bacct

displays accounting statistics about finished jobs

Synopsis

```
bacct [-b | -1] [-d] [-e] [-w] [-x] [-app application_profile_name]
   [-C time0, time1] [-D time0, time1] [-f logfile_name]
   [-Lp ls_project_name ...] [-m host_name ...] [-M host_list_file]
   [-N host_name | -N host_model | -N cpu_factor]
   [-P project_name ...] [-q queue_name ...]
   [-sla service_class_name ...] [-S time0, time1]
   [-u user_name ... | -u all] [job_ID ...]
bacct -U reservation_ID ... | -U all [-u user_name ... | -u all]
bacct [-h | -V]
```

Description

By default, displays accounting statistics for all finished jobs (with a DONE or EXIT status) submitted by the user who invoked the command, on all hosts, projects, and queues in the LSF system.

By default, bacct displays statistics for all jobs logged in the current LSF accounting log file: LSB_SHAREDIR/cluster_name/logdir/lsb.acct.

By default, CPU time is not normalized.

If neither -1 nor -b is present, displays the fields in SUMMARY only.

Statistics not reported by bacct but of interest to individual system administrators can be generated by directly using awk or perl to process the lsb.acct file.

All times are in seconds.

Throughput Calculation

The throughput (T) of the LSF system, certain hosts, or certain queues is calculated by the formula:

```
T = N/(ET-BT)
```

where:

- N is the total number of jobs for which accounting statistics are reported
- BT is the Start time—when the first job was logged
- ET is the End time—when the last job was logged

You can use the option - C time0, time1 to specify the Start time as time0 and the End time as time1. In this way, you can examine throughput during a specific time period.

Jobs involved in the throughput calculation are only those being logged (that is, with a DONE or EXIT status). Jobs that are running, suspended, or that have never been dispatched after submission are not considered, because they are still in the LSF system and not logged in 1sb.acct.

The total throughput of the LSF system can be calculated by specifying -u all without any of the -m, -q, -S, -D or job ID options. The throughput of certain hosts can be calculated by specifying -u all without the -q, -S, -D or *job_ID* options. The throughput of certain queues can be calculated by specifying -u all without the -m, -S, -D or job_ID options.

bacct does not show local pending batch jobs killed using bkill -b. bacct shows MultiCluster jobs and local running jobs even if they are killed using bkill -b.

Options

- -b Brief format. Displays accounting statistics in brief format. See Output for a description of information that is displayed.
- -d Displays accounting statistics for successfully completed jobs (with a DONE status).
- **-e** Displays accounting statistics for exited jobs (with an EXIT status).
- -I Long format. Displays additional accounting statistics. See Output for a description of information that is displayed.
- -w Wide format. Displays accounting statistics in a wide format without truncating the
- -x Displays jobs that have triggered a job exception (overrun, underrun, idle). Use with the -1 option to show the exception status for individual jobs.

-app application profile name

Displays accounting information about jobs submitted to the specified application profile. You must specify an existing application profile configured in 1sb.applications.

-C time0,time1

Displays accounting statistics for jobs that completed or exited during the specified time interval. Reads 1sb.acct and all archived log files (1sb.acct.n) unless -f is also used.

The time format is the same as in bhist(1).

-D time0,time1

Displays accounting statistics for jobs dispatched during the specified time interval. Reads 1sb.acct and all archived log files (1sb.acct.n) unless -f is also used.

The time format is the same as in bhist(1).

-f logfile_name

Searches the specified job log file for accounting statistics. Specify either an absolute or relative path.

Useful for offline analysis.

The specified file path can contain up to 4094 characters for UNIX, or up to 255 characters for Windows.

-Lp ls_project_name ...

Displays accounting statistics for jobs belonging to the specified License Scheduler projects. If a list of projects is specified, project names must be separated by spaces and enclosed in quotation marks (") or (').

-M host_list_file Displays accounting statistics for jobs dispatched to the hosts listed in a file (host_list_file) containing a list of hosts. The host list file has the following format:

Multiple lines are supported

- Each line includes a list of hosts separated by spaces
- The length of each line must be less than 512 characters

If you also specify a host list in a file with -m host_name ..., the last option specified takes effect.

-m host_name ... Displays accounting statistics for jobs dispatched to the specified hosts.

If a list of hosts is specified, host names must be separated by spaces and enclosed in quotation marks (") or (').

If you also specify a host list in a file with -M host_list_file, the last option specified takes effect.

-N host_name | -N host_model | -N cpu_factor

Normalizes CPU time by the CPU factor of the specified host or host model, or by the specified CPU factor.

If you use bacct offline by indicating a job log file, you must specify a CPU factor. Use 1sinfo to get host model and CPU factor information.

-P project_name ...

Displays accounting statistics for jobs belonging to the specified projects. If a list of projects is specified, project names must be separated by spaces and enclosed in quotation marks (") or (').

-q queue_name ...

Displays accounting statistics for jobs submitted to the specified queues.

If a list of queues is specified, queue names must be separated by spaces and enclosed in quotation marks (") or (').

-S time0,time1 Displays accounting statistics for jobs submitted during the specified time interval. Reads 1sb.acct and all archived log files (1sb.acct.n) unless -f is also used.

The time format is the same as in bhist(1).

-sla service_class_name

Displays accounting statistics for jobs that ran under the specified service class.

Run bsla to display the properties of service classes configured in LSB_CONFDIR/cluster_name/configdir/lsb.serviceclasses and dynamic information about the state of each service class.

If a default system service class is configured with ENABLE DEFAULT EGO SLA in 1sb.params but not explicity configured in 1sb.applications, bacct -sla service_class_name displays accounting information for the specified default service class.

-U reservation_id ... | -U all

Displays accounting statistics for the specified advance reservation IDs, or for all reservation IDs if the keyword all is specified.

A list of reservation IDs must be separated by spaces and enclosed in quotation marks (") or (').

When combined with the -U option, -u is interpreted as the user name of the reservation creator. For example:

bacct -U all -u user2

shows all the advance reservations created by user user 2.

Without the -u option, bacct -U shows all advance reservation information about jobs submitted by the user.

In a MultiCluster environment, advance reservation information is only logged in the execution cluster, so bacct displays advance reservation information for local reservations only. You cannot see information about remote reservations. You cannot specify a remote reservation ID, and the keyword all only displays information about reservations in the local cluster.

-u user_name ...|-u all

Displays accounting statistics for jobs submitted by the specified users, or by all users if the keyword all is specified.

If a list of users is specified, user names must be separated by spaces and enclosed in quotation marks (") or ('). You can specify both user names and user IDs in the list of users.

job_ID ... Displays accounting statistics for jobs with the specified job IDs.

> This option overrides all other options except -b, -1, -f, -h, and -V. If the reserved job ID 0 is used, it will be ignored.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

Summary (default format)

Statistics on jobs. The following fields are displayed:

- Total number of done jobs
- Total number of exited jobs
- Total CPU time consumed
- Average CPU time consumed
- Maximum CPU time of a job
- Minimum CPU time of a job
- Total wait time in queues
- Average wait time in queue
- Maximum wait time in queue
- Minimum wait time in queue
- Average turnaround time (seconds/job)
- Maximum turnaround time
- Minimum turnaround time
- Average hog factor of a job (cpu time/turnaround time)
- Maximum hog factor of a job
- Minimum hog factor of a job
- Total throughput
- Beginning time: the completion or exit time of the first job selected
- Ending time: the completion or exit time of the last job selected

The total, average, minimum, and maximum statistics are on all specified jobs.

The wait time is the elapsed time from job submission to job dispatch.

The turnaround time is the elapsed time from job submission to job completion.

The hog factor is the amount of CPU time consumed by a job divided by its

turnaround time.

The throughput is the number of completed jobs divided by the time period to

finish these jobs (jobs/hour).

Brief Format (-b)

In addition to the default format SUMMARY, displays the following fields:

U/UID Name of the user who submitted the job. If LSF fails to get the user name by

getpwuid(3), the user ID is displayed.

OUEUE Queue to which the job was submitted.

SUBMIT TIME Time when the job was submitted.

CPU_T CPU time consumed by the job.

WAIT Wait time of the job.

TURNAROUND Turnaround time of the job.

FROM Host from which the job was submitted.

EXEC ON Host or hosts to which the job was dispatched to run.

The job name assigned by the user, or the command string assigned by default at JOB NAME

job submission with bsub. If the job name is too long to fit in this field, then only

the latter part of the job name is displayed.

The displayed job name or job command can contain up to 4094 characters for

UNIX, or up to 255 characters for Windows.

Long Format (-I)

In addition to the fields displayed by default in SUMMARY and by -b, displays the

following fields:

JOBID Identifier that LSF assigned to the job.

PROJECT NAME Project name assigned to the job.

STATUS Status that indicates the job was either successfully completed (DONE) or exited

(EXIT).

DISPAT_TIME Time when the job was dispatched to run on the execution hosts.

COMPL_TIME Time when the job exited or completed.

HOG_FACTOR Average hog factor, equal to "CPU time" / "turnaround time". Output

MEM Maximum resident memory usage of all processes in a job. By default, memory

usage is shown in MB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a

larger unit for display (MB, GB, TB, PB, or EB).

SWAP Maximum virtual memory usage of all processes in a job. By default, swap space is

shown in MB. Use LSF UNIT FOR LIMITS in 1sf.conf to specify a larger unit

for display (MB, GB, TB, PB, or EB).

CWD Current working directory of the job.

INPUT FILE File from which the job reads its standard input (see bsub -i input_file).

OUTPUT FILE File to which the job writes its standard output (see bsub -o output_file).

ERR FILE File in which the job stores its standard error output (see bsub -e err_file).

EXCEPTION STATUS Possible values for the exception status of a job include:

The job is consuming less CPU time than expected. The job idle factor

(CPU time/runtime) is less than the configured JOB_IDLE threshold for the queue

and a job exception has been triggered.

overrun

The job is running longer than the number of minutes specified by the

JOB_OVERRUN threshold for the queue and a job exception has been triggered.

underrun

The job finished sooner than the number of minutes specified by the

JOB_UNDERRUN threshold for the queue and a job exception has been triggered.

Advance Reservations (-U)

Displays the following fields:

RSVID Advance reservation ID assigned by brsvadd command

TYPE Type of reservation: user or system

CREATOR User name of the advance reservation creator, who submitted the brs vadd

command

USER User name of the advance reservation user, who submitted the job with bsub -U

NCPUS Number of CPUs reserved

RSV HOSTS List of hosts for which processors are reserved, and the number of processors

reserved

Time window for the reservation. TIME WINDOW

A one-time reservation displays fields separated by slashes (month/day/hour/minute). For example:

11/12/14/0-11/12/18/0

A recurring reservation displays fields separated by colons (day:hour:minute). For example:

5:18:0 5:20:0

Termination reasons displayed by bacct

When LSF detects that a job is terminated, bacct -1 displays one of the following termination reasons. The corresponding integer value logged to the JOB_FINISH record in 1sb.acct is given in parentheses.

- TERM ADMIN: Job killed by root or LSF administrator (15)
- TERM BUCKET KILL: Job killed with bkill -b (23)
- TERM_CHKPNT: Job killed after checkpointing (13)
- TERM_CWD_NOTEXIST: current working directory is not accessible or does not exist on the execution host (25)
- TERM_CPULIMIT: Job killed after reaching LSF CPU usage limit (12)
- TERM_DEADLINE: Job killed after deadline expires (6)
- TERM_EXTERNAL_SIGNAL: Job killed by a signal external to LSF (17)
- TERM FORCE ADMIN: Job killed by root or LSF administrator without time for cleanup (9)
- TERM_FORCE_OWNER: Job killed by owner without time for cleanup (8)
- TERM_LOAD: Job killed after load exceeds threshold (3)
- TERM_MEMLIMIT: Job killed after reaching LSF memory usage limit (16)
- TERM_OWNER: Job killed by owner (14)
- TERM_PREEMPT: Job killed after preemption (1)
- TERM_PROCESSLIMIT: Job killed after reaching LSF process limit (7)
- TERM REQUEUE ADMIN: Job killed and requeued by root or LSF administrator (11)
- TERM_REQUEUE_OWNER: Job killed and requeued by owner (10)
- TERM_RUNLIMIT: Job killed after reaching LSF run time limit (5)
- TERM_SLURM: Job terminated abnormally in SLURM (node failure) (22)
- TERM_SWAP: Job killed after reaching LSF swap usage limit (20)
- TERM_THREADLIMIT: Job killed after reaching LSF thread limit (21)
- TERM_UNKNOWN: LSF cannot determine a termination reason—0 is logged but TERM_UNKNOWN is not displayed (0)
- TERM_WINDOW: Job killed after queue run window closed (2)

TERM_ZOMBIE: Job exited while LSF is not available (19)

TIP: The integer values logged to the JOB_FINISH record in $\ensuremath{\mbox{\sc t}}$ and termination reason keywords are mapped in 1 sbatch.h.

