) ed è data dalla relazione
\[
\begin{equation*}
C_{\mathrm{p}}-C_{\mathrm{V}}=T\left(\frac{\partial p}{\partial T}\right)_{V}\left(\frac{\partial V}{\partial T}\right)_{p}=-T\left(\frac{\partial p}{\partial V}\right)_{T}\left(\frac{\partial V}{\partial T}\right)_{p}^{2}=\frac{\beta^{2} V T}{\kappa_{\mathrm{T}}} \tag{array}
\end{equation*}
\]

L'importanza della relazione sta nel fatto che permette di esprimere \(C_{\mathrm{V}}\), difficilmente misurabile, in termini di grandezze più facilmente misurabili.
In general, the functions on the right-side, \(\beta\) and \(\kappa_{\mathrm{T}}\), depend on \(p V T\).
It is worth noting that the difference \(C_{\mathrm{p}}-C_{\mathrm{V}}\) requires the knowledge of the equation of state only, even if thermal capacities are partial derivatives of the internal energy and enthalpy.
As, in all generality,
\[
\kappa_{\mathrm{T}} \geq 0
\]
it follows that
\[
C_{\mathrm{p}} \geq C_{\mathrm{V}}
\]

Equation (61.03.02) implies that:
\[
\{T \rightarrow 0\} \Longrightarrow\left\{C_{\mathrm{p}} \rightarrow C_{\mathrm{v}}\right\}
\]

Equation (61.03.02) also implies that \(C_{\mathrm{p}}=C_{\mathrm{V}}\) whenever \(\kappa_{\mathrm{T}}=0\).
61.03.04 Ratio Between Constant Pressure and Constant Volume Thermal Capacities
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
It can be shown that:
\[
\begin{equation*}
\gamma \equiv \frac{C_{\mathrm{p}}}{C_{\mathrm{v}}}=\frac{\kappa_{\mathrm{T}}}{\kappa_{\mathrm{S}}} \geq 0 \tag{61.03.03}
\end{equation*}
\]

Therefore:
\[
0 \leq C_{\mathrm{v}} \leq C_{\mathrm{p}}
\]
as \(C_{\mathrm{v}}>0\).

\subsection*{61.03.05 Derivatives of Constant Pressure and Constant Volume Thermal Capacities}

Dalle relazioni (61.01.10), (61.01.11), (??) si deducono le relazioni che danno la variazione delle capacità termiche
\[
\left(\frac{\partial C_{\mathrm{v}}}{\partial V}\right)_{T}=+T\left(\frac{\partial^{2} p}{\partial T^{2}}\right)_{V}
\]
\[
\left(\frac{\partial C_{\mathrm{p}}}{\partial p}\right)_{T}=-T\left(\frac{\partial^{2} V}{\partial T^{2}}\right)_{p}
\]
61.03.06 Thermal Capacities From G and F
\[
C_{\mathrm{V}}=-T\left(\frac{\partial^{2} \mathcal{F}}{\partial T^{2}}\right)_{V}
\]
\[
C_{\mathrm{p}}=-T\left(\frac{\partial^{2} \mathcal{G}}{\partial T^{2}}\right)_{p}
\]

\subsection*{61.04}

Equations for Internal Energy and Entalphy
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
Si deducono scrivendo il differenziale dell'energia interna o dell'entalpia, usando l'espressione differenziale del primo principio e le equazioni dell'entropia (61.02), (61.02). La loro importanza sta nel fatto che legano grandezze misurabili ( \(p, V, T\) ) con l'energia interna e l'entalpia che non sono direttamente misurabili.
The derivation of the following expressions requires the second law, as the first law alone is not enough.

Equations for Compressibilities
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
61.05.01 Isothermal Compressibility and Mechanical Equilibrium

It can be shown that:
\[
\begin{equation*}
\kappa_{\mathrm{T}} \geq 0 \tag{61.05.01}
\end{equation*}
\]

Actually, it can be shown that \(\kappa_{\mathrm{T}} \geq 0\) is the condition for mechanical stability of a \(p V T\) system. Read \(\S\) 61.06.04 - Thermodynamics in Action.

\subsection*{61.05.02 Isothermal and Adiabatic Compressibility}

This § is referenced at pages:
[1477, 1477]
I moduli di compressibilità isoterma e adiabatica sono definiti come
\[
\begin{gathered}
\kappa_{\mathrm{T}} \equiv-\frac{1}{V}\left(\frac{\partial V}{\partial p}\right)_{T} \geq 0 \\
\kappa_{\mathrm{S}} \equiv-\frac{1}{V}\left(\frac{\partial V}{\partial p}\right)_{S}
\end{gathered},
\]

The first term can be obtained from measured \(p V T\) data. The second term can be measured as it is related to the sound speed in the material.

\subsection*{61.05.03 Difference Between Isothermal and Adiabatic Compressibility}

It can be shown that:
\[
\begin{equation*}
\kappa_{\mathrm{T}}-\kappa_{\mathrm{S}}=\frac{T V \beta^{2}}{C_{\mathrm{p}}} \tag{61.05.02}
\end{equation*}
\]

As, in all generality,
\[
C_{\mathrm{p}} \geq 0
\]
it follows that
\[
\kappa_{\mathrm{T}} \geq \kappa_{\mathrm{S}}
\]
61.05.04 Ratio Between Isothermal and Adiabatic Compressibility
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||

It can be shown that:
\[
\begin{equation*}
\gamma \equiv \frac{\kappa_{\mathrm{T}}}{\kappa_{\mathrm{S}}}=\frac{C_{\mathrm{p}}}{C_{\mathrm{V}}} \geq 1 \tag{61.05.03}
\end{equation*}
\]

Therefore
\[
0 \leq \kappa_{\mathrm{S}} \leq \kappa_{\mathrm{T}}
\]
as \(\kappa_{\mathrm{T}}>0\)

\section*{© - QUOTE}
©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|4.5||
The propensity of physical systems to increase their entropy can be channelled to deliver useful work. All such applications are governed by the maximum work theorem. Consider a system that is to be taken from a specified initial state to a specified final state. Also available are two auxiliary systems, into one of which work can be transferred, and into the other of which heat can be transferred. Then the maximum work theorem states that for all processes leading from the specified initial state to the specified final state of the primary system, the delivery of work is maximum (and the delivery of heat is minimum) for a reversible process. Furthermore the delivery of work (and of heat) is identical for every reversible process.
The repository system into which work is delivered is called a reversible work source, \(\mathcal{W}\). Reversible work sources are defined as systems enclosed by adiabatic impermeable walls and characterized by relaxation times sufficiently short that all processes within them are essentially quasi-static. From the thermodynamic point of view the conservative (non-frictional) systems considered in the theory of mechanics are reversible work sources.
The repository system into which heat is delivered is called a reversible heat reservoir, \(H\). Reversible heat reservoirs are defined as systems enclosed by rigid impermeable walls and characterized by relaxation times sufficiently short that all processes of interest within them are essentially quasi-static. Note that infinite thermal capacity (implying fixed temperature) is not included in the definition of reversible heat reservoirs. If the temperature of the reversible heat reservoir is \(T_{\mathrm{H}}\) the transfer of heat \(\delta Q\) to the reversible heat reservoir increases its entropy according to the quasi-static relationship \(\delta \mathcal{L}=T_{\mathrm{H}} \mathrm{d} \delta\). The external interactions of a reversible heat reservoir accordingly are fully described by its heat capacity \(C\left(T_{\mathrm{H}}\right)\) (the definition of the reversible heat reservoir implies that this heat capacity is at constant volume, but we shall not so indicate by an explicit subscript). The energy change of the reversible heat reservoir is \(\mathrm{d} U=\delta Q=C\left(T_{\mathrm{H}}\right) \mathrm{d} T_{\mathrm{H}}\) and the entropy change is \(\mathrm{d} \delta=C\left(T_{\mathrm{H}}\right) \mathrm{d} T_{\mathrm{H}} / T_{\mathrm{H}}\).
The proof of the maximum work theorem is almost immediate. Consider two processes. Each leads to the same energy change, \(\Delta \mathcal{U}\), and the same entropy change, \(\Delta \mathcal{S}\), within the primary subsystem \((S)\), for these are determined by the specified initial and final states. The two processes differ only in the apportionment of the energy difference between the reversible work source and the reversible heat reservoir. But the process that delivers the maximum possible work to the reversible work source correspondingly delivers the least possible heat to the reversible heat reservoir, and therefore leads to the least possible entropy increase of the reversible heat reservoir (and thence of the entire system). The absolute minimum of \(\Delta S_{\text {total }}\) for all possible processes, is attained by any reversible
process (for all of which \(\Delta \mathcal{S}_{\text {total }}=0\) ).
\[
\begin{aligned}
& \mathrm{d} \mathcal{U} \text { fixed all quantities referred to the primary sub-system } S \\
& \text { dS fixed all quantities referred to the primary sub-system } S \\
& \mathrm{~d} \mathcal{U}=\delta \mathcal{Q}+\delta \mathcal{W} \quad \text { all quantities referred to the primary sub-system } S \\
& \delta \mathcal{W}_{S \rightarrow A} \equiv-\delta \mathcal{W}=\delta \mathcal{Q}-\mathrm{dU} \quad \text { all quantities referred to the primary sub-system } S \\
& \text { assume: } \quad \mathrm{d} \mathcal{S}_{A}=0 \quad \text { reversible work source }, \quad, \\
& \text { assume: } \quad \mathrm{d} \mathcal{S}_{H}=-\frac{\delta \mathcal{Q}}{T_{\mathrm{H}}} \quad \text { reversible heat reservoir, } H \text {, at temperature } T_{\mathrm{H}} \\
& \mathrm{~d} S_{U}=\mathrm{d} \mathcal{S}_{H}+\mathrm{d} \mathcal{S}_{A}+\mathrm{d} \mathcal{S} \geq 0, \\
& \mathrm{~d} S_{U}=\mathrm{d} \mathscr{S}_{H}+\mathrm{d} S_{A}+\mathrm{d} \mathcal{S}=0 \quad \text { ifoif all reversible transformations }, \\
& -\frac{\delta \mathrm{Q}}{T_{\mathrm{H}}}+\mathrm{d} \delta \geq 0, \\
& -\frac{\mathrm{d} U-\delta \mathcal{W}}{T_{\mathrm{H}}}+\mathrm{d} \mathcal{S} \geq 0, \\
& \frac{\mathrm{~d} \mathcal{U}-\delta \mathcal{W}}{T_{\mathrm{H}}} \leq \mathrm{d} \delta, \\
& \delta \mathcal{W}_{S \rightarrow A} \equiv-\delta \mathcal{W} \leq T_{\mathrm{H}} \mathrm{dS}-\mathrm{d} \mathcal{U}
\end{aligned}
\]

Note: \(\mathrm{d} \mathcal{S}>0\) does not imply that something irreversible is happening in the system, \(\mathrm{d} S_{i}>0\); it might be just heat entering the system, and \(d \mathcal{S}>0\) is compensated by an entry decrease of the heat reservoir.

\subsection*{61.06.02 Reservoirs - Heat Volume Particle}
- A heat reservoir is any system in thermal equilibrium, so large that it is possible to extract/dump heat from/to the heat reservoir without changing its temperature: changing entropy without affecting its temperature. It is sometimes called temperature reservoir. It is sometimes better called entropy reservoir.
- A volume reservoir is any system in mechanical equilibrium, so large that it is possible to extract/dump volume from/to the volume reservoir without changing its pressure: changing volume without affecting its pressure. It is sometimes called pressure reservoir.
- A particle reservoir is any system in chemical equilibrium, so large that it is possible to extract/dump particles from/to the particle reservoir without changing its chemical potential: changing number of particles without affecting its chemical potential.

\subsection*{61.06.03 Equilibrium for Thermodynamic Systems in Different Conditions}
©|N.W.Tschoegl, Fundamentals Of Equilibrium And Steady-State Thermodynamics, 2000, Elsevier, ...Ed., ....|extensive||

In general, the reversible work done on a system will be the sum of different contributions:
\[
\delta \mathcal{W} \equiv-p \mathrm{~d} V+\sum_{i} Y_{i} \mathrm{~d} X_{i} \quad \mathrm{~d} \mathcal{U}=\delta \mathbb{Q}-p \mathrm{~d} V+\sum_{i} Y_{i} \mathrm{~d} X_{i} \equiv \delta \mathbb{Q}-p \mathrm{~d} V+\mathcal{W}^{\prime}
\]

\subsection*{61.06.03.01 Contact With a Heat Reservoir}
©|N.W.Tschoegl, Fundamentals Of Equilibrium And Steady-State Thermodynamics, 2000, Elsevier, ...Ed., ....|extensive||
Il lavoro totale, \(\mathcal{W}_{S \rightarrow A} \equiv-\mathcal{W}\), che può compiere un sistema che sia a contatto termico con l'ambiente a temperatura \(T_{0}\) all'inizio alla fine di un insieme di trasformazioni arbitrarie tra due stati di equilibrio fissati e tali che le variazioni di energia interna ed entropia del sistema siano \(\Delta \mathcal{U}\) e \(\Delta \mathcal{S}\), è limitato superiormente dalla relazione:
\[
\begin{equation*}
\Delta \mathcal{S}_{\mathrm{U}} \geq 0 \Longrightarrow \mathcal{W}_{S \rightarrow A} \equiv-\mathcal{W} \leq-\left(\Delta \mathcal{U}-T_{0} \Delta \mathcal{S}\right) \equiv-\Delta \mathcal{F} \tag{61.06.01}
\end{equation*}
\]

Il lavoro totale massimo, tra tutte le possibili trasformazioni tra due stati di equilibrio arbitrari ma fissati, si ha per una trasformazione reversibile.
Il sistema esterno che assorbe o produce lavoro si assume essere totalmente reversibile.
Se un sistema non compie/riceve lavoro, se ne deduce quindi che l'energia libera di Helmoltz può solo diminuire; ovvero tra tutti i possibili stati finali, fissato lo stato iniziale, ce ne saranno alcuni con energia libera invariata (se e solo se le trasformaioni sono tutte reversibili) ed altri con energia libera minore (se e solo se almeno una trasforamzione è irreversibile).
At the thermodynamic equilibrium, the value of any unconstrained parameter of a system which is in thermal contact with a heat reservoir and does no work, is such that the free energy is minimized:
\[
\left.\mathrm{d} \mathcal{F}\right|_{T}=\left.0 \quad \mathrm{~d}^{2} \mathcal{F}\right|_{T} \geq 0
\]

It is important to emphasize that equation (61.06.01) clarifies that, for reversible transformations, the work done by a system in contact with a heat reservoir is:
\[
\begin{equation*}
\Delta s_{U}=0 \Longrightarrow-\mathcal{W}=-\Delta \mathcal{F} \tag{61.06.02}
\end{equation*}
\]

Since \(\mathcal{F}\) characterizes the work that can be extracted from a system in contact with a thermal reservoir, the relation \(\mathcal{F}<\mathcal{U}\), from the definition, tells us that not all internal energy can be converted into work.
This equation is basic in the study of system such as Polarizable|Magnetizable matter in external fields, given that ElectroMagnetism provides the work for mono-thermal processes.

\section*{© - QUOTE}
S.J.Blundell \& K.M.Blundell, Concepts In Thermal Physics, 2010, Oxford, 2ndEd., ....

Note that if the system is mechanically isolated from its surroundings, so that no work can be applied or extracted, then \(\mathrm{d} \mathcal{F} \leq 0\) Thus any change in \(\mathcal{F}\) will be negative. As the system settles down towards equilibrium, all processes will tend to force \(\mathcal{F}\) downwards. Once the system has reached equilibrium, \(\mathcal{F}\) will be constant at this minimum level. Hence equilibrium can only be achieved by minimizing \(\mathcal{F}\).

\subsection*{61.06.03.02 Contact With a Heat and Volume Reservoir}
©|N.W.Tschoegl, Fundamentals Of Equilibrium And Steady-State Thermodynamics, 2000, Elsevier, ...Ed., ....|extensive||
Il lavoro totale utile, \(\mathcal{W}_{S \rightarrow A}^{\prime} \equiv-\mathcal{W}^{\prime}\), che può compiere un sistema che sia a contatto termico con l'ambiente a temperatura \(T_{0}\) e a contatto con l'ambiente a pressione esterna \(p_{0}\), all'inizio alla fine di un insieme di trasformazioni arbitrarie tra due stati di equilibrio fissati e tali che le variazioni di energia interna ed entropia del sistema siano \(\Delta \mathcal{U}\) e \(\Delta \mathcal{S}\), è limitato superiormente dalla relazione:
\[
\begin{equation*}
\Delta \mathcal{S}_{\mathrm{U}} \geq 0 \Longrightarrow \mathcal{W}_{S \rightarrow A}^{\prime} \equiv-\mathcal{W}^{\prime} \leq-\left(\Delta \mathcal{U}-T_{0} \Delta \mathcal{S}+p_{0} \Delta V\right)=-\Delta \mathcal{G} \tag{61.06.03}
\end{equation*}
\]

Il lavoro totale utile massimo, tra tutte le possibili trasformazioni tra due stati di equilibrio arbitrari ma fissati, si ha per una trasformazione reversibile. Tale lavoro è quello utile, in quanto si sottrae l'inevitabile lavoro contro la pressione esterna.
Il sistema esterno che assorbe o produce lavoro si assume essere totalmente reversibile.

Se un sistema non compie/riceve lavoro, se ne deduce quindi che l'entalpia libera di Gibbs può solo diminuire; ovvero tra tutti i possibili stati finali, fissato lo stato iniziale, ce ne saranno alcuni con entalpia libera invariata (se e solo se le trasformaioni sono tutte reversibili) ed altri con energia libera minore (se e solo se almeno una trasforamzione è irreversibile).

At the thermodynamic equilibrium, the value of any unconstrained parameter of a system coupled with a heat reservoir through a diathermal wall and with a volume reservoir through a movable wall and does no work, is such that the free entalphy is minimized:
\[
\left.\mathrm{d} \mathcal{G}\right|_{p, T}=\left.0 \quad \mathrm{~d}^{2} \mathcal{G}\right|_{p, T} \geq 0
\]

It is important to emphasize that equation (61.06.03) clarifies that, for reversible transformations, the useful work done by a system in contact with a heat reservoir and a volume reservoir is:
\[
\begin{equation*}
\Delta \mathcal{S}_{\mathrm{U}}=0 \Longrightarrow-\mathcal{W}^{\prime}=-\Delta \mathcal{G} \tag{61.06.04}
\end{equation*}
\]

Since \(\mathcal{G}\) characterizes the useful work that can be extracted from a system in contact with a thermal reservoir and a volume reservoir, the relation \(\mathcal{G}<\mathcal{H}\), from the definition, tells us that not all entalphy can be converted into useful work.

This equation is basic in the study of system such as phase transitions and chemical reactions which are typically mono-thermal and mon-bare processes.

\section*{© - QUOTE}

This means that the maximum amount of work is achieved by a reversible (that is quasi-static) process connecting the initial and final states. Keep in mind that the system is assumed to exchange heat with the reservoir at \(T\) and that this assumption puts a constraint on the quasistatic process that results in the maximum amount of work. In fact, such a process is uniquely determined for a particular choice for the initial and the final states. More specifically, we must first follow the adiabatic going through the initial state until the temperature of the system reaches the temperature \(T\) of the reservoir and then go through the quasi-static isothermal process at the temperature \(T\) to reach the adiabatic that goes through the final state and finally follow this adiabatic to arrive at the final state. This is the same construction as for the Carnot cycle.

\section*{© - QUOTE}

For a pure substance in a single phase the two variables \(T\) and \(p\) or \(T\) and \(V\) define the thermodynamic state, which therefore cannot change if both variables are held fixed.
It is important to realize that equations (61.06.01), (61.06.03) applies only to more complicated situations such as phase transitions and chemical reactions.

\subsection*{61.06.04 Summary of the Main Stability Conditions at Thermodynamic Equilibrium}

This § is referenced at pages:
[2610, 2610, 2613, 2613]
- For given \(\mathcal{U}\) and \(V: \mathcal{S}\) is maximum.
- For given \(\mathcal{H}\) and \(p: \mathcal{S}\) is maximum.
- For given \(T\) and \(V: \mathcal{F}\) is minimum.
- For given \(T\) and \(p: \mathcal{G}\) is minimum.

Since temperature is a more convenient variable than entropy, the last two conditions are more useful than the first two, but all of them are as fundamental as any other.
Stability conditions:
\[
\kappa_{\mathrm{T}}>0 \quad C_{\mathrm{V}}>0
\]
and
\[
\kappa_{\mathrm{T}} \geq \kappa_{\mathrm{S}} \geq 0 \quad C_{\mathrm{p}} \geq C_{\mathrm{V}} \geq 0
\]
© - QUOTE
H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd.

Thus both heat capacities and both compressibilities must be positive in a stable system. Addition of heat, either at constant pressure or at constant volume, necessarily increases the temperature of a stable system, the more so at constant volume than at constant pressure. And decreasing the volume, either isothermally or iso-entropically, necessarily increases the pressure of a stable system, the more so isothermally than iso-entropically.

The condition for stability of diffusional equilibrium turns out to be:
\[
\frac{\partial \mu_{k}}{\partial N_{k}} \geq 0
\]

\section*{Equilibrium of Phases of a Single Pure Substance}

This § is referenced at pages:
[2489, 2489]
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|||
A phase is a portion of a system that possesses well defined physical and chemical properties, of homogeneous composition and with well-defined border, so that composition, pressure, volume and temperature can be defined overall.

A pure substance is a system made up of a single chemical species. It can exist in different physical states: gaseous, liquid, solid; we also say under different phases, that is to say under different homogeneous parts characterized by the same physical and chemical properties. When a pure substance evolves from one state of equilibrium to another, we sometimes witness a sudden modification of some of its physical, mechanical, optical, electrical properties, etc. It is said to undergo a change of state or a phase transition. This phenomenon is frequently observed in nature; we know well the solidification of water as well as its vaporization, but the passage of iron from state \(\alpha\) to state \(\gamma\), by heating, is also a phase transition.
A phase transition is a condition such that some discontinuity in some physical property happens.

\section*{© - QUOTE}

A phase transition is an abrupt change in a system that occurs over a small range in a control variable. For thermodynamic phase transitions, typical control variables are the "intensive variables" of temperature, pressure, or magnetic field. Thermodynamic phase transitions in materials and condensed matter, the subject of this book, occur when there is a singularity in the free energy function of the material, or in one of the derivatives of the free energy function. Accompanying a phase transition are changes in some physical properties and structure of the material, and changes in properties or structure are the usual way that a phase transition is discovered. There is a very broad range of systems that can exhibit phase transitions, extending from atomic nuclei to traffic flow or politics. For many systems it is a challenge to find reliable models of the free energy, however, so thermodynamic analyses are not available.

A non trivial example is iron recalescence, the transition of pure iron from state, where the metallic network is cubic centered, in another state, where the network is cubic with centered faces. If we pass a current through an iron wire so that the wire deforms and becomes red, \(T>1200 \mathrm{~K}\), and then remove the current, the wire cools and shorten. We observe that the contraction of the wire marks a stopping time when the temperature is \(T=1179 \mathrm{~K}\). Heat is ejected due to the phase transition.

In the gaseous state, a pure substance or a mixture of pure substances form only one phase. In the liquid state, a pure substance or a mixture of pure substances form, as a rule, only one phase, except in some cases, such as helium, which has two different liquid phases. In the solid state, a pure substance often presents itself under different crystal structures: each of these allotropic varieties then constitute a solid phase (water, iron, for instance).

Experience of water refreezing. A wire stretched by masses hanging at its ends is placed on a bar of ice. Under the action of the strong pressure exerted by the wire, the temperature of fusion decreases and the ice melts on contact with the wire. As the pressure of the wire stops the liquid thus formed refreezes above the wire. Finally the wire completely crosses the block of ice.

\section*{© - QUOTE}

The importance of \(\mathcal{G}\) derives from the fact that its natural variables are temperature, pressure, and composition. Classical solution thermodynamics is an experimental science, and \(T, p\), and \(x\) (the set of mole fractions) are the variables most susceptible to measurement and control in the laboratory. Moreover, these are the independent variables favoured by engineers for use in the design of chemical processes.

It is an experimental observation that the phase transitions take place at constant temperature and pressure, whereby during a phase transition the Gibbs function remains constant, that is:
\[
\mathrm{d} \mathcal{G}=0 \quad \text { at phase equilibrium . }
\]

Le funzioni di Gibbs molari delle due fasi sono quindi uguali nelle condizioni in cui c'è equilibrio di fase. In fact considering an infinitesimal change of number of moles of the two phases, \(n^{\alpha}\) and \(n^{\beta}\), but at constant number of moles, \(n\), for a closed system, indicando con \(\alpha\) e \(\beta\) due diverse fasi, si ha:
\[
\mathrm{d} \mathcal{G}=g^{\alpha}[p, T] \mathrm{d} n^{\alpha}+g^{\beta}[p, T] \mathrm{d} n^{\beta}=0 \quad \text { at } \mathrm{d} p=\mathrm{d} T=0, \text { with } n^{\alpha}+n^{\beta}=n .
\]

Date certe condizioni di pressione e temperatura la fase stabile è quella a cui corrisponde il valore minimo dell'energia di Gibbs molare.
Dalla definizione di \(\mathcal{G}\), equazione (61.01.11), si ha che la fase stabile corrisponde al migliore compromesso tra minimizzare l'energia interna, minimizzare il prodotto \(p V\) (cioè \(V\), se \(p\) è data) e massimizzare \(T S\) (cioè \(\mathcal{S}\), se \(T\) è data).
\[
g^{\alpha}=g^{\beta}
\]
dove \(h^{\beta \alpha}\). è l'entalpia di transizione dalla fase \(\beta\) alla fase \(\alpha\), e \(T\) la temperatura di transizione. Si ha
\[
h_{.}^{\beta \alpha}+h_{.}^{\alpha \beta}=0 .
\]

Inoltre
\[
s^{\alpha}=-\left(\frac{\partial g^{\alpha}}{\partial T}\right)_{p}
\]
per cui \(\mathcal{G}\) ha una cuspide al punto di transizione (discontinuità nella derivata prima).
This equality of the free mass enthalpies of the two phases results in the relation \(p=p(T)\) between the pressure and temperature. As a result, if a pure substance is balanced in two phases, any isothermal evolution of this equilibrium is necessarily isobaric and reciprocal.
If we want to find pressures and temperatures such that phase equilibrium is possible, we should look for infinitesimal changes, \(\mathrm{d} p\) and \(\mathrm{d} T\), such that equality of the molar Gibbs function is maintained:
\[
\mathrm{d} g^{\alpha}=\mathrm{d} g^{\beta} \Longrightarrow-s^{\alpha} \mathrm{d} T+v^{\alpha} \mathrm{d} p=-s^{\beta} \mathrm{d} T+v^{\beta} \mathrm{d} p
\]

Per un sistema a due fasi si ha quindi l'equazione di Clapeyron
\[
\frac{\mathrm{d} p}{\mathrm{~d} T}=\frac{s^{\alpha}-s^{\beta}}{v^{\alpha}-v^{\beta}}=\frac{h_{.}^{\beta \alpha}}{T\left(v^{\alpha}-v^{\beta}\right)} .
\]

The molar/specific latent heat of a pure substance, or molar/specific enthalpy of transition from phase 1 to phase 2, is the heat necessary to achieve, reversibly, at a temperature and a constant pressures, the phase transition of the unit of mole/mass of this substance, from phase 1 to phase 2.
As the molar/specific volumes, as well as the vapor pressure, only depend on temperature, phase transition enthalpies are functions of temperature. In other words, general thermodynamic functions depend on two macroscopic variables, but transition enthalpies are defined on the vapor pressure curve, so that they only depend on one variable.
Per un sistema a più fasi:
\[
g^{\alpha}=g^{\beta}=\ldots=g^{\tau},
\]
which, in general, allows only discrte solutions for triple points at a specified value of \((p, T)\).

Let us consider the unit of mole/mass of pure substance, entirely in the solid state, in the vicinity of the triple point. Let us consider an isothermal and isobaric reversible evolution which first brings the substance to the state liquid, then in the gaseous state and finally brings it back to the initial solid state. For this cyclical development, the variation in mole/mass enthalpy of the system is zero. Therefore:
\[
\Delta h_{l g}+\Delta h_{g s}+\Delta h_{s l}=0
\]

\subsection*{61.08.01 Approximate Solution for Equilibrium With Vapor}

L'equazione di Clapeyron per l'equilibrio liquido-vapore e solido-vapore, trattando il vapore come un gas ideale, trascurando il volume molare della fase liquida/solida rispetto a quello della fase gassosa e considerando il calore latente di vaporizzazione/sublimazione indipendente dalla temperatura si scrive
\[
\begin{align*}
& p[T]=p_{0} \exp \left[-\frac{\lambda_{\text {vap }}^{(\mathrm{mol})}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right]=p_{0} \exp \left[-\frac{M \lambda_{\text {vap }}^{(\mathrm{sp})}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right],  \tag{61.08.01}\\
& p[T]=p_{0} \exp \left[-\frac{\lambda_{\text {sub }}^{(\mathrm{mol})}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right]=p_{0} \exp \left[-\frac{M \lambda_{\mathrm{sub}}^{(\mathrm{sp})}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right] . \tag{61.08.02}
\end{align*}
\]

The criterion for phase equilibrium in \(p V T\) systems of uniform \(T\) and \(p\), with \(m\) substances in different phases, \(\alpha \beta \ldots \pi\), is concisely stated in terms of the chemical potential:
\[
\mu_{k}^{\alpha}=\mu_{k}^{\beta}=\ldots=\mu_{k}^{\pi} \quad k=1 \ldots m
\]

\section*{Chemical Potential for Open Systems}
©|N.W.Tschoegl, Fundamentals Of Equilibrium And Steady-State Thermodynamics, 2000, Elsevier, ...Ed., ....|extensive||
Nel caso di un sistema aperto (cioè un sistema che può acquistare o cedere materia) il primo principio della termodinamica va generalizzato per includere il cambiamento di energia indotto dal flusso di materia. Per un sistema composto di vari componenti, ciascuno con numero di moli \(n_{k}\) e/o numero di particelle \(N_{k}\), si ha
\[
\begin{equation*}
\mathrm{d} \mathcal{U}=T \mathrm{~d} \mathcal{S}-p \mathrm{~d} V+\sum_{k} \mu_{k} \mathrm{~d} N_{k} \quad \mu_{k} \equiv\left(\frac{\partial \mathcal{U}}{\partial N_{k}}\right)_{\delta, V, N_{j}} \tag{61.10.01}
\end{equation*}
\]
dove nella derivazione parziale si tiene fisso il numero di particelle, \(N_{j}\), di tutti i componenti esclusa la specie di cui si valuta il potenziale chimico, \(k\).

\section*{© - QUOTE}

The terms in equation (61.10.01) are interpreted as types of energy fluxes that change the internal energy of the system. In addition to the reversible work and the reversible heat, the third term is an energy flux known as the reversible chemical work.

Analogamente si introducono i potenziali chimici partendo dalle altre relazioni fondamentali:
\[
\begin{array}{|cc|}
\hline \mathrm{d} \mathcal{U}=+T \mathrm{~d} \mathcal{S}-p \mathrm{~d} V+\sum_{k} \mu_{k} \mathrm{~d} N_{k} & \mu_{k} \equiv\left(\frac{\partial \mathcal{U}}{\partial N_{k}}\right)_{\delta, V, N_{j}} \\
\hline \mathrm{~d} \mathcal{H}=+T \mathrm{~d} \mathcal{S}+V \mathrm{~d} p+\sum_{k} \mu_{k} \mathrm{~d} N_{k} & \mu_{k} \equiv\left(\frac{\partial \mathcal{H}}{\partial N_{k}}\right)_{p, S, N_{j}} \\
\hline \mathrm{~d} \mathcal{F}=-\mathcal{S} \mathrm{d} T-p \mathrm{~d} V+\sum_{k} \mu_{k} \mathrm{~d} N_{k} & \mu_{k} \equiv\left(\frac{\partial \mathcal{F}}{\partial N_{k}}\right)_{V, T, N_{j}} \\
\hline \mathrm{~d} \mathcal{G}=-\mathcal{S} \mathrm{d} T+V \mathrm{~d} p+\sum_{k} \mu_{k} \mathrm{~d} N_{k} & \mu_{k} \equiv\left(\frac{\partial \mathcal{G}}{\partial N_{k}}\right)_{T, p, N_{j}} \\
\hline
\end{array}
\]
© - QUOTE
Phase transitions and chemical reactions, which have the same initial and final pressure and temperature, dictate the common practice of defining the chemical potential in terms of the Gibbs function. although it can be defined from the other characteristic functions as well. The chemical potential is a state function because it is derived from another state function.
© - QUOTE
Using the idea of extensive and intensive quantities, we can now derive another useful relation involving the Gibbs free enthalpy. First recall the definition of chemical potential This equation says that if you add one particle to a system, holding the temperature and pressure fixed, the Gibbs free enthalpy of the system increases by \(\mu\). If you keep adding more particles, each one again adds \(\mu\) to the Gibbs free energy. Now you might think that during this procedure the value of \(\mu\) could gradually change, so that by the time you've doubled the number of particles,
\(\mu\) has a very different value from when you started. But in fact, if \(T\) and \(p\) are held fixed, this can't happen: each additional particle must add exactly the same amount to \(\mathcal{G}\), because \(\mathcal{G}\) is an extensive quantity that must simply grow in proportion to the number of particles. The constant of proportionality, according to equation is simply \(\mu\) :
\[
\mathcal{G}=N \mu
\]

This amazingly simple equation gives us a new interpretation of the chemical potential, at least for a pure system with only one type of particle: \(\mu\) is just the Gibbs free energy per particle. The preceding argument is subtle, so please think it through carefully. Perhaps the best way to understand it is to think about why the same logic can't be applied to the Helmholtz free energy. The problem here is that to increase \(\mathcal{F}\) by an amount \(\mu\), you have to add a particle while holding the temperature and volume fixed. Now, as you add more and more particles, \(\mu\) does gradually change, because the system is becoming more dense. It's true that \(\mathcal{F}\) is an extensive quantity, but this does not imply that \(\mathcal{F}\) doubles when you double the density of the system, holding its volume fixed. In the previous section it was crucial that the two variables being held fixed \(T\) and \(p\), were both intensive, so that all extensive quantities could grow in proportion to \(N\).
For a system containing more than one type of particle, the equation generalizes in a natural way:
\[
\mathcal{G}=\sum_{k} \mu_{k} N_{k}
\]

The proof is the same as before, except that we imagine building up the system in infinitesimal increments keeping the proportions of the various species fixed throughout the process. This result does not imply, however, that \(\mathcal{G}\) for a mixture is simply equal to the sum of the \(\mathcal{G}\) for the pure components. In fact the \(\mu_{k}\) in are generally different from their values for the corresponding pure substances.

\subsection*{61.11.01 Chemical Reactions}
©|S.J.Blundell \& K.M.Blundell, Concepts In Thermal Physics, 2010, Oxford, 2ndEd., ....|||
In chemistry, chemical reactions in the laboratories are usually at constant atmospheric pressure. In this case, as discussed in § 59.08.02 - Work Energy Heat and the First Principle,
\[
\Delta \mathcal{H}=\mathcal{Q}
\]
and hence \(\Delta \mathcal{H}\) is the reversible heat added to the system: the heat absorbed by the reaction.
- If \(\Delta \mathcal{H}<0\), the reaction is called exothermic and heat will be emitted.
- If \(\Delta \mathcal{H}>0\), the reaction is called endothermic and heat will be absorbed.

However, this does not explain whether or not a chemical reaction will actually proceed.
Most often, reactions occurs at constant temperature and pressure. In fact, even if the temperature may change during a reaction, the final products usually thermalize with the environment to the original temperature, and therefore, we can use functions of state. Therefore a chemical system will minimize the Gibbs function, so that, if the Gibbs function decreases, the reaction may spontaneously occur.

\section*{© - QUOTE}

However, one may also need to consider the kinetics of the reaction. Often a reaction has to pass via a metastable intermediate state, which may have a higher Gibbs function, so the system cannot spontaneously lower its Gibbs function without having it slightly raised first. This gives a reaction an activation energy that must be added before the reaction can proceed, even though the completion of the reaction gives you all that energy back and more.

\subsection*{61.11.03 Rubber Band}

This § is referenced at pages:
[2496, 2496]
©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|3.7||
For a rubber band a simple good model is:
\[
\begin{equation*}
\mathcal{U}=c L_{0} T \tag{61.11.01}
\end{equation*}
\]
and
\[
\begin{equation*}
\tau=b T\left(\frac{L-L_{0}}{L_{1}-L_{0}}\right) \quad \text { for } L_{0} \leq L \leq L_{1} \tag{61.11.02}
\end{equation*}
\]

The corresponding fundamental equation for the rubber band is:
\[
\mathcal{S}=\mathcal{S}_{0}+c L_{0} \log \left[\frac{U}{\mathcal{U}_{0}}\right]-\frac{b\left(L-L_{0}\right)^{2}}{2\left(L_{1}-L_{0}\right)}
\]
where \(b\) and \(c\) are constants.
1. For the rubber band model, calculate the fractional change in \(\left(L-L_{0}\right)\) that results from an increase \(\Delta T\) temperature, at constant tension. Express the result in terms of the length and the temperature.
2. A rubber band is stretched by an amount \(\mathrm{d} L\), at constant \(T\). Calculate the heat transfer \(\mathrm{d} Q\) to the rubber band. Also calculate the work done. How are these related and why?
3. If the energy of the un-stretched rubber band, equation (61.11.01), were found to increase quadratically with \(T\), instead of linearly, would equation (61.11.02) require alteration? Again find the fundamental equation of the rubber band.

\subsection*{61.11.04 Elastic Wire}

This § is referenced at pages:
[2508, 2508]
Si consideri una sbarra elastica, cioè un sistema solido one-dimensionale descrivibile come un sistema elastico ideale. Si definisce il modulo di Young isotermo, \(E\),
\[
\begin{equation*}
\frac{1}{E} \equiv \frac{1}{X}\left(\frac{\partial X}{\partial \tau}\right)_{T} \tag{61.11.03}
\end{equation*}
\]
che ha le dimensioni di una pressione ed è necessariamente non negativo. Infatti se \(E\) fosse negativo significherebbe che comprimendo la sbarra \((\Delta X<0)\) aumenta la tensione ( \(\Delta \tau>0\) ) e quindi la sbarra eserciterebbe una forza di trazione ai propri estremi tendente ad accorciarla ulteriormente rendendo instabile il sistema per fluttuazioni di lunghezza.

\section*{© - QUOTE}
©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|||
An idiosyncrasy of magnetic systems becomes evident if we attempt to consider problems about the condition of equilibrium of two subsystems following the removal of a constraint.
We soon discover that we do not have the capability of constraining the magnetic moment; in practice the magnetic moment is always unconstrained! We can specify and control the magnetic field applied to a sample Uust as we can control the pressure), and we thereby can bring about a desired value of the magnetic moment. We can even hold that value of the magnetic moment constant by monitoring its value and by continually adjusting the magnetic field-again, just as we might keep the volume of a system constant by a feedback mechanism that continually adjusts the external pressure. But that is very different from simply enclosing the \(=\) system in a restrictive wall. There exist no walls restrictive with respect to magnetic moment. Despite the fact that the magnetic moment is an unconstrainable variable, the over-all structure of thermodynamic theory still applies. The fundamental equation, the equations of state, the Gibbs-Duhem, and the Euler relations maintain their mutual relationships. The nonavailability of walls restrictive to magnetic moment can be viewed as a mere experimental quirk, that does not significantly influence the
applicability of thermodynamic theory.

\subsection*{61.11.06 Ideal Solutions}

This § is referenced at pages:
[2488, 2488]

\section*{© - QUOTE}
M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., .... The correlation and prediction of the properties of real materials is greatly facilitated when one has a standard or model of ideal behavior to which real behavior can be compared. Such models should be simple, and they should conform to the behavior of real materials at least in some limiting condition. Thus, as we have seen, the ideal gas serves as a useful model of the behavior of gases, and it represents real-gas behavior in the limit as \(p\) approaches zero.
Another important model is the ideal solution, which serves as a standard of behavior for the composition dependence of the properties of mixtures.
Thus we define an ideal solution as one for which
\[
\mu_{k}=g_{k}+R T \log \left[x_{k}\right]
\]
for all constituent species at all temperatures, pressures, and compositions as a function of the Gibbs energy of pure \(k\) at the \(T\) and \(p\) of the mixture and in the same physical state (real gas, liquid, or solid) as the mixture.
Ideal-gas mixtures are ideal solutions. However, ideal solutions are not necessarily ideal-gas mixtures. Nevertheless, many features of the ideal solution are superficially similar to those of the ideal-gas mixture.

Una soluzione ideale è una soluzione tale che il potenziale chimico del componente \(k\)-esimo in soluzione è dato dalla relazione
\[
\begin{equation*}
\mu_{k}=g_{k}+R T \log \left[x_{k}\right] \tag{61.11.04}
\end{equation*}
\]
\(\rightarrow\)
dove \(x_{k}\) è la frazione molare del componente \(k\)-esimo e \(g_{k}\) è la funzione di Gibbs molare del componente \(k\)-esimo.

Read § 38.02.01.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for additional topics, § ?? - ??.

The problem with long-range interactions can be readily exposed by observign thar additiviy of the internla elergy is lost:
\[
u_{A+B}=u_{A}+u_{A B}+u_{B} \neq u_{A}+u_{B}
\]
due to the appearance of an interaction term, \(\mathcal{U}_{A B}\) whicih is negligible in the case of short-range interactions.

By keeping this in mind, as avery step of classucal thermodynamics must be reviewed under this new light, it is owever possible to bypass the problem by rearranging the three terms:
\[
u_{A+B}=\mathcal{U}_{A}+\left(\mathcal{U}_{A B}+\mathcal{U}_{B}\right)=\left(\mathcal{U}_{A}+\mathcal{U}_{A B}\right)+\mathcal{U}_{B}
\]
so that additivity is recovered but soem arbotrairt, and possibily ambiguitym, is introdcued. In other words, instead of considering the two sysmtes, \(A\) and \(B\), we consider either the two systems \(A\) and \(B\) plus the interaction energy between \(A\) and \(B\), or the two systems \(A\) plus the interaction energy between \(A\) and \(B\) and \(B\).