Examples

Default format

bacct

```
Accounting information about jobs that are:
 - submitted by users user1.
  - accounted on all projects.
 - completed normally or exited.
  - executed on all hosts.
  - submitted to all queues.
  - accounted on all service classes.
SUMMARY: (time unit: second)
Total number of done jobs: 60 Total number of exited jobs: Total CPU time consumed: 1011.5 Average CPU time consumed: Maximum CPU time of a job: 991.4 Minimum CPU time of a job:
                                          Total number of exited jobs: 118
                                                                           5.7
                                                                           0.0

Total duration time: 0 hour 2 minute 0 second
```

LSF Job termination reason logging

When a job finishes, LSF reports the last job termination action it took against the job and logs it into 1sb.acct.

If a running job exits because of node failure, LSF sets the correct exit information in 1sb.acct, 1sb.events, and the job output file.

Use bacct -1 to view job exit information logged to 1sb.acct:

bacct -1 7265

```
Accounting information about jobs that are:

bapp

displays information about application profile configuration

Synopsis

```
bapp [-1 | -w] [application_profile_name ...]
bapp [-h | -V]
```

Description

Displays information about application profiles configured in lsb.applications.

By default, returns the following information about all application profiles: application name, job slot statistics, and job state statistics.

In MultiCluster, returns the information about all application profiless in the local cluster.

Application profile names and attributes are set up by the LSF administrator.

See 1sb.applications for more information about application profile parameters displayed by bapp.

CPU time is normalized.

Options

- -w Displays application profile information in a wide format. Fields are displayed without truncation.
- -I Displays application profile information in a long multiline format. The -1 option displays the following additional information: application profile description, application profile characteristics and statistics, parameters, resource usage limits, associated commands, and job controls.

application_profile_name ...

Displays information about the specified application profiles.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

Default Output

Displays the following fields:

APPLICATION_NAME

The name of the application profile. Application profiles are named to correspond to the type of application that usually runs within them.

Output

NJOBS The total number of job slots held currently by jobs in the application profile. This

includes pending, running, suspended and reserved job slots. A parallel job that is running on n processors is counted as n job slots, since it takes n job slots in the

application. See bjobs(1) for an explanation of batch job states.

PEND The number of job slots used by pending jobs in the application profile.

RUN The number of job slots used by running jobs in the application profile.

SUSP The number of job slots used by suspended jobs in the application profile.

Long Output (-I)

In addition to the above fields, the -1 option displays the following:

Description A description of the typical use of the application profile.

PARAMETERS/ **STATISTICS**

SSUSP

The number of job slots in the application profile allocated to jobs that are suspended by LSF because of load levels or run windows.

USUSP

The number of job slots in the application profile allocated to jobs that are suspended by the job submitter or by the LSF administrator.

RSV

The number of job slots in the application profile that are reserved by LSF for pending jobs.

Per-job resource usage limits

The soft resource usage limits that are imposed on the jobs associated with the application profile. These limits are imposed on a per-job and a per-process basis.

The possible per-job limits are:

CPULIMIT

The maximum CPU time a job can use, in minutes, relative to the CPU factor of the named host. CPULIMIT is scaled by the CPU factor of the execution host so that jobs are allowed more time on slower hosts.

When the job-level CPULIMIT is reached, a SIGXCPU signal is sent to all processes belonging to the job. If the job has no signal handler for SIGXCPU, the job is killed immediately. If the SIGXCPU signal is handled, blocked, or ignored by the application, then after the grace period expires, LSF sends SIGINT, SIGTERM, and SIGKILL to the job to kill it.

MEMLIMIT

The maximum running set size (RSS) of a process. If a process uses more memory than the limit allows, its priority is reduced so that other processes are more likely to be paged in to available memory. This limit is enforced by the setrlimit system call if it supports the RLIMIT_RSS option.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

PROCESSLIMIT

The maximum number of concurrent processes allocated to a job. If PROCESSLIMIT is reached, the system sends the following signals in sequence to all processes belonging to the job: SIGINT, SIGTERM, and SIGKILL.

PROCLIMIT

The maximum number of processors allocated to a job. Jobs that request fewer slots than the minimum PROCLIMIT or more slots than the maximum PROCLIMIT are rejected. If the job requests minimum and maximum job slots, the maximum slots requested cannot be less than the minimum PROCLIMIT, and the minimum slots requested cannot be more than the maximum PROCLIMIT.

SWAPLIMIT

The swap space limit that a job may use. If SWAPLIMIT is reached, the system sends the following signals in sequence to all processes in the job: SIGINT, SIGTERM, and SIGKILL.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

THREADLIMIT

The maximum number of concurrent threads allocated to a job. If THREADLIMIT is reached, the system sends the following signals in sequence to all processes belonging to the job: SIGINT, SIGTERM, and SIGKILL.

Per-job resource usage limits

The possible UNIX per-process resource limits are:

CORELIMIT The maximum size of a core file. This limit is enforced by the setrlimit system call if it supports the RLIMIT_CORE option.

> If a job submitted to the application profile has any of these limits specified (see bsub(1)), then the lower of the corresponding job limits and application profile limits are used for the job.

If no resource limit is specified, the resource is assumed to be unlimited.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

DATALIMIT

The maximum size of the data segment of a process, in KB. This restricts the amount of memory a process can allocate. DATALIMIT is enforced by the setrlimit system call if it supports the RLIMIT_DATA option, and unsupported otherwise.

FILELIMIT The maximum file size a process can create, in KB. This limit is enforced by the UNIX setrlimit system call if it supports the RLIMIT_FSIZE option, or the ulimit system call if it supports the UL_SETFSIZE option.

RUNLIMIT The maximum wall clock time a process can use, in minutes. RUNLIMIT is scaled by the CPU factor of the execution host. When a job has been in the RUN state for a total of RUNLIMIT minutes, LSF sends a SIGUSR2 signal to the job. If the job does not exit within 5 minutes, LSF sends a SIGKILL signal to kill the job.

STACKLIMIT The maximum size of the stack segment of a process. This restricts the amount of

memory a process can use for local variables or recursive function calls. STACKLIMIT is enforced by the setrlimit system call if it supports the

RLIMIT_STACK option.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to

specify a larger unit for display (MB, GB, TB, PB, or EB).

PRE_EXEC The PRE_EXEC command runs on the execution host before the job associated with

the application profile is dispatched to the execution host (or to the first host

selected for a parallel batch job).

POST_EXEC The post-execution command for the application profile. The POST_EXEC

command runs on the execution host after the job finishes.

JOB_INCLUDE_POSTPROC

If JOB_INCLUDE_POSTPROC= Y, post-execution processing of the job is included as

part of the job.

JOB POSTPROC TIMEOUT

Timeout in minutes for job post-execution processing. If post-execution processing takes longer than the timeout, shatchd reports that post-execution has failed (POST_ERR status), and kills the process group of the job's post-execution

processes.

REQUEUE_EXIT_VALUES

Jobs that exit with these values are automatically requeued.

RES REQ Resource requirements of the application profile. Only the hosts that satisfy these

resource requirements can be used by the application profile.

JOB STARTER An executable file that runs immediately prior to the batch job, taking the batch job

> file as an input argument. All jobs submitted to the application profile are run via the job starter, which is generally used to create a specific execution environment

before processing the jobs themselves.

CHUNK_JOB_SIZE Chunk jobs only. Specifies the maximum number of jobs allowed to be dispatched

> together in a chunk job. All of the jobs in the chunk are scheduled and dispatched as a unit rather than individually. The ideal candidates for job chunking are jobs

that typically takes 1 to 2 minutes to run.

RERUNNABLE If the RERUNNABLE field displays yes, jobs in the application profile are

> rerunnable. That is, jobs in the application profile are automatically restarted or rerun if the execution host becomes unavailable. However, a job in the application profile will not be restarted if you use bmod to remove the rerunnable option from

the job.

RESUME CONTROL

The configured actions for the resume job control. See RESUME_CONTROL

parameter in 1sb.applications.

The configured actions are displayed in the format [action_type, command] where action_type is RESUME.

SUSPEND_CONTROL

The configured actions for the suspend job control. See SUSPEND_CONTROL parameter in lsb.applications.

The configured actions are displayed in the format [action_type, command] where *action_type* is SUSPEND.

TERMINATE_CONTROL

The configured actions for terminate job control. See TERMINATE_CONTROL parameter in lsb.applications.

The configured actions are displayed in the format [action_type, command] where action_type is TERMINATE.

badmin

administrative tool for LSF

Synopsis

```
badmin subcommand
badmin [-h | -V]
```

Description

CAUTION: This command can only be used by LSF administrators.

badmin provides a set of commands to control and monitor LSF. If no subcommands are supplied for badmin, badmin prompts for a command from standard input.

Information about each command is available through the help command.

The badmin commands consist of a set of privileged commands and a set of non-privileged commands. Privileged commands can only be invoked by root or LSF administrators as defined in the configuration file (see

lsf.cluster.cluster(5) for ClusterAdmin). Privileged commands are:

reconfig mbdrestart qopen gclose gact

qinact

hopen

hclose

hrestart hshutdown

hstartup

diagnose

The configuration file lsf.sudoers(5) has to be set in order to use the privileged command hstartup by a non-root user.

All other commands are non-privileged commands and can be invoked by any LSF user. If the privileged commands are to be executed by the LSF administrator, badmin must be installed, because it needs to send the request using a privileged port.

For subcommands for which multiple hosts can be specified, do not enclose the host names in quotation marks.

Subcommand List

ckconfig [-v]

```
diagnose [job_ID ... | "job_ID[index]" ...]
reconfig [-v] [-f]
mbdrestart [-C comment] [-v] [-f]
qopen [-C comment] [queue_name ... | all]

gact [-C comment] [queue name ... | all]
qinact [-C comment] [queue_name ... | all]
qhist [-t time0, time1] [-f logfile_name] [queue_name ...]
hopen [-C comment] [host_name ... | host_group ... | all]
hclose [-C comment] [host_name ... | host_group ... | all]
hrestart [-f] [host_name ... | all]
hshutdown [-f] [host_name ... | all]
hstartup [-f] [host_name ... | all]
hhist [-t time0, time1] [-f logfile_name] [host_name ...]
mbdhist [-t time0, time1] [-f logfile_name]
hist [-t time0, time1] [-f logfile_name]
hghostadd [-C comment] host_group host_name [host_name ...]
hghostdel [-f] [-C comment] host_group host_name [host_name ...]
help [command ...] | ? [command ...]
quit
mbddebug [-c class_name ...] [-1 debug_level] [-f logfile_name] [-o]
mbdtime [-l timing_level] [-f logfile_name] [-o]
sbddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o]
   [host_name ...]
sbdtime [-1 timing_level] [-f logfile_name] [-o] [host_name ...]
schddebug [-c class_name ...] [-l debug_level] [-f logfile_name]
   [ - o ]
schdtime [-l timing_level] [-f logfile_name] [-o]
showconf mbd | [sbd [ host_name ... | all ]]
perfmon start [sample_period] | stop | view | setperiod sample_period
-h
- V
```

Options

subcommand Executes the specified subcommand. See Usage section.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Usage

ckconfig [-v] Checks LSF configuration files located in the

LSB_CONFDIR/cluster_name/configdir directory. Also checks configuration in LSF_ENVDIR/lsf.licensescheduler.

The LSB_CONFDIR variable is defined in 1sf.conf (see 1sf.conf(5)) which is in LSF_ENVDIR or /etc (if LSF_ENVDIR is not defined).

By default, badmin ckconfig displays only the result of the configuration file check. If warning errors are found, badmin prompts you to display detailed messages.

-V

Verbose mode. Displays detailed messages about configuration file checking to

diagnose [job_ID ... | "job_ID]" ...][

Displays full pending reason list if CONDENSE_PENDING_REASONS=Y is set in 1sb.params. For example:

badmin diagnose 1057

reconfig [-v] [-f] Dynamically reconfigures LSF without restarting mbatchd.

Configuration files are checked for errors and the results displayed to stderr. If no errors are found in the configuration files, a reconfiguration request is sent to mbatchd and configuration files are reloaded.

With this option, mbatchd and mbschd are not restarted and 1sb.events is not replayed. To restart mbatchd and mbschd, and replay 1sb.events, use badmin mbdrestart.

When you issue this command, mbatchd is available to service requests while reconfiguration files are reloaded. Configuration changes made since system boot or the last reconfiguration take effect.

If warning errors are found, badmin prompts you to display detailed messages. If fatal errors are found, reconfiguration is not performed, and badmin exits.

If you add a host to a queue, the new host will not be recognized by jobs that were submitted before you reconfigured. If you want the new host to be recognized, you must use the command badmin mbdrestart.

If you add a host to a host group, the new host will not be recognized by jobs that were submitted before you reconfigured. If you want the new host to be recognized, you must use the command badmin mbdrestart.

Resource requirements determined by the queue no longer apply to a running job after running badmin reconfig, For example, if you change the RES_REQ parameter in a queue and reconfigure the cluster, the previous queue-level resource requirements for running jobs are lost.

-V

Verbose mode. Displays detailed messages about the status of the configuration files. Without this option, the default is to display the results of configuration file checking. All messages from the configuration file check are printed to stderr.

-f

Disables interaction and proceeds with reconfiguration if configuration files contain no fatal errors.

mbdrestart [-C comment] [-v] [-f]

Dynamically reconfigures LSF and restarts mbatchd and mbschd.

Configuration files are checked for errors and the results printed to stderr. If no errors are found, configuration files are reloaded, mbatchd and mbschd are restarted, and events in 1sb. events are replayed to recover the running state of the last mbatchd. While mbatchd restarts, it is unavailable to service requests.

If warning errors are found, badmin prompts you to display detailed messages. If fatal errors are found, mbatchd and mbschd restart is not performed, and badmin

If 1sb.events is large, or many jobs are running, restarting mbatchd can take several minutes. If you only need to reload the configuration files, use badmin reconfig.

-C comment

Logs the text of comment as an administrator comment record to lsb.events. The maximum length of the comment string is 512 characters.

Verbose mode. Displays detailed messages about the status of configuration files. All messages from configuration checking are printed to stderr.

-f

Disables interaction and forces reconfiguration and mbatchd restart to proceed if configuration files contain no fatal errors.

qopen [-C comment] [queue_name ... | all]

Opens specified queues, or all queues if the reserved word all is specified. If no queue is specified, the system default queue is assumed (see 1sb. queues (5) for DEFAULT_QUEUE). A queue can accept batch jobs only if it is open.

-C comment

Logs the text of comment as an administrator comment record to 1sb.events. The maximum length of the comment string is 512 characters.

qclose [-C comment] [queue_name ... | all]

Closes specified queues, or all queues if the reserved word all is specified. If no queue is specified, the system default queue is assumed. A queue will not accept any job if it is closed.

-C comment

Logs the text of

as an administrator comment record to 1sb.events. The maximum length of the comment string is 512 characters.

qact [-C comment] [queue_name ... | all]

Activates specified queues, or all queues if the reserved word all is specified. If no queue is specified, the system default queue is assumed. Jobs in a queue can be dispatched if the queue is activated.

A queue inactivated by its run windows cannot be reactivated by this command (see 1sb.gueues(5) for RUN WINDOW).

-C comment

Logs the text of comment as an administrator comment record to lsb.events. The maximum length of the comment string is 512 characters.

qinact [-C comment] [queue_name ... | all]

Inactivates specified queues, or all queues if the reserved word all is specified. If no queue is specified, the system default queue is assumed. No job in a queue can be dispatched if the queue is inactivated.

-C comment

Logs the text of comment as an administrator comment record to lsb.events. The maximum length of the comment string is 512 characters.

qhist [-t time0,time1] [-f logfile_name] [queue_name ...]

Displays historical events for specified queues, or for all queues if no queue is specified. Queue events are queue opening, closing, activating and inactivating.

-t time0,time1

Displays only those events that occurred during the period from time0 to time1. See bhist(1) for the time format. The default is to display all queue events in the event log file (see below).

-f logfile_name

Specify the file name of the event log file. Either an absolute or a relative path name may be specified. The default is to use the event log file currently used by the LSF system: LSB_SHAREDIR/cluster_name/logdir/lsb.events. Option -f is useful for offline analysis.

If you specified an administrator comment with the -C option of the queue control commands gclose, gopen, gact, and ginact, ghist displays the comment text.

hopen [-C comment] [host_name ... | host_group ... | all]

Opens batch server hosts. Specify the names of any server hosts or host groups (see bmgroup). All batch server hosts will be opened if the reserved word all is specified. If no host or host group is specified, the local host is assumed. A host accepts batch jobs if it is open.

IMPORTANT: If EGO-enabled SLA scheduling is configured through ENABLE_DEFAULT_EGO_SLA in 1sb.params, and a host is closed by EGO, it cannot be reopened by badmin hopen. Hosts closed by EGO have status closed_EGO in bhosts -loutput.

-C comment

Logs the text of comment as an administrator comment record to lsb.events. The maximum length of the comment string is 512 characters. If you open a host group, each host group member displays with the same comment string.

hclose [-C comment] [host_name ... | host_group ... | all]

Closes batch server hosts. Specify the names of any server hosts or host groups (see bmgroup). All batch server hosts will be closed if the reserved word all is specified. If no argument is specified, the local host is assumed. A closed host will not accept

any new job, but jobs already dispatched to the host will not be affected. Note that this is different from a host closed by a window; all jobs on it are suspended in that case.

-C comment

Logs the text of comment as an administrator comment record to lsb.events. The maximum length of the comment string is 512 characters. If you close a host group, each host group member displays with the same comment string.

hghostadd [-C comment] host_group host_name [host_name ...]

Dynamically adds hosts to a host group. After receiving the host information from the master LIM, mbatchd dynamically adds the host without triggering a reconfig.

Once the host is added to the group, it will be considered to be part of that group with respect to scheduling decision making for both newly submitted jobs and for existing pending jobs.

This command fails if any of the specified host groups or host names are not valid.

To enable dynamic host configuration, define LSF_MASTER_LIST and LSF_DYNAMIC_HOST_WAIT_TIME in 1sf.conf and LSF_HOST_ADDR_RANGE in lsf.cluster.cluster_name.

RESTRICTION: If EGO-enabled SLA scheduling is configured through ENABLE_DEFAULT_EGO_SLA in 1sb.params, you cannot use hghostadd because all host allocation is under control of Platform EGO.

-C comment

Logs the text of *comment* as an administrator comment record to 1sb.events. The maximum length of the comment string is 512 characters.

hghostdel [-f] [-C comment] host_group host_name [host_name ...]

Dynamically deletes hosts from a host group by triggering an mbatchd reconfig This command fails if any of the specified host groups or host names are not valid.

CAUTION: If you want to change a dynamic host to a static host, first use the command badmin hghostdel to remove the dynamic host from any host group that it belongs to, and then configure the host as a static host in lsf.cluster.cluster_name.

RESTRICTION: If EGO-enabled SLA scheduling is configured through ENABLE_DEFAULT_EGO_SLA in 1sb.params, you cannot use highost del because all host allocation is under control of Platform EGO.

hrestart [-f] [host name ... | all]

Restarts shatchd on the specified hosts, or on all server hosts if the reserved word all is specified. If no host is specified, the local host is assumed. Shatchd will rerun itself from the beginning. This allows new shatchd binaries to be used.

-f

Disables interaction and does not ask for confirmation for restarting shatchd.

hshutdown [-f] [host_name ... | all]

Shuts down shatchd on the specified hosts, or on all batch server hosts if the reserved word all is specified. If no host is specified, the local host is assumed. sbatchd will exit upon receiving the request.

-f

Disables interaction and does not ask for confirmation for shutting down shatchd.

hstartup [-f] [host_name ... | all]

Starts shatchd on the specified hosts, or on all batch server hosts if the reserved word all is specified. Only root and users listed in the file lsf.sudoers(5) can use the all and -f options. These users must be able to use rsh or ssh on all LSF hosts without having to type in passwords. If no host is specified, the local host is assumed.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

-f

Disables interaction and does not ask for confirmation for starting shatchd.

hhist [-t time0,time1] [-f logfile_name] [host_name ...]

Displays historical events for specified hosts, or for all hosts if no host is specified. Host events are host opening and closing. Options -t and -f are exactly the same as those of ghist (see above).

If you specified an administrator comment with the -C option of the host control commands holose or hopen, hhist displays the comment text.

mbdhist [-t time0,time1] [-f logfile_name]

Displays historical events for mbatchd. Events describe the starting and exiting of mbatchd. Options -t and -f are exactly the same as those of qhist (see above).

If you specified an administrator comment with the -C option of the mbdrestart command, mbdhist displays the comment text.

hist [-t time0,time1] [-f logfile_name]

Displays historical events for all the queues, hosts and mbatchd. Options -t and -f are exactly the same as those of qhist (see above).

If you specified an administrator comment with the -C option of the queue, host, and mbatchd commands, hist displays the comment text.

help [command ...] | ? [command ...]

Displays the syntax and functionality of the specified commands.

quit Exits the badmin session.

mbddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o]

Sets message log level for mbatchd to include additional information in log files. You must be root or the LSF administrator to use this command.

See shddebug for an explanation of options.

mbdtime [-I timing_level] [-f logfile_name] [-o]

Sets timing level for mbatchd to include additional timing information in log files. You must be root or the LSF administrator to use this command. See shdtime for an explanation of options.

sbddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o] [host_name ...]

Sets the message log level for spatchd to include additional information in log files. You must be root or the LSF administrator to use this command.

In MultiCluster, debug levels can only be set for hosts within the same cluster. For example, you could not set debug or timing levels from a host in clusterA for a host in clusterB. You need to be on a host in clusterB to set up debug or timing levels for clusterB hosts.

If the command is used without any options, the following default values are used: class_name=0 (no additional classes are logged)

debug_level=0 (LOG_DEBUG level in parameter LSF_LOG_MASK)

logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name

host name=local host (host from which command was submitted)

-c class name ...

Specifies software classes for which debug messages are to be logged.

Format of *class name* is the name of a class, or a list of class names separated by spaces and enclosed in quotation marks. Classes are also listed in 1sf.h.

Valid log classes are:

- ◆ LC AFS Log AFS messages
- LC_AUTH Log authentication messages
- LC_CHKPNT Log checkpointing messages
- LC COMM Log communication messages
- ◆ LC_CONF Print out all parameters in 1sb.params
- LC_DCE Log messages pertaining to DCE support
- ◆ LC_EEVENTD Log eeventd messages
- LC_ELIM Log ELIM messages
- ◆ LC_EXEC Log significant steps for job execution
- LC_FAIR Log fairshare policy messages
- LC_FILE Log file transfer messages
- LC_HANG Mark where a program might hang
- LC_JARRAY Log job array messages
- LC_JLIMIT Log job slot limit messages
- ◆ LC LICENSE Log license management messages (LC LICENCE is also supported for backward compatibility)
- LC_LOADINDX Log load index messages
- LC_M_LOG Log multievent logging messages
- LC_MPI Log MPI messages
- LC_MULTI Log messages pertaining to MultiCluster
- LC_PEND Log messages related to job pending reasons
- LC_PERFM Log performance messages

- LC_PIM Log PIM messages
- LC_PREEMPT Log preemption policy messages
- LC_SIGNAL Log messages pertaining to signals
- LC_SYS Log system call messages
- LC_TRACE Log significant program walk steps
- LC_XDR Log everything transferred by XDR

Default: 0 (no additional classes are logged)

-l debug_level

Specifies level of detail in debug messages. The higher the number, the more detail that is logged. Higher levels include all lower levels.

Possible values:

O LOG_DEBUG level in parameter LSF_LOG_MASK in 1sf.conf.

1 LOG_DEBUG1 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2 LOG_DEBUG1, and LOG_DEBUG levels.

2 LOG_DEBUG2 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2 LOG_DEBUG1, and LOG DEBUG levels.

3 LOG_DEBUG3 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2, LOG_DEBUG1, and LOG DEBUG levels.

Default: 0 (LOG_DEBUG level in parameter LSF_LOG_MASK)

-f logfile_name

Specify the name of the file into which debugging messages are to be logged. A file name with or without a full path may be specified.

If a file name without a path is specified, the file will be saved in the LSF system log directory.

The name of the file that will be created will have the following format:

logfile name.daemon name.log.host name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, if the specified path is not valid, no log file is created.

Default: current LSF system log file in the LSF system log file directory.

Turns off temporary debug settings and resets them to the daemon starting state. The message log level is reset back to the value of LSF_LOG_MASK and classes are reset to the value of LSB_DEBUG_MBD, LSB_DEBUG_SBD.

The log file is also reset back to the default log file.

host name ...

Optional. Sets debug settings on the specified host or hosts.

Lists of host names must be separated by spaces and enclosed in quotation marks.

Default: local host (host from which command was submitted)

sbdtime [-I timing_level] [-f logfile_name] [-o] [host_name ...]

Sets the timing level for shatchd to include additional timing information in log files. You must be root or the LSF administrator to use this command.

In MultiCluster, timing levels can only be set for hosts within the same cluster. For example, you could not set debug or timing levels from a host in cluster A for a host in clusterB. You need to be on a host in clusterB to set up debug or timing levels for clusterB hosts.

If the command is used without any options, the following default values are used: timing_level=no timing information is recorded

logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon name.log.host name

host name=local host (host from which command was submitted)

-l timing_level

Specifies detail of timing information that is included in log files. Timing messages indicate the execution time of functions in the software and are logged in milliseconds.

Valid values: 1 | 2 | 3 | 4 | 5

The higher the number, the more functions in the software that are timed and whose execution time is logged. The lower numbers include more common software functions. Higher levels include all lower levels.

Default: undefined (no timing information is logged)

-f logfile_name

Specify the name of the file into which timing messages are to be logged. A file name with or without a full path may be specified.

If a file name without a path is specified, the file will be saved in the LSF system log file directory.

The name of the file created has the following format:

logfile_name.daemon_name.log.host_name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, if the specified path is not valid, no log file is created.

Note: Both timing and debug messages are logged in the same files.

Default: current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name.

Optional. Turn off temporary timing settings and reset them to the daemon starting state. The timing level is reset back to the value of the parameter for the corresponding daemon (LSB_TIME_MBD, LSB_TIME_SBD).

The log file is also reset back to the default log file.

host name ...

Sets the timing level on the specified host or hosts.

Lists of hosts must be separated by spaces and enclosed in quotation marks.

Default: local host (host from which command was submitted)

schddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o]

Sets message log level for mbschd to include additional information in log files. You must be root or the LSF administrator to use this command.

See sbddebug for an explanation of options.

schdtime [-l timing_level] [-f] [-o]

Sets timing level for mbschd to include additional timing information in log files. You must be root or the LSF administrator to use this command.

See shdtime for an explanation of options.

showconf mbd | [sbd [host_name ... | all]]

Display all configured parameters and their values set in lsf.conf or ego.conf that affect mbatchd and sbatchd.

In a MultiCluster environment, badmin showconf only displays the parameters of daemons on the local cluster.

Running badmin showconf from a master candidate host will reach all server hosts in the cluster. Running badmin showconf from a slave-only host may not be able to reach other slave-only hosts.

badmin showconf only displays the values used by LSF.

For example, if you define LSF_MASTER_LIST in 1sf.conf, and EGO_MASTER_LIST in ego.conf, badmin showconf displays the value of EGO_MASTER_LIST.

badmin showconf displays the value of EGO_MASTER_LIST from wherever it is defined. You can define either LSF_MASTER_LIST or EGO_MASTER_LIST in 1sf.conf. LIM reads 1sf.conf first, and ego.conf if EGO is enabled in the LSF cluster. The value of LSF_MASTER_LIST is displayed only if EGO_MASTER_LIST is not defined at all in ego.conf.

For example, if EGO is enabled in the LSF cluster, and you define LSF MASTER LIST in 1sf.conf, and EGO MASTER LIST in eqo.conf, badmin showconf displays the value of EGO_MASTER_LIST in ego.conf.

If EGO is disabled, ego.conf not loaded, so whatever is defined in 1sf.conf is displayed.

perfmon start [sample_period] | stop | view | setperiod sample_period

Dynamically enables and controls scheduler performance metric collection.

Collecting and recording performance metric data may affect the performance of LSF. Smaller sampling periods will result in the lsb.streams file growing faster.

The following metrics are collected and recorded in each sample period:

- The number of queries handled by mbatchd
- The number of queries for each of jobs, queues, and hosts. (bjobs, bqueues, and bhosts, as well as other daemon requests)

- The number of jobs submitted (divided into job submission requests and jobs actually submitted)
- The number of jobs dispatched
- The number of jobs completed
- The numbers of jobs sent to remote cluster
- The numbers of jobs accepted by from cluster

start [sample_period]

Start performance metric collection dynamically and specifies an optional sampling period in seconds for performance metric collection.

If no sampling period is specified, the default period set in SCHED_METRIC_SAMPLE_PERIOD in 1sb.params is used.

stop

Stop performance metric collection dynamically.

Display real time performance metric information for the current sampling period

setperiod sample_period

Set a new sampling period in seconds.

bbot

moves a pending job relative to the last job in the queue

Synopsis