It must be emphasized that the following discussion is limited to the case of Polarizable and|or Magnetizable materials, and not to fixed Polarization/Magnetization bodies, which need a different dedicated treatment. No hysteresis is allowed as well, which needs a different dedicated treatment as well.

Moreover, an homogeneous and isotropic system is assumed.
In case the material is non homogeneous, the usual local treatment should be carried on to extend the treatment.

In case the material is non isotropic, the relations between ElectroMagnetic fields becomes tensor relations and the usual tensor treatment should be carried on to extend the treatment.

Pressure and volume are thermodynamics variables for every material system. Even if they will be neglected in the present treatment, the formalism of thermodynamics can be used to include pressure and volume changes.

Finally, in order to simplify the mathematical technicalities, very small samples are assumed.
As usual, thermodynamics provides general relations, while statistical physics allows to determine the particular form of the thermodynamic functions according to the specific model.

\section*{© - QUOTE}
... Guggenheim has applied thermodynamics to a static ElectroMagnetic system, which includes the whole infinite field and all bodies in it, the latter in thermal equilibrium with one another at an absolute temperature T. ...
... Expressions for the ElectroMagnetic contributions to the Helmholtz free energy and the entropy follow from ..., and any other thermodynamic function may be derived from these two as required. The following conditions apply to Guggenheim treatment and also to the present work: steady-state conditions and slow reversible thermodynamic processes are assumed; all bodies are constrained to constant volume; Electric|Magnetic susceptibilities maybe anisotropic, vary as functions of position, and may depend on the temperature and field strengths; hysteresis effects are absent. ...
... there is one point that needs emphasizing. The work ... involves integrations over all space where the fields do not effectively vanish. This work is stored by the system as a whole, and not necessarily with an energy density \(\mathbf{E} \cdot \delta \mathbf{D}+\mathbf{H} \cdot \delta \mathbf{B}\). Thus previous results apply to the complete region of the field, without giving any indication of how the work, free energy and entropy may be distributed between the different bodies. It has not always been recognized in the past that there is no physical significance in assuming the energy to be distributed through space in any definite way. The different parts of the field are all closely and automatically coupled, because of the action at a distance nature of ElectroMagnetic forces. The only independent thermodynamic quantities of ElectroMagnetic origin that are directly physically observable are the heat flowing in or out of the individual bodies, and the total net work done on the whole region of the field during any rearrangement of charges, currents and magnets. Thus the individual free energy of one body has no physical significance itself. However, associated with each body there is a definite entropy, from which its individual properties can be deduced; for instance, the cooling on adiabatic deMagnetization. ..
... the thermodynamic behavior of any one of the bodies in the ElectroMagnetic field is determined by introducing the principle that its behavior depends only on the field over the region of that body itself. Hence another system is considered instead, consisting of the particular body, with all other material media being replaced by free space; a certain redistribution of charges and currents ensures that the field strengths inside the body are exactly the same as before. The thermodynamic behavior of this auxiliary system is completely determined by Guggenheim results, because there is only the one body to which heat and temperature changes can refer. ...
... The formulae of the last section will now be re-expressed in terms of the externally applied field. Consider a single body, at a uniform temperature, in a static ElectroMagnetic field produced by some set of charges and currents. ...
... The infinitesimal work, \(\delta W\) done in introducing or rearranging charges or currents may be transformed to:
\[
\delta W=\iiint_{\infty}\left(\mathbf{E}_{0} \cdot \delta \mathbf{D}_{0}\right) \mathrm{d} V+\iiint_{\infty}\left(\mathbf{H}_{0} \cdot \delta \mathbf{B}_{0}\right) \mathrm{d} V+\iiint_{V}\left(-\mathbf{P} \cdot \delta \mathbf{E}_{0}\right) \mathrm{d} V+\iiint_{V}\left(+\mathbf{B}_{0} \cdot d \mathbf{M}\right) \mathrm{d} V
\]
(61.12.01)

The difficulty in this case is that the long-range ElectroMagnetic forces, makes impossible to unambiguously disentangle the field/material/interaction energies.
One starts from the calculation of the work, that is the change of energy, following ElectroMagnetism, and, following thermodynamics, equates this to the adiabatic work, according to the first law of thermodynamics; in fact, thermodynamics tells us that the adiabatic work is a function of state (and only adiabatic work) is a work not depending on the path.

\section*{© - QUOTE}

We may illustrate the point by a simple example due to Purcell. Consider a volume of gas confined in one part of a cylinder and bounded on one side by a piston attached to a compressed spring. The spring exerts a force \(|F|=p A\) on the piston; here \(p\) is the pressure and \(A\) the area of the piston. For small displacements of the piston from the position shown we may take \(F\) as constant. If, as is usual, we take the gas to be the thermodynamic system, we have on heating the gas: \(\mathrm{d} \mathcal{U}_{G}=\delta Q+\delta \mathcal{W}=\delta Q-|F| \Delta x\) as work has to be done to compress more the spring ( \(\delta \mathcal{W}=-|F| \Delta x<0\) ).
We may, however, take the thermodynamic system as composed of both the gas and the spring. Then no external work is done, but \(\mathrm{d} \mathfrak{u}_{G}+\mathrm{d} \mathfrak{U}_{S}=\delta Q\)
These equations are consistent each other. We see that the two ways of dividing up the internal energy of the system have identical thermodynamic consequences; the difference is merely a question of bookkeeping.

Read § 38.01 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology and § 38.02 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for simple examples explicitly calculated. Read § 38.04.06 - ElectroMagnetism - Miscellaneous Complements Applications and Phenomenology for explicit discussion of Polarization/Magnetization by orientation for permanent Dipoles.

\subsection*{61.12.01 Materials in External ElectroMagnetic Fields}

The ElectroMagnetic properties of any substance are not independent of their thermal properties, like other properties, such as physical properties (density for instance), mechanical properties (the Young module, for instance) and optical properties (the refractive index, for instance).
When dealing with electric or magnetic substances in ElectroMagnetic fields one must introduce a fundamental function, the entropy and|or the internal energy, dependent of ElectroMagnetic variables in order to characterize the ElectroMagnetic and thermal properties of the material.
The problem of the choice of the ThermoDynamics variables is a very subtle one because ElectroMagnetic interactions (that is charges and currents) interact at distance by means of the ElectroMagnetic fields. As a consequence the separation between different parts of the system cannot be carried on in a unique way. The very definition of work is thus affected.
Note that in all the following considerations the self-energy of a point charges or Dipoles (either electric or magnetic) or any other fixed-structure object (a fixed structure) does not enter explicitly into the energy considerations as long as the structure does not change. As long as the structure does not change the self-energy stays constant.
There exist different methods and procedures for the definition of the system and of the pair of conjugate variables, differing in the way the ElectroMagnetic fields are taken into account.
It is useful to remind that, when dealing with ElectroMagnetism in matter, the ElectroMagnetic fields and propersts are the macroscopic ElectroMagnetic fields and propertis, resluting from the spatial average of the microscopic ElectroMagnetic fields, averaging to be done on a scale small at the macroscopi level but large at the microscopic level. The spatial average thus condicted allow to get rid of the variation of the ElectroMagnetic fields and propertis at the microscopic scale.
This approach implies that the Polarization and Magnetization vectors, \(\mathbf{P}\) and \(\mathbf{M}\), are slowly varying at the macroscopic scale and therefore the total average charge and current density can be split into the contribution from free charges and those from Electric|Magnetic Dipoles:
\[
\rho=\rho^{\mathrm{F}}+\rho^{\mathrm{P}}=\rho^{\mathrm{F}}-\operatorname{div} \mathbf{P} \quad \mathbf{j}=\mathbf{j}^{\mathrm{F}}+\mathbf{j}^{\mathrm{P}}+\mathbf{j}^{\mathrm{M}}=\mathbf{j}^{\mathrm{F}}+\partial_{\mathrm{t}} \mathbf{P}+\operatorname{rot} \mathbf{M}
\]

Tha charge conservation law and Maxwell Equations apply as well.
Note that in some cases it might be necessary to consider higher orders multipolar contributions in addition to the Electric|Magnetic Dipoles.

\subsection*{61.12.02 Matter in Electric Fields}

This § is referenced at pages:
[2492, 2492, 2515, 2515]
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
The total work received during an adiabatic transformation by the total system made of the external conductors and charges (the external sources), the field and the Polarizable material is calculated:
\[
\begin{equation*}
\delta \mathcal{W}_{\text {TOT }}=\int_{\infty}(\mathbf{E} \cdot \delta \mathbf{D}) \mathrm{d} V \tag{61.12.02}
\end{equation*}
\]

This work to build up the fields and Polarization is produced by the external generators, if any, and|or by the external agents keeping the system in almost-equilibrium at any time in order to implement a quasi-static transformation.

The electric field \(\mathbf{E}\) appears as the intensive variable.
The product of the electric field \(\mathbf{D}\) with the infinitesimal volume element appears as the extensive variable for the whole system.

Up to now the procedure is totally unambiguous.
One can then try to split the work in equation (61.12.02) into contributions from the different parts of the system.

The work in equation (61.12.02) contains both the work done to Polarize the material and the energy used to produce the field.
In the case of a linear Polarizable material:
\[
\begin{equation*}
\delta \mathcal{W}_{\mathrm{TOT}}=\frac{1}{2} \int_{\infty} \delta(\mathbf{D} \cdot \mathbf{E}) \mathrm{d} V \tag{61.12.03}
\end{equation*}
\]

\subsection*{61.12.02.01 Constant Charges}

This § is referenced at pages:
[2635, 2635]
Consider the case when the electric field is produced by a set of fixed charges. Let the electric field produced in absence of the Polarizable material be \(\mathbf{E}_{0}\). This is different from \(\mathbf{E}_{1}\) of \(\S 61.12 .02 .02\) Thermodynamics in Action. The work to produce the electric field in absence of the Polarizable material is:
\[
\begin{equation*}
\delta \mathcal{W}_{\mathrm{EMPTY}}^{0}=\varepsilon_{0} \int_{\infty}\left(\mathbf{E}_{0} \cdot \delta \mathbf{E}_{0}\right) \mathrm{d} V \tag{61.12.04}
\end{equation*}
\]

\section*{System Made of the Polarizable Material Plus Its Interaction With the Applied Field}

It seems to be natural to split the total work into two parts. The first part consists of the part related to the sources and the field when no Polarizable material is present. The second part of the work is related to the Polarizable material and to its interaction with the electric field. The change of this second part during an adiabatic transformation is thus:
\[
\delta \mathcal{W}_{0} \equiv \delta \mathcal{W}_{\mathrm{TOT}}-\delta \mathcal{W}_{\mathrm{EMPTY}}^{0}
\]
which can be written as
\[
\begin{equation*}
\delta W_{0}=-\int_{\mathrm{MAT}}\left(\mathbf{P} \cdot \delta \mathbf{E}_{0}\right) \mathrm{d} V \tag{61.12.05}
\end{equation*}
\]

The two conjugate variables appearing in the definition (61.12.05) of the work received by the Polarizable material are the applied field, \(\mathbf{E}_{0}\), and the Polarization of the material. The work received by the material is expressed as an integral over the volume of the Polarizable material only, in direct contrast with the total work in equation (61.12.02), expressed as an integral over the whole space.
If one knows the equation of state relating \(\mathbf{P}\) to \(\mathbf{E}\) (or, equivalently, \(\mathbf{E}_{0}\) ) one can find a thermodynamic potential by integrating (61.12.05). The Polarization is usually expressed as a function of the applied field \(\mathbf{E}_{0}\) and the temperature. This introduces naturally a free energy, \(\mathcal{F}^{0}\left[T, \mathbf{E}_{0}\right]\). This is the suitable thermodynamic potential to describe the Polarizable material in the field produced by given sources, those which would produce the field \(\mathbf{E}_{0}\) in absence of the Polarizable material. The free energy can thus be expressed as:
\[
\begin{equation*}
\mathcal{F}^{0}\left[T, \mathbf{E}_{0}\right]-\mathcal{F}^{0}[T, \mathbf{0}]=-\int_{0}^{1} \mathrm{~d} \lambda \int_{\mathrm{MAT}}\left(\mathbf{P}\left[T, \lambda \mathbf{E}_{0}\right] \cdot \mathbf{E}_{0}\right) \mathrm{d} V \tag{61.12.06}
\end{equation*}
\]

The difference in equation (61.12.06) is the total work supplied to bring the Polarizable material from infinity to the region where the field is \(\mathbf{E}_{0}\) when the Polarizable material is not there, at constant temperature and for fixed values of the external sources, at fixed charges.

The Legendre transform gives the internal energy of the system consisting of the material and of its interaction with the applied field \(\mathbf{E}_{0}\) which would be created by the external sources alone:
\[
\begin{equation*}
\mathcal{U}^{0}\left[\mathcal{S}, \mathbf{E}_{0}\right]=\mathcal{F}^{0}\left[T, \mathbf{E}_{0}\right]+T \mathcal{S} \tag{61.12.07}
\end{equation*}
\]

The analogous study at the microscopic level can be best carreid on by resticting to a partial Hamiltonian describing the Polarizable material in the applied field \(\mathbf{E}_{0}\) only, instead of writing a global Hamiltonian of the Polarizable material and the outside sources. This Hamiltonian depnds on \(\mathbf{E}_{0}\) only through the term:
\[
\begin{equation*}
-\int\left(\hat{\mathbf{P}} \cdot \mathbf{E}_{0}\right) \mathrm{d} V \tag{61.12.08}
\end{equation*}
\]
where \(\int \hat{\mathbf{P}} \mathrm{d} V\) is the sum of the microscopic Electric Dipoles. It contains other terms accountig for interaxctions between the latter. This approach is the microscopic conterpart of waht describred so far. Infact, if \(\mathbf{E}_{0}\) is varyed slowly and there is no heat exchange with the sourrounding world, the change in the Hamiltonian can be identified with (61.12.08) where \(\mathbf{P}\) is interpreted as the statistical average of \(\hat{\mathbf{P}}\). By regarding this energy variation as as work in an adiabatic transformation we can identify \(\langle\hat{H}\rangle\) with the macroscopic internal energy (61.12.07). The replacement of the applied field \(\mathbf{E}_{0}\) in the macroscopic Maxwell Equations by the total field \(\mathbf{E}\) is the result of the interaction between Dipoles.

\section*{System Made of the Polarizable Material Only}

The contribution of the interaction of the Polarizable material with the applied field can be subtracted as follows. We no longer include the interaction term:
\[
-\int\left(\mathbf{E}_{0} \cdot \hat{P}\right) \mathrm{d} V
\]

The work received by the Polarizable material itself is:
\[
\begin{equation*}
\delta \mathcal{W}=\int\left(\mathbf{E}_{0} \cdot \delta \mathbf{P}\right) \mathrm{d} V \tag{61.12.09}
\end{equation*}
\]

At constant charge:
\[
\begin{equation*}
F_{\xi}=-\left.\left(\frac{\partial W}{\partial \xi}\right)\right|_{Q}=\int_{\text {Volume }}(\mathbf{P} \cdot \boldsymbol{g r a d}) \mathbf{E}_{0} \mathrm{~d} V \tag{61.12.10}
\end{equation*}
\]

\subsection*{61.12.02.02 Constant Voltages}

This § is referenced at pages:
[2633, 2633]
Consider the case when the electric field is produced by a set of fixed potentials. Let the electric field produced in absence of the Polarizable material be \(\mathbf{E}_{1}\). This is different from \(\mathbf{E}_{0}\) of § 61.12.02.01Thermodynamics in Action. The work to produce the electric field in absence of the Polarizable material is:
\[
\begin{equation*}
\delta \mathcal{W}_{\mathrm{EMPTY}}^{1}=\varepsilon_{0} \int_{\text {A11Space }}\left(\mathbf{E}_{1} \cdot \delta \mathbf{E}_{1}\right) \mathrm{d} V . \tag{61.12.11}
\end{equation*}
\]

\section*{System Made of the Polarizable Material Plus Its Interaction With the Applied Field}

It seems to be natural to split the total work into two parts. The first part consists of the part related to the sources and the field when no Polarizable material is present. The second part of the work is related to the Polarizable material and to its interaction with the electric field. The change of this second part during an adiabatic transformation is thus:
\[
\delta W_{1} \equiv \delta W_{\text {TOT }}-\delta \mathcal{W}_{\text {EMPTY }}^{1}
\]
which can be written as
\[
\begin{equation*}
\delta W_{1}=+\int_{\text {MAT }}\left(\mathbf{E}_{1} \cdot \delta \mathbf{P}\right) \mathrm{d} V \tag{61.12.12}
\end{equation*}
\]

The two conjugate variables appearing in the definition (61.12.12) of the work received by the Polarizable material are the applied field, \(\mathbf{E}_{1}\), and the Polarization of the material. The work received by the material is expressed as an integral over the volume of the Polarizable material only, in direct contrast with the total work in equation (61.12.02), expressed as an integral over the whole space.
If one knows the equation of state relating \(\mathbf{P}\) to \(\mathbf{E}\) (or, equivalently, \(\mathbf{E}_{1}\) ) one can find a thermodynamic potential by integrating (61.12.12). The Polarization is usually expressed as a function of the applied field \(\mathbf{E}_{1}\) and the temperature. This introduces naturally a free energy, \(\mathcal{F}^{1}\left[T, \mathbf{E}_{1}\right]\). This is the suitable thermodynamic potential to describe the Polarizable material in the field produced by given sources, those which would produce the field \(\mathbf{E}_{1}\) in absence of the Polarizable material. The free energy can thus be expressed as:
\[
\begin{equation*}
\mathcal{F}^{1}\left[T, \mathbf{E}_{1}\right]-\mathcal{F}^{1}[T, \mathbf{0}]=+\int_{0}^{1} \mathrm{~d} \lambda \int_{\text {MAT }}\left(\mathbf{E}_{1}[T, \lambda \mathbf{P}] \cdot \mathbf{P}\right) \mathrm{d} V \tag{61.12.13}
\end{equation*}
\]

The difference in equation (61.12.13) is the total work supplied to bring the Polarizable material from infinity to the region where the field is \(\mathbf{E}_{1}\) when the Polarizable material is not there, at constant temperature and for fixed values of the external sources, at fixed potentials.
The Legendre transform gives the internal energy of the system consisting of the material and of its interaction with the applied field \(\mathbf{E}_{1}\) which would be created by the external sources alone:
\[
\begin{equation*}
\mathcal{U}^{1}\left[\mathcal{S}, \mathbf{E}_{1}\right]=\mathcal{F}^{1}\left[T, \mathbf{E}_{1}\right]+T \mathcal{S} . \tag{61.12.14}
\end{equation*}
\]

\section*{System Made of the Polarizable Material Only}
\[
\begin{equation*}
\delta W_{1}=-\int_{\mathrm{MAT}}\left(\mathbf{P} \cdot \delta \mathbf{E}_{1}\right) \mathrm{d} V \tag{61.12.15}
\end{equation*}
\]

Forces and Torque on a Polarizable Material in the Electric Field at Constant Voltages
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|4.7||
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|23.3||
\[
\begin{equation*}
F_{\xi}=+\left.\left(\frac{\partial W}{\partial \xi}\right)\right|_{V}=\int_{\text {Volume }}(\mathbf{P} \cdot \mathbf{g r a d}) \mathbf{E}_{0} \mathrm{~d} V \tag{61.12.16}
\end{equation*}
\]

\subsection*{61.12.02.03 Interaction of Polarization With Electric Fields}

The interaction of an Electric Dipole p with the electric field is given by:
\[
u^{\prime}=-\mathrm{p} \cdot \mathbf{E}_{0}
\]

The Dipole p interacts with the external field \(\mathbf{E}_{0}\). The fact that the real electric field is not \(\mathbf{E}_{0}\) but \(\mathbf{E} \neq \mathbf{E}_{0}\) is due to the presence of the Polarizable material itself and therefore it does not enter in the interaction field energy.

\subsection*{61.12.02.04 First Law of ThermoDynamics}

Assume isothermal conditions.
Assume fixed field sources, that is fixed charge distribution. The external generators do no work to keep the fixed charge distribution.

The first law of thermodynamics, for a small volume of matter \(\Delta V\), reads:
\(\mathrm{M}:=\) matter
\(\mathrm{M}+\mathrm{F}:=\) matter plus field interaction
\[
\begin{array}{rlr}
\mathcal{U}_{\mathrm{F}} & =\frac{\varepsilon_{0}}{2}\left(\mathbf{E}_{0} \cdot \mathbf{E}_{0}\right) \Delta V \\
\delta \mathcal{U}_{\mathrm{M}} & =\delta \mathcal{Q}-p \mathrm{~d} V+\left(\mathbf{E}_{0} \cdot \delta \mathbf{P}\right) \Delta V & \delta \mathscr{F}_{\mathrm{M}}=-\mathcal{S} \mathrm{d} T-p \mathrm{~d} V+\left(\mathbf{E}_{0} \cdot \delta \mathbf{P}\right) \Delta V \\
\delta \mathcal{U}_{\mathrm{M}+\mathrm{F}} & =\delta \mathcal{Q}-p \mathrm{~d} V-\left(\mathbf{P} \cdot \delta \mathbf{E}_{0}\right) \Delta V & \delta \mathcal{F}_{\mathrm{M}+\mathrm{F}}=-\left(\mathbf{P} \cdot \delta \mathbf{E}_{0}\right) \Delta V
\end{array}
\]
does not include field interaction energ, does include field interaction en

Both relations are correct; the difference is that the internal energy is defined in ( \(M+F\) ) and ( \(M\) ) for different thermodynamic systems:
\[
\delta \mathrm{U}_{\mathrm{M}+\mathrm{F}}-\delta \mathrm{U}_{\mathrm{M}}=-\Delta V \delta\left(\mathbf{P} \cdot \mathbf{E}_{0}\right)
\]

Clearly, the transformation between \(\mathcal{U}_{M+F}\) and \(\mathcal{U}_{M}\) is a Legendre transformation, similar to the transformation between energy and entalphy.

The different definitions of the energy of the Polarizable material share the energy in a different way between the different parts of the complete system formed by the external conductors, the field and the Polarizable material.

Only the global expression (61.12.02), which includes the field sources, has an intrinsic significance. All other expressions are convenient computational tools. The external sources are eliminated in all cases, but this elimination leads to different results depending on the nature of the sources (either fixed charges or potentials). Moreover, in both cases one may include or not the interaction of the matter with the field.

In all cases the conjugate variables are the Polarization, \(\mathbf{P}\), and the so-called applied field, \(\mathbf{E}_{0}\) or \(\mathbf{E}_{1}\), that is the field which would be produced by the fixed charges or potentials if there were no Polarizable
material. Note also that the role of the displacement is played in any case by the variable under the \(\delta\), which is either \(\mathbf{P}\) or the applied field. The role of the force is played by the other variable. It is important to distinguish these cases in order to identify the natural variables of the thermodynamic potentials, which are always the displacement variables.
The point of view of fixed charges is better suited to the microscopic point of view. In fact the applied field \(\mathbf{E}_{0}\) does not include the Polarization of the Polarizable material. It occurs in the Hamiltonian as in equation (61.12.08).

\subsection*{61.12.03 Matter in Magnetic Fields}

This § is referenced at pages:
[2492, 2492, 2516, 2516]
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|||
The total work received during an adiabatic transformation by the total system made of the external currents (the external sources), the field and the magnetic substance is calculated:
\[
\begin{equation*}
\delta W_{\text {Tот }}=\int_{\infty}(\mathbf{H} \cdot \delta \mathbf{B}) \mathrm{d} V \tag{61.12.17}
\end{equation*}
\]

\footnotetext{
\(\rightarrow\) 26372638
}

This work to build up the fields and Magnetization is produced by the external generators, if any, and|or by the external agents keeping the system in almost-equilibrium at any time in order to implement a quasi-static transformation.
The magnetic field \(\mathbf{H}\) appears as the intensive variable.
The product of the magnetic field \(\mathbf{B}\) with the infinitesimal volume element appears as the extensive variable for the whole system.
Up to now the procedure is totally unambiguous.
One can then try to split the work in equation (61.12.17) into contributions from the different parts of the system.
The work in equation (61.12.17) contains both the work done to Magnetize the material and the energy used to produce the field.
In the case of a linear Magnetizable material:
\[
\begin{equation*}
\delta W_{\text {тот }}=\frac{1}{2} \int_{\infty} \delta(\mathbf{H} \cdot \mathbf{B}) \mathrm{d} V \tag{61.12.18}
\end{equation*}
\]

\subsection*{61.12.03.01 Constant Magnetic Flux}

Let the currents free to change. If the magnetic substance is removed from the fields the equation of current generating circuit is:
\[
\varepsilon=R I+L \dot{I}
\]

Assume \(R\) to be negligible, \(R \simeq 0\). In any case one always neglects the energy dissipated by Joule effect, because it has nothing to do with energy of the matter in the field. Until the material moves: \(\delta \phi_{B} \neq 0\) and \(\dot{I} \neq 0\). Therefore \(I\) is changing. As soon as the material stops moving \(\dot{I}=0\) and the current remains constant. The current at the end of the moving process is different from the one at the beginning. This is the analogous of the constant voltage case for electric fields.

\section*{System Made of the Magnetic Substance Plus Its Interaction With the Applied Field}

Let \(\mathbf{B}_{0}\) be the magnetic field which would occur if the Magnetizable substance were removed without any action on the external currents. Furthermore suppose that the external currents are produced by superconducting wires in order to neglect the Joule dissipation and avoid the need for external generators.
\[
\begin{equation*}
\delta W_{0}=-\int_{\mathrm{MAT}}\left(\mathbf{M} \cdot \delta \mathbf{B}_{0}\right) \mathrm{d} V \tag{61.12.19}
\end{equation*}
\]

The substance is brought into the field without any action on the external currents. Currents are therefore induced and hence the current changes. This work includes this part of energy.

System Made of the Magnetic Substance Only
\[
\delta W_{0}=-\int_{\mathrm{MAT}}\left(\mathbf{B}_{0} \cdot \delta \mathbf{M}\right) \mathrm{d} V
\]

\subsection*{61.12.03.02 Constant External Currents}

Let \(\mathbf{B}_{1}\) be the magnetic field which would occur if the Magnetizable substance were removed while keeping constant external currents.

\section*{System Made of the Magnetic Substance Plus Its Interaction With the Applied Field}

The work received by the substance, including its interaction with the field, for an arbtrary change of parameters is obtained by subtracting from the general expression (61.12.17) the work when no material is present:
\[
\begin{gather*}
\int_{\infty}(\mathbf{H} \cdot \delta \mathbf{B}) \mathrm{d} V-\frac{1}{\mu_{0}} \int\left(\mathbf{B}_{1} \cdot \delta \mathbf{B}_{1}\right) \mathrm{d} V . \\
\delta W=\int\left(\mathbf{B}_{1} \cdot \delta \mathbf{M}\right) \mathrm{d} V . \tag{61.12.20}
\end{gather*}
\]

Using this expression we get by integration the total work released by the generators to maintain the external currents constant and by an observer to bring the substance from infinity into the field.

\section*{System Made of the Magnetic Substance Only}

If one is interested only in the work done on the substance itself with the external currents being kept constant and not in the lectric work provided by the generators the latter must be substracted. The latter is given by:
\[
\begin{array}{cl}
\delta \int \mathbf{j} \cdot \mathbf{A} \mathrm{d} V & \text { if the magntic substance is present } \\
\delta \int \mathbf{j}_{1} \cdot \mathbf{A}_{1} \mathrm{~d} V & \text { if the magntic substance is not present }
\end{array}
\]
\[
\begin{equation*}
\delta W=-\int\left(\mathbf{M} \cdot \delta \mathbf{B}_{1}\right) \mathrm{d} V \tag{61.12.21}
\end{equation*}
\]

This point of view is the best suited for the microscopic study, with the external field \(\mathbf{B}_{1}\) produced by external constant currents.

Forces and Torques on a Magnetic Substance in the Magnetic Field at Constant Currents
©|J.D.Jackson, Classical Electrodynamics, 1999, J.Wiley \& Sons, 3rdEd., ....|6.2||
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|23.3||
\[
\begin{equation*}
F_{\xi}=+\left.\left(\frac{\partial W}{\partial \xi}\right)\right|_{J}=\int_{\text {Voiume }}(\mathbf{M} \cdot \operatorname{grad}) \mathbf{B}_{1} \mathrm{~d} V \tag{61.12.22}
\end{equation*}
\]

In this case the energy change is the total energy change due to the introduction of the material in the magnetic field. it includes the energy delivered by the generators to keep constant currents, like in the case of constant electric potentials.

\subsection*{61.12.03.03 Interaction of Magnetization With Magnetic Fields}
©|R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....|Vol. 2 - § 15.2||
©|D.J.Griffiths|WEB - URL|Excellent|
© ||WEB - URL|Excellent|
© ||WEB - URL \(\mid\) Excellent \(\mid\)
© ||WEB - URL||
©||WEB - URL||
The - Let us name it - mechanical interaction interaction energy of a Magnetic Dipole m with the magnetic field is given by:
\[
\mathfrak{u}^{\prime}=-\mathbf{m} \cdot \mathbf{B}_{1}
\]

The Magnetic Dipole m interacts with the external field \(\mathbf{B}_{1}\). This energy does not include the work done by any generator to keep the currents constant.
The total energy of the system Magnetic Dipole plus current sources, on the other hand, is:
\[
u^{\prime \prime}=+\mathbf{m} \cdot \mathbf{B}_{1}
\]

This energy does include the work done by generators to keep all the currents constant (the current of the Magnetic Dipole and the constant currents generating the external field).
The fact that the real magnetic field, \(\mathbf{B}\), is not \(\mathbf{B}_{1}\) but \(\mathbf{B} \neq \mathbf{B}_{1}\) is due to the field produced by the Magnetic Dipole itself and therefore it does not enter in the interaction field energy.

\subsection*{61.12.03.04 First Law of Thermodynamics}

Assume isothermal conditions.
Assume fixed field sources, that is fixed current distribution. The external generators do work to keep the fixed current distribution.
The first law of thermodynamics, for a small volume of matter \(\Delta V\), reads:
\[
\begin{aligned}
& \mathrm{M}:=\text { matter } \\
& \mathrm{M}+\mathrm{F}:=\text { matter plus field interaction }
\end{aligned}
\]
\[
\begin{aligned}
\mathcal{U}_{\mathrm{F}} & =\frac{1}{2 \mu_{0}}\left(\mathbf{B}_{1} \cdot \mathbf{B}_{1}\right) \Delta V & \\
\delta U_{\mathrm{M}} & =\delta Q-p \mathrm{~d} V-\left(\mathbf{M} \cdot \delta \mathbf{B}_{1}\right) \Delta V & \delta \mathscr{F}_{\mathrm{M}}=-\delta \mathrm{d} T-p \mathrm{~d} V-\left(\mathbf{M} \cdot \delta \mathbf{B}_{1}\right) \Delta V \\
\delta U_{\mathrm{M}+\mathrm{F}} & =\delta Q-p \mathrm{~d} V+\left(\mathbf{B}_{1} \cdot \delta \mathbf{M}\right) \Delta V & \delta \mathscr{F}_{\mathrm{M}+\mathrm{F}}=-\delta \mathrm{d} T-p \mathrm{~d} V+\left(\mathbf{B}_{1} \cdot \delta \mathbf{M}\right) \Delta V
\end{aligned}
\]
does not include field interaction ener
does include field interaction el

Both relations are correct; the difference is that the internal energy is defined in ( \(\mathrm{M}+\mathrm{F}\) ) and ( M ) for different thermodynamic systems:
\[
\delta u_{M+F}-\delta u_{M}=+\Delta V \delta\left(\mathbf{M} \cdot \mathbf{B}_{1}\right)
\]

Clearly, the transformation between \(\mathcal{U}_{M+F}\) and \(\mathcal{U}_{M}\) is a Legendre transformation, similar to the transformation between energy and enthalpy.
Actually, as the ElectroMagnetic relations apply at constant temperature only, all the previous relations do not represent the internal energy, but the free Helmholtz energy.

\subsection*{61.12.04 Summary of Thermo-Mechanics of Matter in ElectroMagnetic Fields}

This § is referenced at pages:
[2606, 2606]
©|R.K. P. Zia, Edward F. Redish, Susan R. McKay|Making sense of the Legendre transform|Am.J.Phys, , ..., ..., ...Ed., ...., Vol. 77, No. 7, July 2
The Legendre transform, in its basic form, shows how to define a function that contains the same information as the smooth strictly convex/concave function \(F[x]\), but as a function of \(F^{\prime}[x]\) :
\[
G[s] \equiv s x[s]-F[x[s]] \Longrightarrow \quad\left\{\quad G^{\prime}[s]=x[s] \quad \text { and } \quad F^{\prime}[x]=s[x] \quad\right\}
\]

Moreover:
\[
G[s]+F[x]=s x \quad G^{\prime \prime}[s]=x^{\prime}[s] \quad F^{\prime \prime}[x]=s^{\prime}[x]
\]

The Legendre transform appears frequently in thermodynamics when different variables are traded for their conjugates.

\subsection*{61.14 \\ Examples and Physical Applications}

\subsection*{61.14.01 Ice Fusion by Adiabatic Reversible Compression}

\subsection*{61.14.02 Polytropic Transformation for a Pure Substance}

Per esprimere la relazione tra pressione e volume in una trasformazione quasi statica generica di una sostanza pura si usa spesso l'equazione empirica:
\[
\begin{equation*}
p V^{\delta}=\text { constant }=p_{0} V_{0}^{\delta} \tag{61.14.01}
\end{equation*}
\]
(detta trasformazione politropica), dove \(\delta\) è una costante adimensionale opportuna che definisce la trasformazione.
- Il caso \(\delta=0\) corrisponde ad una trasformazione isobara.
- Il caso \(\delta=1\) corrisponde ad una trasformazione isoterma, nel caso di un gas ideale.
- Il caso \(\delta \longrightarrow+\infty\) corrisponde ad una trasformazione isocora.
- Il caso \(\delta=\gamma=\) indipendente dalla temperatura corrisponde ad una trasformazione adiabatica

It is implicit that the transformation is reversible, or at least quasi-static, as we have an equation assuming that \(p\) and \(V\) are properties of the system and are defined at each stage.
1. Show that the work is
\[
\mathcal{W}=\frac{p_{0} V_{0}}{\delta-1}\left(\left(\frac{p}{p_{0}}\right)^{(\delta-1) / \delta}-1\right)=\frac{p_{0} V_{0}}{\delta-1}\left(\left(\frac{V}{V_{0}}\right)^{1-\delta}-1\right) \quad \text { per } \delta \neq 1
\]

Verify it is coincident with the known values for \(\delta=0,1, \gamma,+\infty\).
2. Calculate the specific heat along a polytropic transformation and verify it is coincident with the known values for \(\delta=0,1, \gamma,+\infty\).

\subsection*{61.14.03 Properties of a Ideal Gas}

An experiment by Joule in the mid-19th century established that the energy of a low density gas is independent of its volume.
1. Show that for a ideal gas internal energy and|or enthalpy only depends on the temperature.
2. Show that for a ideal gas: \(c_{\mathrm{p}}[T]-c_{\mathrm{V}}[T]=R\).
3. Determine the fundamental equation for the energy.

\subsection*{61.14.04 Properties of Clausius Fluid}

L'equazione di stato di Clausius per un gas è
\[
\begin{equation*}
p(v-b)=R T \quad \Leftrightarrow \quad p(V-n b)=n R T \tag{61.14.02}
\end{equation*}
\]
dove \(b\) è una costante caratteristica del gas.
Demonstrate the following statements.
1. L'energia interna specifica per un gas di Clausius è data dalla relazione
\[
\begin{equation*}
\left(\frac{\partial u}{\partial v}\right)_{T}=0 \quad u=c_{V} T+\text { constant }, \tag{61.14.03}
\end{equation*}
\]
la stessa del gas ideale: perchè?
2. The work on a isothermal transformation.
3. Per un gas di Clausius si ha la relazione
\[
c_{\mathrm{p}}-c_{\mathrm{V}}=R
\]
4. It can be shown that:
\[
\Delta \mathcal{S}=n R \log \left[\frac{V-n b}{V_{0}-n b}\right]+\int_{T_{0}}^{T} \frac{C_{\mathrm{V}}}{T} \mathrm{~d} T
\]
5. L'equazione per un processo adiabatico quasi-statico è
\[
p(V-n b)^{\gamma}=\text { constant } \text {. }
\]
6. Il modulo di compressibilità isoterma di un gas di Clausius è dato da
\[
\kappa_{\mathrm{T}}=\frac{(v-b)}{p v} .
\]
7. L'efficienza di una macchina termica di Carnot che usa un gas di Clausius come sostanza di lavoro è la stessa che del gas ideale, come si deduce dalla (61.14.03).

\subsection*{61.14.05 Properties of Van Der Waals Fluid}
© JJ.M.Powers, Lecture Notes On Thermodynamics, \(\qquad\)
©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|3.5 excellent!!!!||
L'equazione di stato di un fluido di Van der Waals è
\[
\left(p+\frac{a}{v^{2}}\right)(v-b)=R T \quad \Leftrightarrow \quad\left(p+\frac{n^{2} a}{V^{2}}\right)(V-n b)=n R T
\]
dove \(a\) e \(b\) sono costanti caratteristiche del gas.
The rationale is:
- The volume really available to the molecules is not the full volume of the container, \(V\), but it is reduced by an amount proportional to the number of molecules;
- long-range weakly attractive Van Der Waals forces reduce the momenta of the molecules hitting the walls of the volume and thus the pressure and every molecule is slowed by all the others so that the correction term is proportional to the square on the number of molecules.
Clearly, the pressure correction term make the Van der Waals model non extensive.
Demonstrate the following statements.
1. Find \(c_{\mathrm{p}}-c_{\mathrm{V}}\) for a Van der Waals fluid. Per un fluido di Van der Waals si ha la relazione
\[
c_{\mathrm{p}}-c_{\mathrm{V}}=R\left(\frac{R T v^{3}}{R T v^{3}-2 a(v-b)^{2}}\right)
\]
2. Find that the most general expression of \(\mathcal{U}[T, V]\) for a Van der Waals fluid is:
\[
\begin{equation*}
u=c_{\mathrm{V}} T-\frac{a}{v}+\text { constant } \tag{61.14.05}
\end{equation*}
\]

\section*{SOLUTION}

In fact:
\[
\begin{gathered}
\left(\frac{\partial u}{\partial V}\right)_{T}=a \frac{n^{2}}{V^{2}}, \\
\mathrm{~d} u=C_{\mathrm{V}} \mathrm{~d} T+a \frac{n^{2}}{V^{2}} \mathrm{~d} V, \\
\left(\frac{\partial C_{\mathrm{v}}}{\partial V}\right)_{T}=0 \quad \text { from du being an exact differential }, \\
u-u_{0}=\int_{T_{0}}^{T} C_{\mathrm{V}}[T] \mathrm{d} T-a n^{2}\left(\frac{1}{V}-\frac{1}{V_{0}}\right)
\end{gathered}
\]

\section*{© - QUOTE}

It should, perhaps, be noted that equation (2) is integrable term by term, despite our injunction that such an approach generally is not possible. The segregation of the independent variables \(T\) and \(V\) in separate terms in equation (2) is a fortunate but unusual simplification which permits term by term integration in this special case.

It make sense that for a Van der Waals fluid the energy relations are different from a ideal gas, because the pressure-correcting term is linked to internal interaction energy of the molecules and it does affect the energetic of the molecules.
3. It can be shown that:
\[
\Delta \mathcal{S}=n R \log \left[\frac{V-n b}{V_{0}-n b}\right]+\int_{T_{0}}^{T} \frac{C_{\mathrm{v}}}{T} \mathrm{~d} T
\]
4. L'equazione per un processo adiabatico quasi-statico è
\[
T(V-n b)^{R / c_{\mathrm{v}}}=\text { constant }
\]
whenever \(c_{\mathrm{V}}\) is fixed and where it is important to note that the exponent is not \(\gamma-1\), as for the ideal gas; in fact for a Van der Waals fluid \(c_{\mathrm{p}}-c_{\mathrm{V}} \neq R\).
5. L'equazione per un processo adiabatico quasi-statico può esere anche scritta:
\[
\left(p+\frac{a n^{2}}{V^{2}}\right)(V-n b)^{1+R / c_{\mathrm{v}}}=\mathrm{constant}
\]
whenever \(c_{\mathrm{V}}\) is fixed.
6. Calcolare il coefficiente di dilatazione termica a pressione costante:
\[
\beta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{p} .
\]
7. Calcolare il modulo di compressibilità isoterma:
\[
\kappa_{\mathrm{T}} \equiv-\frac{1}{V}\left(\frac{\partial V}{\partial p}\right)_{T}
\]

\section*{© - QUOTE}

Here \(a\) and \(b\) are two empirical constants characteristic of the particular gas. In strictly quantitative terms the success of the equation has been modest, and for detailed practical applications it has been supplanted by more complicated empirical equations with five or more empirical constants. Nevertheless the Van der Waals equation is remarkably successful in representing the qualitative features of real fluids, including the gas-liquid phase transition.
We shall see later that the ideal Van der Waals fluid is unstable in certain regions of temperature and pressure, and that it spontaneously separates into two phases ("liquid" and "gas").

Very pure liquid water can be supercooled at atmospheric pressure to temperatures well below \(T=0^{\circ} \mathrm{C}\). Assume that a mass of water has been cooled as a liquid to \(T=-5^{\circ} \mathrm{C}\). A small crystal of ice (whose mass is negligible) is added to seed the supercooled liquid. If the subsequent change of state occurs adiabatically and at constant (atmospheric) pressure, what fraction of the system solidifies and what is the entropy change (per unit mass) of the system and of the ambient?
- Latent heat of fusion of water at \(T=0^{\circ} \mathrm{C}: \lambda=333.4 \mathrm{~kJ} / \mathrm{kg}\);
- Heat capacity of water in the range \(-5^{\circ} \mathrm{C} \leq T \leq 0^{\circ} \mathrm{C}: C=4.2 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}\).