```
bbot job_ID | "job_ID[index_list]" [position]
bbot [-h | -V]
```

Description

Changes the queue position of a pending job, or a pending job array element, to affect the order in which jobs are considered for dispatch.

By default, LSF dispatches jobs in a queue in the order of arrival (that is, first-come-first-served), subject to availability of suitable server hosts.

The bbot command allows users and the LSF administrator to manually change the order in which jobs are considered for dispatch. Users can only operate on their own jobs, whereas the LSF administrator can operate on any user's jobs. Users can only change the relative position of their own jobs.

If invoked by the LSF administrator, bbot moves the selected job after the last job with the same priority submitted to the queue. The positions of all users' jobs in the queue can be changed by the LSF administrator.

If invoked by a regular user, bbot moves the selected job after the last job with the same priority submitted by the user to the queue.

Pending jobs are displayed by bjobs in the order in which they will be considered for dispatch.

A user may use bbot to change the dispatch order of their jobs scheduled using a fairshare policy. However, if a job scheduled using a fairshare policy is moved by the LSF administrator using btop, the job will not be subject to further fairshare scheduling unless the same job is subsequently moved by the LSF administrator using bbot; in this case the job will be scheduled again using the same fairshare policy (see the FAIRSHARE keyword in 1sb.queues(5) and HostPartition **keyword in** 1sb.hosts(5)).

To prevent users from changing the queue position of a pending job with bbot, configure JOB_POSITION_CONTROL_BY_ADMIN=Y in lsb.params.

You cannot run btop on jobs pending in an absolute priority scheduling (APS) queue.

Options

job_ID | "job_ID[index_list]"

Required. Job ID of the job or job array on which to operate.

For a job array, the index list, the square brackets, and the quotation marks are required. An index list is used to operate on a job array. The index list is a comma separated list whose elements have the syntax start_index[-end_index[:step]] where start_index, end_index and step are positive integers. If the step is omitted, a step of one is assumed. The job array index starts at one. The maximum job array index is 1000. All jobs in the array share the same job_ID and parameters. Each element of the array is distinguished by its array index.

position Optional. The position argument can be specified to indicate where in the queue the job is to be placed. position is a positive number that indicates the target position of the job from the end of the queue. The positions are relative to only the applicable jobs in the queue, depending on whether the invoker is a regular user or the LSF administrator. The default value of 1 means the position is after all other jobs with the same priority.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

bchkpnt

checkpoints one or more checkpointable jobs

Synopsis

```
bchkpnt [-f] [-k] [-p minutes | -p 0]
   [job_ID | "job_ID[index_list]"] ...
bchkpnt [-f] [-k] [-p minutes | -p 0] [-J job_name]
   [-m host_name | -m host_group] [-q queue_name]
   [-u "user_name" | -u all] [0]
bchkpnt [-h | -V]
```

Description

Checkpoints your running (RUN) or suspended (SSUSP, USUSP, and PSUSP) checkpointable jobs. LSF administrators and root can checkpoint jobs submitted by other users.

By default, checkpoints one job, the most recently submitted job, or the most recently submitted job that also satisfies other specified options (-m, -q, -u and -J). Specify -0 (zero) to checkpoint multiple jobs. Specify a job ID to checkpoint one specific job.

By default, jobs continue to execute after they have been checkpointed.

To submit a checkpointable job, use bsub -k or submit the job to a checkpoint queue (CHKPNT in 1sb.queues(5)). Use brestart(1) to start checkpointed jobs.

LSF invokes the echkpnt(8) executable found in LSF_SERVERDIR to perform the checkpoint.

Only running members of a chunk job can be checkpointed. For chunk jobs in WAIT state, mbatchd rejects the checkpoint request.

Options

- **0** (Zero). Checkpoints multiple jobs. Checkpoints all the jobs that satisfy other specified options (-m, -q, -u and -J).
- -f Forces a job to be checkpointed even if non-checkpointable conditions exist (these conditions are OS-specific).
- -k Kills a job after it has been successfully checkpointed.
- -p minutes | -p 0 Enables periodic checkpointing and specifies the checkpoint period, or modifies the checkpoint period of a checkpointed job. Specify -p 0 (zero) to disable periodic checkpointing.

Checkpointing is a resource-intensive operation. To allow your job to make progress while still providing fault tolerance, specify a checkpoint period of 30 minutes or longer.

-J job_name Only checkpoints jobs that have the specified job name.

-m host_name | -m host_group

Only checkpoints jobs dispatched to the specified hosts.

-q queue_name

Only checkpoints jobs dispatched from the specified queue.

-u "user_name" | -u all

Only checkpoints jobs submitted by the specified users. The keyword all specifies all users. Ignored if a job ID other than 0 (zero) is specified. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\user_name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

job_ID | "job_ID[index_list]"

Checkpoints only the specified jobs.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

bchkpnt 1234

Checkpoints the job with job ID 1234.

bchkpnt -p 120 1234

Enables periodic checkpointing or changes the checkpoint period to 120 minutes (2 hours) for a job with job ID 1234.

bchkpnt -m hostA -k -u all 0

When issued by root or the LSF administrator, will checkpoint and kill all checkpointable jobs on hostA. This is useful when a host needs to be shut down or rebooted.

```

bclusters

displays MultiCluster information

Synopsis

```
bclusters [-app]
bclusters [-h | -V]
```

Description

For the job forwarding model, displays a list of MultiCluster queues together with their relationship with queues in remote clusters.

For the resource leasing model, displays remote resource provider and consumer information, resource flow information, and connection status between the local and remote cluster.

Options

-app Displays available application profiles in remote clusters.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

Job Forwarding Information

Displays a list of MultiCluster queues together with their relationship with queues in remote clusters.

 $Information\ related\ to\ the\ job\ forwarding\ model\ is\ displayed\ under\ the\ heading\ \verb"Job" Forwarding\ Information.$

LOCAL_QUEUE

Name of a local MultiCluster send-jobs or receive-jobs queue.

JOB_FLOW

Indicates direction of job flow.

send

The local queue is a MultiCluster send-jobs queue (SNDJOBS_TO is defined in the local queue).

recv

The local queue is a MultiCluster receive-jobs queue (RCVJOBS_FROM is defined in the local queue).

REMOTE

For send-jobs queues, shows the name of the receive-jobs queue in a remote cluster.

For receive-jobs queues, always "-".

CLUSTER

For send-jobs queues, shows the name of the remote cluster containing the receive-jobs queue.

For receive-jobs queues, shows the name of the remote cluster that can send jobs to the local queue.

STATUS

Indicates the connection status between the local queue and remote queue.

ok

The two clusters can exchange information and the system is properly configured.

Communication between the two clusters has not been established. This could occur because there are no jobs waiting to be dispatched, or because the remote master cannot be located.

reject

The remote queue rejects jobs from the send-jobs queue. The local queue and remote queue are connected and the clusters communicate, but the queue-level configuration is not correct. For example, the send-jobs queue in the submission cluster points to a receive-jobs queue that does not exist in the remote cluster.

If the job is rejected, it returns to the submission cluster.

Resource Lease Information

Displays remote resource provider and consumer information, resource flow information, and connection status between the local and remote cluster.

Information related to the resource leasing model is displayed under the heading Resource Lease Information.

REMOTE CLUSTER

For borrowed resources, name of the remote cluster that is the provider.

For exported resources, name of the remote cluster that is the consumer.

RESOURCE FLOW

Indicates direction of resource flow.

IMPORT

Local cluster is the consumer and borrows resources from the remote cluster (HOSTS parameter in one or more local queue definitions includes remote resources).

EXPORT

Local cluster is the provider and exports resources to the remote cluster.

STATUS

Indicates the connection status between the local and remote cluster.

MultiCluster jobs can run.

disc

No communication between the two clusters. This could be a temporary situation or could indicate a MultiCluster configuration error.

The two clusters communicate, but the lease is not established. This should be a temporary situation.

Remote Cluster Application Information

bcluster -app displays information related to application profile configuration under the heading Remote Cluster Application Information. Application profile information is only displayed for the job forwarding model. bclusters does

not show local cluster application profile information.

REMOTE_CLUSTER The name of the remote cluster.

APP_NAME The name of the application profile available in the remote cluster.

DESCRIPTION The description of the application profile.

Files

Reads 1sb.queues and 1sb.applications.

See Also

bapp, bhosts, bqueues, lsclusters, lsinfo, lsb.queues

bgadd

creates job groups

Synopsis

```
bgadd [-L limit] [-sla service_class_name] job_group_name
bgadd [-h | -V]
```

Description

Creates a job group with the job group name specified by *job_group_name*.

You must provide full group path name for the new job group. The last component of the path is the name of the new group to be created.

You do not need to create the parent job group before you create a sub-group under it. If no groups in the job group hierarchy exist, all groups are created with the specified hierarchy.

Options

-L limit Specifies the maximum number of concurrent jobs allowed to run under the job group (including child groups) - L limits the number of started jobs (RUN, SSUSP, USSUP) under the job group.

Specify a positive number between 0 and 2147483647. If the specified limit is zero (0), no jobs under the job group can run.

You cannot specify a limit for the root job group. The root job group has no job limit. Job groups added with no limits specified inherit any limits of existing parent job groups. The - ∟ option only limits the lowest level job group created.

If a parallel job requests 2 CPUs (bsub -n 2), the job group limit is per job, not per slots used by the job.

By default, a job group has no job limit. Limits persist across mbatchd restart or reconfiguration.

-sla service_class_name

The name of a service class defined in 1sb.serviceclasses, or the name of the SLA defined in ENABLE_DEFAULT_EGO_SLA in 1sb.params. The job group is attached to the specified SLA.

job_group_name Full path of the job group name.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

Create a job group named risk_group under the root group /:

bgadd /risk_group

• Create a job group named portfoliol under job group /risk_group: bgadd /risk_group/portfolio1

See Also

bgdel, bjgroup

bgdel

deletes job groups

Synopsis

```
bgdel job_group_name ...
bgde1 [-h | -V]
```

Description

Deletes a job group with the job group name specified by job_group_name and all its subgroups.

You must provide full group path name for the job group to be deleted. The job group cannot contain any jobs.

Options

job_group_name Full path of the job group name.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Example

```
bgdel /risk_group
Job group /risk_group is deleted.
deletes the job group /risk_group and all its subgroups.
```

See Also

bgadd(1), bjgroup(1)

bgmod

modifies job groups

Synopsis

```
bgmod [-L limit | -Ln] job_group_name
bgmod [-h | -V]
```

Description

Modifies the job group with the job group name specified by *job_group_name*.

Only root, LSF administrators, the job group creator, or the creator of the parent job groups can use bgmod to modify a job group limit.

You must provide full group path name for the modified job group. The last component of the path is the name of the job group to be modified.

Options

-L limit Changes the limit of *job_group_name* to the specified *limit* value. If the job group has parent job groups, the new limit cannot exceed the limits of any higher level job groups. Similarly, if the job group has child job groups, the new value must be greater than any limits on the lower level job groups.

limit pecifies the maximum number of concurrent jobs allowed to run under the job group (including child groups) - L limits the number of started jobs (RUN, SSUSP, USSUP) under the job group.

Specify a positive number between 0 and 2147483647. If the specified limit is zero (0), no jobs under the job group can run.

You cannot specify a limit for the root job group. The root job group has no job limit. The -L option only limits the lowest level job group specified.

If a parallel job requests 2 CPUs (bsub -n 2), the job group limit is per job, not per slots used by the job.

-Ln Removes the existing job limit for the job group. If the the job group has parent job groups, the job modified group automatically inherits any limits from its direct parent job group.

job_group_name Full path of the job group name.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

The following command only modifies the limit of group /canada/projects/test1. It does not modify limits of /canada or/canada/projects.

bgmod -L 6 /canada/projects/test1

To modify limits of /canada or/canada/projects, you must specify the exact group name:

bgmod -L 6 /canada bgmod -L 6 /canada/projects

bgadd, bgdel, bjgroup

bhist

displays historical information about jobs

Synopsis

```
bhist [-a | -d | -e |-p | -r | -s] [-b | -w] [-1]
   [-C start_time,end_time] [-D start_time,end_time]
   [-f logfile_name | -n number_logfiles | -n 0]
   [-S start_time, end_time] [-J job_name] [-Lp ls_project_name]
   [-m host_name] [-N host_name | -N host_model | -N CPU_factor]
   [-P project_name] [-q queue_name] [-u user_name | -u all]
bhist [-t] [-f logfile_name] [-T start_time,end_time]
bhist [-J job_name] [-N host_name | -N host_model | -N cpu_factor]
   [job_ID ... | "job_ID[index]" ...]
bhist [-h | -V]
```

Description

By default:

- Displays information about your own pending, running and suspended jobs. Groups information by job
- CPU time is not normalized
- Searches the event log file currently used by the LSF system: \$LSB_SHAREDIR/cluster_name/logdir/lsb.events (see lsb.events(5))
- Displays events occurring in the past week, but this can be changed by setting the environment variable LSB BHIST HOURS to an alternative number of

If neither -1 nor -b is present, the default is to display only the fields shown in Output on page 51.

Options

-a Displays information about both finished and unfinished jobs.

```
This option overrides -d, -p, -s, and -r.
```

- -b Brief format. Displays the information in a brief format. If used with the -s option, shows the reason why each job was suspended.
- -d Only displays information about finished jobs.
- Only displays information about exited jobs.
- -I Long format. Displays additional information. If used with -s, shows the reason why each job was suspended.

If you submitted a job using the OR (||) expression to specify alternative resources, this option displays the successful Execution rusage string with which the job ran.

If you submitted a job with multiple resource requirement strings using the bsub-R option for the order, same, rusage, and select sections, bjobs -1 displays a single, merged resource requirement string for those sections, as if they were submitted using a single - R.

bhist -1 can display job exit codes. A job with exit code 131 means that the job exceeded a configured resource usage limit and LSF killed the job with signal 3 (131-128=3).

bhist -1 can display changes to pending jobs as a result of the following bmod options:

- Absolute priority scheduling (-aps | -apsn)
- Runtime estimate (-We | -Wen)
- Post-execution command (-Ep | -Epn)
- User limits (-ul | -uln)
- Current working directory (-cwd | -cwdn)
- Only displays information about pending jobs.
- Only displays information about running jobs.
- Only displays information about suspended jobs.
- Displays job events chronologically.
- Wide format. Displays the information in a wide format.

-C start time, end time

Only displays jobs that completed or exited during the specified time interval. Specify the span of time for which you want to display the history. If you do not specify a start time, the start time is assumed to be the time of the first occurrence. If you do not specify an end time, the end time is assumed to be now. If you do not specify an end time, the end time is assumed to be now.

Specify the times in the format "yyyy/mm/dd/HH:MM". Do not specify spaces in the time interval string.

The time interval can be specified in many ways. For more specific syntax and examples of time formats, see TIME INTERVAL FORMAT.

-D start time, end time

Only displays jobs dispatched during the specified time interval. Specify the span of time for which you want to display the history. If you do not specify a start time, the start time is assumed to be the time of the first occurrence. If you do not specify an end time, the end time is assumed to be now. If you do not specify an end time, the end time is assumed to be now.

Specify the times in the format "yyyy/mm/dd/HH:MM". Do not specify spaces in the time interval string.

The time interval can be specified in many ways. For more specific syntax and examples of time formats, see TIME INTERVAL FORMAT.

-S start_time,end_time

Only displays information about jobs submitted during the specified time interval. Specify the span of time for which you want to display the history. If you do not specify a start time, the start time is assumed to be the time of the first occurrence. If you do not specify an end time, the end time is assumed to be now. If you do not specify an end time, the end time is assumed to be now.

Specify the times in the format "yyyy/mm/dd/HH:MM". Do not specify spaces in the time interval string.

The time interval can be specified in many ways. For more specific syntax and examples of time formats, see TIME INTERVAL FORMAT.

-T start_time,end_time

Used together with -t.

Only displays information about job events within the specified time interval. Specify the span of time for which you want to display the history. If you do not specify a start time, the start time is assumed to be the time of the first occurrence. If you do not specify an end time, the end time is assumed to be now. If you do not specify an end time, the end time is assumed to be now.

Specify the times in the format yyyy/mm/dd/HH: MM. Do not specify spaces in the time interval string.

The time interval can be specified in many ways. For more specific syntax and examples of time formats, see Time Interval Format on page 52.

-f logfile name

Searches the specified event log. Specify either an absolute or a relative path.

Useful for analysis directly on the file.

The specified file path can contain up to 4094 characters for UNIX, or up to 255 characters for Windows.

-J job name

Only displays the jobs that have the specified job name.

The specified job name can contain up to 4094 characters for UNIX, or up to 255 characters for Windows.

-Lp *ls_project_name*

Only displays information about jobs belonging to the specified License Scheduler project.

-m host_name Only displays jobs dispatched to the specified host.

-n number_logfiles | -n 0

Searches the specified number of event logs, starting with the current event log and working through the most recent consecutively numbered logs. The maximum number of logs you can search is 100. Specify 0 to specify all the event log files in \$(LSB_SHAREDIR)/cluster_name/logdir (up to a maximum of 100 files).

If you delete a file, you break the consecutive numbering, and older files will be inaccessible to bhist.

For example, if you specify 3, LSF searches 1sb.events, 1sb.events.1, and 1sb.events.2. If you specify 4, LSF searches 1sb.events, 1sb.events.1, 1sb.events.2, and 1sb.events.3. However, if 1sb.events.2 is missing, both searches will include only lsb.events and lsb.events.1.

-N host_name | -N host_model | -N cpu_factor

Normalizes CPU time by the specified CPU factor, or by the CPU factor of the

specified host or host model.

If you use bhist directly on an event log, you must specify a CPU factor.

Use 1sinfo to get host model and CPU factor information.

-P project_name Only displays information about jobs belonging to the specified project.