\section*{SOLUTION}

The final state of the system is presumed to be the equilibrium state of a mixture of ice and water at atmospheric pressure. This state exists at \(T=0^{\circ} \mathrm{C}\). The change of state occurs in a closed system at constant pressure and this process is adiabatic, and therefore \(\Delta \mathcal{H}=0\). Note that the system is not isolated, as it is subject to a fixed external pressure.
Since \(\Delta \mathcal{H}\) is a property change its value is independent of path, and, therefore, for purposes of calculation we may consider an arbitrary path made up of two reversible steps: heating of the full mass up to \(T=0^{\circ} \mathrm{C}\) followed by solidification of a fraction \(f \equiv \Delta m / m\) of the mass.
The entalphy required to heat the liquid water is taken by the entalphy released on freezing of the
water:
\[
\begin{gathered}
0=\Delta \mathcal{H}=\Delta \mathcal{H}_{1}+\Delta \mathcal{H}_{2}=m \int_{T_{1}}^{T_{2}} c_{\mathrm{p}} \mathrm{~d} T-f m \lambda=0, \\
c_{\mathrm{p}}\left(T_{2}-T_{1}\right)-f \lambda=0 \quad \text { if } c_{\mathrm{p}} \text { is fixed } .
\end{gathered}
\]

For the entropy:
\[
\begin{gathered}
\Delta \delta_{\mathrm{U}}=\Delta \delta+\Delta \delta_{\mathrm{A}}=m \int_{T_{1}}^{T_{2}} \frac{c_{\mathrm{p}}}{T} \mathrm{~d} T-\frac{f m \lambda}{T} \\
\frac{\Delta \delta_{\mathrm{U}}}{m}=c_{\mathrm{p}} \log \left[\frac{T_{2}}{T_{1}}\right]-\frac{f \lambda}{T_{2}}
\end{gathered}
\]

It is found:
- \(f=0.063\).
- \(\Delta \mathcal{S}=0.7 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K} ; \Delta \mathcal{S}=0\) ambient (adiabatic walls).

Should one find \(f>1\) the conclusion would be that the final state has only liquid water at a temperature larger than the fusion temperature.
Note this does not describe the real process, but just a process with the same initial and final states.

\subsection*{61.14.10 Capacità Termica Di Acqua Più II Contenitore}
©|M.dePodesta, Understanding The Properties Of Matter, 2002, CRC Press, 2ndEd., ....|11.30||
Una robusta scatola di metallo contiene acqua allo stato solido ed è riscaldata lentamente da \(T_{1}=-20^{\circ} \mathrm{C}\) a \(T_{2}=+20^{\circ} \mathrm{C}\) mentre la capacità termica dell'oggetto composto è misurata continuamente. Se non si ha a disposizione nessun metodo per tenere conto separatamente della quantità di calore usata come calore latente di fusione e di quella usata per innalzare la temperatura si concluderebbe che c'è un'anomalia nell'andamento della capacità termica. Discutere qualitativamente l'andamento della capacità termica.

\section*{SOLUTION}

A temperatura inferiore a \(T=0^{\circ} \mathrm{C}\) la capacità termica è circa costante ed uguale alla somma delle capacità termiche della scatola e del ghiaccio. Allo zero diventa infinita. A temperatura superiore a \(T=0^{\circ} \mathrm{C}\) la capacità termica è circa costante ed uguale alla somma delle capacità termiche della scatola e dell'acqua.

\subsection*{61.14.11 Fundamental Equation and Natural Variables for Internal Energy}

The distinction between equations which are fundamental and those which are not fundamental, can be easily explained by comparing the two equations
\[
\begin{aligned}
\mathcal{U} & =\mathcal{U}\left[V, \mathcal{S}, N_{1}, \ldots N_{n}\right], \\
\mathcal{U} & =\mathcal{U}\left[V, T, N_{1}, \ldots N_{n}\right] .
\end{aligned}
\]

Given the relation (61.01.05)
\[
T=\left(\frac{\partial \mathcal{U}}{\partial \mathcal{S}}\right)_{V, N_{k}}
\]
it is clear that temperature can be readily derived from (61.14.11). On the other hand, deriving the entropy from equation (61.14.11) requires to solve the differential equation
\[
\mathcal{U}=U\left[V,\left(\frac{\partial \mathcal{U}}{\partial S}\right)_{V, N_{k}}, N_{1}, \ldots N_{n}\right]
\]
which requires in general appropriate boundary conditions.

\subsection*{61.14.12 Fundamental Equation of the Ideal Gas in the Entropy Representation}
©|N.W.Tschoegl, Fundamentals Of Equilibrium And Steady-State Thermodynamics, 2000, Elsevier, ...Ed., ....|detailed||
The molar fundamental equation of the single-component ideal gas in the entropy representation is:
\[
s=s[\mathrm{u}, v]=s_{0}+\left(f[\mathrm{u}]-f\left[\mathrm{u}_{0}\right]\right)+R \log \left[v / v_{0}\right]
\]
where the subscript denotes a suitably chosen reference state. The function \(f[\mathrm{u}]\) is a function of \(u\) only and its explicit form differs from gas to gas but it is not known in general:
\[
f[\mathrm{u}]=f\left[\mathrm{u}_{0}\right]+\int_{T_{0}}^{T} \frac{c_{\mathrm{v}}}{T} \mathrm{~d} T
\]

\subsection*{61.14.13 Fundamental Equation for a Van Der Waals Fluid}

The fundamental equation of a Van der Waals fluid is:
\[
s=R \log \left[(v-b)(u+a / v)^{\left(c_{\mathrm{V}} / R\right)}\right]+s_{0}
\]
where \(s_{0}\) is a constant; it can be applied, as a particular case, also to a ideal or Clausius fluid.

\subsection*{61.14.14 Properties of an Ideal Photon Gas}
©|H.B.Callen, Thermodynamics, 1985, J.Wiley \& Sons, 2ndEd., ....|3.6||
©|S.J.Blundell \& K.M.Blundell, Concepts In Thermal Physics, 2010, Oxford, 2ndEd., ....|Exercise 23.6||

First note that a photon gas is a really ideal gas of massless (so relativistic) particles.
Un gas di fotoni, gas ideale di particelle ultra-relativistiche a massa nulla, è caratterizzato dall'equazione di stato:
\[
\begin{equation*}
p=\frac{1}{3} \alpha T^{4} \tag{61.14.06}
\end{equation*}
\]
dalla ulteriore equzione di stato che fornisce il numero di fotoni, variabile non indipendente:
\[
N=\beta V T^{3}
\]
e dall'equazione per l'energia interna:
\[
\begin{equation*}
\mathcal{U}=\alpha V T^{4} \tag{61.14.07}
\end{equation*}
\]
con \(\alpha=7.6 \cdot 10^{-16} \mathrm{~J} /\left(\mathrm{m}^{3} \cdot \mathrm{~K}^{4}\right)\) e \(\beta=2.0 \cdot 10^{7} 1 /\left(\mathrm{m}^{3} \cdot \mathrm{~K}^{3}\right)\), entrambe costanti universali.
1. Rappresentare le isoterme nel piano \(p V\) e calcolare la capacità termica a volume costante per \(V=1 \cdot 10^{10} \mathrm{~km}^{3}\) e \(T=2 \cdot 10^{7} \mathrm{~K}\) (temperature e volume tipici di una stella).
2. Calcolare la variazione di entropia per una generica trasformazione isoterma e per una generica trasformazione isocora.
3. Show that the entropy can be written as:
\[
\mathcal{S}[\mathfrak{U}, V]=\frac{4}{3}\left(\alpha V \mathfrak{u}^{3}\right)^{1 / 4}
\]
in terms of its natural variables.
4. Show that:
\[
p V=\left(\frac{\zeta[4]}{\zeta[3]}\right) N[V, T] k_{\mathrm{B}} T \simeq(0.9004) N[V, T] k_{\mathrm{B}} T
\]

Beware that, even if the equation resembles the one for the molecular ideal gas, for the photon gas \(N=N[V, T]\) is not an independent parameter which can be fixed at will, but it is determined by volume and temperature.
5. Show that \(\mathcal{G}=0\); calculate the chemical potential via the internal energy.
6. Calculate \(\mathcal{H}\) and \(\mathcal{F}\) and show that: \(\mathcal{U}=-3 \mathcal{F}, p V=\mathcal{U} / 3, \mathcal{S}=4 \mathcal{U} /(3 T)\); verify the Gibbs-Duhem relation: \(\mathcal{U}=T \mathcal{S}-p V\).
7. Evaluate \(c_{\mathrm{V}}\) and \(c_{\mathrm{p}}\).
8. The universe is considered by cosmologists to be an expanding ElectroMagnetic cavity containing radiation that now is at a temperature of \(T=2.7 \mathrm{~K}\). What will be the temperature of the radiation when the volume of the universe is twice its present value? Assume the expansion to be iso-entropic (this being a non-obvious prediction of cosmological model calculations).
9. Assuming the ElectroMagnetic radiation filling the universe to be in equilibrium at \(T=2.7 \mathrm{~K}\), what is the pressure associated with this radiation?
10. Estimate the energy per cubic meter inside a typical room at ambient conditions due to thermal radiation from the environment.

\section*{SOLUTION}
\(N=N[V, T]\) is not a free parameter, as it is given by \(V\) and \(T\). Therefore the system depends on two variables, and not on two plus \(N\). Moreover, as pressure and temperature are related independently from volume, the permissible pairs of independent variables are only: \((V, T)\) and \((V, p)\), but not \((p, T)\).
1. A horizontal line.
2.
\[
\begin{gather*}
\mathrm{d} \mathcal{S}=\frac{\mathrm{d} U}{T}+\frac{p}{T} \mathrm{~d} V \\
V=\text { constant } \Longrightarrow \mathrm{d} \mathcal{S}=4 \alpha T^{2} V \mathrm{~d} T=\ldots \\
T=\text { constant } \Longrightarrow \mathrm{d} \mathcal{S}=\alpha \mathrm{d} V T^{3}+\frac{\alpha}{3} T^{3} \mathrm{~d} V=\ldots \tag{61.14.08}
\end{gather*}
\]
3. Using equations (59.09.01.06), (59.09.01.06):
\[
\begin{gathered}
\mathrm{d} \mathcal{S}=\frac{\mathrm{d} U}{T}+\frac{p}{T} \mathrm{~d} V=\left(\frac{\alpha V}{\mathcal{U}}\right)^{1 / 4} \mathrm{~d} \mathcal{U}+\frac{\alpha}{3}\left(\frac{\mathcal{U}}{\alpha V}\right)^{3 / 4} \mathrm{~d} V=\frac{4}{3} \mathrm{~d}\left(\alpha V \mathcal{U}^{3}\right)^{1 / 4} \\
\Longrightarrow \mathcal{S}-\mathcal{S}_{0}=\frac{4}{3}\left(\alpha V \mathcal{U}^{3}\right)^{1 / 4}=\frac{4}{3} \alpha V T^{3}=\frac{4 \mathcal{U}}{3 T}
\end{gathered}
\]
4. ...
5. ...
6. As \(\mathcal{G}=0\) it is clear that the chemical potential is zero. This can be cross-checked with the
calculation from the internal energy.
\[
\begin{gathered}
s[u, V]=\frac{4}{3}\left(\alpha V u^{3}\right)^{1 / 4}, \\
\mu \equiv\left(\frac{\partial u}{\partial N}\right)_{s, V}=0
\end{gathered}
\]
7. Use equation (61.14.07):
\[
C_{\mathrm{V}}=4 \alpha V T^{3}=4 \frac{\alpha}{\beta} N[V, T] \propto T^{3} \Longrightarrow c_{\mathrm{V}}^{\prime}=4 \frac{\alpha}{\beta} \quad \text { for a single photon }
\]

For a photon gas, \(C_{\mathrm{p}}\) does not exist, because one cannot vary the temperature at constant pressure for a photon gas.
8. ...

\end{aligned}
\]

\subsection*{61.14.21 Variazione Della Pressione Atmosferica Con L'altezza}

This § is referenced at pages:
[1527, 1527, 1527, 1527]
©|D.V.Schroeder, Thermal Physics, 1999, Addison-Wesley, ...Ed., ....|problem 1.16, 1.40, 5.45||
Si consideri l'aria un gas ideale di massa molecolare media \(\mathcal{M}_{0}=29 \mathrm{~g} / \mathrm{mol}\), si assuma una atmosfera isoterma a \(T=288 \mathrm{~K}\) e la pressione a livello del mare pari a \(p_{0}=1 \mathrm{~atm}\). Assume a fixed acceleration of gravity.
1. Calculate the pressure as a function of the height above the sea-level assuming isothermal atmosphere.
2. Assume the composition of the isothermal atmosphere at sea-level is \(f_{0}=0.8 N_{2}\) and \(f_{1}=0.2 O_{2}\). Determine the change of composition as a function of the height.
3. Calculate mean gravitational potential energy per molecule and the specific heat of a column of isothermal atmosphere.
4. Calculate the pressure as a function of the height above the sea-level assuming a Polytropic \(p-V\) relation (including adiabatic atmosphere with fixed thermal capacities).
Read also § 26-012 - Introduction to Mechanics of Fluids.

\section*{SOLUTION}
1. Hydrostatic equilibrium:
\[
\begin{aligned}
\frac{\mathrm{d} p[z]}{\mathrm{d} z}=-g \rho[z] \quad \text { mechanics }, \\
\frac{\mathrm{d} p[\rho[z], T[z]]}{\mathrm{d} z}=-g \rho[z] \quad \text { thermodynamics }
\end{aligned}
\]

Formula barometrica per atmosfera isoterma composta di un gas ideale di massa molecolare \(\mathcal{M}_{0}\) :
\[
\begin{equation*}
p[z]=p_{0} \exp \left[-\frac{\mathcal{M}_{0} g z}{R T}\right]=p_{0} \exp \left[-\frac{m g z}{k_{\mathrm{B}} T}\right] \quad \text { the barometric equation } \tag{61.14.09}
\end{equation*}
\]
che scritta nella forma tipica di un decadimento esponenziale
\[
\begin{equation*}
p[z]=p_{0} \exp \left[-\frac{z}{\ell}\right] \quad \ell \equiv \frac{R T}{\mathcal{M}_{0} g}=\frac{k_{\mathrm{B}} T}{m g} \tag{61.14.10}
\end{equation*}
\]
da una lunghezza di decadimento della pressione pari a \(\ell \simeq 8.4 \mathrm{~km}\).
2. For the composition af the isothermal atmosphere made of a mixture of ideal gases, one finds:
\[
\eta_{\mathrm{N}} \equiv \eta_{\mathrm{N}} \quad \ell \equiv \frac{R T}{\mathcal{M}_{0} g}=\frac{k_{\mathrm{B}} T}{m g}
\]
\[
\begin{gathered}
\eta_{\mathrm{N}}[z]=\eta_{\mathrm{N} 0} \exp [-z / \ell]=\frac{p_{0}}{k_{\mathrm{B}} T} \exp [-z / \ell] \quad \ell \eta_{\mathrm{N} 0}=\int_{0}^{\infty} \eta_{\mathrm{N}}[z] \mathrm{d} z \quad \ell^{2} \eta_{\mathrm{N} 0}=\int_{0}^{\infty} z \eta_{\mathrm{N}}[z] \mathrm{d} z \quad N=A \int_{0}^{\infty} \eta_{\mathrm{N}}[z] \mathrm{d} z=\eta_{\mathrm{N} 0} A \ell \\
\langle z\rangle=\ell=\frac{R T}{\mathcal{M}_{0} g}=\frac{k_{\mathrm{B}} T}{m g} .
\end{gathered}
\]

The latter equation shows that heavier molecules have a lower mean altitude. For instance, \(\mathrm{CO}_{2}\), is heavier.
3. The total energy of a column of section \(A\) is:
\[
E=N c_{\mathrm{V}} T+\int_{0}^{\infty} m N g z \eta_{\mathrm{N}}[z] \mathrm{d} z=N c_{\mathrm{V}} T+m N g\langle z\rangle=N c_{\mathrm{V}} T+N k_{\mathrm{B}} T=N c_{\mathrm{V}} T+\eta_{\mathrm{N} 0} A \ell k_{\mathrm{B}} T
\]
\[
\langle\phi\rangle=k_{\mathrm{B}} T \quad c=c_{\mathrm{V}}+k_{\mathrm{B}}=c_{\mathrm{p}} \quad \text { specific heat per molecule }
\]
4. polytropic relation for a ideal gas of index \(\gamma\) :
\[
p \mathcal{M}_{0}=\rho R T \quad p V^{\gamma}=\mathrm{constant} \quad p[T]=K T^{(\gamma /(\gamma-1))}
\]

Therefore, derivation of the \(p[T]\) relation gives:
\[
\begin{gathered}
\frac{\mathrm{d} p[z]}{\mathrm{d} z}=\frac{K \gamma}{\gamma-1} T^{(1 /(\gamma-1))} \frac{\mathrm{d} T[z]}{\mathrm{d} z} \\
\frac{\mathrm{~d} p[z]}{\mathrm{d} z}=-g \rho[z]=-\frac{g \mathcal{M}_{0}}{R} \frac{p[z]}{T[z]}=-\frac{K g \mathcal{M}_{0}}{R} T^{(1 /(\gamma-1))}, \\
\Longrightarrow \frac{\gamma}{\gamma-1} \frac{\mathrm{~d} T[z]}{\mathrm{d} z}=-\frac{g \mathcal{M}_{0}}{R} \quad \text { for } \gamma \neq 1 \\
\Longrightarrow \frac{\mathrm{~d} T[z]}{\mathrm{d} z}=\frac{g \mathcal{M}_{0}}{R} \frac{1-\gamma}{\gamma}, \\
T[z]=\frac{g \mathcal{M}_{0}}{R} \frac{1-\gamma}{\gamma}\left(z-z_{0}\right)+T\left[z_{0}\right]
\end{gathered}
\]

\subsection*{61.14.23 Equilibrio Di Fase Tra La Grafite E II Diamante}
©|M.W.Zemansky \& R.H.Dittman, Heat And Thermodynamics, 1997, McGraw-Hill, 7thEd., ....|Diagramma di stato in § x.y|| ©|D.Halliday \& R.Resnick \& K.S.Krane, Fisica, 2003/2004, C.E.A., 5thEd., ....|17.11||

Using the qualitative phase-diagram in figure answer the questions.
- How many triple points are shown in the phase-diagram and what phases can coexist at each triple point?
- Is it possible to say which solid phase, graphite or carbon, has a higher density?
- Synthetic diamond can be made from graphite: how is it possible?
- Can graphite and diamond be sublimated?
- The standard Gibbs energy of the formation of diamond, at \(T_{0}=298 \mathrm{~K}\) and \(p_{0}=1 \mathrm{~atm}\), is \(g_{d}=2.9 \mathrm{~kJ} / \mathrm{mol}\) greater than that of graphite. Which of these two allotropes is more stable at \(T_{0}\) and \(p_{0}\) ?
- Is graphite or liquid carbon denser?
- Why are there two triple points in this diagram?

Sapendo che a \(T_{0}=25^{\circ} \mathrm{C}\) e \(p_{0}=1 \mathrm{~atm}\) i volumi specifici di diamante e grafite sono rispettivamente:
\[
v_{d}=2.85 \cdot 10^{-1} \mathrm{~cm}^{3} / \mathrm{g} \quad v_{g}=4.44 \cdot 10^{-1} \mathrm{~cm}^{3} / \mathrm{g}
\]
mentre i rispettivi coefficienti di compressibilità isoterma valgono:
\[
\kappa_{d}=0.16 \cdot 10^{-6} \mathrm{~atm}^{-1} \quad \kappa_{g}=3.0 \cdot 10^{-6} \mathrm{~atm}^{-1}
\]
mentre
\[
g^{d}=2.390 \cdot 10^{5} \mathrm{~J} / \mathrm{kg} \quad g^{g}=0 \mathrm{~J} / \mathrm{kg} \quad \text { chosen as zero, as it is the stable phase } .
\]

Determinare quale pressione è necessaria per trasformare in diamante la grafite, a \(T_{0}=25^{\circ} \mathrm{C}\).

\section*{SOLUTION}

Poiché si opera a temperatura costante
\[
\mathrm{d} g_{T}=v \mathrm{~d} p_{T}
\]
e la funzione di Gibbs specifica cresce al crescere della pressione. A pressioni e temperature ambiente l'energia di Gibbs specifica del diamante è maggiore di quella della grafite per cui lo stato stabile è la grafite. Tuttavia al crescere della pressione l'energia di Gibbs specifica del diamante cresce meno rapidamente di quella della grafite, a causa dei diversi valori dei volumi specifici, per cui ad una certa pressione il diamante e la grafite potrebbero esistere in equilibrio di fase. Si noti che, in
generale, \(v\) non è indipendente dalla pressione per cui la dipendenza dalla pressione della funzione di Gibbs specifica, \(g(p)\), non è una funzione lineare, eccetto che si possa considerare \(v\) fissato. In generale, quindi, non sono quindi sufficienti queste sole considerazioni a dedurre che esiste una pressione alla quale le due funzioni di Gibbs assumono lo stesso valore, ma occorre determinare il volume specifico in funzione della pressione.
Si ha
\[
v=\left.v[T, p] \quad \frac{\partial v}{\partial p}\right|_{T}=-\kappa_{\mathrm{T}} v
\]

Essendo la temperatura fissata si può sostituire la derivata parziale con quella totale e integrare. Per variazioni di pressione non troppo alte, \(|\Delta p \kappa| \ll 1\), da verificare una volta ottenuto il risultato, si può approssimare l'equazione precedente con
\[
v\left[p, T_{0}\right] \simeq v_{0}\left(1-\kappa_{\mathrm{T}}\left(p-p_{0}\right)\right)
\]

Si noti che il volume specifico non può essere considerato costante, nell'intervallo di pressione considerato, ma il valore di \(\kappa_{\mathrm{T}}\), cioè la variazione relativa del volume specifico la variare della pressione può essere considerato costante.
Ne segue
\[
g-g^{0}=v_{0}\left(p-p_{0}\right)-\frac{v_{0} \kappa}{2}\left(p-p_{0}\right)^{2}
\]
che, definendo \(\Delta p \equiv p-p_{0}\), diventa
\[
g-g^{0}=v_{0}(\Delta p)-\frac{v_{0} \kappa}{2}(\Delta p)^{2}
\]

Allora si ottiene per la grafite e il diamante
\[
\begin{aligned}
& g^{g}\left[p, T_{0}\right]=v_{0}^{g}(\Delta p)-\frac{v_{0}^{g} \kappa_{g}(\Delta p)^{2}}{2}+g_{0}^{g} \\
& g^{d}\left[p, T_{0}\right]=v_{0}^{d}(\Delta p)-\frac{v_{0}^{d} \kappa_{d}(\Delta p)^{2}}{2}+g_{0}^{d} .
\end{aligned}
\]

Uguagliando le due espressioni e risolvendo rispetto alla pressione incognita si determina la minore delle soluzioni per \(p, p^{\star}=1.53 \cdot 10^{3} \mathrm{~atm}\).
Il valore trovato è consistente con l'approssimazione, \(|\Delta p \kappa| \ll 1\), fatta nel corso del calcolo.
A questo livello di approssimazione, l'andamento \(g[p]\) è una parabola con il vertice in alto e derivata prima positiva a \(p_{0}\).
Per avere un idea dell'ordine di grandezza di tale pressioni si può stimare a quale profondità sotto il livello del suolo si ottiene tale pressione assumendo per la Terra una densità costante pari alla densità media \(\rho=5.5 \mathrm{~g} / \mathrm{cm}^{3}\). Si trova una profondità di \(\simeq 2.7 \mathrm{~km}\).
Si noti che tutte queste considerazioni si riferiscono a temperatura costante.
La spiegazione dell'esistenza del diamante, fase solida instabile del carbonio a temperatura e pressione ambiente sta nel fatto che il diamante è uno stato metastabile e/o che la transizione verso la grafite è estremamente lenta.
In entrambi i casi si deve pensare che un diamante non è per sempre....

\subsection*{61.14.24 Calori Specifici Di Un Fluido Di Van Der Waals}

L'energia interna specifica per un fluido di Van der Waals è data dalla relazione
\[
u=c_{\mathrm{v}} T-\frac{a}{v}+\text { constant }
\]
1. Dimostrare, usando l'espressione dell'energia interna specifica, che per un fluido di Van der Waals si ha la relazione
\[
c_{\mathrm{p}}-c_{\mathrm{V}}=R\left(\frac{R T v^{3}}{R T v^{3}-2 a(v-b)^{2}}\right) .
\]
2. Dimostrare la stessa relazione facendo uso solo uso dell'equazione di stato (61.14.04) e della relazione generale tra le capacità termiche a pressione e volume costante di un sistema \(p V T\) a composizione costante:
\[
C_{\mathrm{p}}-C_{\mathrm{V}}=T\left(\frac{\partial p}{\partial T}\right)_{V}\left(\frac{\partial V}{\partial T}\right)_{p}
\]

\subsection*{61.14.25 Equilibrio Liquido-Vapore Entro Un Recipiente Rigido Riscaldato}
©|M.Abbott \& H.VanNess, Schaum's Outline Of Thermodynamics, 1989, McGraw-Hill, 2ndEd., ....|E4.2 4.7 4.8||
Si discuta la seguente situazione, tenendo presente l'andamento tipico del diagramma \(p V\) di una sostanza pura. Un recipiente rigido e sigillato è riempito con una miscela liquido-vapore di una sostanza pura. Il recipiente viene scaldato.
1. Discutere qualitativamente il comportamento della miscela liquido-vapore nel caso il recipiente contenga inizialmente solo una (arbitrariamente) piccola quantità di liquido.
2. Discutere qualitativamente il comportamento della miscela liquido-vapore nel caso il recipiente contenga inizialmente solo una (arbitrariamente) piccola quantità di vapore.
3. Discutere qualitativamente il comportamento della miscela liquido-vapore nel caso il recipiente contenga inizialmente una miscela liquido-vapore di volume pari al volume critico.
4. Il volume totale del recipiente vale \(V=1 \mathrm{~m}^{3}\), e contiene \(V_{l}=0.05 \mathrm{~m}^{3}\) di liquido saturo in equilibrio con \(V_{l}=0.95 \mathrm{~m}^{3}\) di vapore saturo alla pressione di \(1 \cdot 10^{5} a\). Quale è la minima quantità di calore \(\Omega_{g}\) che deve essere fornita all'acqua affinché il liquido si vaporizzi completamente?
5. Il volume totale del recipiente vale \(V=10 \mathrm{ft}^{3}\) e contiene liquido e vapore d'acqua saturi in equilibrio a 200 psia. Se il \(99 \%\) della massa è liquido quale è la minima quantità di calore \(Q_{l}\) che deve essere fornita all'acqua affinché il recipiente diventi pieno di liquido
61.14.26 Problems From H. B. Callen

\section*{PROBLEMS}
1.10-1. The following ten equations are purported to be fundamental equations of various thermodynamic systems. However, five are inconsistent with one or more of postulates II, III, and IV and consequently are not physically acceptable. In each case qualitatively sketch the fundamental relationship between \(S\) and \(U\) (with \(N\) and \(V\) constant). Find the five equations that are not physically permissible and indicate the postulates violated by each.

The quantities \(v_{0}, \theta\), and \(R\) are positive constants, and in all cases in which fractional exponents appear only the real positive root is to be taken.
a) \(S=\left(\frac{R^{2}}{v_{0} \theta}\right)^{1 / 3}(N V U)^{1 / 3}\)
b) \(S=\left(\frac{R}{\theta^{2}}\right)^{1 / 3}\left(\frac{N U}{V}\right)^{2 / 3}\)
c) \(S=\left(\frac{R}{\theta}\right)^{1 / 2}\left(N U+\frac{R \theta V^{2}}{v_{0}^{2}}\right)^{1 / 2}\)
d) \(S=\left(\frac{R^{2} \theta}{v_{0}^{3}}\right) V^{3} / N U\)
e) \(S=\left(\frac{R^{3}}{v_{0} \theta^{2}}\right)^{1 / 5}\left[N^{2} V U^{2}\right]^{1 / 5}\)
f) \(S=N R \ln \left(U V / N^{2} R \theta v_{0}\right)\)
g) \(S=\left(\frac{R}{\theta}\right)^{1 / 2}[N U]^{1 / 2} \exp \left(-V^{2} / 2 N^{2} v_{0}^{2}\right)\)
h) \(S=\left(\frac{R}{\theta}\right)^{1 / 2}(N U)^{1 / 2} \exp \left(-\frac{U V}{N R \theta v_{0}}\right)\)
i) \(U=\left(\frac{v_{0} \theta}{R}\right) \frac{S^{2}}{V} \exp (S / N R)\)
j) \(U=\left(\frac{R \theta}{v_{0}}\right) N V\left(1+\frac{S}{N R}\right) \exp (-S / N R)\)
1.10-2. For each of the five physically acceptable fundamental equations in problem 1.10-1 find \(U\) as a function of \(S, V\), and \(N\).

\subsection*{61.14.27 Temperatura Di Ebollizione Dell'acqua in Montagna}

Si consideri l'aria un gas ideale di massa molecolare media \(M=29 \mathrm{~g} / \mathrm{mol}\), si assuma una atmosfera isoterma a \(T=288 \mathrm{~K}\) e la pressione a livello del mare pari a \(p_{0}=1 \mathrm{~atm}\). La massa molecolare dell'acqua vale \(M_{\mathrm{acq}}=18 \mathrm{~g} / \mathrm{mol}\) e il calore latente di vaporizzazione dell'acqua vale \(\lambda_{\text {vap }}^{(\text {spe })}=540 \mathrm{cal} / \mathrm{gr}=2.259 \cdot 10^{6} \mathrm{~J} / \mathrm{kg}\) a \(T=100^{\circ} \mathrm{C}\).
1. Valutare la temperatura \(T_{1}\) di ebollizione dell'acqua in una località ad un'altezza \(h=1500 \mathrm{~m}\) rispetto al livello del mare.
2. Valutare la temperatura di ebollizione dell'acqua in una pentola a pressione la cui valvola sia tarata alla pressione differenziale di \(\Delta p=1 \mathrm{~atm}\).

\section*{SOLUTION}

Per valutare la temperatura di ebollizione dell'acqua in una località ad un'altezza \(h\) rispetto al livello del mare occorre dapprima determinare la pressione atmosferica in quella località.
Con i dati del testo si trova \(p(h)=0.837 \mathrm{~atm}\).
Si può ora determinare a quale temperatura la tensione di vapore dell'acqua, calcolata tramite l'equazione di Clapeyron, uguaglia la pressione atmosferica richiesta. L'equazione di Clapeyron per l'equilibrio liquido-vapore, trattando il vapore come un gas ideale, trascurando il volume specifico della fase liquida rispetto a quello della fase gassosa e considerando il calore latente di vaporizzazione indipendente dalla temperatura si scrive
\[
\begin{equation*}
p(T)=p_{0} \exp \left[-\frac{\lambda_{\text {vap }}^{(\text {mo1 })}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right]=p_{0} \exp \left[-\frac{M \lambda_{\text {vap }}^{(\mathrm{spe})}}{R}\left(\frac{1}{T}-\frac{1}{T_{0}}\right)\right] \tag{61.14.11}
\end{equation*}
\]

La relazione tra il generico calore molare e specifico per una massa \(m\) e numero di moli \(n\) di una sostanza di massa molecolare \(M\) è data da
\[
\begin{equation*}
m \lambda^{(\mathrm{spe})}=n \lambda^{(\mathrm{mol})} \Longrightarrow \lambda^{(\mathrm{mol})}=\frac{m}{n} \lambda^{(\mathrm{spe})}=M \lambda^{(\mathrm{spe})} \tag{61.14.12}
\end{equation*}
\]

Ne segue, risolvendo per \(T, T_{1}=95.1^{\circ} \mathrm{C}\).
Analogamente si può rispondere alla seconda domanda la sola differenza è che ora occorre trovare la temperatura alla quale la tensione di vapore vale 2 atm che risulta essere \(T_{2}=121^{\circ} \mathrm{C}\).

\section*{SOLUTION}
1. \(T_{1}=95.1^{\circ} \mathrm{C}\)
2. \(T_{2}=121^{\circ} \mathrm{C}\).

\subsection*{61.14.28 Variazione Del Punto Di Fusione Del Ghiaccio}

La densità del ghiaccio vale \(\rho_{\mathrm{gh}}=0.92 \mathrm{~g} / \mathrm{cm}^{3}\), la densità dell'acqua vale \(\rho_{\mathrm{ac}}=1 \mathrm{~g} / \mathrm{cm}^{3}\) e il calore latente di fusione vale \(\lambda_{\text {fus }}=80 \mathrm{cal} / \mathrm{g}\) a \(0^{\circ} \mathrm{C}\).
1. Calcolare la variazione di pressione \(\Delta p\) necessaria per far diminuire di \(\Delta T=1{ }^{\circ} \mathrm{C}\) la temperatura di fusione del ghiaccio a pressione atmosferica.
2. Calcolare quale deve essere lo spessore \(h\) di una lastra di ghiaccio a \(0^{\circ} \mathrm{C}\) affinché la temperatura di fusione del ghiaccio alla base si abbassi di \(\Delta T=1{ }^{\circ} \mathrm{C}\).
Dati
Water triple point: \(T=273.16 \mathrm{~K}=0.01^{\circ} \mathrm{C} ; p=612 \mathrm{~Pa}=0.006 \mathrm{~atm}\).
Water freezing point at \(1 \mathrm{~atm}: T=273.15 \mathrm{~K}=0.00^{\circ} \mathrm{C} ; p=101.325 \mathrm{kPa}=1 \mathrm{~atm}\).

\section*{SOLUTION}

Si noti che la variazione di temperatura richiesta è piccola rispetto alla temperatura stessa. è quindi possibile risolvere l'equazione di Clapeyron in modo approssimato supponendo \(\mathrm{d} p / \mathrm{d} T\) costante. Si può utilizzare la forma approssimativa finita dell'equazione di Clapeyron (61.14.11)
\[
\begin{equation*}
\frac{\Delta p}{\Delta T} \simeq \frac{\lambda_{\text {fus }}}{T \Delta v}<0 \tag{61.14.13}
\end{equation*}
\]
dato che la variazione della temperatura richiesta (variabile indipendente) è piccola. Si possono allora considerare costanti, nell'intervallo di temperatura considerato, sia il calore latente che i volumi specifici mentre la variazione relativa delle temperatura assoluta è piccola. Di conseguenza il valore della derivata della tensione di vapore saturo rispetto alla temperatura è approssimativamente costante e si può usare la relazione approssimata (61.14.13). Con i dati del testo si trova \(\Delta p=1.41 \cdot 10^{7} a=139 \mathrm{~atm}\). Si noti che la variazione di pressione è grande nonostante il piccolo intervallo di temperatura considerato. Questo è dovuto al grande valore della variazione della pressione in funzione della temperatura per la curva di coesistenza dell'acqua
\[
\frac{\Delta p}{\Delta T} \simeq \frac{\lambda_{\text {fus }}}{T \Delta v} \simeq-1.4 \cdot 10^{7} \mathrm{~Pa} / \mathrm{K}<0
\]

Una conseguenza di ciò è la notevole differenza di pressione tra il punto del ghiaccio (punto a cui si ha equilibrio ghiaccio-acqua a pressione atmosferica) e il punto triplo dell'acqua, nonostante la piccola differenza di temperatura, \(\Delta T=0.01 \mathrm{~K}\).
Un calcolo più esatto si può fare facilmente a partire dall'equazione di Clapeyron supponendo di poter considerare costanti, nell'intervallo di temperatura considerato, il calore latente e i volumi specifici e integrando l'equazione differenzale risultante:
\[
\frac{\mathrm{d} p}{\mathrm{~d} T}=\frac{\lambda_{\mathrm{fus}}}{T \Delta v} \Longrightarrow \Delta p=\frac{\lambda_{\mathrm{fus}}}{\Delta v} \log \left[1+\frac{\Delta T}{T_{0}}\right]
\]

La lastra di ghiaccio deve esercitare sulla sua base questa pressione addizionale affinché la temperatura di fusione alla base si abbassi della quantità richiesta. L'altezza \(h\) della lastra di ghiaccio si ricava dunque dalla
\[
\Delta p=\rho_{\mathrm{gh}} g h
\]

Ne segue \(h=1.5 \mathrm{~km}\).

\section*{SOLUTION}
1. \(\Delta p=1.41 \cdot 10^{7} a=139 \mathrm{~atm}\)
2. \(h=1.5 \mathrm{~km}\).

\subsection*{61.14.29 Temperature Di Flash Di Un Liquido Infiammabile}
©|F.H.Crawford, Heat Thermodynamics And Statistical Physics, 1963, Harcourt Brace and World, ...Ed., ....|§ 11.9||

This § is referenced at pages:
[2662, 2662]
Il punto di flash di un liquido infiammabile volatile è definito come quella temperatura alla quale la tensione di vapore del liquido è tale da fornire alla superficie del liquido esposto all'atmosfera una concentrazione di vapore uguale al limite di infiammabilità inferiore \(l_{\text {inf }}\), cioè alla concentrazione in volume critica al di sopra della quale il vapore costituisce una miscela infiammabile con l'aria.

La sostanza n-pentano ha \(l_{\text {inf }}=1.4 \%\) (in volume) e tensione di vapore \(p_{1}=10 \mathrm{mmHg}\) a \(T_{1}=-50.1^{\circ} \mathrm{C}\) e \(p_{2}=40 \mathrm{mmHg}\) a \(T_{2}=-29.2^{\circ} \mathrm{C}\).
1. Determinare il punto di flash di n-pentano.
2. Determinare il punto di ebollizione di n-pentano.
3. Determinare il valore del calore latente specifico di evaporazione medio di \(n\)-pentano nell'intervallo di temperatura considerato.
4. Discuss the effect of atomospheric air on the vapor pressure.

\section*{SOLUTION}
1. Occorre determinare a quale temperatura la concentrazione dei vapori di n-pentano in prossimità della superficie del liquido corrisponde a \(l_{\text {inf }}\). Supponendo che sia il vapore che l'aria circostante siano trattabili come gas perfetti e assumendo temperatura uniforme, la pressione parziale è proporzionale alla concentrazione in volume
\[
p=\left(\frac{n}{V}\right) R T
\]
e la pressione totale è quella atmosferica \(p_{\text {atm }}\). La pressione parziale è dunque proporzionale alla concentrazione in volume. La pressione parziale corrispondente alla composizione cercata è dunque
\[
p_{\text {inf }}=p_{\mathrm{atm}} l_{\mathrm{inf}}=10.6 \mathrm{mmHg}
\]

Quindi quando il liquido è in equilibrio con il suo vapore ad una pressione \(p_{\text {inf }}\) la concentrazione del vapore in atmosfera corrisponde a \(l_{\text {inf }}\) e si ha il punto di flash. Occorre ora determinare a quale temperatura la tensione di vapore assume il valore \(p_{\text {inf }}\). L'interpolazione lineare tra due punti di una funzione \(y(x)\) è data dalla formula
\[
\begin{equation*}
y-y_{1}=\left(\frac{y_{2}-y_{1}}{x_{2}-x_{1}}\right)\left(x-x_{1}\right) \tag{61.14.14}
\end{equation*}
\]
da cui, usando \(x \equiv T\) e \(y \equiv p\), si trova
\[
T-T_{1}=\left(\frac{T_{2}-T_{1}}{p_{2}-p_{1}}\right)\left(p-p_{1}\right)
\]
da cui si ricava \(T=-49.7^{\circ} \mathrm{C}\). Tuttavia sappiamo che l'andamento della tensione di vapore in funzione della temperatura non è lineare ma è approssimativamente lineare l'andamento del logaritmo della tensione di vapore in funzione di \(1 / T\) dove la temperatura è la temperatura assoluta
\[
\begin{equation*}
\log [p]=A-\frac{B}{T} \tag{61.14.15}
\end{equation*}
\]

Effettuiamo allora l'interpolazione in termini di \(\pi=\log [p]\) e \(\theta=1 / T\). Si ha allora \(\theta_{1} \equiv 1 / T_{1}=4.48 \cdot 10^{-3} \mathrm{~K}^{-1}, \theta_{2} \equiv 1 / T_{2}=4.10 \cdot 10^{-3} \mathrm{~K}^{-1} \mathrm{e}\), misurando \(p\) in mmHg , \(\pi \equiv \log [p]=2.36, \pi_{1} \equiv \log \left[p_{1}\right]=2.30, \pi_{2} \equiv \log \left[p_{2}\right]=3.69\) e la formula da applicare è ora
\[
\begin{equation*}
\theta-\theta_{1}=\left(\frac{\theta_{2}-\theta_{1}}{\pi_{2}-\pi_{1}}\right)\left(\pi-\pi_{1}\right) \tag{61.14.16}
\end{equation*}
\]
da cui si deduce \(T=-49.3^{\circ} \mathrm{C}\). Tale secondo valore, pur approssimato, è più vicino del precedente al valore che si otterrebbe usando una curva più completa della tensione di vapore e che darebbe \(T_{\text {flash }}=-49.44\). Si noti che il valore approssimativo ottenuto con l'interpolazione lineare in termini di \(p\) e \(T\) è relativamente preciso perché cade molto vicino ad uno dei due punti dati.
2. Il punto di ebollizione si ricava dalla stessa formula (61.14.16) usata ora come formula di estrapolazione per determinare la temperatura alla quale la tensione di vapore vale \(1 \mathrm{~atm} . \mathrm{Si}\) trova \(T=31.4^{\circ} \mathrm{C}\) che differisce alquanto dalla temperatura di ebollizione reale \(T_{\mathrm{eb}}=36.1^{\circ} \mathrm{C}\). Ciò è dovuto al fatto che la linearità di \(\log [p]\) in funzione di \(1 / T\) è solo approssimata e l'estrapolazione fatta è molto al di fuori dell'intervallo di cui sono dati i valori.
3. Il calore latente di vaporizzazione medio nell'intervallo considerato può essere ricavato dai dati del problema e dall'equazione di Clapeyron
\[
\begin{equation*}
\log \left[\frac{p_{2}}{p_{1}}\right]=\frac{\lambda M}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \tag{61.14.17}
\end{equation*}
\]

Si trova \(\lambda=4.16 \cdot 10^{5} \mathrm{~J} / \mathrm{kg}\).
Una soluzione più precisa del problema si potrebbe ottenere usando valori della tensione di vapore per più valori di temperatura anziché solo due. Questo permetterebbe di tenere conto della non esatta linearità dell'andamento della curva del logaritmo della tensione di vapore in funzione del reciproco della temperatura assoluta.
4. Si osservi che in questo problema si è ignorato l'effetto dell'aria sulla tensione di vapore. L'unico effetto dell'introduzione dell'aria a temperatura costante è quello di modificare la pressione alla superficie del liquido che non è più uguale alla tensione di vapore ma diventa uguale alla pressione atmosferica. Viceversa, in approssimazione di gas perfetto, l'introduzione dell'aria non influenza in alcun modo il vapore in modo diretto. Tuttavia l'effetto sul potenziale chimico del liquido della variazione di pressione è piccolo è può essere, in prima approssimazione, trascurato. Immaginiamo infatti di partire dall'equilibrio liquido-vapore della sostanza pura e introdurre a temperatura costante l'aria fino ad una pressione totale \(p_{\text {Tot }}\) in un recipiente. La variazione della funzione di Gibbs molare del liquido, causata dalla variazione di pressione, deve essere compensata da una uguale variazione della funzione di Gibbs molare del vapore affinché sussista ancora equilibrio di fase
\[
\Delta g_{\mathrm{L}}=v_{\mathrm{L}} \Delta p_{\mathrm{L}}=v_{\mathrm{V}} \Delta p_{\mathrm{V}}=\Delta g_{\mathrm{V}}
\]
dove \(\Delta p_{\mathrm{L}}=p_{\text {TOT }}-p_{\mathrm{V}}^{0}\) e si considerano \(v_{\mathrm{L}}\) e \(v_{\mathrm{V}}\) costanti. Si può allora ricavare \(\Delta p_{\mathrm{V}}\) che risulta molto minore di \(\Delta p_{\mathrm{L}}\) a causa del rapporto dei volumi specifici che da per l'acqua un fattore \(\approx 5 \cdot 10^{-5}\) nel rapporto tra l'aumento della pressione totale del liquido e la variazione della pressione del vapore.
Un secondo effetto che si è ignorato è il fatto che aggiungendo aria una parte di questa passa in soluzione nell'acqua per cui a rigore anche la fase liquida del sistema è composta da due componenti.