Only displays information about jobs submitted to the specified queue. -q queue_name

Displays information about jobs submitted by the specified user, or by all users if -u user name | -u all

the keyword all is specified. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\

user name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

job_ID | "job_ID[index]"

Searches all event log files and only displays information about the specified jobs. If you specify a job array, displays all elements chronologically.

This option overrides all other options except -J, -N, -h, and -V. When it is used with -J, only those jobs listed here that have the specified job name are displayed.

-h Prints command usage to stderr and exits.

-V Prints LSF release version to stderr and exits.

Output

Default format

Statistics of the amount of time that a job has spent in various states:

PEND The total waiting time excluding user suspended time before the job is dispatched.

PSUSP The total user suspended time of a pending job.

RUN The total run time of the job.

USUSP The total user suspended time after the job is dispatched.

SSUSP The total system suspended time after the job is dispatched.

UNKWN The total unknown time of the job (job status becomes unknown if sbatchd on the

execution host is temporarily unreachable).

TOTAL The total time that the job has spent in all states; for a finished job, it is the

turnaround time (that is, the time interval from job submission to job completion).

Long format (-I)

The -1 option displays a long format listing with the following additional fields:

Project The project the job was submitted from.

Application Profile The application profile the job was submitted to.

Command

The job command.

Detailed history includes job group modification, the date and time the job was forwarded and the name of the cluster to which the job was forwarded.

The displayed job command can contain up to 4094 characters for UNIX, or up to 255 characters for Windows.

1sb.events, bgadd, bgdel, bjgroup, bsub, bjobs, lsinfo

Time Interval Format

You use the time interval to define a start and end time for collecting the data to be retrieved and displayed. While you can specify both a start and an end time, you can also let one of the values default. You can specify either of the times as an absolute time, by specifying the date or time, or you can specify them relative to the current time.

Specify the time interval is follows:

start_time,end_time|start_time,|,end_time|start_time

Specify *start_time* or *end_time* in the following format:

[year/][month/][day][/hour:minute|/hour:]]...-relative_int

Where:

- *year* is a four-digit number representing the calendar year.
- month is a number from 1 to 12, where 1 is January and 12 is December.
- day is a number from 1 to 31, representing the day of the month.
- hour is an integer from 0 to 23, representing the hour of the day on a 24-hour clock.
- *minute* is an integer from 0 to 59, representing the minute of the hour.
- . (period) represents the current month/day/hour:minute.
- .-relative_int is a number, from 1 to 31, specifying a relative start or end time prior to now.

start_time,end_time

Specifies both the start and end times of the interval.

start time,

Specifies a start time, and lets the end time default to now.

,end_time

Specifies to start with the first logged occurrence, and end at the time specified.

start_time

Starts at the beginning of the most specific time period specified, and ends at the maximum value of the time period specified. For example, 2/ specifies the month of February—start February 1 at 00:00 a.m. and end at the last possible minute in February: February 28th at midnight.

Absolute Time Examples

Assume the current time is May 9 17:06 2008:

1,8 = May 1 00:00 2008 to May 8 23:59 2008

4 = 4 the time of the first occurrence to May 4 23:59 2008

6 = May 6 00:00 2008 to May 6 23:59 2008

2/ = Feb 1 00:00 2008 to Feb 28 23:59 2008

/12: = May 9 12:00 2008 to May 9 12:59 2008

2/1 = Feb 1 00:00 2008 to Feb 1 23:59 2008

2/1, = Feb 1 00:00 to the current time

,. = the time of the first occurrence to the current time

,2/10: = the time of the first occurrence to May 2 10:59 2008

2001/12/31,2008/5/1 = from Dec 31, 2001 00:00:00 to May 1st 2008 23:59:59

Relative Time Examples

.-9, = April 30 17:06 2008 to the current time

,.-2/ = the time of the first occurrence to Mar 7 17:06 2008

.-9,.-2 = nine days ago to two days ago (April 30, 2008 17:06 to May 7, 2008 17:06)

bhosts

displays hosts and their static and dynamic resources

Synopsis

```
bhosts [-e | -1 | -w] [-x] [-X] [-R "res_req"]
   [host_name | host_group] ...
bhosts [-e | -1 | -w] [-X] [-R "res_req"] [cluster_name]
bhosts [-e ] -s [shared_resource_name ...]
bhosts [-h | -V]
```

Description

By default, returns the following information about all hosts: host name, host status, job state statistics, and job slot limits.

bhosts displays output for condensed host groups. These host groups are defined by CONDENSE in the Host Group section of 1sb. hosts. These host groups are displayed as a single entry with the name as defined by GROUP_NAME in the HostGroup section of 1sb.hosts.

The -1 and -X options display uncondensed output.

The -s option displays information about the numeric shared resources and their associated hosts.

With MultiCluster, displays the information about hosts available to the local cluster. Use -e to view information about exported hosts.

Options

- -e MultiCluster only. Displays information about resources that have been exported to another cluster.
- -I Displays host information in a (long) multi-line format. In addition to the default fields, displays information about the CPU factor, the current load, and the load thresholds.

Also displays information about the dispatch windows.

If you specified an administrator comment with the -C option of the host control commands holose or hopen, -1 displays the comment text.

-w Displays host information in wide format. Fields are displayed without truncation. For condensed host groups, the -w option dispays the overall status and the number of hosts with the ok, unavail, unreach, and busy status in the following format: host_group_status num_ok/num_unavail/num_unreach/num_busy

where

- host_group_status is the overall status of the host group. If a single host in the host group is ok, the overall status is also ok.
- num ok, num unavail, num unreach, and num busy are the number of hosts that are ok, unavail, unreach, and busy, respectively.

For example, if there are five ok, two unavail, one unreach, and three busy hosts in a condensed host group hgl, its status is displayed as the following:

hg1 ok 5/2/1/3

If any hosts in the host group are closed, the status for the host group is displayed as closed, with no status for the other states:

hg1 closed

-x Display hosts whose job exit rate has exceeded the threshold configured by EXIT_RATE in 1sb.hosts for longer than JOB_EXIT_RATE_DURATION configured in 1sb.params, and are still high. By default, these hosts will be closed the next time LSF checks host exceptions and invokes eadmin.

Use with the -1 option to show detailed information about host exceptions.

If no hosts exceed the job exit rate, bhosts -x displays:

There is no exceptional host found

-X Displays uncondensed output for host groups.

-R "res_req" Only displays information about hosts that satisfy the resource requirement expression. For more information about resource requirements, see lsfintro(1). The size of the resource requirement string is limited to 512 bytes.

> LSF supports ordering of resource requirements on all load indices, including external load indices, either static or dynamic.

-s [shared resource name ...]

Displays information about the specified shared resources. The resources must have numeric values. Returns the following information: the resource names, the total and reserved amounts, and the resource locations. If no shared resources are specified, displays information about all numeric shared resources.

When LOCAL_TO is configured for a license feature in lsf.licensescheduler, bhosts -s shows different resource information depending on the cluster locality of the features. For example:

From clusterA:

bhosts -s

| RESOURCE | TOTAL | RESERVED | LOCATION |
|----------|-------|----------|----------|
| hspice | 36.0 | 0.0 | host1 |

From clusterB in siteB:

bhosts -s

| RESOURCE | TOTAL | RESERVED | LOCATION |
|----------|-------|----------|----------|
| hspice | 76.0 | 0.0 | host2 |

host name ... | host group ...

Only displays information about the specified hosts. Do not use quotes when specifying multiple hosts.

For host groups, the names of the hosts belonging to the group are displayed instead of the name of the host group. Do not use quotes when specifying multiple host groups.

cluster_name MultiCluster only. Displays information about hosts in the specified cluster.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

Host-Based Default

Displays the following fields:

HOST NAME

The name of the host. If a host has batch jobs running and the host is removed from the configuration, the host name will be displayed as lost_and_found.

For condensed host groups, this is the name of host group.

STATUS

With MultiCluster, not shown for fully exported hosts.

The current status of the host and the shatchd daemon. Batch jobs can only be dispatched to hosts with an ok status. The possible values for host status are as follows:

ok

The host is available to accept batch jobs.

For condensed host groups, if a single host in the host group is ok, the overall status is also shown as ok.

If any host in the host group is not ok, bhosts displays the first host status it encounters as the overall status for the condensed host group. Use bhosts - X to see the status of indidual hosts in the host group.

unavail

The host is down, or LIM and shatchd on the host are unreachable.

unreach

LIM on the host is running but shatchd is unreachable.

The host is not allowed to accept any remote batch jobs. There are several reasons for the host to be closed (see Host-Based - 1 Options).

unlicensed

The host does not have a valid LSF license.

JL/U

With MultiCluster, not shown for fully exported hosts.

The maximum number of job slots that the host can process on a per user basis. If a dash (-) is displayed, there is no limit.

For condensed host groups, this is the total number of job slots that all hosts in the host group can process on a per user basis.

The host will not allocate more than JL/U job slots for one user at the same time. These job slots are used by running jobs, as well as by suspended or pending jobs that have slots reserved for them.

For preemptive scheduling, the accounting is different. These job slots are used by running jobs and by pending jobs that have slots reserved for them (see the description of PREEMPTIVE in 1sb.queues(5) and JL/U in 1sb.hosts(5)).

MAX

The maximum number of job slots available. If a dash (-) is displayed, there is no limit.

For condensed host groups, this is the total maximum number of job slots available in all hosts in the host group.

These job slots are used by running jobs, as well as by suspended or pending jobs that have slots reserved for them.

If preemptive scheduling is used, suspended jobs are not counted (see the description of PREEMPTIVE in 1sb.queues(5) and MXJ in 1sb.hosts(5)).

A host does not always have to allocate this many job slots if there are waiting jobs; the host must also satisfy its configured load conditions to accept more jobs.

NJOBS

The number of job slots used by jobs dispatched to the host. This includes running, suspended, and chunk jobs.

For condensed host groups, this is the total number of job slots used by jobs dispatched to any host in the host group.

RUN

The number of job slots used by jobs running on the host.

For condensed host groups, this is the total number of job slots used by jobs running on any host in the host group.

SSUSP

The number of job slots used by system suspended jobs on the host.

For condensed host groups, this is the total number of job slots used by system suspended jobs on any host in the host group.

USUSP

The number of job slots used by user suspended jobs on the host. Jobs can be

suspended by the user or by the LSF administrator.

For condensed host groups, this is the total number of job slots used by user suspended jobs on any host in the host group.

RSV

The number of job slots used by pending jobs that have jobs slots reserved on the

For condensed host groups, this is the total number of job slots used by pending jobs that have job slots reserved on any host in the host group.

Host-Based -I Option

In addition to the above fields, the -1 option also displays the following:

loadSched, loadStop

The scheduling and suspending thresholds for the host. If a threshold is not defined, the threshold from the queue definition applies. If both the host and the queue define a threshold for a load index, the most restrictive threshold is used.

The migration threshold is the time that a job dispatched to this host can remain suspended by the system before LSF attempts to migrate the job to another host.

If the host's operating system supports checkpoint copy, this is indicated here. With checkpoint copy, the operating system automatically copies all open files to the checkpoint directory when a process is checkpointed. Checkpoint copy is currently supported only on Cray systems.

STATUS

The long format shown by the -1 option gives the possible reasons for a host to be closed:

closed Adm

The host is closed by the LSF administrator or root (see badmin(8)). No job can be dispatched to the host, but jobs that are executing on the host will not be affected.

closed Lock

The host is locked by the LSF administrator or root (see lsadmin(8)). All batch jobs on the host are suspended by LSF.

closed Wind

The host is closed by its dispatch windows, which are defined in the configuration file lsb.hosts(5). Jobs already started are not affected by the dispatch windows.

closed_Full

The configured maximum number of batch job slots on the host has been reached (see MAX field below).

closed_Excl

The host is currently running an exclusive job.

closed_Busy

The host is overloaded, because some load indices go beyond the configured thresholds (see <code>lsb.hosts(5)</code>). The displayed thresholds that cause the host to be busy are preceded by an asterisk (*).

closed LIM

LIM on the host is unreachable, but shatchd is ok.

closed EGO

For EGO-enabled SLA scheduling, host is closed because it has not been allocated by EGO to run LSF jobs. Hosts allocated from EGO display status ok.