\section*{SOLUTION}
1. \(T=-49.3^{\circ} \mathrm{C}\);
2. \(T=31.4^{\circ} \mathrm{C}\)
3. \(\lambda=4.16 \cdot 10^{5} \mathrm{~J} / \mathrm{kg}\).

\subsection*{61.14.30 Stima Della Temperatura Di Equilibrio Di Un Pianeta}
©|B.W.Carroll \& D.A.Ostlie, An Introduction To Modern Astrophysics, ..., ..., 1stEd., ....|???||

In prima approssimazione si può supporre che la temperatura di un pianeta dipenda dal bilancio energetico dell'energia che riceve per irraggiamento dal Sole e di quella che emette verso lo spazio, supponendo di considerare sia il pianeta che il Sole due corpi neri. Si consideri il caso della Terra. L'energia irradiata dal Sole vale \(P_{S}=3.846 \cdot 10^{26} \mathrm{~W}\), il raggio equatoriale medio del Sole vale \(R=6.96 \cdot 10^{8} \mathrm{~m}\) e la distanza media tra la Terra e il Sole vale \(d=1.496 \cdot 10^{11} \mathrm{~m}\). Si supponga che una frazione \(a=30 \%\) (l'albedo della Terra) dell'energia che arriva sulla Terra venga riflessa e la restante assorbita.
1. Supponendo che la temperatura del pianeta sia uniforme, determinare l'espressione del valore della temperatura di equilibrio \(T\) nel caso il pianeta ruoti così velocemente che si possa considerare uniforme la temperatura su tutta la sua superficie.
2. Determinare l'espressione del valore della temperatura di equilibrio \(T\) nel caso il pianeta ruoti in modo da rivolgere sempre la stessa faccia verso il Sole.
3. Si commentino i risultati nel caso della Terra.

\subsection*{61.14.31 Equazione Di Stato Di Un Solido O Liquido}

Per descrivere il comportamento di un solido o di un liquido si può spesso usare l'equazione di stato
\[
\begin{equation*}
V=V_{0}+3 \alpha V_{0}\left(T-T_{0}\right)-\kappa_{\mathrm{T}} V_{0}\left(p-p_{0}\right) \tag{61.14.18}
\end{equation*}
\]
dove \(V_{0}\) è il volume alla pressione \(p_{0}\) e temperatura \(T_{0}\) e \(\alpha\) e \(\kappa_{\mathrm{T}}\) sono costanti.
1. Giustificare l'espressione e interpretare i coefficienti che vi compaiono.
2. Verificare che \(C_{\mathrm{V}}\) dipende solo dalla temperatura.
3. Determinare l'espressione dell'energia interna.
4. Determinare l'espressione dell'entropia.

\subsection*{61.14.32 Innalzamento Della Temperatura Di Ebollizione Di Una Soluzione}
©|M.W.Zemansky \& M.M.Abbot \& H.C.VanNess, Fondamenti Di Termodinamica per Ingegneri, ..., ..., ...Ed., ....|11.34||

This § is referenced at pages:
[2661, 2661]
Si scioglie una piccola quantità di zucchero \(z\) in acqua (liquida). La soluzione è in equilibrio di fase con il vapor d'acqua puro. Si assuma che la soluzione si comporti come una soluzione ideale, cioè che il potenziale chimico del componente \(k\)-esimo in soluzione sia dato dalla relazione
\[
\mu_{k}=g_{k}+R T \log \left[x_{k}\right]
\]
dove \(x_{k}\) è la frazione molare del componente \(k\)-esimo e \(g_{k}\) è la funzione di Gibbs molare del componente \(k\)-esimo.
1. Motivare il fatto che si può considerare trascurabile la frazione di zucchero allo stato di vapore.
2. Mostrare che l'equazione dell'equilibrio di fase è \(g_{a}^{v}=g_{a}^{l}+R T \log \left[1-x_{z}\right]\), dove \(g_{a}^{v}\) è la funzione di Gibbs molare del vapor d'acqua puro, \(g_{a}^{l}\) è la funzione di Gibbs molare del liquido, e \(x_{z}\) la frazione molare dello zucchero nella soluzione.
3. Mostrare che per un variazione infinitesima di \(x_{z}\) a pressione costante si ha
\[
-s_{a}^{v} \mathrm{~d} T=-s_{a}^{l} \mathrm{~d} T+R \log \left[1-x_{z}\right] \mathrm{d} T+R T \mathrm{~d} \log \left[1-x_{z}\right] .
\]
4. Combinando i risultati dei punti precedenti mostrare che il risultato della domanda precedente si riduce a \(0=\left(h_{a}^{v}-h_{a}^{l}\right) \mathrm{d} T+R T^{2} \mathrm{~d} \log \left[1-x_{z}\right]\)
5. Osservando che \(x_{z} \ll 1\) e che \(h_{a}^{v}-h_{a}^{l} \equiv \Delta h_{a}^{l v}\), il calore latente di vaporizzazione dell'acqua pura, mostrare che il punto di ebollizione della soluzione si innalza approssimativamente della quantità \(\Delta T=x_{z} R T^{2} / \Delta h_{a}^{l v}\).

A working substance (gas) in a piston-cylinder. Let us cool it, starting from a thermostat at the initial temperature. Practical experimental problems are not considered.
1. Isothermal reversible compression in contact with the thermostat: work is done on the substance and heat is given off to the thermostat; try to make the final volume as small as possible.
2. Adiabatic reversible expansion after thermal insulation from the surroundings: the substance does work and its internal energy (and thus temperature) decreases; try to make the final pressure as small as possible.
3. If you can use (part of) the cooled substance as a new thermostat at a starting temperature you may repeat the cycle.

From table 61.2 we have, for matter only and fixed currents:
\[
\delta \mathcal{W}=-\left(\mathbf{M} \cdot \delta \mathbf{B}_{1}\right)
\]
the work done on the sample per unit volume when the field \(\mathbf{B}_{1}\) changes.
Note that, to keep a parallelism with a \(p V T\) system, we have to identify, formally and only formally, \(\mathbf{B}_{1}\) with volume and \(\mathbf{M}\) with pressure.

Consider a paramagnetic salt.
For an infinitesimal transformation, the balance of energy per unit volume gives, for the heat received, as \(\mathcal{U}=-M B\) (see for instance equation (38.04.06)):
\[
\delta \mathcal{Q}=\mathrm{d} \mathcal{U}-\delta \mathcal{W}=\mathrm{d}(-M B)+M \mathrm{~d} B=-B \mathrm{~d} M=T \mathrm{~d} \mathcal{S}
\]
- Isothermal Magnetization (by increasing the external magnetic field); work is done on the system.
- Adiabatic (isoentropic) deMagnetization; no work.

Plane \(\mathcal{S} T\), or better \(T \mathcal{S}\).
Recall that Langevin equation is the equation of state.
It can be shown, working as for a \(p V T\) system, that a Maxwell relation applies:
\[
\left(\frac{\partial S}{\partial B}\right)_{T}=\left(\frac{\partial M}{\partial T}\right)_{B} \leq 0
\]
negative from Langevin equation and easily interpreted as negative in the probabilistic order/disorder entropy interpretation.

Use the first law to show that any closed path in the \(p V\) plane maps into a closed path with the same enclosed area.

61-005 Maxwell Relations and Jacobian
©|S.J.Blundell \& K.M.Blundell, Concepts In Thermal Physics, 2010, Oxford, 2ndEd., ....|§ 16||
Consider a reversible cycle, represented in both the \(p V\) and \(T S\) planes. The fundamental equation (60.09.01), for the closed cycle, implies:
\[
0=\oint \mathrm{d} \mathcal{U}=\oint T \mathrm{~d} \mathcal{S}-\oint p \mathrm{~d} V \Longrightarrow \oint T \mathrm{~d} \mathcal{S}=\oint p \mathrm{~d} V \Longrightarrow \iint \mathrm{~d} T \mathrm{~d} \mathcal{S}=\iint \mathrm{d} p \mathrm{~d} V
\]

Show that the above relation is able to generate all Maxwell Equations via the Jacobian.

\section*{Introduction}

\section*{© - QUOTE}
R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....

Kinetic theory is based upon the analysis of the elementary mechanical processes, free motion of the molecules between two successive collisions, collisions between those molecules, and, furthermore, upon calculating averages over the system of gas molecules and striking the balance.

Important preliminary concepts:
- Cross-section: read § 28.06 - Introduction to Many-Particles Systems.
- Mean free path: read § 28.06.01 - Introduction to Many-Particles Systems.
- Beer-Lambert law: see equation (42.04.01).
- Virial Theorem: read § 28.07 - Introduction to Many-Particles Systems.
- Collisions, Kinetic Temperature and thermalization: read § 58.04.04.02 - Framework of Thermodynamics and Temperature.

\section*{© - QUOTE}
©|L.D.Landau et al., Statistical Physics, ..., ..., ...Ed., DOI - ISBN: 0-08-023039-3.|§ 29|excellent|

Let us consider the probability distribution for the momenta, and once again emphasise the very important fact that in classical statistics this distribution does not depend on the nature of the interaction of particles within the system or on the nature of the external field, and so can be expressed in a form applicable to all bodies.

\title{
Mean Free Path Collision Time and Scattering Cross Section
}
©|Berkeley Physics Course, Vol. 5, Statistical Physics, 1965, McGraw-Hill, ...Ed., ....|||
©|F.Reif, Fundamentals Of Statistical And Thermal Physics, 2009, Waveland Press, ...Ed., ....|||
Let us consider \(N\) all-identical molecules of a dilute gas in a volume \(V\) and neglect all interactions among molecules. We will treat the molecules as rigid spheres of finite size to allow collisions to occur and start considering collision process between two hard spheres.
If the diameter of the molecules is \(d\), the effective cross-sectional area for scattering is \(\pi d^{2}\). In fact, focusing on a single molecule as it makes its way through the gas, while traveling a distance \(\ell\) and sweeping out a volume \(\Delta V=\pi d^{2} \ell\) it will collide with any other molecule whose center lies within this volume.
The mean free path is defined as the average distance traveled by the molecule between each collision; therefore for one collision, using the relative velocity to account for relative motion of the molecules, and \(\ell=\lambda:\)
\[
\eta_{\mathrm{N}} \pi d^{2} \lambda=\eta_{\mathrm{N}} \pi d^{2}\langle u\rangle \tau=1=\eta_{\mathrm{N}} \pi d^{2} \sqrt{2}\langle v\rangle \tau \Longrightarrow \lambda=\langle v\rangle \tau=\frac{1}{\eta_{\mathrm{N}} \pi d^{2} \sqrt{2}} .
\]

Note that:
- \(\eta_{\mathrm{N}} \pi d^{2}\langle u\rangle \tau=1\) requires \(\langle u\rangle\), that is the relative molecule velocity; it is a molecule moving inside a set of fixed targets with speed given by the relative speed.
- \(\lambda=\langle v\rangle \tau\) needs \(\langle v\rangle\), the real molecule velocity.

A more refined analysis requires the use of the concept of cross-section, giving:
\[
\begin{equation*}
\lambda=\langle v\rangle \tau=\frac{1}{\eta_{\mathrm{N}} \sigma \sqrt{2}} \tag{62.02.01}
\end{equation*}
\]

Read § 28.06.01 - Introduction to Many-Particles Systems.
Dilute gas means: \(\lambda \gg d\).
Summarizing the relations between cross-section and interaction rate, for a totally random set of identical molecules in a dilute gas, is:
\[
\lambda=\langle v\rangle \tau=\frac{\langle v\rangle}{\langle u\rangle} \frac{1}{\eta_{\mathrm{N}} \sigma}=\frac{1}{\sqrt{2} \eta_{\mathrm{N}} \sigma} \quad \mathbf{u} \equiv \mathbf{v}_{2}-\mathbf{v}_{1} \quad\langle u\rangle \approx \sqrt{2}\langle v\rangle
\]

\section*{Examples}

Mean free path in atmosphere at NTP: \(\lambda \simeq 0.07 \mu \mathrm{~m} \gg d\). Therefore the approximations based on relatively infrequent encounters among molecules (dilute gas) are justified

\subsection*{62.02.01 Kinetic Diameter}
© |WEB - URL \(\mid\) Molecular Physics \(\mid\) § 2|
The kinetic diameter is a measure of molecules that expresses the likelihood that a molecule in a dilute gas will collide with another molecule. It is an indication of the size of the molecule as a projectile/target. The kinetic diameter is not the same as atomic diameter defined in terms of the size of the atom's electron shell, which is generally a lot smaller, depending on the exact definition used. Rather, it is the size of the sphere of influence that can lead to a scattering event. In other words, it is the size which would give the cross-section in case the interaction would be a black-disk one.
Kinetic diameter it is obviously related to the mean free path of molecules in the gas and is defined by the relations of this section.

\section*{Examples}

Mean diameters as derived from the co-volume in Van der Waals equation:
- water: 0.29 nm ;
- \(O_{2}: 0.29 \mathrm{~nm}\);
- \(H_{2}: 0.28 \mathrm{~nm}\);
- \(\mathrm{CO}_{2}: 0.32 \mathrm{~nm}\);
- \(C_{6} H_{6}: 0.45 \mathrm{~nm}\).

©|R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....|§ 9.2.1||
It is remarkable that the Maxwell distribution is thus valid in the, either gas or liquid, fluid phases, even at higher densities. The spatial correlations between molecules become very strong in the liquid, but their velocities remain statistically decoupled, at least as long as the classical approximation is valid.

The Maxwell-Boltzmann velocity distribution follows immediately from the Boltzmann-Gibbs factor,
\[
\exp \left[-\frac{H[q, p]}{k_{\mathrm{B}} T}\right],
\]
whenever classical statistical mechanics applies, by integrating out the potential energy terms of the Hamiltonian as long as potential energy only depends only on coordinates and not on momenta.
The Center-Of-Mass coordinates of molecules are usually well described by classical statistical physics, while rotational and vibrational usually are not.

\subsection*{62.03.01 Heuristic Derivation}

The following hypotheses are assumed.
- The diameter of the molecules are much smaller than the distance between them (dilute gas).
- The collisions between molecules are elastic.
- The positions and velocities of the molecules are initially at random (homogeneous and isotropic in position and velocity).
- The three components of the velocity of a particle are independent: \(f\left[v_{x}, v_{y}, v_{z}\right]=h\left[v_{x}\right] h\left[v_{y}\right] h\left[v_{z}\right]\). It follows:
\(\mathrm{d} N \equiv f\left[v_{x}, v_{y}, v_{z}\right] \mathrm{d} v_{x} \mathrm{~d} v_{y} \mathrm{~d} v_{z} \equiv h\left[v_{x}\right] h\left[v_{y}\right] h\left[v_{z}\right] \mathrm{d} v_{x} \mathrm{~d} v_{y} \mathrm{~d} v_{z} \equiv 4 \pi v^{2} \phi[v] \mathrm{d} V \equiv \Phi[v] \mathrm{d} V \quad\) thanks to isotropy,
\[
\begin{gathered}
h\left[v_{x}\right] h\left[v_{y}\right] h\left[v_{z}\right]=f\left[v_{x}, v_{y}, v_{z}\right] \equiv \Phi[v] \quad \text { thanks to isotropy }, \\
\Longrightarrow h^{\prime}\left[v_{x}\right] h\left[v_{y}\right] h\left[v_{z}\right] \propto \Phi^{\prime}[v] \frac{\mathrm{d} v}{\mathrm{~d} v_{x}}=\Phi^{\prime}[v] \frac{v_{x}}{v}, \\
\Longrightarrow \frac{1}{v_{x}} \frac{h^{\prime}\left[v_{x}\right]}{h\left[v_{x}\right]} \propto \frac{1}{v} \frac{\Phi^{\prime}[v]}{\Phi[v]},
\end{gathered}
\]
\(\Longrightarrow \frac{1}{v_{x}} \frac{h^{\prime}\left[v_{x}\right]}{h\left[v_{x}\right]} \propto \frac{1}{v} \frac{\Phi^{\prime}[v]}{\Phi[v]} \equiv \lambda \quad \lambda\) is independent from \(v\) and \(v_{x}\), as well as from \(v_{y}\) and \(v_{z}, \quad\),
\[
\begin{gathered}
\Longrightarrow \Phi^{\prime}[v]=\lambda v \Phi[v] \\
\Longrightarrow \Phi[v]=\exp \left(\frac{\lambda}{2} v^{2}\right),
\end{gathered}
\]
\[
\text { and similarly: } \quad h\left[v_{k}\right] \propto \exp \left(\frac{\lambda}{2} v_{k}^{2}\right) .
\]

Note that the derivation does not require to assume that the molecules move between collisions without interacting at a constant speed in a straight line (no interactions among molecules). In fact, the MaxwellBoltzmann distribution is valid for any system of classical particles at equilibrium.
Note that some of the results in kinetic theory do not depend on the explicit expressions of the distribution functions.

\subsection*{62.03.02 Single-Particle Velocity Distribution}

Common choices for the normalization of the distribution functions include:
- normalization to \(N\), the total number of particles;
- normalization to one (the distribution function is a probability function);
- normalization to the number density of particles, the concentration, \(\eta_{\mathrm{N}}\).

The expressions in orthonormal Cartesian Coordinates Coordinate System of the single-particle distri-
bution functions, are as follows:
\(\mathrm{d} \wp\left[v_{x}, v_{y}, v_{z}\right] \equiv f\left[v_{x}, v_{y}, v_{z}\right] \mathrm{d} v_{x} \mathrm{~d} v_{y} \mathrm{~d} v_{z}=h\left[v_{x}\right] h\left[v_{y}\right] h\left[v_{z}\right] \mathrm{d} v_{x} \mathrm{~d} v_{y} \mathrm{~d} v_{z} \quad\) homogeneity, independent from \(x, y, z, ~, ~\)
\[
\begin{aligned}
1=\iiint \mathrm{d} \wp\left[v_{x}, v_{y}, v_{z}\right]= & \iiint_{-\infty}^{+\infty} f\left[v_{x}, v_{y}, v_{z}\right] \mathrm{d} v_{x} \mathrm{~d} v_{y} \mathrm{~d} v_{z} \quad \text { normalization } \\
& \left\langle v_{x}\right\rangle=\left\langle v_{y}\right\rangle=\left\langle v_{z}\right\rangle=0
\end{aligned}
\]
\(\mathrm{d} \wp\left[v_{k}\right]=h\left[v_{k}\right] \mathrm{d} v_{k} \quad\) homogeneity, independent from \(x, \quad\),
\[
\begin{gathered}
1=\int_{-\infty}^{+\infty} h\left[v_{k}\right] \mathrm{d} v_{k} \quad, \\
\left\langle v_{k}\right\rangle=0, \\
h\left[v_{k}\right]=\sqrt{\frac{m}{2 \pi k_{\mathrm{B}} T}} \exp \left[-\frac{m v_{k}^{2}}{2 k_{\mathrm{B}} T}\right]
\end{gathered},
\]

The expressions in spherical coordinates of the single-particle distribution functions, are as follows:
\[
\begin{aligned}
& \mathrm{d} \wp[v, \theta, \phi] \equiv \frac{g[v]}{4 \pi} \mathrm{~d} V \mathrm{~d} \Omega \quad \text { isotropy, independent from } \theta \text { and } \phi \\
& 1= \iiint \mathrm{d} \wp[v, \theta, \phi]=\iiint \frac{g[v]}{4 \pi} \mathrm{~d} V \mathrm{~d} \Omega=\int_{0}^{+\infty} g[v] \mathrm{d} V \quad \text { normalization }
\end{aligned}
\]
\[
\mathrm{d} \wp[v]=g[v] \mathrm{d} V=\frac{4}{\sqrt{\pi}}\left(\frac{m}{2 k_{\mathrm{B}} T}\right)^{3 / 2} v^{2} \exp \left[-\frac{m v^{2}}{2 k_{\mathrm{B}} T}\right] \mathrm{d} V=4 \pi\left(\frac{m}{2 \pi k_{\mathrm{B}} T}\right)^{3 / 2} v^{2} \exp \left[-\frac{m v^{2}}{2 k_{\mathrm{B}} T}\right] \mathrm{d} V
\]

The relation with the kinetic temperature, assuming the fluid has zero overall (Center-Of-Mass) velocity, is:
\[
\frac{1}{2} m\left\langle v^{2}\right\rangle \equiv \frac{3}{2} k_{\mathrm{B}} T \quad \text { kinetic temperature } \quad \text { if } \quad\langle v\rangle=0
\]
read § 58.04.04.01 - Framework of Thermodynamics and Temperature.
Note that for a real gas in a real container the distribution of velocities would be generally different near the walls, where isotropy and homogeneity are lost. In fact, for instance, near the walls particles directing towards the wall might be slowed down by the bulk particles, and|or possibly being accelerated by the interaction with the particles of the walls.
So, the Single-Particle Velocity Distribution is a Gaussian.
The Single-Particle Velocity squared Distribution is a chi-square distribution.
\[
\begin{aligned}
& \left\langle v^{2}\right\rangle=\frac{3 k_{\mathrm{B}} T}{m}, \quad, \\
& \langle v\rangle=\sqrt{\frac{8 k_{\mathrm{B}} T}{\pi m}} \propto \sqrt{\frac{T}{m}}, \quad, \\
& v_{\text {RMS }}=\sqrt{\frac{3 k_{\mathrm{B}} T}{m}} \propto \sqrt{\frac{T}{m}} \quad, \quad, \\
& v_{\text {MAX }}=\sqrt{\frac{2 k_{\mathrm{B}} T}{m}} \propto \sqrt{\frac{T}{m}} \quad, \quad, \\
& v_{\text {MAX }}<\langle v\rangle<v_{\text {RMS }} .
\end{aligned}
\]

\subsection*{62.03.03 Mathematical Relations for the Maxwell-Boltzmann Distribution}

The following functions are normalized to one in \((-\infty,+\infty)(\operatorname{Re}(a>0)\) and \(\operatorname{Re}(b>0))\) :
\[
\begin{gathered}
\frac{\sqrt{a} \exp -a w^{2}}{\sqrt{\pi}} \\
\frac{2 a^{3 / 2} w^{2} \exp -a w^{2}}{\sqrt{\pi}}, \\
\frac{\sqrt{a} \exp -\frac{b^{2}}{4 a}-a w^{2}-b w}{\sqrt{\pi}}
\end{gathered}
\]

The following functions are normalized to one in \((0,+\infty)(\operatorname{Re}(a>0)\) and \(\mathfrak{R e}(b>0))\) :
\[
\begin{array}{ccc}
\frac{2 \sqrt{a} \exp -a w^{2}}{\sqrt{\pi}} & , \\
2 a w \exp -a w^{2} \\
\frac{4 a^{3 / 2} w^{2} \exp -a w^{2}}{\sqrt{\pi}}, & , \\
\frac{2 a^{2} w^{3} \exp -a w^{2}}{}, & , \\
\frac{8 a^{5 / 2} w^{4} \exp -a w^{2}}{3 \sqrt{\pi}}, & , \\
\frac{2 \sqrt{a} \exp -\frac{b^{2}}{4 a}-a w^{2}-b w}{\sqrt{\pi} \operatorname{erfc}\left(\frac{b}{2 \sqrt{a}}\right)} .
\end{array}
\]

The correct normalization factors for the most common integrals can be calculated as follows:
\[
\begin{gathered}
\int_{-\infty}^{+\infty} \exp -a z^{2} \mathrm{~d} z=\sqrt{\frac{\pi}{a}} \quad \operatorname{Re}(\mathrm{a}>0), \\
\int_{0}^{+\infty} z \exp -a z^{2} \mathrm{~d} z=\frac{1}{2 a} \quad \operatorname{Re}(\mathrm{a}>0), \\
\int_{-\infty}^{+\infty} z^{2} \exp -a z^{2} \mathrm{~d} z=\frac{1}{2} \sqrt{\frac{\pi}{a^{3 / 2}}} \quad \operatorname{Re}(\mathrm{a}>0)
\end{gathered}
\]

\subsection*{62.03.04 Towards Interacting Particles}

\section*{© - QUOTE}
©|R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....|§ 9||
In \(\S 7\) and 8 we restricted ourselves to the study of low density gases. When a gas is compressed, its molecules get closer to one another and the approximation which consists in neglecting their interactions is no longer valid. As the density increases there thus appear corrections to the ideal gas laws and we shall now give a theory for those. However, the occurrence of interaction terms in the Hamiltonian gives rise to a new mathematical difficulty: the partition function can no longer be factorized into the contributions of the single molecules. Calculating it involves more or less well controlled approximations, even when one introduces simplified models for the interactions (§ 9.1 and § 9.2).
The interactions between the molecules play a more interesting role, namely, they produce a phenomenon which is remarkable, although well known from experience: liquefaction. We know that
if the temperature is not too high - more precisely, if it does not lie above the critical temperature - compressing a gas makes it abruptly go over into the liquid state, when one reaches the saturated vapor pressure. If we try to forget that this is a trivial fact and try to examine it critically, we find that it has surprising aspects: the thermodynamic quantities show a discontinuity or a singularity, and the fluid separates into two phases, the liquid and the vapor one. How can we explain that these two phases coexist and how can we explain their qualitatively different properties, if they consist of the same molecules which interact with the same forces? How can we derive from a single microscopic theory a discontinuous macroscopic behavior? The same questions crop up for the numerous other instances of phase transitions which one observes on a macroscopic scale: solidification, the possibility to obtain various liquid phases for mixtures or various crystalline phases for solids, ferromagnetism, superconductivity, and so on. Their discontinuous nature is difficult to understand when we start from the microscopic structure of matter, and this has given rise to a long controversy: is there a sudden change in the forces between the elementary constituents? or is it possible to explain the existence of phases which are macroscopically so different starting from a single microscopic model? The second solution has won the day thanks to many researches which constitute one of the most spectacular contributions of statistical physics. We cite amongst the first important stages the elaboration of approximate microscopic theories of magnetism (P.Weiss, 1924; W.L. Bragg and E.J.Williams, 1934) and of liquefaction (J.Yvon, J.E. Mayer, 1937), which showed the appearance of a phase transition as a cooperative phenomenon where, for instance, the magnetic moments orient themselves all in the same direction below the Curie temperature due to their mutual interactions. A decisive conceptual step was the first rigorous solution of a microscopic model which shows a phase transition, the two-dimensional Ising model (L.Onsager, 1944). More recently, the singular behavior of the thermodynamic functions near a critical point, which had been known and studied experimentally for a long time, found its explanation thanks to the work by K.Wilson (1971).

In § 7.1 we saw that the ideal gas model, which is sufficient for describing rarefied mono-atomic gases, is based upon three approximations: the internal degrees of freedom of the molecules are frozen in, their center of mass motion has a classical nature and there are no interactions between the molecules. The first condition was abandoned in \(\S 8\) when we wanted to study rarefied polyatomic gases. On the other hand, we showed in \(\S 7.1 .3\) that the second approximation - the use of classical statistical mechanics for the translational degrees of freedom - is valid not only for gases, but also for almost all liquids. However, we must take into account the interactions between the molecules, if we want to study the properties of a compressed gas or of a liquid.
It is difficult to make a simple model of the interactions between poly-atomic molecules as their collisions can produce transitions from one state to another in each of the molecules. The interactions thus affect the internal structure of the molecules. The situation is simpler for mono-atomic fluids and we shall restrict ourselves to those in the present chapter. In all cases the interactions between the molecules are due to the Coulomb forces between their constituents, the electrons and the nuclei. In the case of a mono-atomic gas, the electrons remain frozen in into their ground state at the temperatures of interest; when two atoms approach one another, the deformation of the electron cloud produces an effective potential between them.
We sketched the theory of this interaction: attractive for long distances apart and repulsive for short distances apart.

Of course, even though the elementary forces between the constituents, the nuclei and electrons, which are Coulomb forces, are two-body forces, the effective interactions between the atoms also contain three-, four-, ... body forces. However, at the usual gas densities and even at liquid densities, the probability for three or more atoms to be sufficiently close to one another so that the effects of these three-, four-, ... body forces can come into play is small. We shall therefore restrict ourselves mainly to a study of Hamiltonians which, apart from the kinetic energy, contain
solely the binary potential which we have just described and which is a function of the relative positions of the molecular nuclei, taken in pairs.
Thus, we can write for the effective Hamiltonian
\[
\begin{equation*}
H=\sum_{i} \frac{p_{i}^{2}}{2 m_{i}}+\frac{1}{2} \sum_{a \neq b} \Phi\left(\left|\mathbf{r}_{a}-\mathbf{r}_{b}\right|\right) \tag{62.03.01}
\end{equation*}
\]
where the potential energy \(\Phi\) of the interaction between the molecules depends only on their distance apart since they are mono-atomic, and has the shape shown in Fig. 9.1. This potential has a quantum mechanical origin as its calculation involves crucially the freezing- in of the electronic degrees of freedom into their ground state. Nevertheless, the effective Hamiltonian, which results from eliminating the motion of the electrons and which depends on the positions and momenta of the nuclei of the atoms in the gas, can be treated classically for all mono-atomic fluids - bar helium at low temperatures - as we saw in \(\S 7.1 .3\). The fluid is therefore finally satisfactorily described by a model of classical point particles with the Hamiltonian (62.03.01).

The presence of the interaction not only changes (through \(T\) ) the thermodynamic or (through \(\mu\) ) the chemical quantities, but also the equation of state, which now differs from that for a ideal gas. Unfortunately, the canonical partition function which occurs in the grand canonical potential ... for each particle is a multiple integral over a very large number of variables, and its evaluation is impossible, even for the simplest models for the potential \(\Phi\). We must therefore in what follows appeal to various approximations without always being able to give a rigorous justification for them.
Let us bear in mind that ... in the grand canonical potential ... is based solely on two approximations: the interactions between the molecules are taken into account by a binary isotropic potential, which is realistic for a mono-atomic gas, and we use the classical limit. This expression is therefore justified not only for the gas phase, but also for the liquid phase of the substance studied.
As we indicated at the start of this section, statistical mechanics thus provides a single expression, which contains a potential \(\Phi\), fixed once and for all, and which should describe the liquid-vapor transition. Nevertheless, nothing enables us to discern from the grand canonical potential ... the presence of a line of singularities which would separate the two phases, liquid and vapor. The theory of the transition and of the critical point must start from the grand canonical potential ... but we expect that it will be difficult mathematically. To give an idea of how complicated it is we note that even the proof itself of the extensivity is by no means easy.

One property remains very simple, notwithstanding the presence of inter-molecular interactions, namely, the velocity distribution.
exactly as in the case of a system without interactions. It is remarkable that the Maxwell distribution is thus valid in the, gas or liquid, fluid phases, even at higher densities. The spatial correlations between molecules become very strong in the liquid, but their velocities remain statistically decoupled, at least as long as the classical approximation is valid.

The Center-Of-Mass motion is always a classical motion in non-extreme conditions. The only approximation needed to derive the Maxwell-Boltzmann distribution is the classical approximation for fluids. Obviously, for crystalline solids, the classical approximation is not good, as the crystal is a quantum system.

\subsection*{62.04.01 Jet-Like (Collinear) Velocity Distribution}

Consider a fixed plane portion of a surface, either real or purely geometric, \(\mathrm{d} \mathbf{S} \equiv \hat{\mathbf{n}} \mathrm{d} \mathbf{S}\), parallel to the \(x y\) plane, \(\hat{\mathbf{n}}=\{0,0,1\}\), and a steady flow for a velocity distribution along the positive \(z\) and uniform in the \(x y\) plane, with uniform and constant velocity, \(v\) :
\[
\begin{equation*}
\frac{\mathrm{d} N}{\mathrm{~d} \mathbf{S} \mathrm{~d} t}=\eta_{\mathrm{N}} v \tag{62.04.01}
\end{equation*}
\]

Compare with the more general equation (14.06.16): a different notation is used in equation (62.04.01) as this is a simpler situation.

It is useful to note that equation (62.04.01), as it should be, is the same equation, with the proper reinterpretation of physics quantities, as equation (59.09.01.06), when the speed of light is replaced to \(\langle v\rangle\) and the energy density is replaced to the number density.

\subsection*{62.04.02 Isotropic Velocity Distribution}

Consider a fixed plane portion of a surface, either real or purely geometric, \(\mathrm{d} \mathbf{S} \equiv \hat{\mathbf{n}} \mathrm{d} \mathbf{S}\), and a steady flow for a isotropic velocity distribution.

A crude calculation, assuming that all particles are moving at the mean speed and \(1 / 6\) of them (that is \(1 / 6\) for each orthogonal direction) are hitting the wall, gives the rough approximation:
\[
\frac{\mathrm{d} N}{\mathrm{~d} \mathbf{S} \mathrm{~d} t} \approx \frac{1}{6} \eta_{\mathrm{N}}\langle v\rangle
\]

The full calculations gives:
\[
\mathrm{d} N[v, \theta, \phi] \equiv N\left(g[v] \mathrm{d} V \frac{\mathrm{~d} \Omega}{4 \pi}\right)\left(\frac{\mathrm{d} \mathbf{S} \cos \theta v \mathrm{~d} t}{V}\right)=
\]
integrating in azimuth and polar angle: \(\quad 2 \pi \frac{1}{2} \mathrm{~d} \mathbf{S} \mathrm{~d} t \frac{N}{V} \frac{1}{4 \pi} \int v g[v] \mathrm{d} V=\quad\),
\[
\mathrm{d} N=\frac{1}{4} \eta_{\mathrm{N}}\langle v\rangle \mathrm{d} \mathbf{S} \mathrm{~d} t \quad \Leftrightarrow \quad \frac{\mathrm{~d} N}{\mathrm{~d} \mathbf{S} \mathrm{~d} t}=\frac{1}{4} \eta_{\mathrm{N}}\langle v\rangle
\]

Strictly speaking, the above derivation is only valid for ideal gases, as the module of the velocity is assumed to be constant, while for a real gas the particles approaching the walls are typically attracted and slowed-down by the bulk particles.

\subsection*{62.04.03 Effusion From a Small Hole}

The molecules inside the container, in thermodynamic equilibrium, have a isotropic velocity distribution. By effusion from a small hole, one means the case when the hole is so small not to perturb the local equilibrium near the hole itself.
These relationships are applicable in the case the mean free path in the gas within the container is much larger than the linear dimension of the hole, to prevent the presence of the hole to alter the equilibrium distribution within the container, in case a particle suffers many interactions near the hole.
Furthermore, the mean free path in the gas must be much smaller than the linear dimensions of the container to prevent the walls from having a predominant role in the mechanics of the system, as in the case the bumps occur between the particles and the walls only.

\subsection*{62.04.03.01 Effusion Into Vacuum From a Small Hole}

L'effusione di un gas attraverso un piccolo buco di sezione \(\mathrm{d} \mathbf{S}\) in un contenitore è data dalla relazione
\[
\begin{equation*}
\frac{\mathrm{d} N}{\mathrm{~d} \mathbf{S} \mathrm{~d} t}=\frac{1}{4} \eta_{\mathrm{N}}\langle v\rangle \equiv \frac{1}{4} \eta_{\mathrm{N}}\langle v\rangle \tag{62.04.02}
\end{equation*}
\]
dove \(\eta_{\mathrm{N}}\) è la concentrazione e \(\langle v\rangle\) la velocità media delle molecole del gas entro il recipiente.
It is useful to note that equation (62.04.02), as it should be, is the same equation, with the proper reinterpretation of physics quantities, as equation (59.09.01.06), when the speed of light is replaced to \(\langle v\rangle\) and the energy density is replaced to the number density.
For a ideal gas it can be written as:
\[
\begin{equation*}
\frac{1}{4} \eta_{\mathrm{N}}\langle v\rangle=\frac{p}{\sqrt{2 \pi m k_{\mathrm{B}} T}} \tag{62.04.03}
\end{equation*}
\]

\subsection*{62.04.03.02 Cross-Effusion From a Small Hole}

If there is gas on two containers on both sides of the hole, one must balance the passages in both directions. In the effusion regime, \(\lambda \gg D\), the system will achieve equilibrium when the two molecular fluxes balance. If the temperature is uniform, a rate of effusion which is proportional to the difference in the densities, that is, to the difference in pressure at the two sides is found.

\subsection*{62.04.03.03 Cross-Effusion From a Large Hole}

In the hydrodynamics regime, \(\lambda \ll D\), at equilibrium the pressures balance.

\subsection*{62.04.04 Kinetic Pressure - Molecular Perfect Gas Equation of State}

This § is referenced at pages:
[2691, 2691, 2691, 2691]
Consider a fixed plane portion of a surface, either real or purely geometric, \(\mathrm{d} \mathbf{S} \equiv \hat{\mathbf{n}} \mathrm{d} \mathbf{S}\).
Pressure is the rate of linear momentum given off per unit area, by a molecule whose Center-Of-Mass has velocity \(\mathbf{v}\).
Perfect gas: \(\mathcal{K}=\mathcal{U}\)
The same calculations as in § 62.04 - Elements of Kinetic Theory and Transport Phenomena, adding the additional factor \(\Delta q_{\perp}=2 m v_{\perp}=2 m v \cos \theta\), provides:
\(\mathrm{d}\left(\Delta q_{\perp}\right)[v, \theta, \phi, \mathrm{~d} \mathbf{S}, \mathrm{~d} t] \equiv N\left(g[v] \mathrm{d} V \frac{\mathrm{~d} \Omega}{4 \pi}\right)(2 m v \cos \theta)\left(\frac{\mathrm{d} \mathbf{S} \cos \theta v \mathrm{~d} t}{V}\right)=(2 \pi)\left(\frac{1}{3}\right)(\mathrm{d} \mathbf{S} \mathrm{d} t) \frac{2 m N}{V} \frac{1}{4 \pi} \int v^{2} g[v] \mathrm{d} V \quad\),
\[
p=\frac{2}{3} \eta_{\mathrm{N}} \frac{m}{2}\left\langle v^{2}\right\rangle=\frac{2}{3} \frac{\mathcal{K}}{V}=\frac{2}{3} \frac{U}{V}
\]

If the gas is not ideal, the particles about to collide the walls will be slowed-down by the bulk of the fluid; it is the same argument as for the corrective term of Van der Waals equation of state. Therefore the calculation of pressure is not strictly valid because, even if the Maxwell distribution is still valid for a real fluid, it is valid in the bulk fluid, not at the edges where surface effects might appear.

\subsection*{62.04.05 Kinetic Pressure - Photon Gas Equation of State}

This § is referenced at pages:
[Never referenced.]
©|Lim Yung-Kuo, Problems And Solutions On Thermodynamics And Statistical Physics, 1990, World Scientific, ...Ed., ....|2164, 2165||
Consider a fixed plane portion of a surface, either real or purely geometric, \(\mathrm{d} \mathbf{S} \equiv \hat{\mathbf{n}} \mathrm{d} \mathbf{S}\).
Pressure is the rate of linear momentum given off per unit area, by a photon with linear momentum \(\mathbf{q}\). The same calculations as in § 62.04 - Elements of Kinetic Theory and Transport Phenomena, adding the additional factor \(\Delta q_{\perp}=2 q_{\perp}=2 q \cos \theta\) :
\(\mathrm{d}\left(\Delta q_{\perp}\right)[\epsilon, \theta, \phi, \mathrm{d} \mathbf{S}, \mathrm{d} t] \equiv N\left(g[\epsilon] \mathrm{d} \epsilon \frac{\mathrm{d} \Omega}{4 \pi}\right)(2 q \cos \theta)\left(\frac{\mathrm{d} \mathbf{S} \cos \theta c \mathrm{~d} t}{V}\right)=(2 \pi)\left(\frac{1}{3}\right)(c \mathrm{~d} \mathbf{S} \mathrm{~d} t) \frac{2 N}{c V} \frac{1}{4 \pi} \int \epsilon g[\epsilon] \mathrm{d} \epsilon\), \(p=\frac{1}{3} \eta_{\mathrm{N}}\langle\epsilon\rangle=\frac{1}{3} \frac{U}{V}\).

\section*{© - QUOTE}
R.P.Feynman et al., The Feynman's Lectures On Physics, 1964, Addison-Wesley, ...Ed., ....

We have considered so far only the molecular motions ... in thermal equilibrium. We want now to discuss what happens when things are near, but not exactly in, equilibrium. In a situation far from equilibrium, things are extremely complicated, but in a situation very close to equilibrium we can easily work out what happens. To see what happens, we must, however, return to the kinetic theory. Statistical mechanics and thermodynamics deal with the equilibrium situation, but away from equilibrium we can only analyse what occurs atom by atom, so to speak.

\section*{© - QUOTE}

\section*{REICHL}

We will assume that the interaction is very short ranged compared to the mean free path. For a low density gas of \(N\) particles contained in a volume \(V\), the interaction energy between particles is negligible compared to the kinetic energy of the particles.
The mean free path, \(\lambda\), of a particle is the average distance it travels between collisions. We shall assume that collisions occur at random in the gas, so a particle has the same chance of collision in any interval of length \((\ell, \ell+\mathrm{d} \mathbf{L})\). The average number of collisions per unit length is \(1 / \lambda\). The probability that a collision occurs in an interval \(\mathrm{d} \mathbf{L}\) is therefore \(\mathrm{d} \mathbf{L} / \lambda\).

There are two distinct type of processes:
- mobility, the drift of particles due to outside forces;
- diffusion, the spreading determined only by the internal forces, the random collisions.

In general, for many particles, the motion will be the superposition between a drift, that is motion of the Center-Of-Mass of any infinitesimal part, and a diffusive motion, that is motion around the Center-Of-Mass.

\subsection*{62.05.01 Equation of Continuity}

Let us suppose \(\mathcal{J}\), a scalar, is the volume density of a conserved quantity, \(\varrho \equiv \mathcal{J}\). L'equazione di continuità (equazione (19.01.03) or equation (26.03.01)), si esprime in termine della densità di volume della grandezza conservata, \(\varrho\), e del flusso della grandezza conservata, \(\mathbf{j}\) :
\[
\begin{equation*}
\varrho[\mathbf{x}, t] \quad \mathbf{j}[\mathbf{x}, t] \quad \mathbf{d i v} \mathbf{j}+\partial_{t} \varrho=0 \tag{62.05.01}
\end{equation*}
\]

Let us suppose instead that \(\mathcal{J}\), a scalar, is the volume density of a non-conserved quantity, \(\varrho \equiv \mathcal{J}\).
L'equazione di continuità (equazione (19.01.03) or equation (26.03.01)), in tal caso, oltre alla densità di volume della grandezza conservata, \(\varrho\), e all flusso della grandezza conservata, \(\mathbf{j}\), must include the amount of \(\mathcal{C}\) generate per unit volume per unit time, \(\sigma[\mathbf{x}, t]\), so that it becomes:
\[
\begin{array}{|lllll}
\hline \varrho[\mathbf{x}, t] & \mathbf{j}[\mathbf{x}, t] & \sigma[\mathbf{x}, t] & \operatorname{div} \mathbf{j}+\partial_{t} \varrho=\sigma  \tag{62.05.02}\\
\hline
\end{array}
\]

\subsection*{62.05.02 Convective Motion - the Drift of Particles}

The motion is caused by an external field of forces, such as in the case of the motion of electric charges in the presence of an electric field or massive particles in the gravity field. It is assumed that the motion is slowed by a viscous resistance, so that, in steady conditions, the velocity is constant: the drift velocity.
In general, the drift velocity is a function of the external force, \(\mathbf{F}: \mathbf{v}=\mathbf{v}[\mathbf{F}]\) :
\[
\begin{array}{r}
\varrho \equiv \frac{\mathrm{dC}}{\mathrm{~d} V} \quad \begin{array}{r}
\text { the amount of transported quantity } \\
\mathbf{j} \equiv \varrho \mathbf{v}=\varrho \mu \mathbf{F} \quad \text { the current dens } \\
\quad \mathbf{v} \equiv \mu \mathbf{F} \quad \mu=\frac{\tau}{m}
\end{array}
\end{array}
\]
e la velocità è data dall'effetto combinato del campo di forza che provoca il moto e dalle interazione con le altre particelle che rallentano, in termini della mobilità, \(\mu\).

\subsection*{62.05.03 Diffusive Motion - the Diffusion of Particles}

Consider a small volume of matter and, applying the Koënig theorem for kinetic energy, separate the Center-Of-Mass motion, the convective motion, from the diffusive random motion in the CMRF. The description of the system in the CMRF, the frame comoving with the fluid, leaves the motion due to the molecular random fluctuations around the Center-Of-Mass velocity.
In generale ad ogni variabile di stato intensiva, \(\mathcal{J}\), è associata una variabile coniugata, \(\mathcal{C}\), tale che per ottenere uniformità nella variabile \(\mathfrak{J}\) occorre un flusso della corrispondente variabile coniugata \(\mathfrak{C}\). In generale ogni cambiamento di \(\mathfrak{J}\) avviene tramite un flusso di \(\mathfrak{C}\).
In generale, se \(\mathbf{j}\) è il flusso di \(\mathcal{C}\), la relazione più semplice, quando \(\mathcal{J}\) è una grandezza scalare e le proprietà di diffusione sono omogenee \(e\) isotrope, è data da:
\[
|\mathbf{j}|=\frac{\mathrm{d} C}{\mathrm{~d} \mathbf{S}_{\perp} \mathrm{d} t} \quad \mathbf{j}=-K \mathbf{g r a d} \mathcal{J} \quad K>0 \quad[\mathrm{~K}]=\mathrm{m}^{2} / \mathrm{s}
\]
dove \(K\) è un'opportuna costante.
In generale si definiscono la variabile, \(\mathcal{J}\), e il flusso di \(\mathfrak{C}\) in modo che un flusso entrante una superficie chiusa causi un aumento della variabile intensiva all'intenro del volume (tenendo costanti le eventuali altre grandezze fisiche del problema). Inoltre il flusso deve andare in direzione opposta al gradiente, se la variabile intensiva deve tendere a diventare uniforme.
Si hanno dunque in generale le seguenti proprietà per un moto diffusivo:
- la legge dell'evoluzione verso l'equilibrio, caratterizzato da un valore uniforme di \(\mathcal{F}\);
- la relazione di positività \(\partial \mathcal{J} / \partial \mathrm{C}>0\), (con le eventuali altre variabili costanti);
- la relazione flusso e gradiente: \(\mathbf{j} \cdot \mathbf{g r a d} \mathcal{J} \leq 0\).

Si dimostra che due qualunque delle proprietà precedenti implicano la terza.
In the case of diffusive motion, even in the absence of external forces, the current density, \(\mathbf{j}\), depends on \(\mathcal{J}\), via the relation:
\[
\begin{equation*}
j_{p}[\mathbf{x}, t]=-K_{p q}^{\prime}[\mathbf{x}, t] \frac{\partial \mathcal{J}}{\partial x^{q}}[\mathbf{x}, t] \quad \text { with } \mathbb{K} \text { positive definite } \tag{62.05.03}
\end{equation*}
\]
which is a constitutive equation, defined by a suitable second-order tensor \(\mathbb{K}\), which is positive definite due to \(\mathbf{j} \cdot \operatorname{grad} \mathcal{J} \leq 0\).
The usual simplification might apply in any give problem, whenever the system is either homogeneous or isotropic, and|or does not explicitly depend on time.

\subsection*{62.05.04 Diffusion Equation}

This § is referenced at pages:
[1964, 1964]
Suppose \(\mathcal{C}\) is a conserved quantity. Whenever \(\mathbb{K}\) is a fixed tensor proportional to the identity, that is the system is homogeneous and isotropic and independent of time, the diffusive current density in equation (62.05.03) can be inserted into the continuity equation (62.05.01) finding:
\[
\begin{equation*}
K \nabla^{2} \mathcal{J}=\partial_{t} \mathcal{J}, \tag{62.05.04}
\end{equation*}
\]
that is the diffusion equation.
The Green function of the diffusion equation in \(n\)-dimension is:
\[
G\left[\mathbf{x}, t, \mathbf{x}_{0}, t_{0}\right]=\frac{\exp -\frac{\left|\mathbf{x}-\mathbf{x}_{0}\right|^{2}}{4 K\left(-t_{0}\right)}}{\left(4 \pi K\left(t-t_{0}\right)\right)^{n / 2}} \Theta\left(t-t_{0}\right) \quad t>t_{0}
\]
representing a point source at \(\mathbf{x}=\mathbf{x}_{0}\) and \(t=t_{0}\).
Figure 62.1 shows the Green function of the 1D diffusion equation at different times.

Figure 62.1: Green function of the 1D diffusion equation
The Green function of the 1D diffusion equation at different times.
Figure 62.2 shows the Green function of the 2D diffusion equation at different times. Some properties of the Green function of the diffusion equation on the line, plane and space are:
1. 1D: \(\langle r\rangle=2 \sqrt{K t / \pi} ;\left\langle r^{2}\right\rangle=2 K t\);
2. 2D: \(\langle r\rangle=\sqrt{\pi K t} ;\left\langle r^{2}\right\rangle=4 K t\);
3. 3D: \(\langle r\rangle=4 \sqrt{K t / \pi} ;\left\langle r^{2}\right\rangle=6 K t\).

Note that the diffusion equation is not compatible with relativistic causality, as the Green function is non zero at arbitrarily large distances for any time \(t>0\).

(c) Green function of the 9 D diffusion equation - time (3)

(e) Green function of the 2D diffusion equation - time evolution (5)

Figure 62.2: Green function of the 2 D diffusion equation at different times.
62.05.05 Diffusion - Crude Calculation in the Mean Free Path Approximation
\[
j_{z}=-\frac{1}{3} \eta_{\mathrm{N}}\langle v\rangle \lambda \frac{\partial Q}{\partial z}
\]

\subsection*{62.05.06 Diffusion of Energy - Constitutive Equation for the Energy Flux (Heat)}

This § is referenced at pages:
[2544, 2544]
Read also § 59.09.02 - Work Energy Heat and the First Principle.
Nel caso in cui esista un gradiente di temperatura (variabile intensiva \(\varrho\) ) si genera un flusso di energia (variabile coniugata \(\mathcal{C}\) ), il calore, che tende a rendere uniforme la temperatura. La relazione, per un materiale isotropo, è data dalla legge di Fourier, che regola il calore (flusso di energia):
\[
\begin{equation*}
\mathbf{j}[\mathbf{x}, t]=-F[\mathbf{x}, t] \mathbf{g r a d}(T[\mathbf{x}, t]) \quad F \geq 0, \text { thermal conductivity }, \tag{62.05.05}
\end{equation*}
\]
dove \(F\) è il coefficiente di conducibilità termica, \(T[\mathbf{x}, t](\equiv \varrho[\mathbf{x}, t])\) la temperatura e \(\mathbf{j}\) il flusso di energia, il calore, \(Q(\equiv \mathcal{C})\).
Nel caso più generale di materiale non isotropo la condicibilità diventa un tensore di secondo ordine.
A crude calculation, assuming that all particles are moving at the mean speed and \(1 / 6\) of them (that is \(1 / 6\) for each orthogonal direction) are hitting the wall, gives the rough approximation:
\[
F \approx \frac{1}{3} \eta_{\mathrm{N}}\langle v\rangle c \lambda
\]

The thermal conductivity for gases does not depend on density. In fact, the heat transport is proportional to the density and to the mean free path, but the mean free path is inversely proportional on the density.

\subsection*{62.05.07 Diffusion of Linear Momentum - Constitutive Equation for the Linear Momentum Flux}
©|S.J.Blundell \& K.M.Blundell, Concepts In Thermal Physics, 2010, Oxford, 2ndEd., ....|§ 9.1||
As linear momentum is a vector, the flux of linear momentum is a second order tensor.
Il fenomeno della viscosità è data dal trasporto di quantità di moto, grandezza vettoriale. See equation (26.05.03). In generale, la relazione tra gradiente della quantità di moto e il flusso di quantità di moto (sforzo di taglio) è una relazione tensoriale: read § 30.08.03 - Introduction to the Mechanics of Continuous Media.
In the simple case of a dilute gas, the coefficient of viscosity can be calculated readily on the basis of kinetic theory.
A crude calculation, assuming that all particles are moving at the mean speed and \(1 / 6\) of them (that is \(1 / 6\) for each orthogonal direction) are hitting the area of the plane from above. But molecules which cross the plane from below have, on the average, experienced their last collision at a distance given by the mean free path below the plane, where the component of the velocity parallel to the plane is larger/smaller. The simple calculation gives the rough approximation:
\[
\begin{equation*}
\eta \approx \frac{1}{3} \eta_{\mathrm{N}}\langle v\rangle \lambda m \tag{62.05.06}
\end{equation*}
\]

The exact calculation gives the same result as equation (62.05.06).

\subsection*{62.05.08 Diffusion of Mass - Constitutive Equation for the Mass Flux}

One speaks of self-diffusion whenever the diffusing molecules are, except for being labelled, identical to the remaining molecules of the substance. The more general and complicated situation would be that of mutual diffusion, where the diffusing and background molecules are unlike.
Nel caso della diffusione la più semplice relazione tra flusso (densità di corrente) e concentrazione è lineare ed è data dalla legge di Fick
\[
\begin{equation*}
\mathbf{j}[\mathbf{x}, t]=-D[\mathbf{x}, t] \mathbf{g r a d}\left(\eta_{\mathrm{N}}[\mathbf{x}, t]\right) \quad D>0, \tag{62.05.07}
\end{equation*}
\]
dove \(D\) è il coefficiente di diffusione, \(\eta_{\mathrm{N}}[\mathbf{x}, t](\equiv \varrho[\mathbf{x}, t])\) la concentrazione e \(\mathbf{j}\) il flusso di numero di particelle \(N(\equiv \mathcal{C})\).
In non isotropic materials, \(D\), is a second-rank tensors, the diffusivity.

\subsection*{62.05.08.01 Self-Diffusion}

Self-diffusion: labelled molecules diffuse amongst unlabelled, but otherwise identical, molecules.
Consider a gas in equilibrium and look at the motion of a given molecule, tagged but otherwise identical to the others, such as considering molecules with atomic nuclei made of different isotopes. These molecules follows straight trajectories interrupted by collisions that change its direction of motion, and, after a few collisions, the molecules will be mixed with the others.
The tagged molecule is said to follow a random walk; this is the self-diffusion process.
Example: diffusion of a radio-tracer isotope that, while chemically identical to the host element, is easily tracked; however, the mass of the different isotopes are slightly different.
The coefficient of self-diffusion is:
\[
\begin{equation*}
D \approx \frac{1}{3}\langle v\rangle \lambda \tag{62.05.08}
\end{equation*}
\]

\subsection*{62.05.08.02 Mutual-Diffusion}

Diffusion processes, are processes such that particles of a certain kind diffuse in a medium made of particles of a different kind.
Consider the diffusion of molecules of one type (type 1 , mass \(m_{1}\), diameter \(d_{1}\) ) amongst molecules of another type (type 2, mass \(m_{2}\), diameter \(d_{2}\) ). In this case the diffusion constant \(D_{12}\) is the same as equation (62.05.08) with the diameter of the molecule replaced by The average diameter and the mass replaced by the reduced mass.
Example: a perfume diffusing in a room.

\subsection*{62.05.09 Diffusion of Particle - Constitutive Equation for the Particle Flux}

It is totally analogous to the diffusion of mass, just replacing the conserved mass with the conserved number of particles.
62.05.10 Diffusion in External Fields

Total current:
\[
\mathbf{j}=\varrho \mu \mathbf{F}-K \operatorname{grad}\left(\eta_{\mathbb{N}}[\mathbf{x}, t]\right)
\]

In addition, the continuity equation applies.
In steady conditions, \(\mathbf{j}=0\).

Read § 62.08.15 - Elements of Kinetic Theory and Transport Phenomena, § 62.08.16 - Elements of Kinetic Theory and Transport Phenomena.

\subsection*{62.07}

\section*{Detailed Balance}
©|J.Oxenius, Kinetic Theory Of Particles And Photons|§ 1|Excellent full clear discussion.|
The reciprocity relation,
\[
\wp[i \rightarrow f]=\wp[f \rightarrow i]
\]
is not generally valid, not even when the Hamiltonian of the system is invariant under space reflection and time-reversal. However, it holds in the framework of perturbation theory, and thus applies to radiative processes and to collisions in the Born approximation. Moreover, the reciprocity relation holds for all collision processes involving un-Polarized particles, provided that the Hamiltonian is invariant under space reflection and time-reversal.

\section*{Examples and Physical Applications}

\subsection*{62.08.01 Pompa Di Gas}
©|I.E.Irodov, Problems In General Physics, 1988, MIR publishers Moscow, ...Ed., ....|2.8||
Un contenitore rigido di volume \(V\) contiene \(n\) moli di un gas a temperatura \(T\) e deve essere evacuato tramite una pompa che evacua un volume per unità di tempo \(c=\Delta V / \Delta t\) (misurato alla pressione del gas a quell'istante) costante e indipendente dalla pressione. Determinare l'andamento temporale della pressione entro il contenitore.

\section*{SOLUTION}

Si supponga che all'inizio di ogni ciclo il gas occupi uniformemente tutto il volume a disposizione incluso il volume \(\Delta V\) della camera della pompa che verrà evacuato durante il ciclo. Si suppone cioè che al termine di ogni ciclo il gas occupi l'intero volume in un tempo molto più breve del periodo della pompa e che all'inizio del ciclo successivo il gas abbia raggiunto uno stato di equilibrio termodinamico.
Il numero di moli evacuate ad ogni ciclo vale allora
\[
-\Delta n=\frac{n(t) \Delta V}{V}
\]
da cui si trova, dividendo per l'intervallo di tempo di durata di un ciclo \(\Delta t\),
\[
-\frac{\Delta n}{\Delta t}=\frac{n(t)}{V} \frac{\Delta V}{\Delta t}=c \frac{n(t)}{V}
\]

Passando al limite per \(\Delta t\) che tende a zero, nell'ipotesi di poter considerare il processo continuo, cioè che \(\Delta V \ll V\) (ovvero \(\Delta n \ll n\) ), si ha
\[
-\frac{\mathrm{d} n}{\mathrm{~d} t}=c \frac{n(t)}{V}
\]
che risolta per \(c\) costante da
\[
\begin{equation*}
n(t)=n_{0} \exp \left[-\frac{c t}{V}\right] \tag{62.08.01}
\end{equation*}
\]
e analogo andamento per la pressione.
Se l'approssimazione di processo continuo non è valida occorre trattare in tutta generalità il processo discreto. Sia \(n_{k}\) il numero di moli nel recipiente al termine del ciclo \(k\)-esimo. Si ha allora la corrispondenza
\[
t=k \Delta t \quad t=0 \text { per } k=0
\]
tra il tempo e il numero di cicli di pompaggio. Si ha allora
\[
n_{k+1}=n_{k}(1-\alpha) \quad k \geq 0 \quad \alpha \equiv \frac{\Delta V}{V}<1
\]
che ha per soluzione
\[
n_{k}=n_{0}(1-\alpha)^{k}=n_{0}(1-\alpha)^{t / \Delta t}=n_{0}(1-\alpha)^{c t / \alpha V}=n_{0}(1-\alpha) \frac{c \Delta t k}{\alpha V}
\]
data la condizione iniziale \(n_{0}\) all'inizio del pompaggio. Al limite per \(\alpha \rightarrow 0\), mantenedo \(k\), costante si ottiene l'andamento continuo in funzione del tempo (62.08.01). Si osservi che \(\alpha V=c \Delta t\).
Si noti che la sola ipotesi fatta è che all'inizio di ogni ciclo il gas occupi uniformemente l'intero volume. Non si richiede che il gas sia perfetto. Non si richiede che la temperatura del gas non
cambi. Se il gas non è perfetto le sue espansioni ad occupare l'intero contenitore tipicamente ne diminuiranno l'energia interna e quindi la temperatura. Se si vuole conoscere l'andamento della pressione entro il contenitore, anziché quello del numero di moli occorre sapere come varia la temperatura del gas durante il processo.
62.08.02 Gas Effusion With Two Containers
©|Lim Yung-Kuo, Problems And Solutions On Thermodynamics And Statistical Physics, 1990, World Scientific, ...Ed., ....|2154, 2161, 2196||
A rigid and thermal isolated box of volume \(2 V\) is divided into two equal parts by a thin, heat-conducting partition. One side contains an ideal gas of molecules at atmospheric pressure and \(T=293 \mathrm{~K}\). A small hole of surface \(A\) is opened in the partition, small enough so that thermal equilibrium between the two sides is maintained via heat conduction through the partition.
1. Calculate the number of particles, pressure and temperature as functions of time in both halves of the box.
2. Suppose the partition is a non-conductor of heat. Discuss briefly and qualitatively any deviations from the time-dependence of number of particles, temperature and pressure found in the previous question.

Atoms|Molecules in thermal motion act as sources in motion, when emitting ElectroMagnetic radiation, so that the measured frequency shows a spectrum related to the velocity distribution of the Atoms \(\mid\) Molecules. When looking at the spectral lines of hot gas Atoms \(\mid\) Molecules, the limit on resolution is often given by this effect.
In fact, the light emitted, with frequency \(\omega^{\prime}\), by Atoms|Molecules traveling with radial velocity with respect to the detector, will be detected with frequency, \(\omega\), differing from those of Atoms|Molecules at rest, due to the Doppler shift.

Consider a set of Atoms|Molecules with no macroscopic velocity with respect to the observer, that is with zero velocity of the Center-Of-Mass in the Rest Frame of rest of the observer. In this Rest Frame, the velocity distribution of the Atoms|Molecules, as seen from the observer, is the Maxwell-Boltzmann distribution of velocities. Show that a Gaussian shape of the spectral line \(I[\omega]\) is produced starting from emission at fixed frequency \(\omega^{\prime}\).

\section*{© - QUOTE}
R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....

The composition of planetary atmospheres is directly affected by the molecular velocity distribution. In fact, the escape velocity from a star, \(\sqrt{2 \mathcal{G M / R}}\), where \(\mathcal{G}\) is the gravitational constant, depends on the mass, \(M\), and the radius, \(R\), of the star. Molecules with larger velocities can escape from the gravitational field of the star. This escape is easier for light molecules and that it is helped by high temperatures. This enables us to understand why there is no hydrogen in the Earth atmosphere, even though that element is so very abundant in the Universe. If the temperature at the top of the atmosphere is sufficiently high and if the molecules are sufficiently light, we have in equilibrium an appreciable fraction of molecules with velocities above the escape velocity, which for the Earth is \(11 \mathrm{~km} / \mathrm{s}\). Those molecules can escape and at equilibrium will be replaced by others which, in their turn, escape. This has happened for hydrogen. For oxygen and nitrogen the molecular masses are sufficiently large that the losses are insignificant, even at the rather high temperatures prevailing when the Earth was formed. On the Moon the escape velocity is so low that the whole atmosphere has had time to escape.

\section*{© - QUOTE}

MüllerAndWWeiss Entropy AndEnergy
The atmosphere of a planet is a case in point for the competition of energy and entropy. Energy tends to assemble all atmospheric molecules on the surface of the planet while entropy tends to spread the molecules evenly throughout space. In the end the entropy wins and planets will be bare of atmosphere. This will happen earlier for a hot planet than for a cold one. Earth, which is a temperate planet in the solar system, has already lost all light gases but it holds on - for the time being - to the heavier ones like nitrogen, oxygen and argon.
We consider an atmosphere of total mass of a planet as an ideal gas of constant and uniform temperature. Therefore the internal energy is constant. The density distribution in the atmosphere will arrange itself so as to minimize the available free energy which in this case has only two essential parts: The potential energy and the entropy. The potential energy will tend to assemble the atoms of the atmosphere on the surface of the planet, because that is where the potential energy has its minimum. On the other hand, the entropy will tend to become maximal by scattering the atoms through infinite space. Thus the planetary atmosphere is subject to opposing tendencies and it provides a paradigm for the competition of energy and entropy. In order to investigate this competition suggestively we convert the available free energy from a functional of to a function of
a single variable by considering a model atmosphere which is constrained between the planetary surface and an imagined roof of fixed height H . We consider this model atmosphere as being in partial equilibrium in the sense that the available free energy under the roof is minimal. In this manner .... become functions of the single variable H and we investigate their extrema in order to determine the density distribution in full unconstrained equilibrium.
62.08.14 Thermal Excitation of Hydrogen Atoms
©|D.V.Schroeder, Thermal Physics, 1999, Addison-Wesley, ...Ed., ....|§ 6.1||
© - QUOTE
©|D.V.Schroeder, Thermal Physics, 1999, Addison-Wesley, ...Ed., ....|§ 6.1||

As a simple application of Boltzmann factor, let us consider a Hydrogen atom in the atmosphere of the Sun, where the temperature is about 5800 K .
Let us compare the probability of finding the hydrogen atom in one of its first excited states \(\left(s_{2}\right)\) to the probability of finding it in the ground state \(\left(s_{1}\right)\). The ratio of probabilities is the ratio of Boltzmann factors, and the difference in energy is 10.2 eV while \(k_{\mathrm{B}} T\) is 0.50 eV . So, the ratio of probabilities to find the atom in one specific state \(s_{2}\) with respect state \(s_{1}\), is approximately \(1.4 \cdot 10^{-9}\). However, there are four such excited states, \(s_{2}\), all with the same energy but different angular momentum, so, the ratio of probabilities to find the atom in any one state \(s_{2}\) with respect state \(s_{1}\), is approximately \(5.6 \cdot 10^{-9}\), about 5.6 atoms in the first excited state for every billion in the ground state

The statistical interpretation of entropy links the thermodynamics concept of entropy to the statistical laws which underlie physical systems consisting of a large number of particles. It was only with great difficulty accepted by the international scientific community of the time.
© - QUOTE
R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....

In \(\S 3\) we defined the statistical entropy \(S(D)\) which measures the random nature, or disorder, of a density operator. In those two chapters we assumed that the latter was given. However, in order actually to be able to calculate the properties of a system which has been prepared in some given way we must know how to assign to it a density operator representing the physical situation that we want to describe. This problem of the choice of \(D\) will be solved in the present chapter for thermodynamic equilibrium states. In order to find the general form, the so-called BoltzmannGibbs distribution, of the density operators, or the densities in phase, describing these states, we shall use a postulate of a statistical nature which is similar to the criteria used in statistics to find the unbiased probability law for a set of random events. We introduce in this way a general prediction method (§4.1.3). This method leads us to represent a system in thermodynamic equilibrium by the most disordered macro-state compatible with the macroscopic data (§ 4.1).

\section*{Introduction}
©|L.D.Landau et al., Statistical Physics, ... .Ed., DOI - ISBN: 0-08-023039-3.|§ 1-4||

\subsection*{63.01.01 Micro-State and Macro-State}

The macroscopic state (macro-state) of a system can be characterized, globally, using few quantities directly accessible to our senses.

The microscopic state (micro-state) of a system is one state compatible with its macroscopic state that can be described using all the many physical quantities required and defined at the microscopic scale and therefore not accessible to our senses.

A system is generally subject to constraints, that is, to conditions that its macroscopic variables must satisfy, for example: if the system is isolated, its energy is constant; if the system is closed, it is the number of material particles that remains constant; if the walls of the system are rigid, its volume is constant.

Most often, a very large number of microscopic states correspond to the same macroscopic state. This number differs according to whether the particles are distinguishable, or not; they are so if they have different physical characteristics. If they are identical, they are classically always distinguishable, thanks to classical determinism so that, once a particle has been labelled it can followed and identified forever; in quantum physics they are always indistinguishable as the concept of trajectory is lost. When the particles are indistinguishable, the number of microscopic states corresponding to one macroscopic state, is smaller than for the corresponding distinguishable case.

The number of accessible microscopic states corresponding to a macroscopic state is a fundamental quantity in statistical physics.

Macroscopic variables are averages of suitable sets of microscopic variables. This average value should be understood as an average over a large number of systems identical to our system; this generally coincides with the time average of the magnitude over one single system (ergodic hypothesis).

Properties of the macro-state are obtained by integrating (averaging) over a large number of variables which seem to be less relevant to what we see in the macroscopic world. That is, the macroscopic theory is an effective theory of an underlining more complete theory. The same happens in fundamental physics.

\section*{© - QUOTE}
©|L.D.Landau et al., Statistical Physics, ..., ..., ...Ed., DOI - ISBN: 0-08-023039-3.|||

The theory of processes relating to the attainment of an equilibrium state is called kinetics. It is not part of statistical physics proper, which deals only with systems in statistical equilibrium.
Statistical physics applies to macroscopic bodies having a very large number of degrees of freedom (order of \(\mathcal{N}_{\mathrm{A}}\) ).
Even if we could solve the equations of motion in a general form, it would be impossible to substitute in the general solution the initial conditions for the velocities and coordinates of all the particles.
When the number of particles is very large, new types of regularity appear.
Let a given macroscopic mechanical system have \(s\) degrees of freedom: the position of points of the system in space be described by \(s\) generalized coordinates, \(q_{i}, i=1,2, \ldots, s\).
The state of the system at a given instant will be defined by the values at that instant of the \(s\) generalized coordinates \(q_{i}\) and the \(s\) corresponding velocities, \(\dot{q}_{i}, i=1,2, \ldots, s\). However, in statistics it is customary to describe a system by its generalized coordinates and momenta, \(p_{i}\), \(i=1,2, \ldots, s\), not velocities, since this affords a number of advantages.

Let us now consider a macroscopic body or system of bodies, and assume that the system is isolated \({ }^{\text {a }}\), i.e. does not interact with any other bodies. A part of the system, which is very small compared with the whole system but still macroscopic, may be imagined to be separated from the rest; clearly, when the number of particles in the whole system is sufficiently large, the number in a small part of it may still be very large. Such relatively small but still macroscopic parts will be called subsystems. A subsystem is again a mechanical system, but not an isolated one; on the contrary, it interacts in various ways with the other parts of the system. Because of the very large number of degrees of freedom of the other parts, these interactions will be very complex and intricate. Thus the state of the subsystem considered will vary with time in a very complex and intricate manner.
An exact solution for the behavior of the subsystem can be obtained only by solving the mechanical problem for the entire isolated system, i.e. by setting up and solving all the differential equations of motion with given initial conditions, which, as already mentioned, is an impracticable task. Fortunately, it is just this very complicated manner of variation of the state of subsystems which, though rendering the methods of mechanics inapplicable, allows a different approach to the solution of the problem.
A fundamental feature of this approach is the fact that, because of the extreme complexity of the external interactions with the other parts of the system, during a sufficiently long time the subsystem considered will be many times in every possible state. This may be more precisely formulated as follows. Let \(\Delta q \Delta p\) denote some small volume of the phase space of the subsystem, corresponding to coordinates \(q_{i}\) and momenta \(p_{i}\) lying in short intervals \(\Delta q_{i} \Delta p_{i}\). We can say that, in a sufficiently long time \(T\), the extremely intricate phase trajectory passes many times through each such volume of phase space. Let \(\Delta t\) be the part of the total time \(T\) during which the subsystem was in the given volume of phase space \(\Delta q \Delta p\). When the total time \(T\) increases indefinitely, some limit is assumed to exist:
\[
\equiv \lim _{T \rightarrow \infty} \frac{\Delta t}{T}
\]

This quantity may clearly be regarded as the probability that, if the subsystem is observed at an arbitrary instant, it will be found in the given volume of phase space \(\Delta q \Delta p\).

This probability, \(\mathrm{d} w\), may be written:
\[
\mathrm{d} w=\rho\left[q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s}\right] \mathrm{d} q_{1} \ldots \mathrm{~d} q_{s} \mathrm{~d} p_{1} \ldots \mathrm{~d} p_{s}
\]
where \(\rho\left[q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s}\right]\) is a function of all the coordinates and momenta. The function \(\rho\left[q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s}\right]\) which represents the density of the probability distribution in phase space, is called the statistical distribution function.
This function must be obviously normalised.
The following circumstance is extremely important in statistical physics. The statistical distribution of a given subsystem does not depend on the initial state of any other small part of the same system, since over a sufficiently long time the effect of this initial state will be entirely outweighed by the effect of the much larger remaining parts of the system. It is also independent of the initial state of the particular small part considered, since in time this part passes through all possible states, any of which can be taken as the initial state. Without having to solve the mechanical problem for a system (taking account of initial conditions), we can therefore find the statistical distribution for small parts of the system.

The determination of the statistical distribution for any subsystem is in fact the fundamental problem of statistical physics. In speaking of "small parts" of a isolated system, we must bear in mind that the macroscopic bodies with which we have to deal are usually themselves such "small parts" of a large isolated system consisting of these bodies together with the external medium which surrounds them.

The averaging with respect to the distribution function (called statistical averaging) frees us from the necessity of following the variation with time of the actual value of the physical quantity \(f[p, q]\) in order to determine its mean value.

In practice, however, when statistical physics is applied to macroscopic bodies, its probabilistic nature is not usually apparent. The reason is that, if any macroscopic body (in external conditions independent of time) is observed over a sufficiently long period of time, it is found that all physical quantities describing the body are practically constant (and equal to their mean values) and undergo appreciable changes relatively very rarely; we mean, of course, macroscopic quantities describing the body as a whole or macroscopic parts of it, but not individual particles. This result, which is fundamental to statistical physics, follows from very general considerations and becomes more and more nearly valid as the body considered becomes more complex and larger. In terms of the statistical distribution, we can say that, if by means of the distribution function we construct the probability distribution function for various functions \(f[p, q]\), this function will have an extremely sharp maximum around the mean value, and will be appreciably different from zero only in the immediate vicinity of this point.

If a closed macroscopic system is in a state such that in any macroscopic subsystem the macroscopic physical quantities are to a high degree of accuracy equal to their mean values, the system is said to be in a state of statistical equilibrium (or thermodynamic or thermal equilibrium). It is seen from the foregoing that, if a closed macroscopic system is observed for a sufficiently long period of time, it will be in a state of statistical equilibrium for much the greater part of this period. If, at any initial instant, a closed macroscopic system was not in a state of statistical equilibrium (if, for example, it was artificially disturbed from such a state by means of an external interaction and then left to itself, becoming again a closed system), it will necessarily enter an equilibrium state. The time within which it will reach statistical equilibrium is called the relaxation time. In using the term "sufficiently long" intervals of time, we have meant essentially times long compared with the relaxation time.

The subsystems previously discussed are not themselves isolated systems; on the contrary, they are subject to the continuous interaction of the remaining parts of the system. But since these parts, which are small in comparison with the whole of the large system, are themselves macroscopic bodies also, we can still suppose that over not too long intervals of time they behave approximately as isolated systems. For the particles which mainly take part in the interaction of a subsystem with the surrounding parts are those near the surface of the subsystem; the relative number of such particles, compared with the total number of particles in the subsystem, decreases rapidly when the size of the subsystem increases, and when the latter is sufficiently large the energy of its interaction with the surrounding parts will be small in comparison with its internal energy. Thus we may say that the subsystems are quasi-isolated. It should be emphasised once more that this property holds only over not too long intervals of time. Over a sufficiently long interval of time, the effect of interaction of subsystems, however weak, will ultimately appear. Moreover, it is just this relatively weak interaction which leads finally to the establishment of statistical equilibrium. The fact that different subsystems may be regarded as weakly interacting has the result that they may also be regarded as statistically independent.
By statistical independence we mean that the state of one subsystem does not affect the probabilities of various states of the other subsystems.
Let us consider any two subsystems, \(A\) and \(B\) :
\[
\rho_{A+B}=\rho_{A} \rho_{B}
\]

A similar relation is valid for a group of several subsystems.
The converse statement is clearly also true: if the probability distribution for a compound system is a product of factors, each of which depends only on quantities describing one part of the system,
then the parts concerned are statistically independent, and each factor is proportional to the probability of the state of the corresponding part.
If \(f_{A}\) and \(f_{B}\) are two physical quantities relating to two different subsystems, then it follows immediately that:
\[
\begin{gathered}
\left\langle f_{A}+f_{B}\right\rangle=\left\langle f_{A}\right\rangle+\left\langle f_{B}\right\rangle, \\
\left\langle f_{A} f_{B}\right\rangle=\left\langle f_{A}\right\rangle\left\langle f_{B}\right\rangle, \\
\left\langle\Delta f_{A}\right\rangle=\left\langle\Delta f_{B}\right\rangle=0, \\
\left\langle\Delta f_{A} \Delta f_{B}\right\rangle=0, \\
\left\langle(\Delta f)^{2}\right\rangle \equiv\left\langle\left(\Delta f_{A}+\Delta f_{B}\right)^{2}\right\rangle=\left(\Delta f_{A}\right)^{2}+\left(\Delta f_{B}\right)^{2}
\end{gathered}
\]

It follows that, as \(N\) increases, the mean square also increases in proportion to \(N\). The relative fluctuation is therefore inversely proportional to \(1 / \sqrt{N}\) :
\[
\frac{\left\langle(\Delta f)^{2}\right\rangle^{1 / 2}}{\langle f\rangle} \sim \frac{1}{\sqrt{N}}
\]

: uses the term closed system where nowadays the term isolated system is normally used.
63.01.02 Phase-Space
©|L.D.Landau et al., Statistical Physics, ..., ..., ...Ed., DOI - ISBN: 0-08-023039-3.|||
Let a given macroscopic system have \(s\) degrees of freedom, with \(s \approx \mathcal{N}_{A}\).
Let the positions of points of the system in space be described by \(s\) generalized coordinates, \(q_{i}\), \(i=1,2, \ldots, s\).
The state of the system at any given instant will be defined by the values, at that instant, of the \(s\) generalized coordinates \(q_{i}[t]\) and the \(s\) corresponding velocities, \(\dot{q}_{i}[t], i=1,2, \ldots, s\).
However, in statistics it is customary to describe the system by its generalized coordinates, \(q_{i}[t]\), and momenta, \(p_{i}[t], i=1,2, \ldots, s\), not velocities, since this affords a number of advantages.
This is the so-called micro-state, as from the microscopic approach of thermodynamics.
The classical volume in phase space is defined as:
\[
\mathrm{d} \Phi \equiv \frac{\mathrm{~d} q_{1} \ldots \mathrm{~d} q_{s} \mathrm{~d} p_{1} \ldots \mathrm{~d} p_{s}}{h^{2 s}}
\]
by dividing by \(h^{2 s}\). so to make it dimensionless.

\subsection*{63.01.03 Distribution Function}
©|L.D.Landau et al., Statistical Physics, ..., ..., ...Ed., DOI - ISBN: 0-08-023039-3.|||
The distribution function in phase-space gives the probability, in general time-dependent, to find the system in a certain infinitesimal volume of the phase space, around ( \(q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s}\) ):
\[
\mathrm{d} \wp\left[q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s} ; t\right]=\mathcal{F}\left[q_{1}, \ldots, q_{s} ; p_{1}, \ldots, p_{s} ; t\right] \mathrm{d} q_{1} \ldots \mathrm{~d} q_{s} \mathrm{~d} p_{1} \ldots \mathrm{~d} p_{s} \quad 1=\int \mathrm{d} \wp
\]

By integrating out any set of variables one finds the marginal (or reduced) distribution function in the remaining variables.
This process is the same as the general effective theory approach: you have a large number of variables, some of which are not accessible, others are not interesting, so one integrates them out, leaving a theory which is applicable whenever the ignored degrees of freedom are not relevant. This is the same as:
- approximating the Earth shape as a regular geometric shape, instead of all the details of mountains, seas, ...;
- ignoring the effects of asteroids on the orbit of an Earth satellite, possbily adding an effective perturbation....

\subsection*{63.02.01 Micro-Canonical Ensemble}

\section*{Classical Systems}

In classical statistical physics, consider a isolated system described by the generalized coordinates \(q \equiv\left\{q_{i}\right\}, i=1,2, \ldots, s\) and momenta \(p \equiv\left\{p_{i}\right\}, i=1,2, \ldots, s\).
The probability to find the system in a micro-state defined by the hyper-volume \(\mathrm{d} q \mathrm{~d} p\) of its phase space is given by:
\[
\begin{equation*}
\mathrm{d} \wp \propto \mathrm{~d} q \mathrm{~d} p \tag{63.02.01}
\end{equation*}
\]

If the system is made of \(N\) identical (indistinguishable) particles, the above probability must be divided by \(N\) !.
That is, all equal volumes in the phase space are equally probable.

\section*{Quantum Systems}

In quantum statistical physics, consider a system which is isolated, has a continuous energy spectrum; the same recipe as for classical systems applies:
\[
\mathrm{d} \wp \propto \mathrm{~d} q \mathrm{~d} p .
\]

For a quantum system which is isolated, has discrete states labeled by \(s\), energy levels \(\epsilon_{s}\), and multiplicity of each level \(g_{s}\), the probability to find the system in state \(s\) is given by:
\[
\begin{equation*}
\wp_{s} \propto g_{s} \tag{63.02.02}
\end{equation*}
\]

That is, all discrete states are equally probable.
The extension to systems with both discrete and continuous spectrum follows trivially.

\subsection*{63.02.02 Canonical Ensemble}

\section*{Classical Systems}

In classical statistical physics, consider a system described by the generalized coordinates \(q \equiv\left\{q_{i}\right\}, i=1,2, \ldots, s \boldsymbol{\square}\) and momenta \(p \equiv\left\{p_{i}\right\}, i=1,2, \ldots, s\), which is in contact with a heat reservoir at temperature \(T\) and has Hamiltonian \(H[q, p]\).
The probability to find the system in a micro-state defined by the hyper-volume \(\mathrm{d} q \mathrm{~d} p\) of its phase space is given by:
\[
\begin{equation*}
\mathrm{d} \wp \propto \exp \left[-\frac{H[q, p]}{k_{\mathrm{B}} T}\right] \mathrm{d} q \mathrm{~d} p . \tag{63.02.03}
\end{equation*}
\]

If the system is made of \(N\) identical (indistinguishable) particles, the above probability must be divided by \(N\) !.