CPUF

Displays the CPU normalization factor of the host (see <code>lshosts(1)</code>).

DISPATCH WINDOW

Displays the dispatch windows for each host. Dispatch windows are the time windows during the week when batch jobs can be run on each host. Jobs already started are not affected by the dispatch windows. When the dispatch windows close, jobs are not suspended. Jobs already running continue to run, but no new jobs are started until the windows reopen. The default for the dispatch window is no restriction or always open (that is, twenty-four hours a day and seven days a week). For the dispatch window specification, see the description for the DISPATCH_WINDOWS keyword under the -1 option in bqueues(1).

CURRENT LOAD

Displays the total and reserved host load.

Reserved

You specify reserved resources by using bsub -R (see lsfintro(1)). These resources are reserved by jobs running on the host.

Total

The total load has different meanings depending on whether the load index is increasing or decreasing.

For increasing load indices, such as run queue lengths, CPU utilization, paging activity, logins, and disk I/O, the total load is the consumed plus the reserved amount. The total load is calculated as the sum of the current load and the reserved load. The current load is the load seen by 1sload(1).

For decreasing load indices, such as available memory, idle time, available swap space, and available space in tmp, the total load is the available amount. The total load is the difference between the current load and the reserved load. This difference is the available resource as seen by 1sload(1).

LOAD THRESHOLD

Displays the scheduling threshold loadSched and the suspending threshold loadStop. Also displays the migration threshold if defined and the checkpoint support if the host supports checkpointing.

The format for the thresholds is the same as for batch job queues (see bqueues (1)) and 1sb.queues(5)). For an explanation of the thresholds and load indices, see the description for the "QUEUE SCHEDULING PARAMETERS" keyword under the -1 **option in** bqueues(1).

THRESHOLD AND LOAD USED FOR EXCEPTIONS

Displays the configured threshold of EXIT RATE for the host and its current load value for host exceptions.

ADMIN ACTION COMMENT

If the LSF administrator specified an administrator comment with the -C option of the badmin host control commands holose or hopen, the comment text is displayed.

Resource-Based -s Option

The -s option displays the following: the amounts used for scheduling, the amounts reserved, and the associated hosts for the shared resources. Only shared resources with numeric values are displayed. See lim(8), and lsf.cluster(5) on how to configure shared resources.

The following fields are displayed:

RESOURCE The name of the resource.

TOTAL The total amount free of a shared resource used for scheduling.

RESERVED The amount reserved by jobs. You specify the reserved resource using bsub -R (see

lsfintro(1).

LOCATION The hosts that are associated with the shared resource. Files

Files

Reads 1sb.hosts.

bhpart

displays information about host partitions

Synopsis

```
bhpart [-r] [host_partition_name ...]
bhpart [-h | -V]
```

Description

By default, displays information about all host partitions. Host partitions are used to configure host-partition fairshare scheduling.

Options

-r Displays the entire information tree associated with the host partition recursively.

host_partition_name ...

Displays information about the specified host partitions only.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

The following fields are displayed for each host partition:

HOST_PARTITION_NAME

Name of the host partition.

HOSTS

Hosts or host groups that are members of the host partition. The name of a host group is appended by a slash (/) (see bmgroup(1)).

USER/GROUP

Name of users or user groups who have access to the host partition (see bugroup(1)).

SHARES

Number of shares of resources assigned to each user or user group in this host partition, as configured in the file lsb.hosts. The shares affect dynamic user priority for when fairshare scheduling is configured at the host level.

PRIORITY

Dynamic user priority for the user or user group. Larger values represent higher priorities. Jobs belonging to the user or user group with the highest priority are considered first for dispatch.

In general, users or user groups with larger SHARES, fewer STARTED and RESERVED, and a lower CPU_TIME and RUN_TIME will have higher PRIORITY. Files

STARTED

Number of job slots used by running or suspended jobs owned by users or user groups in the host partition.

RESERVED

Number of job slots reserved by the jobs owned by users or user groups in the host partition.

CPU_TIME

Cumulative CPU time used by jobs of users or user groups executed in the host partition. Measured in seconds, to one decimal place.

LSF calculates the cumulative CPU time using the actual (not normalized) CPU time and a decay factor such that 1 hour of recently-used CPU time decays to 0.1 hours after an interval of time specified by HIST_HOURS in 1sb.params (5 hours by default).

RUN TIME

Wall-clock run time plus historical run time of jobs of users or user groups that are executed in the host partition. Measured in seconds.

LSF calculates the historical run time using the actual run time of finished jobs and a decay factor such that 1 hour of recently-used run time decays to 0.1 hours after an interval of time specified by HIST_HOURS in 1sb.params (5 hours by default). Wall-clock run time is the run time of running jobs.

Files

Reads 1sb.hosts.

See Also

bugroup(1), bmgroup(1), lsb.hosts(5)

bjgroup

displays information about job groups

Synopsis

bjgroup [-N] [-s [group_name]] bjgroup [-h | -V]

Description

Displays job group information.

Options

-s Sorts job groups by group hierarchy.

For example, for job groups named /A, /A/B, /X and /X/Y, bjgroup without -s displays:

| GROUP_NAME | NJOBS | PEND | RUN | SSUSP | USUSP | FINISH | SLA | JLIMIT | OWNER |
|------------|-------|------|-----|-------|-------|--------|-----|--------|-------|
| / A | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/10 | user1 |
| / X | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/- | user2 |
| /A/B | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/5 | user1 |
| /X/Y | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/5 | user2 |

For the same job groups, bjgroup -s displays:

bjgroup -s

| GROUP_NAME | NJOBS | PEND | RUN | SSUSP | USUSP | FINISH | SLA | JLIMIT | OWNER |
|------------|-------|------|-----|-------|-------|--------|-----|--------|-------|
| / A | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/10 | user1 |
| /A/B | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/5 | user1 |
| / X | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/- | user2 |
| /X/Y | 0 | 0 | 0 | 0 | 0 | 0 | () | 0/5 | user2 |

Specify a job group name to show the hierarchy of a single job group:

bjgroup -s /X

| GROUP_NAME | NJOBS | PEND | RUN | SSUSP | USUSP | FINISH | SLA | JLIMIT | OWNER |
|------------|-------|------|-----|-------|-------|--------|---------|--------|-------|
| / X | 25 | 0 | 25 | 0 | 0 | 0 | puccini | 25/100 | user1 |
| /X/Y | 20 | 0 | 20 | 0 | 0 | 0 | puccini | 20/30 | user1 |
| / X / Z | 5 | 0 | 5 | 0 | 0 | 0 | puccini | 5/10 | user2 |

Specify a job group name with a trailing slash character (/) to show only the root job group:

bjgroup -s /X/

| GROUP_NAME | NJOBS | PEND | RUN | SSUSP | USUSP | FINISH | SLA | JLIMIT | OWNER |
|------------|-------|------|-----|-------|-------|--------|---------|--------|-------|
| / X | 25 | 0 | 25 | 0 | 0 | 0 | puccini | 25/100 | user1 |

-N Displays job group information by job slots instead of number of jobs. NSLOTS, PEND, RUN, SSUSP, USUSP, RSV are all counted in slots rather than number of jobs:

bjgroup -N

| GROUP_NAME | NSLOTS | PEND | RUN | SSUSP | USUSP | RSV | SLA | OWNER |
|------------|--------|------|-----|-------|-------|-----|---------|-------|
| / X | 25 | 0 | 25 | 0 | 0 | 0 | puccini | user1 |
| /A/B | 20 | 0 | 20 | 0 | 0 | 0 | wagner | batch |

- N by itself shows job slot info for all job groups, and can combine with -s to sort the job groups by hierarchy:

bjgroup -N -s

| GROUP_NAME | NSLOTS | PEND | RUN | SSUSP | USUSP | RSV | SLA | OWNER |
|------------|--------|------|-----|-------|-------|-----|---------|-------|
| / A | 0 | 0 | 0 | 0 | 0 | 0 | wagner | batch |
| /A/B | 0 | 0 | 0 | 0 | 0 | 0 | wagner | user1 |
| / X | 25 | 0 | 25 | 0 | 0 | 0 | puccini | user1 |
| /X/Y | 20 | 0 | 20 | 0 | 0 | 0 | puccini | batch |
| /X/Z | 5 | 0 | 5 | 0 | 0 | 0 | puccini | batch |

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Default output

A list of job groups is displayed with the following fields:

GROUP_NAME

The name of the job group.

NJOBS

The current number of jobs in the job group. A parallel job is counted as 1 job, regardless of the number of job slots it will use.

PEND

The number of pending jobs in the job group.

RUN

The number of running jobs in the job group.

SSUSP

The number of system-suspended jobs in the job group.

USUSP

The number of user-suspended jobs in the job group.

FINISH

The number of jobs in the specified job group in EXITED or DONE state.

SLA

The name of the service class that the job group is attached to with bgadd -sla service_class_name. If the job group is not attached to any service class, empty parentheses () are displayed in the SLA name column.

JLIMIT

The job group limit set by bgadd -L or bgmod -L. Job groups that have no configured limits or no limit usage are indicated by a dash (-). Job group limits are displayed in a USED/LIMIT format. For example, if a limit of 5 jobs is configured and 1 job is started, bjgroup displays the job limit under JLIMIT as 1/5.

OWNER

The job group owner.

Example

bjgroup

| GROUP_NAME | NJOBS | PEND | RUN | SSUSP | USUSP | FINISH | SLA | JLIMIT | OWNER |
|------------|-------|------|-----|-------|-------|--------|---------|--------|-------|
| /fund1_grp | 5 | 4 | 0 | 1 | 0 | 0 | Venezia | 1/5 | user1 |
| /fund2_grp | 11 | 2 | 5 | 0 | 0 | 4 | Venezia | 5/5 | user1 |
| /bond_grp | 2 | 2 | 0 | 0 | 0 | 0 | Venezia | 0/- | user2 |
| /risk_grp | 2 | 1 | 1 | 0 | 0 | 0 | () | 1/- | user2 |
| /admi_grp | 4 | 4 | 0 | 0 | 0 | 0 | () | 0/- | user2 |

Job slots (-N) output

NSLOTS, PEND, RUN, SSUSP, USUSP, RSV are all counted in slots rather than number of jobs. A list of job groups is displayed with the following fields:

GROUP_NAME

The name of the job group.

NSLOTS

The total number of job slots held currently by jobs in the job group. This includes pending, running, suspended and reserved job slots. A parallel job that is running on *n* processors is counted as *n* job slots, since it takes *n* job slots in the job group.

PEND

The number of job slots used by pending jobs in the job group.

RUN

The number of job slots used by running jobs in the job group.

SSUSP

The number of job slots used by system-suspended jobs in the job group.

USUSP

The number of job slots used by user-suspended jobs in the job group.

RSV

The number of job slots in the job group that are reserved by LSF for pending jobs.

SLA

The name of the service class that the job group is attached to with bgadd -sla service_class_name. If the job group is not attached to any service class, empty parentheses () are displayed in the SLA name column.

OWNER

The job group owner.