\section*{Quantum Systems}

In quantum statistical physics, consider a system which is in contact with a heat reservoir at temperature \(T\) and having a continuous energy spectrum; the same recipe as for classical systems applies:
\[
\mathrm{d} \wp \propto g_{s} \exp \left[-\frac{H[q, p]}{k_{\mathrm{B}} T}\right] \mathrm{d} q \mathrm{~d} p
\]

For a quantum system which is in contact with a heat reservoir at temperature \(T\), has discrete states labelled by \(s\), energy levels \(\epsilon_{s}\) and multiplicity of each level \(g_{s}\), the probability to find the system in state \(s\) is given by:
\[
\begin{equation*}
\left.\wp_{s} \propto \exp \left[-\frac{\epsilon_{s}}{k_{\mathrm{B}} T}\right]\right] \tag{63.02.04}
\end{equation*}
\]

The extension to systems with both discrete and continuous spectrum follows trivially.

\subsection*{63.02.02.01 Equipartition Theorem}

This § is referenced at pages:
[2482, 2482]
©|R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....|8.4.2||

One of the problems of statistical mechanics consists in determining how the energy of a system is distributed over its various degrees of freedom. The general answer to this question is obtained by writing down that the temperatures associated with the independent degrees of freedom become equal. The result takes a particularly simple form for all problems in classical statistical mechanics where the Hamiltonian is quadratic in each of the phase space variables which occur in it.

In thermal equilibrium the internal energy, \(\mathcal{U}=\langle H\rangle\) is the sum of the average energies, \(\left\langle h_{i}\right\rangle\), associated with the \(s\) degrees of freedom. The energy equipartition theorem states that in the canonical system framework the internal energy per independent quadratic degree of freedom, \(\left\langle h_{i}\right\rangle\), is equal to \(k_{\mathrm{B}} T / 2\), whatever the value of the constants coefficients of the second degree Hamiltonian polynomial. The total energy is thus equally distributed over all degrees of freedom and it is proportional to the temperature:
\[
\begin{equation*}
\left\langle a q^{2}\right\rangle=\left\langle b p^{2}\right\rangle=\frac{k_{\mathrm{B}} T}{2} \tag{63.02.05}
\end{equation*}
\]
©|J.P.Pérez et al., Thermodynamique, ..., DUNOD, ...Ed., WEB - URL.|§ 15||
Without any loss of generality, consider an isolated system.
Macroscopic state: state of a system which can be globally characterized by a few macroscopic variables. Microscopic state: state compatible with the macroscopic state and described by a large number of microscopic variables, not directly accessible; every microscopic state is known to within a certain extent and with some quantic uncertainly: the smallest volume in phase-space for any pair of conjugate variables is dictated by quantum physics:
\[
\Delta q \Delta p \geq \frac{\hbar}{2}
\]

The system will have in general states, labelled by \(s\), with energy \(E_{s}\) and multiplicity, \(g_{s}\), typically infinite in number, with either discrete or continuous spectrum.
The possible states must be compatible with the conserved quantities of the system, the mechanical invariant quantities, such as energy, linear momentum and angular momentum.

\subsection*{63.03.01 Three Particles With Four States}

Consider a system of three particles, A, B, C, whose total energy is \(E=3 \varepsilon\) and any particle can have energies \(e=0, e=\varepsilon, e=2 \varepsilon, e=3 \varepsilon\). The macroscopic state is characterized by its total energy \(E\).
The micro-states are characterized by stating for every particle which state is in.
The number of microscopic states corresponding to the same macroscopic state are calculated as follows.
For distinguishable particles:
- all three particles have energy \(e=\varepsilon\) (1 state);
- one particle has energy \(e=3 \varepsilon\) and the others zero (3 states);
- one particle has energy \(e=2 \varepsilon\), another one has energy \(e=\varepsilon\), the third one has zero energy ( 6 states).
In total, 10 different microscopic states are accessible for the given macroscopic state.
For indistinguishable particles:
- all three particles have energy \(e=\varepsilon\) (1 state);
- one particle has energy \(e=3 \varepsilon\) and the others zero ( 1 state);
- one particle has energy \(e=2 \varepsilon\), another one has energy \(e=\varepsilon\), the third one has zero energy ( 1 state).
In total, 3 different microscopic states are accessible for the given macroscopic state.

\subsection*{63.03.02 Many Distinguishable Particles With Two States}

The system of \(N\) particles with two states, for each of the considered particles, is very important in physics. It is indeed a simple and effective model to study the behavior of many significant physical systems.
Consider two different such systems:
- \(N\) particles located inside a rigid and adiabatic container ideally divided in two identical subvolumes, with \(n_{+}\)particle inside the right container and \(n_{-}\)particle inside the left container. Consider, for instance, the center of mass position \(z_{\mathrm{CM}} \simeq \ell\left(n_{+}-n_{-}\right)\)
- \(N\) identical spin \(1 / 2\) particles, with \(n_{+}\)with spin up and \(n_{-}\)with spin down, so that \(s_{z}=\left(n_{+}-n_{-}\right) \hbar / 2\); for instance paramagnetic particles in an external uniform and constant magnetic field, with energies \(\pm \mu B_{z}\).

The macroscopic state is defined by: \(\left(n_{+}-n_{-}\right)\). Nothing else is relevant on the macroscopic scale.
How many corresponding microscopic states correspond to any given macroscopic state, that is for any given values of \(n_{+}\)particles on the right and \(n_{-}\)on the left. The number of micro-states of the system is the number of ways to get \(n_{+}\)particles on the right side, among the \(N\) total particles, and \(n_{-}\)on the left side, that is to say the number of combinations:
\[
n_{+}+n_{-}=N \quad g=\binom{N}{n_{+}}=\binom{N}{n_{-}}=\frac{N!}{n_{+}!n_{-}!}
\]

For \(p=q=1 / 2\) and \(N=10\) with \(2^{10}=1024, \sigma=1.6\), possible configurations:
\begin{tabular}{rrr}
\(n_{+}\) & \(g\) &, \\
\hline 0 & 1 &, \\
1 & 10 &, \\
2 & 45 &, \\
3 & 120 &, \\
4 & 210 &, \\
5 & 252 &, \\
6 & 210 &, \\
7 & 120 &, \\
8 & 45 &, \\
9 & 10 &, \\
10 & 1 &, \\
\hline
\end{tabular}

For \(p=q=1 / 2\) and \(N=1000\), with \(2^{1000}=1.1 \cdot 10^{301}, \sigma=1.58\), possible configurations:
\begin{tabular}{|c|c|}
\hline \(n_{+}\) & \(g\) \\
\hline 484. & \(1.62051 \times 10^{299}\) \\
\hline & \(1.72409 \times 10^{299}\) \\
\hline 486. & \(1.82697 \times 10^{299}\) \\

\hline 513. & \(1.92826 \times 10^{299}\) \\
\hline & \(1.82697 \times 10^{299}\) \\
\hline 515. & \(1.72409 \times 10^{299}\) \\
\hline & \(1.62051 \times 10^{299}\) \\
\hline
\end{tabular}

For air at NTP the average molecular speed is \(v \approx 500 \mathrm{~m} / \mathrm{s}\). Considering \(1 / 3\) of mulecules with velociy mainly along the long direction of the box, each molecule moves to the other half every \(\approx(1 / 3)(L / v)\)

\section*{Statistical Entropy and Missing Information}
©|R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....|§ 3||

This § is referenced at pages:
[2714, 2714]
Statistical entropy is also called (missing) information entropy.
In order to assign a number to the amount of information which is missing because the expected event is random define:
\[
p_{i}: i=1, \ldots, M \quad p_{i} \geq 0 \quad \sum_{i=1}^{M} p_{i}=1 \quad \mathcal{S}\left[p_{i}\right] \equiv-k_{\mathrm{B}} \sum_{i=1}^{M} p_{i} \ln \left[p_{i}\right] \equiv-k_{\mathrm{B}}\langle\ln [p]\rangle \geq 0
\]

Some properties follows.
1.
\[
\begin{gathered}
f[p] \equiv-p \log p \quad \text { for } 0 \leq p \leq 1 \\
0 \leq f[p] \leq e^{-1}
\end{gathered}
\]
2. Minimum entropy.

The quantity \(\mathcal{S}\) reaches a minimum, equal to zero, whenever anyone of the events is a certainty. One gains no information, when one knows in advance which message one is about to receive.
3. Maximum entropy.

For fixed \(M, S\) is maximum when \(p_{i}=1 / M\). In fact, \(\mathcal{S} \leq k_{\mathrm{B}} \ln [M]\) : find the stationary points of \(\mathcal{S}\left[p_{i}\right]-\lambda\left(\sum_{i=1}^{M} p_{i}\right)\); by equating to zero the gradient, one finds that the stationary point correspond to all \(p_{i}\) are equal which implies \(p_{i}=1 / M\) and \(\delta\left[p_{i}=1 / M\right]=k_{\mathrm{B}} \ln [M] \geq 0\); as the second derivative is negative, the point is maximum. Indeed, we know least about the system in this case. More generally, \(\mathcal{S}\) increases whenever any two probabilities get closer to one another.
4. Increase of entropy.

In the case of \(M\) equiprobable events the statistical entropy increases with \(M\).
5. Impossibility of Events.

If some events have zero probability, they can just as well be left out of the reckoning when we evaluate the uncertainty.
6. Symmetry. As the \(M\) events are treated on the same footing, is a symmetric function of its \(M\) arguments.
7. Additivity. If we consider the occurrence of any one among the set of events \(1, \ldots, m\) as a single event \(A\), with probability \(q_{A}=p_{1}+\ldots+p_{m}\), and similarly one of the events \(m+1, \ldots, M\) as a single event \(B\), it follows that
\[
\mathcal{S}\left[p_{1}, \ldots, p_{m}, p_{m+1}, \ldots, p_{M}\right]=\mathcal{S}\left[q_{A}, q_{B}\right]+q_{A} \delta\left[\frac{p_{1}}{q_{A}}, \ldots, \frac{p_{m}}{q_{A}}\right]+q_{B} \delta\left[\frac{p_{m+1}}{q_{B}}, \ldots, \frac{p_{M}}{q_{B}}\right]
\]

This equation expresses that the average information acquired in two stages must be added: the first term corresponds to the choice between \(A\) and \(B\), and the next two terms to the choices inside the groups \(A\) and \(B\).
8. Sub-additivity. Consider a composite event corresponding to the combination of two events belonging one to a set \(a=\{\ldots, m, \ldots, M\}\) and the other to a \(b=\{\ldots, n, \ldots, N\}\). If the composite event \(\{m, n\}\) has a probability, \(p_{m n}\), the probability of the event \(m\) is \(p_{m}^{a}=\sum_{n} p_{m n}\) and that of event \(n\) is \(p_{n}^{b}=\sum_{m} p_{m n}\) One can show that the statistical entropies associated with these probability laws satisfy the so-called sub-additivity inequality:
\[
\mathcal{S}\left[p_{1}^{a}, \ldots, p_{m}^{a}, \ldots, p_{M}^{a}\right]+\mathcal{S}\left[p_{1}^{b}, \ldots, p_{n}^{b}, \ldots, p_{N}^{b}\right] \geq \mathcal{S}\left[p_{11}, \ldots, p_{m n}, \ldots, p_{M N}\right]
\]

The equal sign holds when the sets \(a\) and \(b\) are statistically independent, that is, when there is no correlation between the events \(m\) and \(n\), in which case the factorization of the probabilities, \(p_{m n}=p_{m}^{a} p_{n}^{b}\) entails the additivity of the statistical entropies. The inequality thus expresses that we lack less information about a composite system when we know the correlations between the events \(m\) and \(n\) than when we only know the separate probabilities of these events.
9. Concavity \({ }^{1}\).
10. Shannon theorems \({ }^{2}\).
11. Consider a isolated system made of two independent sub-systems: the number of microscopic states accessible to the system, \(\Omega\), is given by
\[
\begin{equation*}
\Omega=\Omega_{1} \Omega_{2} \Longrightarrow \mathcal{S}=\mathcal{S}_{1}+\mathcal{S}_{2} \tag{63.04.01}
\end{equation*}
\]
so that entropies are additive. The hypothesis means that the surface interaction energy is negligible with respect to the bulk volume energy, that is short range forces.
The less the information in the probability law, the larger the entropy.

\footnotetext{

}

\section*{© |WEB - URL|||}

The probability distribution for micro-states of any system at thermodynamic equilibrium corresponds to maximizing the entropy subject to all the constraints.

As nothing distinguishes the different microscopic states corresponding to the same macroscopic state of an isolated system, Boltzmann enunciated the following simple hypothesis, known as micro-canonical hypothesis: for an isolated system the energy is fixed and all microscopic states corresponding to the same macroscopic state have the same probability.
According the maximum entropy principle approach, and considering that all and only the microstates corresponding to the given total energy are possible, all the others having zero probability and being thus irrelevant according to the impossibility of events in \(\S 63.04\) - Elements of Statistical Physics, the maximum entropy this corresponds to all equal probabilities for all the compatible microstates. In fact, the only constraint is, in this case, the normalization to one of the probabilities. Therefore the entropy becomes:
\[
\mathcal{S}=k_{\mathrm{B}} \sum_{s=1}^{M} \frac{1}{M} \log [M]=k_{\mathrm{B}} \log [M] \equiv k_{\mathrm{B}} \log [\Omega]
\]

\subsection*{63.07}

\section*{Canonical Ensemble}

So far we have only considered isolated systems. The assumptions made in this context, however, make possible to deduce the Boltzmann distribution, that is to say, the probability that a system, in a state \(s\) of energy \(E_{s}\), interacting with the outside environment at the temperature \(T\) is in thermodynamic equilibrium with the latter.
By maximizing the entropy with the two constraints of the sum of the probabilities and the fixed mean value for the energy, one finds:
\(\mathrm{d} \delta\left[p_{s}\right]=-k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln \left[p_{s}\right]=-k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln \left[\frac{\exp -\beta E_{s}}{z}\right]=-k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln \left[\exp -\beta E_{s}\right]+k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln [z]=\) \(=-k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln \left[\exp -\beta E_{s}\right]=+\beta k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} E_{s}=\frac{1}{T} \sum_{s=1}^{M} E_{s} \mathrm{~d} p_{s} \equiv \frac{\delta \mathcal{Q}}{T}\)
\[
\delta Q=\sum_{s=1}^{M} E_{s} \mathrm{~d} p_{s} \quad \text { reversible }
\]
\[
\begin{equation*}
\delta \mathcal{W}=\sum_{s=1}^{M} p_{s} \mathrm{~d} E_{s} \quad \text { reversible } . \tag{63.07.01}
\end{equation*}
\]
\[
\begin{aligned}
& \mathcal{S}=-k_{\mathrm{B}} \sum_{s=1}^{M}\left(p_{s} \ln \left[p_{s}\right]\right)+k_{\mathrm{B}} \mu\left(1-\sum_{s=1}^{M} p_{s}\right)+k_{\mathrm{B}} \lambda\left(\langle E\rangle-\sum_{s=1}^{M} p_{s} E_{s}\right), \\
& \frac{\partial \delta}{\partial p_{s}}=-k_{\mathrm{B}}\left(\ln \left[p_{s}\right]+1-\mu-\lambda E_{s}\right)=0 \Longrightarrow p_{s}=\exp \lambda E_{s} \exp \mu-1, \\
& z \equiv \sum_{s=1}^{M} \exp \lambda E_{s}, \\
& \sum_{s=1}^{M} p_{s}=1 \Longrightarrow \exp \mu-1 \sum_{s=1}^{M} \exp \lambda E_{s}=1 \Longrightarrow \text { to determine } \mu \\
& p_{s}=\frac{\exp \lambda E_{s}}{z}, \\
& p_{s}\left[E_{s}\right] \propto \exp \left[-\beta E_{s}\right] \quad \beta \equiv \frac{1}{k_{\mathrm{B}} T} \quad \text { to determine } \lambda . \\
& \mathcal{S}\left[p_{s}\right]=-k_{\mathrm{B}} \sum_{s=1}^{M} p_{s} \ln \left[p_{s}\right] \quad, \\
& p_{s}\left[E_{s}\right] \propto \exp -\beta E_{s} \quad \beta \equiv \frac{1}{k_{\mathrm{B}} T} \quad z=\sum_{s=1}^{M} \exp -\beta E_{s} \quad p_{s}\left[E_{s}\right]=\frac{\exp -\beta E_{s}}{z}, \\
& \mathrm{~d} \delta\left[p_{s}\right]=-k_{\mathrm{B}} \sum_{s=1}^{M}\left(\mathrm{~d} p_{s} \ln \left[p_{s}\right]+\mathrm{d} p_{s}\right)=-k_{\mathrm{B}} \sum_{s=1}^{M} \mathrm{~d} p_{s} \ln \left[p_{s}\right] \quad, \\
& \langle E\rangle=\sum_{s=1}^{M} p_{s} E_{s} \quad\langle E\rangle=-\frac{\partial}{\partial \beta} \ln [z] \quad \text { to determine } \beta \text { for any given }\langle E\rangle \\
& \mathrm{d} E=\sum_{s=1}^{M} \mathrm{~d} p_{s} E_{s}+\sum_{s=1}^{M} p_{s} \mathrm{~d} E_{s}
\end{aligned}
\]
\[
\begin{gathered}
\mathrm{d} E=\sum_{s} \mathrm{~d} p_{s} E_{s}+\sum_{s} p_{s} \mathrm{~d} E_{s}, \\
\mathrm{~d} \delta=-\sum_{s} \mathrm{~d} p_{s} \ln \left[p_{s}\right] \\
\mathrm{d} \delta=\frac{1}{T} \sum_{s} E_{s} \mathrm{~d} p_{s} \equiv \frac{\delta Q}{T}, \\
\delta Q=\sum_{s} E_{s} \mathrm{~d} p_{s} \quad \text { reversible }, \\
\delta W=\sum_{s} p_{s} \mathrm{~d} E_{s} \quad \text { reversible } .
\end{gathered}
\]

The precise meaning of the different nature of the transfer of energy by heat and by work is now clear:
- in the heat transfer, only the probabilities (that is the occupation numbers) of the various states are changed, not the values of the energies;
- in the work transfer, the energy levels are changed while the probabilities (that is the occupation numbers) of the levels remain the same.
In general, the energy levels depend on the external parameters, such as volume. Therefore the maximized entropy will depend on the external parameters, for instance volume, and on the average energy, to be identified with the internal energy here: \(\langle E\rangle \equiv \mathcal{U}\). As from equation (61.01.01), considering a system with volume as the unique external parameter, one has
\[
\mathcal{S}=S[u, V] .
\]

\subsection*{63.08}

\section*{Grand-Canonical Ensemble}

By maximizing the entropy with the three constraints of the sum of the probabilities, the fixed mean value for the energy and the fixed mean values of all the components, one finds:
\[
p\left[E, n_{a}, N_{b}, \ldots\right]=\frac{\exp \left[-\beta E+\mu_{a} N_{a}+\mu_{b} N_{b}+\ldots\right]}{Z}
\]

\section*{General Boltzmann-Gibbs Distribution}
©|R.Balian, From Microphysics To Macrophysics, 2007, Springer, ...Ed., ....|§ 4||
The expression, which is called the Boltzmann-Gibbs distribution, represents the general form of the density operators in thermodynamic equilibrium when the averages of the constants of the motion \(A_{i}\) are given:
\[
p_{j}=\frac{\exp \left[-\sum_{i} \lambda_{i} A_{i}[j]\right]}{z} \quad z=\sum_{j=1}^{M} \exp \left[-\sum_{i} \lambda_{i} A_{i}[j]\right] \quad\left\langle A_{i}\right\rangle=-\frac{\partial}{\partial \lambda_{i}} \ln \left[z\left[\lambda_{j}\right]\right]
\]
63.09.01 Non-Zero Total Linear Momentum
\[
p[E, \mathbf{P}]=\frac{\exp [-\beta E+\lambda \cdot \mathbf{P}]}{z} \quad \mathbf{v}=\lambda / \beta
\]

The entropy of a system at equilibrium in the absence of external fields remains unchanged if the system is subjected to a uniform translation (Galilei-Invariance).

\subsection*{63.09.02 Non-Zero Total Angular Momentum}
\[
p[E, \mathbf{J}]=\frac{\exp [-\beta E+\boldsymbol{\lambda} \cdot \mathbf{J}]}{z} \quad \boldsymbol{\omega}=\boldsymbol{\lambda} / \beta
\]

Mathematical Tools
\[
\ln [n!] \approx n \ln [n]-n
\]
\[
n!\simeq \sqrt{2 \pi n} n^{n} \exp -n
\]
\[
\log [x] \leq x-1
\]

\section*{CHAPTER I}

\section*{THE FUNDAMENTAL PRINCIPLES OF STATISTICAL PHYSICS}

\section*{§ 1. Statistical distributions}

Statistical physics, often called for brevity simply statistics, consists in the study of the special laws which govern the behaviour and properties of macroscopic bodies (that is, bodies formed of a very large number of individual particles, such as atoms and molecules). To a considerable extent the general character of these laws does not depend on the mechanics (classical or quantum) which describes the motion of the individual particles in a body, but their substantiation demands a different argument in the two cases. For convenience of exposition we shall begin by assuming that classical mechanics is everywhere valid.

In principle, we can obtain complete information concerning the motion of a mechanical system by constructing and integrating the equations of motion of the system, which are equal in number to its degrees of freedom. But if we are concerned with a system which, though it obeys the laws of classical mechanics, has a very large number of degrees of freedom, the actual application of the methods of mechanics involves the necessity of setting up and solving the same number of differential equations, which in general is impracticable. It should be emphasised that, even if we could integrate these equations in a general form, it would be completely impossible to substitute in the general solution the initial conditions for the velocities and coordinates of all the particles.

At first sight we might conclude from this that, as the number of particles increases, so also must the complexity and intricacy of the properties of the mechanical system, and that no trace of regularity can be found in the behaviour of a macroscopic body. This is not so, however, and we shall see below that, when the number of particles is very large, new types of regularity appear.

These statistical laws resulting from the very presence of a large number of particles forming the body cannot in any way be reduced to purely mechanical laws. One of their distinctive features is that they cease to have meaning when applied to mechanical systems with a small number of degrees of
freedom. Thus, although the motion of systems with a very large number of degrees of freedom obeys the same laws of mechanics as that of systems consisting of a small number of particles, the existence of many degrees of freedom results in laws of a different kind.

The importance of statistical physics in many other branches of theoretical physics is due to the fact that in Nature we continually encounter macroscopic bodies whose behaviour can not be fully described by the methods of mechanics alone, for the reasons mentioned above, and which obey statistical laws.

In proceeding to formulate the fundamental problem of classical statistics, we must first of all define the concept of phase space, which will be constantly used hereafter.
Let a given macroscopic mechanical system have \(s\) degrees of freedom: that is, let the position of points of the system in space be described by \(s\) coordinates, which we denote by \(q_{i}\), the suffix \(i\) taking the values \(1,2, \ldots, s\). Then the state of the system at a given instant will be defined by the values at that instant of the \(s\) coordinates \(q_{i}\) and the \(s\) corresponding velocities \(\dot{q}_{i}\). In statistics it is customary to describe a system by its coordinates and momenta \(p_{i}\), not velocities, since this affords a number of very important advantages. The various states of the system can be represented mathematically by points in phase space (which is, of course, a purely mathematical concept); the coordinates in phase space are the coordinates and momenta of the system considered. Every system has its own phase space, with a number of dimensions equal to twice the number of degrees of freedom. Any point in phase space, corresponding to particular values of the coordinates \(q_{i}\) and momenta \(p_{i}\) of the system, represents a particular state of the system. The state of the system changes with time, and consequently the point in phase space representing this state (which we shall call simply the phase point of the system) moves along a curve called the phase trajectory.
Let us now consider a macroscopic body or system of bodies, and assume that the system is closed, i.e. does not interact with any other bodies. A part of the system, which is very small compared with the whole system but still macroscopic, may be imagined to be separated from the rest; clearly, when the number of particles in the whole system is sufficiently large, the number in a small part of it may still be very large. Such relatively small but still macroscopic parts will be called subsystems. A subsystem is again a mechanical system, but not a closed one; on the contrary, it interacts in various ways with the other parts of the system. Because of the very large number of degrees of freedom of the other parts, these interactions will be very complex and intricate. Thus the state of the subsystem considered will vary with time in a very complex and intricate manner.
An exact solution for the behaviour of the subsystem can be obtained only
by solving the mechanical problem for the entire closed system, i.e. by setting up and solving all the differential equations of motion with given initial conditions, which, as already mentioned, is an impracticable task. Fortunately, it is just this very complicated manner of variation of the state of subsystems which, though rendering the methods of mechanics inapplicable, allows a different approach to the solution of the problem.

A fundamental feature of this approach is the fact that, because of the extreme complexity of the external interactions with the other parts of the system, during a sufficiently long time the subsystem considered will be many times in every possible state. This may be more precisely formulated as follows. Let \(\Delta p \Delta q\) denote some small "volume" of the phase space of the subsystem, corresponding to coordinates \(q_{i}\) and momenta \(p_{i}\) lying in short intervals \(\Delta q_{i}\) and \(\Delta p_{i}\). We can say that, in a sufficiently long time \(T\), the extremely intricate phase trajectory passes many times through each such volume of phase space. Let \(\Delta t\) be the part of the total time \(T\) during which the subsystem was in the given volume of phase space \(\Delta p \Delta q .^{\dagger}\) When the total time \(T\) increases indefinitely, the ratio \(\Delta t / T\) tends to some limit
\[
\begin{equation*}
w=\lim _{T \rightarrow \infty} \Delta t / T \tag{1.1}
\end{equation*}
\]

This quantity may clearly be regarded as the probability that, if the subsystem is observed at an arbitrary instant, it will be found in the given volume of phase space \(\Delta p \Delta q\).
On taking the limit of an infinitesimal phase volume \(\ddagger\)
\[
\begin{equation*}
\mathrm{d} q \mathrm{~d} p=\mathrm{d} q_{1} \mathrm{~d} q_{2} \ldots \mathrm{~d} q_{s} \mathrm{~d} p_{1} \mathrm{~d} p_{2} \ldots \mathrm{~d} p_{s} \tag{1.2}
\end{equation*}
\]
we can define the probability \(\mathrm{d} w\) of states represented by points in this volume element, i.e. the probability that the coordinates \(q_{i}\) and momenta \(p_{i}\) have values in given infinitesimal intervals between \(q_{i}, p_{i}\) and \(q_{i}+\mathrm{d} q_{i}, p_{i}+\mathrm{d} p_{i}\). This probability \(\mathrm{d} w\) may be written
\[
\begin{equation*}
\mathrm{d} w=\varrho\left(p_{1}, \ldots, p_{s}, q_{1}, \ldots, q_{s}\right) \mathrm{d} p \mathrm{~d} q \tag{1.3}
\end{equation*}
\]
where \(\varrho\left(p_{1}, \ldots, p_{s}, q_{1}, \ldots, q_{s}\right)\) is a function of all the coordinates and momenta; we shall usually write for brevity \(\varrho(p, q)\) or even \(\varrho\) simply. The function \(\varrho\), which represents the "density" of the probability distribution in phase space, is called the statistical distribution function, or simply the
\({ }^{\dagger}\) For brevity, we shall usually say, as is customary, that the system "is in the volume \(\Delta p \Delta q\) of phase space", meaning that the system is in states represented by phase points in that volume.
\(\ddagger\) In what follows we shall always use the conventional notation \(\mathrm{d} p\) and \(\mathrm{d} q\) to denote the products of the differentials of all the momenta and all the coordinates of the system respectively.
distribution function, for the body concerned. This function must obviously satisfy the normalisation condition
\[
\begin{equation*}
\int \varrho \mathrm{d} p \mathrm{~d} q=1 \tag{1.4}
\end{equation*}
\]
(the integral being taken over all phase space), which simply expresses the fact that the sum of the probabilities of all possible states must be unity.
The following circumstance is extremely important in statistical physics. The statistical distribution of a given subsystem does not depend on the initial state of any other small part of the same system, since over a sufficiently long time the effect of this initial state will be entirely outweighed by the effect of the much larger remaining parts of the system. It is also independent of the initial state of the particular small part considered, since in time this part passes through all possible states, any of which can be taken as the initial state. Without having to solve the mechanical problem for a system (taking account of initial conditions), we can therefore find the statistical distribution for small parts of the system.
The determination of the statistical distribution for any subsystem is in fact the fundamental problem of statistical physics. In speaking of "small parts" of a closed system, we must bear in mind that the macroscopic bodies with which we have to deal are usually themselves such "small parts" of a large closed system consisting of these bodies together with the external medium which surrounds them.
If this problem is solved and the statistical distribution for a given subsystem is known, we can calculate the probabilities of various values of any physical quantities which depend on the states of the subsystem (i.e. on the values of its coordinates \(q\) and momenta \(p\) ). We can also calculate the mean value of any such quantity \(f(p, q)\), which is obtained by multiplying each of its possible values by the corresponding probability and integrating over all states. Denoting the averaging by a bar, we can write
\[
\begin{equation*}
f=\int f(p, q) \varrho(p, q) \mathrm{d} p \mathrm{~d} q \tag{1.5}
\end{equation*}
\]
from which the mean values of various quantities can be calculated by using the statistical distribution function. \({ }^{\dagger}\)
The averaging with respect to the distribution function (called statistical averaging) frees us from the necessity of following the variation with time of the actual value of the physical quantity \(f(p, q)\) in order to determine its mean value. It is also obvious that, by the definition (1.1) of the probability, the statistical averaging is exactly equivalent to a time averaging. The latter
\({ }^{\dagger}\) In this book we shall denote averaging by a bar over the symbol or by angle brackets: \(\bar{f}\) or \(\langle f\rangle\), being influenced in this solely by convenience in writing the formulae. The second way is preferable for writing the mean values of lengthy expressions.
would involve following the variation of the quantity with time, establishing the function \(f=f(t)\), and determining the required mean value as
\[
f=\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T} f(t) \mathrm{d} t
\]

The foregoing discussion shows that the deductions and predictions concerning the behaviour of macroscopic bodies which are made possible by statistical physics are probabilistic. In this respect statistical physics differs from (classical) mechanics, the deductions of which are entirely deterministic. It should be emphasised, however, that the probabilistic nature of the results of classical statistics is not an inherent property of the objects considered, but simply arises from the fact that these results are derived from much less information than would be necessary for a complete mechanical description (the initial values of the coordinates and momenta are not needed).

In practice, however, when statistical physics is applied to macroscopic bodies, its probabilistic nature is not usually apparent. The reason is that, if any macroscopic body (in external conditions independent of time) is observed over a sufficiently long period of time, it is found that all physical quantities describing the body are practically constant (and equal to their mean values) and undergo appreciable changes relatively very rarely; we mean, of course, macroscopic quantities describing the body as a whole or macroscopic parts of it, but not individual particles. \({ }^{\dagger}\) This result, which is fundamental to statistical physics, follows from very general considerations (to be discussed in § 2) and becomes more and more nearly valid as the body considered becomes more complex and larger. In terms of the statistical distribution, we can say that, if by means of the function \(\varrho(p, q)\) we construct the probability distribution function for various values of the quantity \(f(p, q)\), this function will have an extremely sharp maximum for \(f=\bar{f}\), and will be appreciably different from zero only in the immediate vicinity of this point.

Thus, by enabling us to calculate the mean values of quantities describing macroscopic bodies, statistical physics enables us to make predictions which are valid to very high accuracy for by far the greater part of any time interval which is long enough for the effect of the initial state of the body to be entirely eliminated. In this sense the predictions of statistical physics become

\footnotetext{
\({ }^{\dagger}\) We may give an example to illustrate the very high degree of accuracy with which this is true. If we consider a region in a gas which contains, say, only \(1 / 100\) gram-molecule, we find that the mean relative variation of the energy of this quantity of matter from its mean value is only \(\sim 10^{-11}\). The probability of finding (in a single observation) a relative deviation of the order of \(10^{-6}\), say, is given by a fantastically small number, \(\sim 10^{-3 \times 10^{18}}\).
}
practically determinate and not probabilistic.(For this reason, we shall henceforward almost always omit the bar when using mean values of macroscopic quantities.)

If a closed macroscopic system is in a state such that in any macroscopic subsystem the macroscopic physical quantities are to a high degree of accuracy equal to their mean values, the system is said to be in a state of statistical equilibrium (or thermodynamic or thermal equilibrium). It is seen from the foregoing that, if a closed macroscopic system is observed for a sufficiently long period of time, it will be in a state of statistical equilibrium for much the greater part of this period. If, at any initial instant, a closed macroscopic system was not in a state of statistical equilibrium (if, for example, it was artificially disturbed from such a state by means of an external interaction and then left to itself, becoming again a closed system), it will necessarily enter an equilibrium state. The time within which it will reach statistical equilibrium is called the relaxation time. In using the term "sufficiently long" intervals of time, we have meant essentially times long compared with the relaxation time.
The theory of processes relating to the attainment of an equilibrium state is called kinetics. It is not part of statistical physics proper, which deals only with systems in statistical equilibrium.

\section*{§ 2. Statistical independence}

The subsystems discussed in § 1 are not themselves closed systems; on the contrary, they are subject to the continuous interaction of the remaining parts of the system. But since these parts, which are small in comparison with the whole of the large system, are themselves macroscopic bodies also, we can still suppose that over not too long intervals of time they behave approximately as closed systems. For the particles which mainly take part in the interaction of a subsystem with the surrounding parts are those near the surface of the subsystem; the relative number of such particles, compared with the total number of particles in the subsystem, decreases rapidly when the size of the subsystem increases, and when the latter is sufficiently large the energy of its interaction with the surrounding parts will be small in comparison with its internal energy. Thus we may say that the subsystems are quasi-closed. It should be emphasised once more that this property holds only over not too long intervals of time. Over a sufficiently long interval of time, the effect of interaction of subsystems, however weak, will ultimately appear. Moreover, it is just this relatively weak interaction which leads finally to the establishment of statistical equilibrium.
The fact that different subsystems may be regarded as weakly interacting has the result that they may also be regarded as statistically independent.

By statistical independence we mean that the state of one subsystem does not affect the probabilities of various states of the other subsystems.
Let us consider any two subsystems, and let \(\mathrm{d} p^{(1)} \mathrm{d} q^{(1)}\) and \(\mathrm{d} p^{(2)} \mathrm{d} q^{(2)}\) be volume elements in their phase spaces. If we regard the two subsystems together as one composite subsystem, then the statistical independence of the subsystems signifies mathematically that the probability of the composite subsystem's being in its phase volume element \(\mathrm{d} p^{(12)} \mathrm{d} q^{(12)}=\mathrm{d} p^{(1)} \mathrm{d} q^{(1)}\). \(\mathrm{d} p^{(2)} \mathrm{d} q^{(2)}\) can be written as the product of the probabilities for the two subsystems to be respectively in \(\mathrm{d} p^{(1)} \mathrm{d} q^{(1)}\) and \(\mathrm{d} p^{(2)} \mathrm{d} q^{(2)}\), each of these probabilities depending only on the coordinates and momenta of the subsystem concerned. Thus we can write
\[
\varrho_{12} \mathrm{~d} p^{(12)} \mathrm{d} q^{(12)}=\varrho_{1} \mathrm{~d} p^{(1)} \mathrm{d} q^{(1)} \cdot \varrho_{2} \mathrm{~d} p^{(2)} \mathrm{d} q^{(2)}
\]
or
\[
\begin{equation*}
\varrho_{12}=\varrho_{1} \varrho_{2} \tag{2.1}
\end{equation*}
\]
where \(\varrho_{12}\) is the statistical distribution of the composite subsystem, and \(\varrho_{1}, \varrho_{2}\) the distribution functions of the separate subsystems. A similar relation is valid for a group of several subsystems. \({ }^{\dagger}\)
The converse statement is clearly also true: if the probability distribution for a compound system is a product of factors, each of which depends only on quantities describing one part of the system, then the parts concerned are statistically independent, and each factor is proportional to the probability of the state of the corresponding part.
If \(f_{1}\) and \(f_{2}\) are two physical quantities relating to two different subsystems, then from (2.1) and the definition (1.5) of mean values it follows immediately that the mean value of the product \(f_{1} f_{2}\) is equal to the product of the mean values of the quantities \(f_{1}\) and \(f_{2}\) separately:
\[
\begin{equation*}
\overline{f_{1} f_{2}}=\overline{f_{1}} \cdot f_{2} \tag{2.2}
\end{equation*}
\]

Let us consider a quantity \(f\) relating to a macroscopic body or to a part of it. In the course of time this quantity varies, fluctuating about its mean value. We may define a quantity which represents the average range of this fluctuation. The mean value of the difference \(\Delta f=f-f\) is not suitable for this purpose, since the quantity \(f\) varies fromits mean value in both directions, and the difference \(f-\bar{f}\), which is alternately positive and negative, has mean value zero regardless of how often \(f\) undergoes considerable deviations from its mean value. The required characteristic may conveniently be defined as the mean square of this difference. Since \((\Delta f)^{2}\) is always positive, its mean value tends to zero only if \((\Delta f)^{2}\) itself tends to zero; that is, the mean value
\({ }^{\dagger}\) Provided, of course, that these subsystems together still form only a small part of the whole closed system.
is small only when the probability of considerable deviations of \(f\) from \(f\) is small. The quantity \(\left\langle(\Delta f)^{2}\right\rangle^{1 / 2}\) is called the root-mean-square (r.m.s.) fluctuation of the quantity \(f\). Multiplying out the square \((f-\bar{f})^{2}\) shows that
\[
\begin{equation*}
\left\langle(\Delta f)^{2}\right\rangle=\overline{f^{2}}-(f)^{2} \tag{2.3}
\end{equation*}
\]
i.e. the r.m.s. fluctuation is determined by the difference between the mean square of the quantity and the square of its mean.

The ratio \(\left\langle(\Delta f)^{2}\right\rangle^{1 / 2} / f\) is called ther relative fluctuation of the quantity \(f\). The smaller this ratio is, the more negligible is the proportion of time during which the body is in states where the deviation of \(f\) from its mean value is a considerable fraction of the mean value.

We shall show that the relative fluctuations of physical quantities decrease rapidly when the size of the bodies (that is, the number of particles) to which they relate increases. To prove this, we first note that the majority of quantities of physical interest are additive. This property is a consequence of the fact that the various parts of a body are quasi-closed systems, and signifies that the value of such a quantity for the whole body is the sum of its values for the various (macroscopic) parts of the body. For example, since the internal energies of these parts are, as shown above, large compared with their interaction energies, it is sufficiently accurate to assume that the energy of the whole body is equal to the sum of the energies of its parts.
Let \(f\) be such an additive quantity. We imagine the body concerned to be divided into a large number \(N\) of approximately equal small parts. Then
\[
f=\sum_{i=1}^{N} \bar{f}_{i},
\]
where the quantities \(f_{i}\) relate to the individual parts of the body.
It is clear that, as the size of the body increases, \(f\) increases approximately in proportion to \(N\). Let us also determine the r.m.s. fluctuation of \(f\). We have
\[
\left\langle(\Delta f)^{2}\right\rangle=\left\langle\left(\sum_{i} \Delta f_{i}\right)^{2}\right\rangle
\]

Because of the statistical independence of the different parts of the body, the mean values of the products \(\Delta f_{i} \Delta f_{k}\) are
\[
\overline{\Delta f_{i} \Delta f_{k}}=\overline{\Delta f_{i}} \cdot \overline{\Delta f_{k}}=0 \quad(i \neq k)
\]
since each \(\overline{\Delta f}_{i}=0\). Hence
\[
\begin{equation*}
\left\langle(\Delta f)^{2}\right\rangle=\sum_{i=1}^{N}\left\langle\left(\Delta f_{i}\right)^{2}\right\rangle . \tag{2.4}
\end{equation*}
\]

It follows that, as \(N\) increases, the mean square \(\left\langle(\Delta f)^{2}\right\rangle\) also increases in proportion to \(N\). The relative fluctuation is therefore inversely proportional
to \(\sqrt{ } N\) :
\[
\begin{equation*}
\frac{\left\langle(\Delta f)^{2}\right\rangle^{1 / 2}}{f} \propto \frac{1}{\sqrt{ } N} . \tag{2.5}
\end{equation*}
\]

On the other hand, if we consider a homogeneous body to be divided into parts of a given small size, it is clear that the number of parts will be proportional to the total number of particles (molecules) in the body. Hence the result can also be stated by saying that the relative fluctuation of any additive quantity \(f\) decreases inversely as the square root of the number of particles in a macroscopic body, and so, when the number of these is sufficiently large, the quantity \(f\) itself may be regarded as practically constant in time and equal to its mean value. This conclusion has already been used in § 1.

\section*{§ 3. Liouville's theorem}

Let us now return to a further study of the properties of the statistical distribution function, and suppose that a subsystem is observed over a very long interval of time, which we divide into a very large (in the limit, infinite) number of equal short intervals between instants \(t_{1}, t_{2}, \ldots\). At each of these instants the subsystem considered is represented in its phase space by a point \(A_{1}, A_{2}, \ldots\). The set of points thus obtained is distributed in phase space with a density which in the limit is everywhere proportional to the distribution function \(\varrho(p, q)\). This follows from the significance of the latter function as determining the probabilities of various states of the subsystem.

Instead of considering points representing states of one subsystem at different instants \(t_{1}, t_{2}, \ldots\), we may consider simultaneously, in a formal manner, a very large (in the limit, infinite) number of exactly identical subsystems, \({ }^{\dagger}\) which at some instant, say \(t=0\), are in states represented by the points \(A_{1}, A_{2}, \ldots\).

We now follow the subsequent movement of the phase points which represent the states of these subsystems over a not too long interval of time, such that a quasi-closed subsystem may with sufficient accuracy be regarded as closed. The movement of the phase points will then obey the equations of motion, which involve the coordinates and momenta only of the particles in the subsystem.

It is clear that at any instant \(t\) these points will be distributed in phase space according to the same distribution function \(\varrho(p, q)\), in just the same way as at \(t=0\). In other words, as the phase points move about in the course of time, they remain distributed with a density which is constant at any given point and is proportional to the corresponding value of \(\varrho\).
\({ }^{\dagger}\) Such an imaginary set of identical systems is usually called a statistical ensemble.

This movement of phase points may be formally regarded as a steady flow of a "gas" in phase space of \(2 s\) dimensions, and the familiar equation of continuity may be applied, which expresses the constancy of the total number of "particles" (in this case, phase points) in the gas. The ordinary equation of continuity is
\[
\partial \varrho / \partial t+\operatorname{div}(\varrho \mathbf{v})=0
\]
where \(\varrho\) is the density and \(\mathbf{v}\) the velocity of the gas. For steady flow, we have
\[
\operatorname{div}(\varrho \mathbf{v})=0
\]

For a space of \(2 s\) dimensions, this will become
\[
\sum_{i=1}^{2 s} \frac{\partial}{\partial x_{i}}\left(\varrho v_{i}\right)=0 .
\]

In the present case the "coordinates" \(x_{i}\) are the coordinates \(q\) and momenta \(p\), and the "velocities" \(v_{i}=\dot{x}_{i}\) are the time derivatives \(\dot{q}\) and \(\dot{p}\) given by the equations of motion. Thus we have
\[
\sum_{i=1}^{s}\left[\frac{\partial}{\partial q_{i}}\left(\varrho \dot{q}_{i}\right)+\frac{\partial}{\partial p_{i}}\left(\varrho \dot{p}_{i}\right)\right]=0
\]

Expanding the derivatives gives
\[
\begin{equation*}
\sum_{i=1}^{s}\left[\dot{q}_{i} \frac{\partial \varrho}{\partial q_{i}}+\dot{p}_{i} \frac{\partial \varrho}{\partial p_{i}}\right]+\varrho \sum_{i=1}^{s}\left[\frac{\partial \dot{q}_{i}}{\partial q_{i}}+\frac{\partial \dot{p}_{i}}{\partial p_{i}}\right]==0 \tag{3.1}
\end{equation*}
\]

With the equations of motion in Hamilton's form:
\[
\dot{q}_{i}=\partial H / \partial p_{i}, \quad \dot{p}_{i}=-\partial H / \partial q_{i}
\]
where \(H=H(p, q)\) is the Hamiltonian for the subsystem considered, we see that
\[
\partial \dot{q}_{i} / \partial q_{i}=\partial^{2} H / \partial q_{i} \partial p_{i}=-\partial \dot{p}_{i} / \partial p_{i}
\]

The second term in (3.1) is therefore identically zero. The first term is just the total time derivative of the distribution function. Thus
\[
\begin{equation*}
\frac{\mathrm{d} \varrho}{\mathrm{~d} t}=\sum_{i=1}^{s}\left(\frac{\partial \varrho}{\partial q_{i}} \dot{q}_{i}+\frac{\partial \varrho}{\partial p_{i}} \dot{p}_{i}\right)=0 \tag{3.2}
\end{equation*}
\]

We therefore reach the important conclusion that the distribution function is constant along the phase trajectories of the subsystem. This is Liouville's theorem. Since quasi-closed subsystems are under dicussion, the result is valid only for not too long intervals of time, during which the subsystem behaves as if closed, to a sufficient approximation.

\section*{§ 4. The significance of energy}

It follows at once from Liouville's theorem that the distribution function must be expressible entirely in terms of combinations of the variables \(p\) and \(q\) which remain constant when the subsystem moves as a closed subsystem. These combinations are the mechanical invariants or integrals of the motion, which are the first integrals of the equations of motion. We may therefore say that the distribution function, being a function of the mechanical invariants, is itself an integral of the motion.
It proves possible to restrict very considerably the number of integrals of the motion on which the distribution function can depend. To do this, we must take into account the fact that the distribution \(\varrho_{12}\) for a combination of two subsystems is equal to the product of the distribution functions \(\varrho_{1}\) and \(\varrho_{2}\) of the two subsystems separately: \(\varrho_{12}=\varrho_{1} \varrho_{2}\). Hence
\[
\begin{equation*}
\log \varrho_{12}=\log \varrho_{1}+\log \varrho_{2}, \tag{4.1}
\end{equation*}
\]
so that the logarithm of the distribution function is an additive quantity. We therefore reach the conclusion that the logarithm of the distribution function must be not merely an integral of the motion, but an additive integral of the motion.
As we know from mechanics, there exist only seven independent additive integrals of the motion: the energy, the three components of the momentum vector and the three components of the angular momentum vector. We shall denote these quantities for the \(a\) th subsystem (as functions of the coordinates and momenta of the particles in it) by \(E_{a}(p, q), \mathbf{P}_{a}(p, q), \mathbf{M}_{a}(p, q)\) respectively. The only additive combination of these quantities is a linear combination of the form
\[
\begin{equation*}
\log \varrho_{a}=\alpha_{a}+\beta E_{a}(p, q)+\gamma \cdot \mathbf{P}_{a}(p, q)+\boldsymbol{\delta} \cdot \mathbf{M}_{a}(p, q) \tag{4.2}
\end{equation*}
\]
with constant coefficients \(\alpha_{a}, \beta, \gamma, \delta\), of which \(\beta, \gamma, \delta\) must be the same for all subsystems in a given closed system.

We shall return in Chapter III to a detailed study of the distribution (4.2); here we need note only the following points. The coefficient \(\alpha_{a}\) is just the normalisation constant, given by the condition \(\int \varrho_{a} \mathrm{~d} p^{(a)} \mathrm{d} q^{(a)}=1\). The constants \(\beta, \gamma, \delta\), involving seven independent quantities altogether, may be determined from the seven constant values of the additive integrals of the motion for the whole closed system. Thus we reach a conclusion very important in statistical physics. The values of the additive integrals of the motion (energy, momentum and angular momentum) completely define the statistical properties of a closed system, i.e. the statistical distribution of any of its subsystems, and therefore the mean values of any physical quantities relating to them. These seven additive integrals of the motion replace the
unimaginable multiplicity of data (initial conditions) which would be required in the approach from mechanics.

The above arguments enable us at once to set up a simple distribution function suitable for describing the statistical properties of a closed system. Since, as we have seen, the values of non-additive integrals of the motion do not affect these properties, the latter can be described by any function \(\varrho\) which depends only on the values of the additive integrals of the motion for the system and which satisfies Liouville's theorem. The simplest such function is \(\varrho=\) constant for all points in phase space which correspond to given constant values of the energy ( \(E_{0}\) ), momentum ( \(\mathbf{P}_{0}\) ) and angular momentum ( \(\mathbf{M}_{0}\) ) of the system (regardless of the values of the non-additive integrals) and \(\varrho=0\) at all other points. It is clear that a function so defined will certainly remain constant along a phase trajectory of the system, i.e. will satisfy Liouville's theorem.

This formulation, however, is not quite exact. The reason is that the points defined by the equations
\[
\begin{equation*}
E(p, q)=E_{0}, \quad \mathbf{P}(p, q)=\mathbf{P}_{0}, \quad \mathbf{M}(p, q)=\mathbf{M}_{0} \tag{4.3}
\end{equation*}
\]
form a manifold of only \(2 s-7\) dimensions, not \(2 s\) like the phase volume. Consequently, if the integral \(\int \varrho \mathrm{d} p \mathrm{~d} q\) is to be different from zero, the function \(\varrho(p, q)\) must become infinite at these points. The correct way of writing the distribution function for a closed system is
\[
\begin{equation*}
\varrho=\operatorname{constant} \times \delta\left(E-E_{0}\right) \delta\left(\mathbf{P}-\mathbf{P}_{0}\right) \delta\left(\mathbf{M}-\mathbf{M}_{0}\right) \tag{4.4}
\end{equation*}
\]

The presence of the delta functions \({ }^{\dagger}\) ensures that \(\varrho\) is zero at all points in phase space where one or more of the quantities \(E, \mathbf{P}, \mathbf{M}\) is not equal to the given value \(E_{0}, \mathbf{P}_{0}\) or \(\mathbf{M}_{0}\). The integral of \(\varrho\) over the whole of a phase volume which includes all or part of the above-mentioned manifold of points is finite. The distribution (4.4) is called microcanonical. \(\ddagger\)
The momentum and angular momentum of a closed system depend on its motion as a whole (uniform translation and uniform rotation). We can therefore say that the statistical state of a system executing a given motion depends only on its energy. In consequence, energy is of exceptional importance in statistical physics.
\(\dagger\) The definition and properties of the delta function are given, for example, in Quantum Mechanics, § 5.
\(\ddagger\) It should be emphasised once more that this distribution is not the true statistical distribution for a closed system. Regarding it as the true distribution is equivalent to asserting that, in the course of a sufficiently long time, the phase trajectory of a closed system passes arbitrarily close to every point of the manifold defined by equations (4.3). But this assertion (called the ergodic hypothesis) is certainly not true in general.

In order to exclude the momentum and angular momentum from the subsequent discussion we may use the following device. We imagine the system to be enclosed in a rigid "box" and take coordinates such that the "box" is at rest. Under these conditions the momentum and angular momentum are not integrals of the motion, and the only remaining additive integral of the motion is the energy. The presence of the "box", on the other hand, clearly does not affect the statistical properties of small parts of the system (subsystems). Thus for the logarithms of the distribution functions of the subsystems, instead of (4.2), we have the still simpler expressions
\[
\begin{equation*}
\log \varrho_{a}=\alpha_{a}+\beta E_{a}(p, q) \tag{4.5}
\end{equation*}
\]

The microcanonical distribution for the whole system is
\[
\begin{equation*}
\varrho=\operatorname{constant} \times \delta\left(E-E_{0}\right) \tag{4.6}
\end{equation*}
\]

So far we have assumed that the closed system as a whole is in statistical equilibrium; that is, we have considered it over times long compared with its relaxation time. In practice, however, it is usually necessary to discuss a system over times comparable with or even short relative to the relaxation time. For large systems this can be done, owing to the existence of what are called partial (or incomplete) equilibria as well as the complete statistical equilibrium of the entire closed system. Such equilibria occur because the relaxation time increases with the size of the system, and so the separate small parts of the system attain the equilibrium state considerably more quickly than equilibrium is established between these small parts. This means that each small part of the system is described by a distribution function of the form (4.2), with the parameters \(\beta, \gamma, \delta\) of the distribution having different values for different parts. In such a case the system is said to be in partial equilibrium. In the course of time, the partial equilibrium gradually becomes complete, and the parameters \(\beta, \gamma, \delta\) for each small part slowly vary and finally become equal throughout the closed system.
Another kind of partial equilibrium is also of frequent occurrence, namely that resulting from a difference in the rates of the various processes occurring in the system, not from a considerable difference in relaxation time between the system and its small parts. One obvious example is the partial equilibrium in a mixture of several substances involved in a chemical reaction. Owing to the comparative slowness of chemical reactions, equilibrium as regards the motion of the molecules will be reached, in general, considerably more rapidly than equilibrium as regards reactions of molecules, i.e. as regards the composition of the mixture. This enables us to regard the partial equilibria of the mixture as equilibria at a given (actually non-equilibrium) chemical composition.

The existence of partial equilibria leads to the concept of macroscopic states of a system. Whereas a mechanical microscopic description of the system specifies the coordinates and momenta of every particle in the system, a macroscopic description is one which specifies the mean values of the physical quantities determining a particular partial equilibrium, for instance the mean values of quantities describing separate sufficiently small but macroscopic parts of the system, each of which may be regarded as being in a separate equilibrium.

\section*{§ 5. The statistical matrix}

Turning now to the distinctive features of quantum statistics, we may note first of all that the purely mechanical approach to the problem of determining the behaviour of a macroscopic body in quantum mechanics is of course just as hopeless as in classical mechanics. Such an approach would require the solution of Schrödinger's equation for a system consisting of all the particles in the body, a problem still more hopeless, one might even say, than the integration of the classical equations of motion. But even if it were possible in some particular case to find a general solution of Schrödinger's equation, it would be utterly impossible to select and write down the particular solution satisfying the precise conditions of the problem and specified by particular values of an enormous number of different quantum numbers. Moreover, we shall see below that for a macroscopic body the concept of stationary states itself becomes to some extent arbitrary, a fact of fundamental significance.

Let us first elucidate some purely quantum-mechanical features of macroscopic bodies as compared with systems consisting of a relatively small number of particles.
These features amount to an extremely high density of levels in the energy eigenvalue spectrum of a macroscopic body. The reason for this is easily seen if we note that, because of the very large number of particles in the body, a given quantity of energy can, roughly speaking, be "distributed" in innumerable ways among the various particles. The relation between this fact and the high density of levels becomes particularly clear if we take as an example a macroscopic body consisting of a "gas" of \(N\) particles which do not interact at all, enclosed in some volume. The energy levels of such a system are just the sums of the energies of the individual particles, and the energy of each particle can range over an infinite series of discrete values. \({ }^{\dagger}\) It is clear that, on choosing in all possible ways the values of the \(N\) terms in this sum, we shall

\footnotetext{
\({ }^{\dagger}\) The separations between successive energy levels of a single particle are inversely proportional to the square of the linear dimensions \(L\) of the volume enclosing it ( \(\sim \hbar^{2} / m L^{2}\), where \(m\) is the mass of the particle and \(\hbar\) the quantum constant).
}
\(\boldsymbol{k}\); its value is \({ }^{\dagger}\)
\[
k=1.38 \times 10^{-16} \mathrm{erg} / \mathrm{deg}
\]

In all subsequent formulae the temperature will be assumed measured in energy units. To convert to the temperature measured in degrees, in numerical calculations, we need only replace \(T\) by \(k T\). The continual use of the factor \(k\), whose only purpose is to indicate the conventional units of temperature measurement, would merely complicate the formulae.

If the temperature is in degrees, the factor \(k\) is usually included in the definition of entropy:
\[
\begin{equation*}
S=k \log \Delta \Gamma \tag{9.2}
\end{equation*}
\]
instead of (7.7), in order to avoid the appearance of \(k\) in the general relations of thermodynamics. Then formula (9.1) defining the temperature, and therefore all the general thermodynamic relations derived subsequently in this chapter, are unaffected by the change to degrees.

Thus the rule for conversion to degrees is to substitute in all formulae
\[
\begin{equation*}
T \rightarrow k T, \quad S \rightarrow S / k \tag{9.3}
\end{equation*}
\]

\section*{§ 10. Macroscopic motion}

As distinct from the microscopic motion of molecules, the macroscopic motion is that in which the various macroscopic parts of a body participate as a whole. Let us consider the possibility of macroscopic motion in a state of thermodynamic equilibrium.

Let the body be divided into a large number of small (but macroscopic) parts, and let \(M_{a}, E_{a}\) and \(\mathbf{P}_{a}\) denote the mass, energy and momentum of the \(a\) th part. The entropy \(S_{a}\) of each part is a function of its internal energy, i.e. the difference between its total energy \(E_{a}\) and the kinetic energy \(P_{a}^{2} / 2 M_{a}\) of its macroscopic motion. \(\ddagger\) The total entropy of the body can therefore be written
\[
\begin{equation*}
S=\sum_{a} S_{a}\left(E_{a}-P_{a}^{2} / 2 M_{a}\right) \tag{10.1}
\end{equation*}
\]
\({ }^{\dagger}\) For reference, we may also give the conversion factor between degrees and electron-volts:
\[
1 \mathrm{eV}=11,606 \mathrm{deg} .
\]
\(\ddagger\) The fact that the entropy of a body is a function only of its internal energy follows at once from Galileo's relativity principle; the number of quantum states, and therefore the statistical weight (whose logarithm is the entropy), must be the same in all inertial frames of reference, and in particular that in which the body is at rest.

We shall assume that the body is a closed system. Then its total momentum and angular momentum are conserved, as well as its energy:
\[
\begin{equation*}
\sum_{a} \mathbf{P}_{a}=\text { constant }, \quad \sum_{a} \mathbf{r}_{a} \times \mathbf{P}_{a}=\text { constant } \tag{10.2}
\end{equation*}
\]
where \(\mathbf{r}_{a}\) is the radius vector of the \(a\) th part. In a state of equilibrium, the total entropy \(S\) of the body as a function of the momenta \(\mathbf{P}_{a}\) has a maximum subject to the conditions (10.2). Using the familiar Lagrange's method of undetermined multipliers, we find the necessary conditions for a maximum by equating to zero the derivatives with respect to \(P_{a}\) of the sum
\[
\begin{equation*}
\sum_{a}\left\{S_{a}+\mathbf{a} \cdot \mathbf{P}_{a}+\mathbf{b} \cdot \mathbf{r}_{a} \times \mathbf{P}_{a}\right\} \tag{10.3}
\end{equation*}
\]
where \(\mathbf{a}\) and \(\mathbf{b}\) are constant vectors. Differentiation of \(S_{a}\) with respect to \(\mathbf{P}_{a}\) gives, \({ }^{\dagger}\) by the definition of the temperature,
\[
\frac{\partial}{\partial \mathbf{P}_{a}} S_{a}\left(E_{a}-\frac{P_{a}^{2}}{2 M_{a}}\right)=-\frac{\mathbf{P}_{a}}{M_{a} T}=-\frac{\mathbf{v}_{a}}{T}
\]
where \(\mathbf{v}_{a}=\mathbf{P}_{a} / M_{a}\) is the velocity of the \(a\) th part of the body. Differentiation of (10.3) therefore gives
\[
-\mathbf{v}_{a} / \boldsymbol{T}+\mathbf{a}+\mathbf{b} \times \mathbf{r}_{a}=0,
\]
or
\[
\begin{equation*}
\mathbf{v}_{a}=\mathbf{u}+\boldsymbol{\Omega} \times \mathbf{r}_{a} \tag{10.4}
\end{equation*}
\]
where \(\mathbf{u}=T \mathbf{a}\) and \(\Omega=T \mathbf{b}\) are constant vectors.
This result has a simple physical significance. If the velocities of all the parts of a body are given by formula (10.4) with the same \(\mathbf{u}\) and \(\Omega\), this means that we have a translational motion of the body as a whole with constant velocity \(\mathbf{u}\) and a rotation of the body as a whole with constant angular velocity \(\Omega\). Thus we arrive at the important result that in thermodynamic equilibrium a closed system can execute only a uniform translational and rotational motion as a whole. No internal macroscopic motion is possible in a state of equilibrium. \(\ddagger\)
\({ }^{\dagger}\) The derivative with respect to a vector is to be understood as another vector whose components are equal to the derivatives with respect to the components of the first vector.
\(\ddagger\) To avoid misunderstanding, an important exception to this rule should be noted: superfluid liquid helium cannot rotate as a whole. This effect will be discussed elsewhere in the Course of Theoretical Physics. Here we shall only mention that the proof given above is invalid in that case, because the velocity distribution is subject to a further condition (the superfluid flow is a potential flow) and the entropy maximum is to be sought under this condition.

In what follows we shall usually consider bodies at rest, and the energy \(E\) will accordingly be the internal energy of the body.
So far we have made use only of the necessary condition for a maximum of entropy as a function of the momenta, but not of the sufficient condition to be imposed on the second derivatives. It is easy to see that the latter condition leads to the very important result that the temperature must be positive: \(T>0 .^{\dagger}\) To deduce this, it is not in fact necessary to calculate the second derivatives; instead, we can argue as follows.
Let us consider a body forming a closed system, at rest as a whole. If the temperature were negative, the entropy would increase with decreasing argument. Since the entropy tends to increase, the body would spontaneously seek to break up into dispersing parts (with total momentum \(\Sigma \mathbf{P}_{a}=0\) ), so that the argument of each \(S_{a}\) in the sum (10.1) should take its least possible value. In other words, bodies in equilibrium could not exist with \(T<0\).
The following point should be noted, however. Although the temperature of a body or any part of it can never be negative, there may exist partial equilibria in which the temperature corresponding to a particular group of degrees of freedom of the body is negative. This is further discussed in § 73.

\section*{§ 11. Adiabatic processes}

Among the various kinds of external interactions to which a body is subject, those which consist in a change in the external conditions form a special group. By "external conditions" we mean in a wide sense various external fields. In practice the external conditions are most often determined by the fact that the body must have a prescribed volume. In one sense this case may also be regarded as a particular type of external field, since the walls which limit the volume are equivalent in effect to a potential barrier which prevents the molecules in the body from escaping.
If the body is subject to no interactions other than changes in external conditions, it is said to be thermally isolated. It must be emphasised that, although a thermally isolated body does not interact directly with any other bodies, it is not in general a closed system, and its energy may vary with time.
In a purely mechanical way, a thermally isolated body differs from a closed system only in that its Hamiltonian (the energy) depends explicitly on the time: \(E=E(p, q, t)\), because of the variable external field. If the body also interacted directly with other bodies, it would have no Hamiltonian of its

\footnotetext{
\(\dagger\) The temperature \(T=0\) (absolute zero) corresponds to \(-273.15^{\circ} \mathrm{C}\).
}
own, since the interaction would depend not only on the coordinates of the molecules of the body in question but also on those of the molecules in the other bodies.
This leads to the result that the law of increase of entropy is valid not only for closed systems but also for a thermally isolated body, since here we regard the external field as a completely specified function of coordinates and time, and in particular neglect the reaction of the body on the field. That is, the field is a purely mechanical and not a statistical object, whose entropy can in this sense be taken as zero. This proves the foregoing statement.

Let us suppose that a body is thermally isolated, and is subject to external conditions which vary sufficiently slowly. Such a process is said to be adiabatic. We shall show that, in an adiabatic process, the entropy of the body remains unchanged, i.e. the process is reversible.
We shall describe the external conditions by certain parameters which are given functions of time. For example, suppose that there is only one such parameter, which we denote by \(\lambda\). The time derivative \(\mathrm{d} S / \mathrm{d} t\) of the entropy will depend in some manner on the rate of variation \(\mathrm{d} \lambda / \mathrm{d} t\) of the parameter \(\lambda\). Since \(\mathrm{d} \lambda / \mathrm{d} t\) is small, we can expand \(\mathrm{d} S / \mathrm{d} t\) in powers of \(\mathrm{d} \lambda / \mathrm{d} t\). The zero-order term in this expansion, which does not involve \(\mathrm{d} \lambda / \mathrm{d} t\), is zero, since if \(\mathrm{d} \lambda / \mathrm{d} t=0\) then \(\mathrm{d} S / \mathrm{d} t=0\) also, because the entropy of a closed system in thermodynamic equilibrium must remain constant under constant external conditions. The first-order term, which is proportional to \(\mathrm{d} \lambda / \mathrm{d} t\), must also be zero, since this term changes sign with \(\mathrm{d} \lambda / \mathrm{d} t\), whereas \(\mathrm{d} S / \mathrm{d} t\) is always positive, according to the law of increase of entropy. Hence it follows that the expansion of \(\mathrm{d} S / \mathrm{d} t\) begins with the second-order term, i.e. for small \(\mathrm{d} \lambda / \mathrm{d} t\) we have
or
\[
\begin{aligned}
& \mathrm{d} S / \mathrm{d} t=A(\mathrm{~d} \lambda / \mathrm{d} t)^{2} \\
& \mathrm{~d} S / \mathrm{d} \lambda=A \mathrm{~d} \lambda / \mathrm{d} t
\end{aligned}
\]

Thus, when \(\mathrm{d} \hat{\lambda} / \mathrm{d} t\) tends to zero, so does \(\mathrm{d} S / \mathrm{d} \lambda\), which proves that the adiabatic process is reversible.

It must be emphasised that, although an adiabatic process is reversible, not every reversible process is adiabatic. The condition for a process to be reversible requires only that the total entropy of the whole of a closed system be constant, while the entropies of its individual parts may either increase or decrease. In an adiabatíc process, a stronger conditíon holds: the entropy of a body which is only a part of a closed system also remains constant.

We have defined an adiabatic process as one which is sufficiently slow. More precisely, we can say that the external conditions must change so

Thus we see that the correction to the classical distribution function for the momenta is equivalent to adding to the kinetic energy in the exponent an expression quadratic in the momenta, with coefficients depending on the law of interaction between the particles in the body.
If it is desired to find the probability distribution for any one momentum \(p_{i}\), then (33.17) must be integrated with respect to all the other momenta. All the terms involving the squares \(p_{k}^{2}(k \neq i)\) will then give constants negligible compared with unity, while the terms containing products of different momenta give zero. The result is, again in exponential form,
\[
\begin{equation*}
\mathrm{d} w_{p_{i}}=\text { constant } \times \exp \left\{-\frac{p_{i}^{2}}{2 m_{i} T}\left[1-\frac{\hbar^{2}}{12 T^{3} m_{i}} \overline{\left(\frac{\partial U}{\partial q_{i}}\right)^{2}}\right]\right\} \mathrm{d} p_{i} \tag{33.19}
\end{equation*}
\]

Thus the distribution obtained differs from the Maxwellian only in that the true temperature \(T\) is replaced by a somewhat higher "effective temperature":
\[
T_{\mathrm{eff}}=T+\frac{\hbar^{2}}{12 T^{2} m_{i}} \overline{\left(\frac{\partial U}{\partial q_{i}}\right)^{2}}
\]

Similarly we can calculate the corrected coordinate distribution function by integrating \(I\) with respect to the momenta:
\[
\mathrm{d} w_{q}=\text { constant } \times \mathrm{d} q \int I \mathrm{~d} p
\]

The same calculations as led to (33.13) give
\(\mathrm{d} w_{q}=\) constant \(\times \exp \left\{-\frac{1}{T}\left[U-\frac{\hbar^{2}}{24 T^{2}} \sum_{i} \frac{1}{m_{i}}\left(\frac{\partial U}{\partial q_{i}}\right)^{2}+\frac{\hbar^{2}}{12 T} \sum_{i} \frac{1}{m_{i}} \frac{\partial^{2} U}{\partial q_{i}^{2}}\right]\right\} \mathrm{d} q\).

\section*{\(\S\) 34. The Gibbs distribution for rotating bodies}

The problem of the thermodynamic relations for rotating bodies has already been considered in § 26 . Let us now see how the Gibbs distribution is to be formulated for rotating bodies. This will complete the investigation of their statistical properties. As regards the uniform translational motion, Galileo's relativity principle shows that, as already mentioned in \(\S 26\), this motion has only a trivial effect on the statistical properties and so needs no special consideration.

In a system of coordinates rotating with the body, the usual Gibbs distribution is valid; in classical statistics,
\[
\begin{equation*}
\varrho=(2 \pi \hbar)^{-s} e^{\left[F^{\prime}-E^{\prime}(p, q)\right] / T} \tag{34.1}
\end{equation*}
\]
where \(E^{\prime}(p, q)\) is the energy of the body in this system, as a function of the coordinates and momenta of its particles, and \(F^{\prime}\) the free energy in the same system (which, of course, is not the same as the free energy of the body when at rest). The energy \(E^{\prime}(p, q)\) is related to the energy \(E(p, q)\) in a fixed system by
\[
\begin{equation*}
E^{\prime}(p, q)=E(p, q)-\boldsymbol{\Omega} \cdot \mathbf{M}(p, q) \tag{34.2}
\end{equation*}
\]
where \(\Omega\) is the angular velocity of rotation and \(\mathbf{M}(p, q)\) the angular momentum of the body (see § 26). Substituting (34.2) in (34.1), we find the Gibbs distribution for a rotating body in the form \({ }^{\dagger}\)
\[
\begin{equation*}
\varrho=(2 \pi \hbar)^{-s} e^{\left[F^{\prime}-E(p, q)+\Omega \cdot \mathrm{M}(p, q)\right] / T} . \tag{34.3}
\end{equation*}
\]

In classical statistics the Gibbs distribution for a rotating body can also be represented in another form. To obtain this, we use the following expression for the energy of the body in the rotating coordinate system:
\[
\begin{equation*}
E^{\prime}=\Sigma \frac{1}{2} m v^{\prime 2}-\frac{1}{2} \Sigma m(\Omega \times \mathbf{r})^{2}+U \tag{34.4}
\end{equation*}
\]
where the \(\mathbf{v}^{\prime}\) are the velocities of the particles relative to the rotating system, and the \(\mathbf{r}\) their radius vectors (see Mechanics, § 39). Denoting by
\[
\begin{equation*}
E_{0}\left(\mathbf{v}^{\prime}, \mathbf{r}\right)=\Sigma \frac{1}{2} m v^{\prime 2}+U \tag{34.5}
\end{equation*}
\]
the part of the energy which is independent of \(\Omega\), we obtain the Gibbs distribution in the fo:m
\[
\underline{o}=(2 \pi \hbar)^{-s} \exp \left\{\frac{1}{T}\left[F^{\prime}-E_{0}\left(\mathbf{v}^{\prime}, \mathbf{r}\right)+\frac{1}{2} \Sigma m(\Omega \times \mathbf{r})^{2}\right]\right\}
\]

The function \(\varrho\) determines the probability corresponding to the element of phase space \(\mathrm{d} x_{1} \mathrm{~d} y_{1} \mathrm{~d} z_{1} \ldots \mathrm{~d} p_{1 x}^{\prime} \mathrm{d} p_{1 y}^{\prime} \mathrm{d} p_{1 z}^{\prime} \ldots\), where \(\mathbf{p}^{\prime}=m \mathbf{v}^{\prime}+m \boldsymbol{\Omega} \times \mathbf{r}\) (see Mechanics, § 39). Since, in obtaining the differentials of the momenta, we must regard the coordinates as constant, \(\mathrm{d}^{\prime}=m \mathrm{~d} \mathbf{v}^{\prime}\), and the probability distribution expressed in terms of the coordinates and velocities of the particle is
\[
\begin{align*}
\mathrm{d} w= & C \exp \left\{\frac{F^{\prime}}{T}-\frac{1}{T}\left[E_{0}\left(\mathbf{v}^{\prime}, \mathbf{r}\right)-\Sigma \frac{1}{2} m(\Omega \times \mathbf{r})^{2}\right]\right\} \\
& \times \mathrm{d} x_{1} \mathrm{~d} y_{1} \mathrm{~d} z_{1} \ldots \mathrm{~d} v_{1 x}^{\prime} \mathrm{d} v_{1 y}^{\prime} \mathrm{d} v_{1 z}^{\prime} \ldots \tag{34.6}
\end{align*}
\]
where \(C\) denotes for brevity the factor \((2 \pi \hbar)^{-s}\) together with the product of the particle masses which appears when we go from the momentum differentials to the velocity differentials.
\(\dagger\) The distribution (34.3), like the ordinary Gibbs distribution, is fully in agreement with the result (4.2) derived in § 4 from Liouville's theorem: the logarithm of the distribution function is a linear function of the energy and angular momentum of the body.

For a body at rest we have
\[
\begin{equation*}
\mathrm{d} w=C e^{\left[F-E_{0}(\mathrm{v}, \mathrm{r})\right] / T} \mathrm{~d} x_{1} \mathrm{~d} y_{1} \mathrm{~d} z_{1} \ldots \mathrm{~d} v_{1, x} \mathrm{~d} v_{1 y} \mathrm{~d} v_{1 z} \ldots, \tag{34.7}
\end{equation*}
\]
with the same expression (34.5) for \(E_{0}(\mathbf{v}, \mathbf{r})\), now a function of the velocities in the fixed coordinate system. Thus we see that the Gibbs distribution for the coordinates and velocities for a rotating body differs from that for a body at rest only by the additional potential energy \(-\frac{1}{2} \sum m(\Omega \times \mathbf{r})^{2}\). In other words, as regards the statistical properties of the body, the rotation is equivalent to the existence of an external field corresponding to the centrifugal force. The statistical properties are not affected by the Coriolis force.
It should be emphasised, however, that this last result applies only to classical statistics. In the quantum case the expression
\[
\begin{equation*}
\hat{w}=\exp \left[\left(F^{\prime}-\hat{H}+\Omega \cdot \hat{\mathbf{M}}\right) / T\right] \tag{34.8}
\end{equation*}
\]
gives the statistical operator corresponding to (34.3) for a rotating body. Formally we can reduce this operator to a form analogous to (34.6), the velocities \(\mathbf{v}^{\prime}\) being replaced by the operators \(\hat{\mathbf{v}}^{\prime}=\hat{\mathbf{p}}^{\prime} / m-\Omega \times \mathbf{r}\), but the components of this vector operator do not commute, unlike those of the operator \(\hat{\mathbf{v}}\) in the fixed system. The statistical operators corresponding to the expressions (34.6) and (34.7) will therefore in general be markedly different from each other, quite apart from the fact that one of them contains the centrifugal energy.

\section*{§ 35. The Gibbs distribution for a variable number of particles}

So far we have always tacitly assumed that the number of particles in a body is some given constant, and have deliberately passed over the fact that in reality particles may be exchanged between different subsystems. In other words, the number \(N\) of particles in a subsystem will necessarily fluctuate about its mean value. In order to formulate precisely what we mean by the number of particles, we shall use the term subsystem to refer to a part of the system which is enclosed in a fixed volume. Then \(N\) will denote the number of particles within that volume. \({ }^{\dagger}\)
Thus the problem arises of generalising the Gibbs distribution to bodies with a variable number of particles. Here we shall write the formulae for bodies consisting of identical particles; the further generalisation to systems containing different particles is obvious (§85).

\footnotetext{
\({ }^{\dagger}\) In deriving the Gibbs distribution in \(\S 28\) we have in essence already understood subsystems in this sense; in going from (28.2) to (28.3) we differentiated the entropy whilst regarding the volume of the body (and therefore of the medium) as constant.
}

The distribution function now depends not only on the energy of the quantum state but also on the number \(N\) of particles in the body, and the energy levels \(E_{n N}\) are of course themselves different for different \(N\) (as indicated by the suffix \(N\) ). The probability that the body contains \(N\) particles and is in the \(n\)th state will be denoted by \(w_{n N}\).
The form of this function can be determined in exactly the same way as the function \(w_{n}\) in \(\S 28\). The only difference is that the entropy of the medium is now a function not only of its energy \(E^{\prime}\) but also of the number \(N^{\prime}\) of particles in it: \(S^{\prime}=S^{\prime}\left(E^{\prime}, N^{\prime}\right)\). Writing \(E^{\prime}=E^{(0)}-E_{n N}\) and \(N^{\prime}=N^{(0)}-N\) (where \(N\) is the number of particles in the body, and \(N^{(0)}\) the given total number of particles in the entire closed system, which is large compared with \(N\) ), we have in accordance with (28.2)
\[
w_{n N}=\mathrm{constant} \times \exp \left\{S^{\prime}\left(E^{(0)}-E_{n N}, N^{(0)}-N\right)\right\}
\]
the quantity \(\Delta E^{\prime}\) is regarded as constant, as in § 28.
Next, we expand \(S^{\prime}\) in powers of \(E_{n N}\) and \(N\), again taking only the linear terms. Equation (24.5), in the form
\[
\mathrm{d} S=\frac{\mathrm{d} E}{T}+\frac{P}{T} \mathrm{~d} V-\frac{\mu}{T} \mathrm{~d} N
\]
shows that \((\partial S / \partial E)_{V, N}=1 / T,(\partial S / \partial N)_{E, V}=-\mu / T\). Hence
\[
S^{\prime}\left(E^{(0)}-E_{n N}, N^{(0)}-N\right) \cong S^{\prime}\left(E^{(0)}, N^{(0)}\right)-\frac{E_{n N}}{T}+\frac{\mu N}{T},
\]
the chemical potential \(\mu\) (and the temperature) being the same for the body and the medium, from the conditions of equilibrium.

Thus we obtain for the distribution function the expression
\[
\begin{equation*}
w_{n N}=A e^{\left(\mu N-E_{n N}\right) / T} . \tag{35.1}
\end{equation*}
\]

The normalisation constant \(A\) can be expressed in terms of the thermodynamic quantities in the same way as in \(\$ 31\). The entropy of the body is
\[
S=-\left\langle\log w_{n N}\right\rangle=-\log A-\frac{\mu \bar{N}}{T}+\frac{\bar{E}}{T},
\]
and so
\[
T \log A=\bar{E}-T S-\mu \bar{N}
\]

But \(E-T S=F\), and the difference \(F-\mu \bar{N}\) is the thermodynamic potential \(\Omega\). Thus \(T \log A=\Omega\), and (35.1) may be rewritten as
\[
\begin{equation*}
w_{n N}=e^{\left(\Omega+\mu N-E_{n N}\right) / T} \tag{35.2}
\end{equation*}
\]

\section*{VECTOR IDENTITIES \({ }^{4}\)}

Notation: \(f, g\), are scalars; \(\mathbf{A}, \mathbf{B}\), etc., are vectors; \(T\) is a tensor; \(I\) is the unit dyad.
(1) \(\mathbf{A} \cdot \mathbf{B} \times \mathbf{C}=\mathbf{A} \times \mathbf{B} \cdot \mathbf{C}=\mathbf{B} \cdot \mathbf{C} \times \mathbf{A}=\mathbf{B} \times \mathbf{C} \cdot \mathbf{A}=\mathbf{C} \cdot \mathbf{A} \times \mathbf{B}=\square \times \mathbf{A} \cdot \mathbf{B}\)
(2) \(\mathbf{A} \times(\mathbf{B} \times \mathbf{C})=(\mathbf{C} \times \mathbf{B}) \times \mathbf{A}=(\mathbf{A} \cdot \mathbf{C}) \mathbf{B}-(\mathbf{A} \cdot \mathbf{B}) \mathbf{C}\)
(3) \(\mathbf{A} \times(\mathbf{B} \times \mathbf{C})+\mathbf{B} \times(\mathbf{C} \times \mathbf{A})+\mathbf{C} \times(\mathbf{A} \times \mathbf{B})=0\)
(4) \((\mathbf{A} \times \mathbf{B}) \cdot(\mathbf{C} \times \mathbf{D})=(\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D})-(\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C})\)
(5) \((\mathbf{A} \times \mathbf{B}) \times(\mathbf{C} \times \mathbf{D})=(\mathbf{A} \times \mathbf{B} \cdot \mathbf{D}) \mathbf{C}-(\mathbf{A} \times \mathbf{B} \cdot \mathbf{C}) \mathbf{D}\)
(6) \(\nabla(f g)=\nabla(g f)=f \nabla g+g \nabla f\)
(7) \(\nabla \cdot(f \mathbf{A})=f \nabla \cdot \mathbf{A}+\mathbf{A} \cdot \nabla f\)
(8) \(\nabla \times(f \mathbf{A})=f \nabla \times \mathbf{A}+\nabla f \times \mathbf{A}\)
(9) \(\nabla \cdot(\mathbf{A} \times \mathbf{B})=\mathbf{B} \cdot \nabla \times \mathbf{A}-\mathbf{A} \cdot \nabla \times \mathbf{B}\)
\((10) \nabla \times(\mathbf{A} \times \mathbf{B})=\mathbf{A}(\nabla \cdot \mathbf{B})-\mathbf{B}(\nabla \cdot \mathbf{A})+(\mathbf{B} \cdot \nabla) \mathbf{A}-(\mathbf{A} \cdot \nabla) \mathbf{B}\)
(11) \(\mathbf{A} \times(\nabla \times \mathbf{B})=(\nabla \mathbf{B}) \cdot \mathbf{A}-(\mathbf{A} \cdot \nabla) \mathbf{B}\)
(12) \(\nabla(\mathbf{A} \cdot \mathbf{B})=\mathbf{A} \times(\nabla \times \mathbf{B})+\mathbf{B} \times(\nabla \times \mathbf{A})+(\mathbf{A} \cdot \nabla) \mathbf{B}+(\mathbf{B} \cdot \nabla) \mathbf{A}\)
(13) \(\nabla^{2} f=\nabla \cdot \nabla f\)
(14) \(\nabla^{2} \mathbf{A}=\nabla(\nabla \cdot \mathbf{A})-\nabla \times \nabla \times \mathbf{A}\)
(15) \(\nabla \times \nabla f=0\)
(16) \(\nabla \cdot \nabla \times \mathbf{A}=0\)

If \(\mathbf{e}_{1}, \mathbf{e}_{2}, \mathbf{e}_{3}\) are orthonormal unit vectors, a second-order tensor \(T\) can be written in the dyadic form
(17) \(T=\sum_{i, j} T_{i j} \mathbf{e}_{i} \mathbf{e}_{j}\)

In cartesian coordinates the divergence of a tensor is a vector with components
\[
\begin{equation*}
(\nabla \cdot T)_{i}=\sum_{j}\left(\partial T_{j i} / \partial x_{j}\right) \tag{18}
\end{equation*}
\]
[This definition is required for consistency with Eq. (29)]. In general
\((19) \nabla \cdot(\mathbf{A B})=(\nabla \cdot \mathbf{A}) \mathbf{B}+(\mathbf{A} \cdot \nabla) \mathbf{B}\)
\((20) \nabla \cdot(f T)=\nabla f \cdot T+f \nabla \cdot T\)

\title{
A concise summary of the International System of Units, SI
}

\begin{abstract}
Metrology is the science of measurement and its application. Metrology includes all theoretical and practical aspects of measurement, whatever the measurement uncertainty and field of application.
\end{abstract}

The International Bureau of Weights and Measures (BIPM) was established by Article 1 of the Metre Convention, which was signed on 20 May 1875. It is charged with providing the basis for a single, coherent system of measurements to be used throughout the world and it operates under the authority of the International Committee of Weights and Measures (CIPM). The decimal metric system, dating from the time of the French Revolution, was based in 1799 on the metre and the kilogram. Under the terms of the Metre Convention, new international prototypes of the metre and kilogram were manufactured and formally adopted by the first General Conference on Weights and Measures (CGPM) in 1889. In 1960 the 11th CGPM formally defined and established the International System of Units (SI). Since then the SI has been periodically updated to take account of advances in science and the need for measurements in new domains. The last major revision was adopted by the 26th CGPM (2018), which decided that the SI would be based on the fixed numerical values of a set of seven defining constants from which the definitions of the seven base units of the SI would be deduced. This document is a summary of the SI Brochure, a publication produced by the BIPM, which gives a detailed explanation of the current status of the SI.

The SI is the system of units in which:
- the unperturbed ground state hyperfine transition frequency of the caesium 133 atom \(\Delta \nu_{\mathrm{Cs}}\) is 9192631770 Hz ,
- the speed of light in vacuum c is \(299792458 \mathrm{~m} / \mathrm{s}\),
- the Planck constant \(h\) is \(6.62607015 \times 10^{-34} \mathrm{~J}\) s,
- the elementary charge \(e\) is \(1.602176634 \times 10^{-19} \mathrm{C}\),
- the Boltzmann constant \(k\) is \(1.380649 \times 10^{-23} \mathrm{~J} / \mathrm{K}\),
- the Avogadro constant \(N_{\mathrm{A}}\) is \(6.02214076 \times 10^{23} \mathrm{~mol}^{-1}\),
- the luminous efficacy of monochromatic radiation of frequency \(540 \times 10^{12} \mathrm{~Hz}, K_{\mathrm{cd}}\), is \(683 \mathrm{~lm} / \mathrm{W}\),
where the hertz, joule, coulomb, lumen, and watt, with unit symbols \(\mathrm{Hz}, \mathrm{J}, \mathrm{C}, \mathrm{lm}\), and W , respectively, are related to the units second, metre, kilogram, ampere, kelvin, mole, and candela, with unit symbols s, m, kg, A, K, mol, and cd, respectively, according to \(\mathrm{Hz}=\mathrm{s}^{-1}, \mathrm{~J}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2}, \mathrm{C}=\mathrm{A} \mathrm{s}, \mathrm{lm}=\mathrm{cd} \mathrm{m}^{2} \mathrm{~m}^{-2}=\mathrm{cd} \mathrm{sr}\), and \(\mathrm{W}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-3}\).

These definitions specify the exact numerical value of each constant when its value is expressed in the corresponding SI unit. By fixing the exact numerical value the unit becomes defined, since the product of the numerical value and the unit has to equal the value of the constant, which is invariant.

The defining constants have been chosen such that, when taken together, their units cover all of the units of the SI. In general, there is no one-to-one correspondence between the defining constants and the SI base units, except for the caesium frequency \(\Delta v_{\mathrm{Cs}}\) and the Avogadro constant \(N_{\mathrm{A}}\). Any SI unit is a product of powers of these seven constants and a dimensionless factor.
For example: using \(\mathrm{Hz}=\mathrm{s}^{-1}\), one metre can be derived from the speed of light \(c\) and caesium frequency \(\Delta v_{\mathrm{C}}\),
\[
1 \mathrm{~m}=\left(\frac{c}{299792458}\right) \mathrm{s}=\frac{9192631770}{299792458} \frac{c}{\Delta v_{\mathrm{Cs}}} \approx 30.663319 \frac{c}{\Delta v_{\mathrm{Cs}}} .
\]

The concept of base units and derived units was used to define the SI until 2018. These categories, although no longer essential in the SI, are maintained in view of their convenience and widespread use. The definitions of the base units, which follow from the definition of the SI in terms of the seven defining constants, are given in Table 1.

Table 1 The seven base units of the SI
\begin{tabular}{|c|c|}
\hline Quantity & SI unit \\
\hline time & The second, symbol s, is the SI unit of time. It is defined by taking the fixed numerical value of the caesium frequency \(\Delta v_{\mathrm{CS}}\), the unperturbed ground-state hyperfine transition frequency of the caesium 133 atom, to be 9192631770 when expressed in the unit \(\mathrm{Hz}, \mathrm{w} . .\). ch is equal to \(\mathrm{s}^{-1}\). \\
\hline length & The metre, symbol m , is the SI unit of length. It is defined by taking the fixed numerical value of the speed of light in vacuum \(c\) to be 299792458 when expressed in the ul... \(\mathrm{m} \mathrm{s}^{-1}\), where the second is defined in terms of \(\Delta v_{\mathrm{Cs}}\). \\
\hline mass & The kilogram, symbol kg , is the SI unit of mass. It is defined by taking the fixed nut..erical value of the Planck constant \(h\) to be \(6.62607015 \times 10^{-34}\) when expressed in the unit J s, which is equal to \(\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-1}\), where the metre and the second are defined in terms of \(c\) and \(\Delta v_{\mathrm{Cs}}\). \\
\hline electric current & The ampere, symbol A, is the SI unit of electric current. It is defined by taking the fixed numerical value of the elementary charge \(e\) to be \(1.602176634 \times 10^{-19}\) when expressed in the unit C , which is equal to \(\mathrm{A} s\), where the second is defined in terms of \(\Delta v_{\mathrm{Cs}}\). \\
\hline thermodynamic temperature & The kelvin, symbol K, is the SI unit of thermodynamic temperature. It is defined by taking the fixed numerical value of the Boltzmann constant \(k\) to be \(1.380649 \times 10^{-23}\) when expressed in the unit \(\mathrm{J} \mathrm{K}^{-1}\), which is equal to \(\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2} \mathrm{~K}^{-1}\), where the kilogram, metre and second are defined in terms of \(h, c\) and \(\Delta v_{\mathrm{Cs}}\). \\
\hline amount of substance & \begin{tabular}{l}
The mole, symbol mol, is the SI unit of amount of substance. One mole contains exactly \(6.02214076 \times 10^{23}\) elementary entities. This number is the fixed numerical value of the Avogadro constant, \(N_{\mathrm{A}}\), when expressed in the unit \(\mathrm{mol}^{-1}\) and is called the Avogadro number. \\
The amount of substance, symbol \(n\), of a system is a measure of the number of specified elementary entities. An elementary entity may be an atom, a molecule, an ion, an electron, any other particle or specified group of particles.
\end{tabular} \\
\hline luminous intensity & The candela, symbol cd, is the SI unit of luminous intensity in a given direction. It is defined by taking the fixed numerical value of the luminous efficacy of monochromatic radiation of frequency \(540 \times 10^{12} \mathrm{~Hz}, K_{\mathrm{cd}}\), to be 683 when expressed in the unit \(\mathrm{lm} \mathrm{W}^{-1}\), which is equal to \(\mathrm{cd} \mathrm{sr} \mathrm{W} \mathrm{W}^{-1}\), or \(\mathrm{cd} \mathrm{sr} \mathrm{kg}{ }^{-1} \mathrm{~m}^{-2} \mathrm{~s}^{3}\), where the kilogram, metre and second are defined in terms of \(h, c\) and \(\Delta v_{\mathrm{C}}\). \\
\hline
\end{tabular}

All other quantities may be called "derived quantities" and are measured using derived units, which can be written as products of powers of base units. Twenty-two derived units are given a special name, as listed in Table 2.

Table 2 Derived units with special names in the SI
\begin{tabular}{|c|c|c|c|}
\hline Derived quantity & Name of derived unit & Symbol for unit & Expression in terms of other units \\
\hline plane angle & radian & rad & m/m \\
\hline solid angle & steradian & sr & \(\mathrm{m}^{2} / \mathrm{m}^{2}\) \\
\hline frequency & hertz & Hz & \(\mathrm{s}^{-1}\) \\
\hline force & newton & N & \(\mathrm{kg} \mathrm{m} \mathrm{s}{ }^{-2}\) \\
\hline pressure, stress & pascal & Pa & \(\mathrm{N} / \mathrm{m}^{2}=\mathrm{kg} \mathrm{m}^{-1} \mathrm{~s}^{-2}\) \\
\hline energy, work, amount of heat & joule & J & \(\mathrm{Nm}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2}\) \\
\hline power, radiant flux & watt & W & \(\mathrm{J} / \mathrm{s}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-3}\) \\
\hline electric charge & coulomb & C & A s \\
\hline electric potential difference & volt & V & \(\mathrm{W} / \mathrm{A}=\mathrm{kg} \mathrm{m} \mathrm{m}^{2}{ }^{-3} \mathrm{~A}^{-1}\) \\
\hline capacitance & farad & F & \(\mathrm{C} / \mathrm{V}=\mathrm{kg}^{-1} \mathrm{~m}^{-2} \mathrm{~s}^{4} \mathrm{~A}^{2}\) \\
\hline electric resistance & ohm & \(\Omega\) & \(\mathrm{V} / \mathrm{A}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-3} \mathrm{~A}^{-2}\) \\
\hline electric conductance & siemens & S & \(\mathrm{A} / \mathrm{V}=\mathrm{kg}^{-1} \mathrm{~m}^{-2} \mathrm{~s}^{3} \mathrm{~A}^{2}\) \\
\hline magnetic flux & weber & Wb & \(\mathrm{Vs}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2} \mathrm{~A}^{-1}\) \\
\hline magnetic flux density & tesla & T & \(\mathrm{Wb} / \mathrm{m}^{2}=\mathrm{kg} \mathrm{s}^{-2} \mathrm{~A}^{-1}\) \\
\hline inductance & henry & H & \(\mathrm{Wb} / \mathrm{A}=\mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2} \mathrm{~A}^{-2}\) \\
\hline Celsius temperature & degree Celsius & \({ }^{0} \mathrm{C}\) & K \\
\hline luminous flux & lumen & \(\mathrm{lm}=\mathrm{cd} \mathrm{sr}\) & cd sr \\
\hline illuminance & lux & \(\mathrm{lx}=\mathrm{cd} \mathrm{sr} \mathrm{m}{ }^{-2}\) & \(\mathrm{lm} / \mathrm{m}^{2}\) \\
\hline activity referred to a radionuclide & becquerel & Bq & \(\mathrm{s}^{-1}\) \\
\hline absorbed dose, kerma & gray & Gy & \(\mathrm{J} / \mathrm{kg}=\mathrm{m}^{2} \mathrm{~s}^{-2}\) \\
\hline dose equivalent & sievert & Sv & \(\mathrm{J} / \mathrm{kg}=\mathrm{m}^{2} \mathrm{~s}^{-2}\) \\
\hline catalytic activity & katal & kat & \(\mathrm{mol} \mathrm{s}^{-1}\) \\
\hline
\end{tabular}

Although the hertz and the becquerel are both equal to the reciprocal second, hertz used only for periodic phenomena, and becquerel is used only for stochastic processes in radioactive decay.

The unit of Celsius temperature is the degree Celsius, \({ }^{\circ} \mathrm{C}\), which is equal in magnit \({ }^{1} \mathrm{e}\) to the kelvin, K , the unit of thermodynamic temperature. The quantity Celsius temperature \(t\) is related to thermodynamic temperature \(T\) by the equation \(t /{ }^{\circ} \mathrm{C}=T / \mathrm{K}-273.15\).

The sievert is also used for the quantities 'directional dose equivalent' and 'personal dose equivalent'.
There are many more quantities than units. For each quantity, there is only one SI unit (although this may 'ten be expressed in different ways by using the special names), while the same SI unit may be used to express the values of several different quantities (for example, the SI unit \(\mathrm{J} / \mathrm{K}\) may be used to express the value of both heat capacity and entropy). It is therefore important not to use the unit alone to specify the quantity. This applies both to scientific texts and also . 0 measuring instruments (i.e. an instrument read-out should indicate both the quantity concerned and the unit).
There are quantities with the unit one, 1, i.e. ratios of two quantities of the same kind. For example, refractive index is the ratio of two speeds, and relative permittivity is the ratio of the permittivity of a dielectric medium to that of free space. There are also quantities with the character of a count, for example, the number of cellular or biomolecular entities. These quantities als have the unit one. The unit one is by nature an element of any system of units. Quantities with the unit one can therefore be considered as traceable to the SI. However, when expressing the values of dimensionless quantities, the unit 1 is not written.

\section*{Decimal multiples and sub-multiples of SI units}

A set of prefixes have been adopted for use with the SI units in order to express the values of quantities that are either much larger than, or much smaller than, the SI unit when used without any prefix. They can be used with any SI unit. The SI prefixes are listed in Table 3.

Table 3 The SI prefixes
\begin{tabular}{|l|l|c|l|l|c|}
\hline Factor & Name & Symbol & Factor & Name & Symbol \\
\hline \(10^{1}\) & deca & da & \(10^{-1}\) & deci & d \\
\hline \(10^{2}\) & hecto & h & \(10^{-2}\) & centi & c \\
\hline \(10^{3}\) & kilo & k & \(10^{-3}\) & milli & m \\
\hline \(10^{6}\) & mega & M & \(10^{-6}\) & micro & \(\mu\) \\
\hline \(10^{9}\) & giga & G & \(10^{-9}\) & nano & n \\
\hline \(10^{12}\) & tera & T & \(10^{-12}\) & pico & p \\
\hline \(10^{15}\) & peta & P & \(10^{-15}\) & femto & f \\
\hline \(10^{18}\) & exa & E & \(10^{-18}\) & atto & a \\
\hline \(10^{21}\) & zetta & Z & \(10^{-21}\) & zepto & z \\
\hline \(10^{24}\) & yotta & Y & \(10^{-24}\) & yocto & y \\
\hline
\end{tabular}

When the prefixes are used, the prefix name and the unit name are combined to form a single word. Similarly, the prefix symbol and the unit symbol are written without any space to form a single symbol, which may itself be raised to any power. For example, we may write: kilometre, km; microvolt, \(\mu \mathrm{V}\); or femtosecond, fs.
When the SI units are used without any prefixes, the resulting set of units is described as being coherent in the following sense: when only coherent units are used, equations between the numerical values of quantities take exactly the same form as the equations between the quantities themselves. The use of a coherent set of units has technical advantages, for example in algebraic calculus (see the SI Brochure).

The kilogram, kg, is problematic because the name already includes a prefix, for historical reasons. Multiples and sub-multiples of the kilogram are written by combining prefixes with the gram: thus we write milligram, mg, not microkilogram, \(\mu \mathrm{kg}\).

\section*{Units outside the SI}

The SI is the only system of units that is universally recognized, so it has a distinct advantage for establishing international dialogue. The use of the SI, as a standard system of units, simplifies the teaching of science. For these reasons, the use of SI units is recommended in all fields of science and technology. Other units, i.e. non-SI units, are generally defined in terms of SI units using conversion factors.
Nonetheless, some non-SI units are still widely used. A few, such as the minute, hour and day as units of time, will always be used because they are part of our culture. Others are used for historical reasons, to meet the needs of special interest groups, or because there is no convenient SI alternative. It will always remain the prerogative of a scientist to use the units that are considered to be best suited to the purpose. However, when non-SI units are used, the correspondence to the SI should always be quoted. A selection of non-SI units is listed in Table 4 with their conversion factors to the SI. For a more comprehensive list, see the SI Brochure.

Table 4 A selection of non-SI units
\begin{tabular}{|l|l|l|l|}
\hline Quantity & Unit & Symbol & Relation to SI \\
\hline time & minute & min & \(1 \mathrm{~min}=60 \mathrm{~s}\) \\
\hline time & hour & h & \(1 \mathrm{~h}=3600 \mathrm{~s}\) \\
\hline time & day & d & \(1 \mathrm{~d}=86400 \mathrm{~s}\) \\
\hline volume & litre & L or l & \(1 \mathrm{~L}=1 \mathrm{dm}^{3}\) \\
\hline mass & tonne & t & \(1 \mathrm{t}=1000 \mathrm{~kg}\) \\
\hline energy & electronvolt \((e / \mathrm{C}) \mathrm{J}\) & eV & \(1 \mathrm{eV}=1.602176634 \times 10^{-19} \mathrm{~J}\) \\
\hline
\end{tabular}

When units are named after an individual their symbol should begin with a capital letter (for example: ampere, A; ke n, K; hertz, Hz; or coulomb, C). In all other cases, except the litre, they begin with a lower case letter (for example: metre, m; second, s ; or mole, mol). The symbol for the litre is an exception; either a lower case letter 'l' or a capital 'L' may be used, th' capital is allowed in this case to avoid confusion between the lower case letter l and the number one, 1 .

\section*{The language of science: using the SI to express the values of quantities}

The value of a quantity is written as the product of a number and a unit. The number multiplying the unit is the numerical value of the quantity in that unit. A single space is always left between the number and the unit. The numerical value depends on the choice of unit, so that the same value of a quantity may have different numerical values when expressed in different units, as in the examples provided below.

The speed of a bicycle is approximately
\(v=5.0 \mathrm{~m} / \mathrm{s}=18 \mathrm{~km} / \mathrm{h}\).
The wavelength of one of the yellow lines of the sodium doublet is
\(\lambda=5.896 \times 10^{-7} \mathrm{~m}=589.6 \mathrm{~nm}\).
Quantity symbols are written using italic (slanting) type, and they are generally single letters of the Latin or Greek alphabet. Either capital or lower case letters may be used, and additional information on the quantity may be added as a subscript or as information in brackets.
Authorities such as the International Organization for Standardization (ISO) and international scientific unions such as the International Union of Pure and Applied Physics (IUPAP) and the International Union of Pure and Applied Chemistry (IUPAC) have specified recommended symbols for many quantities. Examples include:
\(T \quad\) for thermodynamic temperature
\(C_{p} \quad\) for heat capacity at constant pressure
\(x_{i} \quad\) for the mole fraction (amount fraction) of species \(i\)
\(\mu_{\mathrm{r}} \quad\) for relative permeability.
Unit symbols are written using roman (upright) type, regardless of the type used in the surrounding text. They are mathematical entities and not abbreviations; unit symbols are never followed by a full stop (except at the end of a sentence) nor by an ' \(s\) ' for the plural. The use of the correct form for unit symbols is mandatory, and is illustrated by examples in the SI Brochure. Unit symbols may be more than a single letter. They are written in lower case letters, the exception being that the first letter is a capital when the unit is named after a person. However, when the name of a unit is spelled in full, it should begin with a lower case letter (except at the beginning of a sentence), to distinguish the unit from the person (for example a temperature of 293 kelvin).
When writing the value of a quantity as the product of a numerical value and a unit, both the number and the unit may be treated by the ordinary rules of algebra. For example, the equation \(T=293 \mathrm{~K}\) may equally be written as \(T / \mathrm{K}=293\). This procedure is described as the use of quantity calculus, or the algebra of quantities. It is often useful to use the ratio of a quantity to its unit as the heading for columns in a table, or for labelling the axes of a graph, so that the entries in the table or the labels for the tick marks on the axes are all simply denoted by numbers. The example (Table 5) shows a table of the velocity squared versus pressure, with the columns labelled in this way.

Table 5 Example of column heading in a table of the velocity squared versus pressure
\begin{tabular}{|c|c|}
\hline\(p / \mathrm{kPa}\) & \(v^{2} /(\mathrm{m} / \mathrm{s})^{2}\) \\
\hline 48.73 & 94766 \\
\hline 72.87 & 94771 \\
\hline 135.42 & 94784 \\
\hline
\end{tabular}

In forming products or quotients of unit symbols the normal rules of algebra appl\({ }^{1}\) In forming products of unit symbols, a space should be left between units (or alternatively a half-high centred dot can be used as a multiplication symbol). The importance of the space should be noted: the product of a metre and a second is denoted by ms (with a space), but ms (without a space) is used to denote a millisecond. In addition, when forming complic. d products of units, brackets or negative exponents should be used to avoid ambiguities. For example, the molar gas constant \(R\) is given by:
\[
\begin{aligned}
p V_{\mathrm{m}} / T=R & =8.314 \mathrm{~Pa} \mathrm{~m}^{3} \mathrm{~mol}^{-1} \mathrm{~K}^{-1} \\
& =8.314 \mathrm{~Pa} \mathrm{~m}^{3} /\left(\mathrm{mol} \mathrm{~K}^{2} .\right.
\end{aligned}
\]

When formatting numbers, the decimal marker may be either a point (i.e. a full stop) or a comn depending on the circumstances. For documents in the English language a point is usual, but for many languages and in many countries a comma is usual.

When a number has many digits, it is customary to group the digits into threes about the decimal point to aid readability. This is not essential, but it is often done and is generally helpful. When this format is used, the groups of three digits should be separated only by a space; neither a point nor a comma should be used. The uncertainty in the numerical value of a 4 -antity may often be conveniently shown by giving the uncertainty in the least significant digits in brackets after the number.
For example: The value of the electron mass is given in the 2014 CODATA listing of fundamental constants as
\[
m_{\mathrm{e}}=9.10938356(11) \times 10^{-31} \mathrm{~kg},
\]
where 11 is the standard uncertainty in the final digits quoted for the numerical value.

\section*{Physics Constants}
N National Institute of Standards and Technology • U.S. Department of Commerce
An extensive list of constants is available on the NIST Physics Laboratory Web site physics.nist.gov/constants. For numerical values a number in parentheses, if present, is the one-standarddeviation uncertainty in the last two digits. For units with square brackets the full descriptions of \(\mathrm{m}^{-1}\) and m are cycles per meter and meter per cycle, respectively. For the first radiation constant the full description of \(\mathrm{m}^{2}\) is \(\mathrm{m}^{-2}(\mathrm{~m} / \mathrm{cycle})^{4}\)

\hline
\end{tabular}
\({ }^{*}\) The energy of a photon with frequency \(\nu\) expressed in unit Hz is \(E=h \nu\) in J. Unitary time evolution of the state of this photon is given by \(\exp (-i E t / \hbar)|\varphi\rangle\), where \(|\varphi\rangle\) is the photon state at time \(t=0\) and time is expressed in unit s. The ratio \(E t / \hbar\) is a phase.
\({ }^{\dagger}\) The full description of \(\mathrm{m}^{-1}\) is cycles or periods per meter and that of m is meter per cycle ( \(\mathrm{m} /\) cycle). The scientific community is aware of the implied use of these units. It traces back to the conventions for phase and angle and the use of unit Hz versus cycles/s. No solution has been agreed upon.
\(\ddagger\) Value recommended by the Particle Data Group (Tanabashi, et al., 2018).
\({ }^{\S}\) Based on the ratio of the masses of the W and Z bosons \(m_{\mathrm{W}} / m_{\mathrm{Z}}\) recommended by the Particle Data Group (Tanabashi, et al., 2018). The value for \(\sin ^{2} \theta_{\mathrm{W}}\) they recommend, which is based on a variant of the modified minimal subtraction ( \(\left.\overline{\mathrm{MS}}\right)\) scheme, is \(\sin ^{2} \hat{\theta}_{\mathrm{W}}\left(M_{\mathrm{Z}}\right)=0.23122(4)\).
\({ }^{\top}\) This and other constants involving \(m_{\tau}\) are based on \(m_{\tau} c^{2}\) in MeV recommended by the Particle Data Group (Tanabashi, et al., 2018).
\({ }^{11}\) The relative atomic mass \(A_{\mathrm{r}}(X)\) of particle \(X\) with mass \(m(X)\) is defined by \(A_{\mathrm{r}}(X)=m(X) / m_{\mathrm{u}}\), where \(m_{\mathrm{u}}=m\left({ }^{12} \mathrm{C}\right) / 12=1 \mathrm{u}\) is the atomic mass constant and u is the unified atomic mass unit. Moreover, the mass of particle \(X\) is \(m(X)=A_{\mathrm{r}}(X) \mathrm{u}\) and the molar mass of \(X\) is \(M(X)=A_{\mathrm{r}}(X) M_{\mathrm{u}}\), where \(M_{\mathrm{u}}=N_{\mathrm{A}} \mathrm{u}\) is the molar mass constant and \(N_{\mathrm{A}}\) is the Avogadro constant.
\({ }^{* *}\) The entropy of an ideal monoatomic gas of relative atomic mass \(A_{\mathrm{r}}\) is given by \(S=S_{0}+\frac{3}{2} R \ln A_{\mathrm{r}}-R \ln \left(p / p_{0}\right)+\frac{5}{2} R \ln (T / \mathrm{K})\).
\({ }^{\dagger \dagger}\) The full description of \(\mathrm{m}^{2}\) is \(\mathrm{m}^{-2} \times(\mathrm{m} / \text { cycle })^{4}\). See also footnote for \(\mathrm{m}^{-1}\).

\section*{APPENDIX D}

\section*{Periodic table of the Elements}

\section*{4. Periodic Table of the Elements}

Table 4.1. Revised June 2019 by D.E. Groom (LBNL). The atomic number (top left) is the number of protons in the nucleus. The atomic masses (bottom) of stable elements are weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of \({ }^{12} \mathrm{C}\), defined to be exactly 12 unified atomic mass units u) ( \(1 \mathrm{u} \approx 1 \mathrm{~g} /\) mole). The exceptions are Th , Pa, and U , which have no stable isotopes but do have characteristic terrestrial compositions. Relative isotopic abundance https://www.nist.gov/pml/atomic-weights-and-isotopic-compositions-relative-atomic-masses. If there is no stable isotope, the atomic mass of the most stable isotope known as of June 2019 is given in parentheses.

\section*{Atomic electronic structure of the elements}

\section*{5. Electronic Structure of the Elements}

Table 5.1. Reviewed 2011 by J.E. Sansonetti (NIST). The electronic configurations and the ionization energies are from the NIST database, "Ground Levels and Ionization Energies for the Neutral Atoms," W.C. Martin, A. Musgrove, S. Kotochigova, and J.E. Sansonetti, http://www.nist.gov/pml/data/ion_energy.cfm. The electron configuration for, say, iron indicates an argon electroni re (see argon) plus six \(3 d\) electrons and two \(4 s\) electrons.
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \multicolumn{2}{|l|}{Element} & Electron configuration ( \(3 d^{5}=\) five \(3 d\) electrons, etc.) & Ground state \({ }^{2 S+1} L_{J}\) & Ionization energy (eV) \\
\hline 1 & H & Hydrogen & \(1 s\) & \({ }^{2} S_{1 / 2}\) & 13.5984 \\
\hline 2 & He & Helium & \(1 s^{2}\) & \({ }^{1} S_{0}\) & 24.5874 \\

\section*{Atomic and Nuclear properties of the materials}

\section*{6. Atomic and Nuclear Properties of Materials}

Table 6.1 Abridged from pdg.lbl.gov/AtomicNuclearProperties by D.E. Groom (2017). See web pages for more detail about entries in this table and for several hundred others. Parentheses in the \(d E / d x\) and density columns indicate gases at \(20^{\circ} \mathrm{C}\) and 1 atm . Boiling points are at 1 atm. Refractive indices \(n\) are evaluated at the sodium D line blend ( 589.2 nm ); values \(\gg 1\) in brackets indicate \((n-1) \times 10^{6}\) for g . at \(0^{\circ} \mathrm{C}\) and 1 atm .

\section*{APPENDIX H}

\section*{Properties of Matter: data tables}

CHAPTER 2

\section*{Tables}

These tables are from

\section*{Understanding the properties of matter}
by Michael de Podesta.
The copyright of these tables resides with the publishers, Taylor and Francis.

They may be used freely for educational purposes, but their source must be acknowledged.

For more details see www.physicsofmatter.com

Table 2.1 The properties of particles that are treated as fundamental in this book. The most important properties of the particles for understanding the properties of matter are the first two rov of the table: mass and electric charge. The internal angular momentum (spin) and magnetic moment of the particles are discussed in the text below.
\begin{tabular}{|c|c|c|c|c|}
\hline Property & Units & Electron & Neutron & Proton \\
\hline \multirow[t]{2}{*}{Mass} & Atomic mass units & \(5.485 \times 10^{-4}\) & 1.0085 & 1.0071 \\
\hline & \(u=1.661 \times 10^{-27} \mathrm{~kg}\) & \(\approx 1 / 1836\) & & \\
\hline Electric charge & Proton charge
\[
e=1.602 \times 10^{-19} \mathrm{C}
\] & -1 & 0 & +1 \\
\hline \multirow[t]{2}{*}{Magnetic moment} & Bohr magneton & 1.001 & \(1.0419 \times 10^{-3}\) & \(1.521 \times 10^{-3}\) \\
\hline & \(\mu_{\mathrm{B}}=9.274 \times 10^{-24} \mathrm{~J} \mathrm{~T}^{-1}\) & & & \\
\hline \multirow[t]{2}{*}{Magnetic moment} & Nuclear magneton & 1837.8 & 1.913 & 2.793 \\
\hline & \(\mu_{\mathrm{N}}=5.051 \times 10^{-27} \mathrm{~J} \mathrm{~T}^{-1}\) & & & \\
\hline Intrinsic (spin) angular momentum & Planck constant divided by \(2 \pi\) \(\hbar=1.054 \times 10^{-34} \mathrm{~J} \mathrm{~s}\) & 1/2 & 1/2 & 1/2 \\
\hline Electric dipole moment & Cm & 0 & 0 & 0 \\
\hline Lifetime & & Stable & Stable within nuclei half life \(\approx 15\) minutes in free space. & Stable \\
\hline
\end{tabular}

Table 2.2. The elements with atomic numbers up to 105 together with their date of aiscovery. The term 'Old' as a date of discovery indicates that the element was known in antiquity. The names of the elements tell many fascinating stories about their discovery.
\begin{tabular}{|c|c|c|c|c|c|}
\hline Z & Element, symbol, date o discovery & Origin of name & Z & Element, symbol, date of discovery & Origin of nan. \\
\hline 1 & Hydrogen, H, (1766) & Greek: Hydros Genes: meaning Water Forming & 34
35 & \begin{tabular}{l}
Selenium, Se, (1817) \\
Bromine, Br, (1826)
\end{tabular} & Greek: Selene meaning Moon Greek: Bromos meaning \\
\hline 2 & Helium, He, (1895) & Greek: Helios meaning Sun & & & Stench \\
\hline 3 & Lithium, Li, (1817) & Greek: Lithos meaning Stone & 36 & Krypton, Kr, (1898) & Greek: Kryptos meaning Hid- \\
\hline 4 & Beryllium, Be, (1797) & Greek: Beryllos meaning Beryl & & & den \\
\hline 5 & Boron, B, (1808) & Arabic: Buraq & 37 & Rubidium, Rb, (1861) & Latin: Rubidius meaning \\
\hline 6 & Carbon, C, (Old) & Latin: Carbo meaning Charcoal & 38 & Strontium, Sr, (1790) & Deepest Red
English: Strontian in Scotland \\
\hline 7 & Nitrogen, N, (1772) & Greek: Nitron Genes meaning Nitre Forming & 39
40 & \begin{tabular}{l}
Yttrium, Y , (1794) \\
Zirconium, Zr, (1789)
\end{tabular} & The town of Ytterby in Sweden Arabic: Zargun meaning Gold \\
\hline 8 & Oxygen, O, (1774) & Greek: Oxy Genes meaning Acid Forming & 41 & Niobium, Nb, (1801) & \begin{tabular}{l}
Colour \\
Greek: Niobe, a daughter of
\end{tabular} \\
\hline 9 & Fluorine, F, (1886) & Latin: Fluere meaning To Flow & & & Tantalus: Also called Colum- \\
\hline 10 & Neon, Ne , (1898) & Greek: Neos meaning New & & & bium in USA \\
\hline 11 & Sodium, Na, (1807) & English: Soda: The symbol comes from the Latin Natrium & 42 & Molybdenum, Mo, (1781) & Greek: Molybdos meaning Lead \\
\hline 12 & Magnesium, Mg, (1755) & Greek: Magnesia, a district in Thessaly & 43 & Technetium, Tc, (1937) & Greek: Technikos meaning Artificial \\
\hline 13 & Aluminium, Al, (1825) & Latin: alumen meaning alum & 44 & Ruthenium, Ru, (1808) & Latin: Ruthenia meaning Rus- \\
\hline 14 & Silicon, Si, , (1824) & Latin: Silicis meaning Flint & & & \\
\hline 15 & Phosphorus, P, (1669) & Greek: Phosphorus meaning Bringer of Light & 45
46 & \begin{tabular}{l}
Rhodium, Rh, (1803) \\
Palladium, Pd, (1803)
\end{tabular} & Greek: Rhodon meaning Rose The asteroid Pallas \\
\hline 16 & Sulphur, S, (Old) & Sanskrit: Sulvere meaning Sulphur & 47 & Silver, Ag, (Old) & Saxon: Siolfur meaning Silver: The symbol comes from the \\
\hline 17 & Chlorine, Cl, (1774) & Greek: Chloros meaning Pale Green & 48 & Cadmium, Cd, (1817) & \begin{tabular}{l}
Latin Argentum \\
Latin: Cadmia meaning Calo-
\end{tabular} \\
\hline 18 & Argon, Ar, (1894) & Greek: Argos meaning Inactive & & & \\
\hline 19 & Potassium, K, (1807) & English: Potash: The symbol comes from the Latin Kalium & \[
\begin{aligned}
& 49 \\
& 50
\end{aligned}
\] & \begin{tabular}{l}
Indium, In, (1863) \\
Tin, Sn, (Old)
\end{tabular} & \begin{tabular}{l}
Indigo \\
Saxon: Tin: The symbol comes from the Latin Stannum
\end{tabular} \\
\hline 20 & Calcium, Ca, (1808) & Latin: Calix meaning Lime & & & \begin{tabular}{l}
from the Latin Stannum \\
Greek: Anti+Monos meaning
\end{tabular} \\
\hline 21 & Scandium, Sc, (1879) & Latin: Scandia meaning Scandinavia & 51 & Antimony, Sb, (Old) & Greek: Anti+Monos meaning not alone. The symbol is from Latin Stibium \\
\hline 22 & Titanium, Ti, (1791) & Titans, Sons of the Earth Goddess. & 52 & Tellurium, Te , (1783) & Latin Stibium
Latin: Tellus meaning Earth \\
\hline 23 & Vanadium, V, (1801) & Vanadis, Scandinavian goddess & 53
54 & \begin{tabular}{l}
lodine, I, (1811) \\
Xenon, Xe, (1898)
\end{tabular} & Greek: lodes meaning Violet Greek: Xenos meaning \\
\hline 24 & Chromium, Cr, (1780) & Greek: Chroma meaning Colour & 55 & Caesium, Cs, (1860) & \begin{tabular}{l}
Stranger \\
Latin: Caesius meaning Sky
\end{tabular} \\
\hline 25 & Manganese, Mn, (1774) & Latin: Magnes meaning Magnet & 56 & Barium, Ba, (1808) & Blue
Greek: Barys meaning Heavy \\
\hline 26 & Iron, Fe, (Old) & Saxon: Iron: The symbol comes from the Latin Ferrum & 57 & Lanthanum, La, (1839) & Greek: Lanthanein meaning To Lie Hidden \\
\hline 27 & Cobalt, Co, (1735) & German: kobald meaning Goblin & 58 & Cerium, Ce, (1803) & Ceres, an asteroid discovered in 1801 \\
\hline 28 & Nickel, Ni, (1751) & German: Kupfernickel meaning either Devil's Copper or St & 59 & Praseodymium, Pr, (1885) & Greek: Prasios Didymos meaning Green Twin \\
\hline 29 & Copper, Cu, (Old) & \begin{tabular}{l}
Nicholas' Copper \\
Latin: Cuprum meaning Cyprus
\end{tabular} & 60 & Neodymium, Nd, (1885) & Greek: Neos Didymos meaning New Twin \\
\hline 30 & Zinc, Zn, (1400) & German: Zink & 61 & Promethium, Pm, (1945) & Greek: Prometheus \\
\hline 31 & Gallium, Ga, (1875) & Latin: Gallia meaning France & 62 & Samarium, Sm, (1879) & The mineral Samarskite \\
\hline 32 & Germanium, Ge, (1886) & Latin: Germania meaning & 63 & Europium, Eu, (1901) & Europe \\
\hline & & German & 64 & Gadolinium, Gd, (1880) & J. Gadolin, a Finnish chemist \\
\hline 33 & Arsenic, As, (1280) & Greek: Arsenikon meaning & 65 & Terbium, Tb, (1843) & The town of Ytterby in Sweden \\
\hline & & Yellow Orpiment & 66 & Dysprosium, Dy, (1886) & Greek: Dysprositos meaning Hard To Obtain \\
\hline
\end{tabular}

\end{tabular}

Table 3.1 The SI base units. Notice that, with the exception of the kilogram, the definitions are in terms of physical phenomena and not defining artefacts. Although the definitions seem obs are, the language is carefully chosen in order to make accurate realisations of the standards feasible.
The copyright of this table belongs to the National Physical Laboratory. It has been re, Jduced with permission from with the National Physical Laboratory. It may be used freely for educational purposes, but its source (NPL) must be acknowledged.
\begin{tabular}{|c|c|}
\hline Quantity: Unit (abbreviation) & Definition \\
\hline Time: second (s) & The second is the duration of \(9,192,631,770\) periods of the radiation corresponding to the transition between two hyperfine levels of the ground state of the caesium133 atom. \\
\hline Length: metre (m) & \begin{tabular}{l}
The metre is the length of the path travelled by light in vacuum during a time interval \(1 / 299,792,458\) of a second. \\
Note: This defines \(299,792,458 \mathrm{~ms}^{-1}\) as the exact speed of light in a vacuum.
\end{tabular} \\
\hline \begin{tabular}{l}
Mass: \\
kilogram (kg)
\end{tabular} & The kilogram is the unit of mass; it is equal to the mass of the international prototype of the kilogram \\
\hline Electric Current: ampere (A) & The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross-section, and placed 1 metre apart in vacuum, would produce between these conductors a force equal to \(2 \times 10^{-7}\) newton, per metre of length. \\
\hline Thermodynamic temperature: kelvin (K) & The kelvin, unit of thermodynamic temperature, is the fraction \(1 / 273.16\) of the thermodynamic temperature of the triple point of pure water. \\
\hline Amount of substance: mole (mol) & The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon 12. \\
\hline Luminous Intensity: candela (cd) & The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation \(540 \times 10^{12}\) hertz and that has a radiant intensity of 1/683 watt per steradian \\
\hline

\end{tabular}

Table 5.16 The relative dielectric permittivity \(\varepsilon\) of various gases at atmospheric pressure \(\left(1.013 \times 10^{5}\right.\) Pa ). For pressures below atmospheric pressure \(\varepsilon\) varies linearly with pressure. The . lative permittivity of vacuum is exactly 1 , and all the gases in the table have values of \(\varepsilon\) within \(1 \%\) of unity. The table shows the value of \(10^{4}(\varepsilon-1)\), which clearly shows the variation between gases. The ta \(\llcorner\) also shows the relative molecular mass of the molecules of the gas.
Different experimenters find different values of \(\varepsilon\) and the data for \(10^{4}(\varepsilon-1)\) should all be treated as accurate to only about \(10 \%\). The entry for ethanol has two alternative values to indicate two particularlv divergent values for \(10^{4}(\varepsilon-1)\). For other entries I have taken averages of tabulated results, or ignored entries in tables that were clearly in error.
The data refer to values obtained with electric fields oscillating at radio frequencies, \(\approx 10^{6} \mathrm{~Hz}\). The shaded entries in the table, i.e. helium, hydrogen, argon, oxygen, nitrogen, and air, are typical results for \(\varepsilon\) valid from DC up to optical frequencies \(\approx 10^{15} \mathrm{~Hz}\). The variation over that range is within \(\pm 2\) of the least significant figure in the table.

Table 5.19 Comparison of the experimental values of the refractive index of gases with the prediction of their refractive index based on Equation 2.17. Before comparing the data, the dic...ctric constant data have been corrected to STP using factors discussed in §5.6.2. The first three entries in the table are for non-polar gases and the last two are for polar gases. Notice the good agreement between cory and experiment for the non-polar gases, and the massive disagreement for water vapour.

Table 7.1 The approximate values of the density of some solids.
\begin{tabular}{lr}
\hline Solid & \(\boldsymbol{\rho}\left(\mathbf{k g ~ m}^{\mathbf{- 3}}\right)\) \\
\hline Metals & \\

Table 7.2 The density of the elements \(\left(\mathrm{kg} \mathrm{m}^{-3}\right)\). Also shown is the atomic number \(Z\) and the atomic weight \(A\) in units of the atomic mass unit \(\mathbf{u}=1.66 \times 10^{-27} \mathrm{~kg}\). For example, the d€ ...ity of magnesium, whose atoms each contain 12 protons, is \(1.738 \times 10^{3} \mathrm{~kg} \mathrm{~m}^{-3}\). The mass of an atom of magnesium is \(24.31 \times 1.66 \times 10^{-27} \mathrm{~kg}\). The densities of elements that are normally gaseous at room tc...perature are evaluated at a temperature just below their freezing point at atmospheric pressure. For helium, which does not solidify at atmospheric pressure at any temperature, the density is evaluated at 4.2 K nd 25 atmospheres \(\left(25 \times 10^{5} \mathrm{~Pa}\right)\) pressure which is sufficient to cause solidification.

Table 7.3 The atomic number \(Z\), atomic mass \(A\) and the density \(\rho\) of the lanthanide elements extracted from Table 7.2. The row marked \(\% A\) is the \(\%\) density increase (compared with La) expected if the separation between atoms is unchanged and only the atomic mass changes. The row marked \(\% \rho\) is the \(\%\) density increase (compared with La) actually found. It shows that the \(59 \%\) density increase is much greater than can be explained by the \(26 \%\) increase in atomic mass alone.

Table 9.19 The results of calculations of the molecular polarisability of non-polar molecules based on dielectric constant data for both liquid and gaseous states. The value of on Equation \(9.51{ }^{\prime} \mathrm{s}_{\mathrm{o}}=(\varepsilon-1) / n\) with \(n\) estimated by either Equation 9.49 or 9.50 as appropriate. The data for the densities of liquid hydrogen, nitrogen and oxygen are estimates based on a \(10 \%\) decrease of the density of the solid. Seo Table 5.16 for gas data and Table 9.18 for liquid data. The gas data refer to atmospheric pressure ( \(1.0 \mathrm{r} 5 \times 10^{5}\) \(\mathrm{Pa})\). Notice that the inferred value of \(\alpha\) is quite similar in liquid and gaseous states.

\end{tabular}

Table 11.4 The critical parameters of various substances discussed in Chapter 6 and Chapter 8. \(P_{\mathrm{C}}, V_{\mathrm{C}}\) and \(T_{\mathrm{C}}\) are the critical pressure, molar volume and temperature. \(Z_{\mathrm{C}}\) is the compression frtor which is discussed in \(\S 11.5 .3\). The next column gives the density at the critical point, calculated trom the molecular mass and \(V_{\mathrm{C}}\). This may be compared with the density of the substance in the liquid state well away from \(T_{\mathrm{C}}\). For the inorganic substances where the liquid density data is not available, the sond density has been used instead The final column gives the ratio of the density at the critical point to that at a temperature well below the critical point.

61.1 Work per unit volume on matter in electric fields for infinitesimal changes of the field configuration.
61.2 Work per unit volume on matter in magnetic fields for infinitesimal changes of the field con-
figuration. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 2640```

[^0]:    ${ }^{*}$ The energy of a photon with frequency $\nu$ expressed in unit Hz is $E=h \nu$ in J . Unitary time evolution of the state of this photon is given by $\exp (-i E t / \hbar)|\varphi\rangle$, where $|\varphi\rangle$ is the photon state at time $t=0$ and time is expressed in unit s. The ratio $E t / \hbar$ is a phase.