Example

bjgroup -N

| GROUP_NAME | NSLOTS | PEND | RUN | SSUSP | USUSP | RSV | SLA | OWNER |
|------------|--------|------|-----|-------|-------|-----|---------|-------|
| / X | 25 | 0 | 25 | 0 | 0 | 0 | puccini | user1 |
| /A/B | 20 | 0 | 20 | 0 | 0 | 0 | wagner | batch |

   [-g job_group] [-sla service_class] [-P project_name]
   [-N host_spec] [-Lp license_project] [-app application_profile]
   [-J name_spec] [job_ID | "job_ID[index_list]" ...]
bjobs [-h | -V]
```

Description

By default, displays information about your own pending, running and suspended jobs.

bjobs displays output for condensed host groups. These host groups are defined by CONDENSE in the Host Group section of 1sb. hosts. These host groups are displayed as a single entry with the name as defined by GROUP_NAME in the HostGroup section of 1sb.hosts. The -1 and -X options display uncondensed output.

If you defined LSB SHORT HOSTLIST=1 in 1sf.conf, parallel jobs running in the same condensed host group are displayed as an abbreviated list.

To display older historical information, use bhist.

Options

-A Displays summarized information about job arrays. If you specify job arrays with the job array ID, and also specify - A, do not include the index list with the job array

You can use -w to show the full array specification, if necessary.

-a Displays information about jobs in all states, including finished jobs that finished recently, within an interval specified by CLEAN_PERIOD in 1sb.params (the default period is 1 hour).

Use -a with -x option to display all jobs that have triggered a job exception (overrun, underrun, idle).

Displays absolute priority scheduling (APS) information for pending jobs in a queue with APS_PRIORITY enabled. The APS value is calculated based on the current scheduling cycle, so jobs are not guaranteed to be dispatched in this order.

Pending jobs are ordered by APS value. Jobs with system APS values are listed first, from highest to lowest APS value. Jobs with calculated APS values are listed next ordered from high to low value. Finally, jobs not in an APS queue are listed. Jobs with equal APS values are listed in order of submission time. APS values of jobs not in an APS queue are shown with a dash (-).

If queues are configured with the same priority, bjobs -aps may not show jobs in the correct expected dispatch order. Jobs may be dispatched in the order the queues are configured in 1sb.queues. You should avoid configuring queues with the same priority.

- -d Displays information about jobs that finished recently, within an interval specified by CLEAN_PERIOD in 1sb.params (the default period is 1 hour).
- -I Long format. Displays detailed information for each job in a multiline format.

The -1 option displays the following additional information: project name, job command, current working directory on the submission host, pending and suspending reasons, job status, resource usage, resource usage limits information, runtime resource usage information on the execution hosts.

Use bjobs -A -1 to display detailed information for job arrays including job array job limit (%job_limit) if set.

If JOB_IDLE is configured in the queue, use bjobs -1 to display job idle exception information.

If you submitted your job with the -U option to use advance reservations created with the brsvadd command, bjobs -1 shows the reservation ID used by the job.

If LSF_HPC_EXTENSIONS="SHORT_PIDLIST" is specified in lsf.conf, the output from bjobs is shortened to display only the first PID and a count of the process group IDs (PGIDs) and process IDs for the job. Without SHORT_PIDLIST, all of the process IDs (PIDs) for a job are displayed.

If you submitted a job with multiple resource requirement strings using the bsub - R option for the order, same, rusage, and select sections, bjobs -1 displays a single, merged resource requirement string for those sections, as if they were submitted using a single - R.

If you submitted a job using the OR(|||) expression to specify alternative resources, this option displays the Execution rusage string with which the job runs.

For jobs submitted to an absolute priority scheduling (APS) queue, -1 shows the ADMIN factor value and the system APS value if they have been set by the administrator for the job:

-p Displays pending jobs, together with the pending reasons that caused each job not to be dispatched during the last dispatch turn. The pending reason shows the number of hosts for that reason, or names the hosts if -1 is also specified.

With MultiCluster, -1 shows the names of hosts in the local cluster.

Each pending reason is associated with one or more hosts and it states the cause why these hosts are not allocated to run the job. In situations where the job requests specific hosts (using bsub -m), users may see reasons for unrelated hosts also being displayed, together with the reasons associated with the requested hosts.

The life cycle of a pending reason ends after the time indicated by PEND REASON UPDATE INTERVAL in 1sb.params.

When the job slot limit is reached for a job array

(bsub -J "jobArray[indexList]%job_slot_limit") the following message is displayed:

The job array has reached its job slot limit.

- **-r** Displays running jobs.
- -s Displays suspended jobs, together with the suspending reason that caused each job to become suspended.

The suspending reason may not remain the same while the job stays suspended. For example, a job may have been suspended due to the paging rate, but after the paging rate dropped another load index could prevent the job from being resumed. The suspending reason will be updated according to the load index. The reasons could be as old as the time interval specified by SBD_SLEEP_TIME in 1sb.params. So the reasons shown may not reflect the current load situation.

- **-W** Provides resource usage information for: PROJ_NAME, CPU_USED, MEM, SWAP, PIDS, START_TIME, FINISH_TIME.
- -w Wide format. Displays job information without truncating fields.
- **-X** Displays uncondensed output for host groups.
- -x Displays unfinished jobs that have triggered a job exception (overrun, underrun, idle). Use with the -1 option to show the actual exception status. Use with -a to display all jobs that have triggered a job exception.

-app application_profile_name

Displays information about jobs submitted to the specified application profile. You must specify an existing application profile.

-G user_group

Only displays jobs associated with a user group submitted with bsub -G for the specified user group. The -G option does not display jobs from subgroups within the specified user group.

The -G option cannot be used together with the -u option. You can only specify a user group name. The keyword all is not supported for -G.

-g job_group_name

Displays information about jobs attached to the job group specified by *job_group_name*. For example:

| bjobs | -g /risk_ | _group | | | | | |
|-------|-----------|--------|--------|-----------|-----------|----------|--------------|
| JOBID | USER | STAT | QUEUE | FROM_HOST | EXEC_HOST | JOB_NAME | SUBMIT_TIME |
| 113 | user1 | PEND | normal | hostA | | myjob | Jun 17 16:15 |
| 111 | user2 | RUN | normal | hostA | hostA | myjob | Jun 14 15:13 |
| 110 | user1 | RUN | normal | hostB | hostA | myjob | Jun 12 05:03 |
| 104 | user3 | RUN | normal | hostA | hostC | myjob | Jun 11 13:18 |

Use - g with - sla to display job groups attached to a service class. Once a job group is attached to a service class, all jobs submitted to that group are subject to the SLA. bjobs -1 with -g displays the full path to the group to which a job is attached. For example:

bjobs -l -g /risk_group

```
Job <101>, User <user1>, Project <default>, Job Group </risk_group>, Status <RUN>, Queue
<normal>, Command <myjob>
Tue Jun 17 16:21:49: Submitted from host <hostA>, CWD </home/user1;
Tue Jun 17 16:22:01: Started on <hostA>;
```

-J job_name Displays information about the specified jobs or job arrays.

The job name can be up to 4094 characters long for UNIX and Linux or up to 255 characters for Windows.

-Lp *Is project_name* Displays jobs that belong to the specified LSF License Scheduler project.

-m host_name ... | -m host_group ... | -m cluster_name ...

Only displays jobs dispatched to the specified hosts. To see the available hosts, use bhosts.

If a host group is specified, displays jobs dispatched to all hosts in the group. To determine the available host groups, use bmgroup.

With MultiCluster, displays jobs in the specified cluster. If a remote cluster name is specified, you will see the remote job ID, even if the execution host belongs to the local cluster. To determine the available clusters, use belusters.

-N host_name | -N host_model | -N cpu_factor

Displays the normalized CPU time consumed by the job. Normalizes using the CPU factor specified, or the CPU factor of the host or host model specified.

-P project_name Only displays jobs that belong to the specified project.

Only displays jobs in the specified queue. -q queue_name

> The command bqueues returns a list of queues configured in the system, and information about the configurations of these queues.

In MultiCluster, you cannot specify remote queues.

-sla service_class_name

Displays jobs belonging to the specified service class.

bjobs also displays information about jobs assigned to a default SLA configured with ENABLE_DEFAULT_EGO_SLA in 1sb.params.

Use -sla with -g to display job groups attached to a service class. Once a job group is attached to a service class, all jobs submitted to that group are subject to the SLA.

Use ball to display the configuration properties of service classes configured in 1sb.serviceclasses, the default SLA configured in 1sb.params, and dynamic information about the state of each service class.

-u user_name... | -u user_group... | -u all

Only displays jobs that have been submitted by the specified users or user groups. The keyword all specifies all users. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\ user_name) in a Windows command line or a double backslash (DOMAIN NAME\\user name) in a UNIX command line.

The -u option cannot be used with the -G option.

job_ID | "job_ID[index]"

Displays information about the specified jobs or job arrays. If you use - A, specify job array IDs without the index list.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

Pending jobs are displayed in the order in which they will be considered for dispatch. Jobs in higher priority queues are displayed before those in lower priority queues. Pending jobs in the same priority queues are displayed in the order in which they were submitted but this order can be changed by using the commands btop or bbot. If more than one job is dispatched to a host, the jobs on that host are listed in the order in which they will be considered for scheduling on this host by their queue priorities and dispatch times. Finished jobs are displayed in the order in which they were completed.

Default Display

A listing of jobs is displayed with the following fields:

JOBID The job ID that LSF assigned to the job.

USER The user who submitted the job.

STAT The current status of the job (see JOB STATUS below).

OUEUE The name of the job queue to which the job belongs. If the queue to which the job

> belongs has been removed from the configuration, the queue name will be displayed as lost_and_found. Use bhist to get the original queue name. Jobs in the lost_and_found queue remain pending until they are switched with the

bswitch command into another queue.

In a MultiCluster resource leasing environment, jobs scheduled by the consumer cluster display the remote queue name in the format *queue_name@cluster_name*. By default, this field truncates at 10 characters, so you might not see the cluster

name unless you use -w or -1.

FROM HOST The name of the host from which the job was submitted.

> With MultiCluster, if the host is in a remote cluster, the cluster name and remote job ID are appended to the host name, in the format host name@cluster name:job ID. By default, this field truncates at 11 characters; you might not see the cluster name

and job ID unless you use -w or -1.

Output

EXEC_HOST The name of one or more hosts on which the job is executing (this field is empty if

the job has not been dispatched). If the host on which the job is running has been removed from the configuration, the host name is displayed as lost_and_found.

Use bhist to get the original host name.

If the host is part of a condensed host group, the host name is displayed as the name

of the condensed host group.

If you configure a host to belong to more than one condensed host groups using wildcards, bjobs can display any of the host groups as execution host name.

JOB NAME The job name assigned by the user, or the command string assigned by default at

job submission with bsub. If the job name is too long to fit in this field, then only

the latter part of the job name is displayed.

The displayed job name or job command can contain up to 4094 characters for

UNIX, or up to 255 characters for Windows.

SUBMIT_TIME The submission time of the job.

-l output

The -1 option displays a long format listing with the following additional fields:

Project The project the job was submitted from.

Application Profile The application profile the job was submitted to.

Command The job command.

CWD The current working directory on the submission host.

Post-execute Command

The post-execution command specified at the job-level, by bsub -Ep.

PENDING REASONS The reason the job is in the PEND or PSUSP state. The names of the hosts

associated with each reason will be displayed when both -p and -1 options are

specified.

SUSPENDING REASONS

The reason the job is in the USUSP or SSUSP state.

loadSched

The load scheduling thresholds for the job.

loadStop

The load suspending thresholds for the job.

JOB STATUS Possible values for the status of a job include:

PEND

The job is pending, that is, it has not yet been started.

PSUSP

The job has been suspended, either by its owner or the LSF administrator, while pending.

RUN

The job is currently running.

USUSP

The job has been suspended, either by its owner or the LSF administrator, while running.

SSUSP

The job has been suspended by LSF. The job has been suspended by LSF due to either of the following two causes:

- The load conditions on the execution host or hosts have exceeded a threshold according to the loadStop vector defined for the host or queue.
- The run window of the job's queue is closed. See bqueues(1), bhosts(1), and 1sb.queues(5).

DONE

The job has terminated with status of 0.

EXIT

The job has terminated with a non-zero status – it may have been aborted due to an error in its execution, or killed by its owner or the LSF administrator.

For example, exit code 131 means that the job exceeded a configured resource usage limit and LSF killed the job.

UNKWN

mbatchd has lost contact with the sbatchd on the host on which the job runs.

WAIT

For jobs submitted to a chunk job queue, members of a chunk job that are waiting to run.

ZOMBI

A job will become ZOMBI if:

- A non-rerunnable job is killed by bkill while the sbatchd on the execution host is unreachable and the job is shown as UNKWN.
- The host on which a rerunnable job is running is unavailable and the job has been requeued by LSF with a new job ID, as if the job were submitted as a new
- After the execution host becomes available, LSF will try to kill the ZOMBI job. Upon successful termination of the ZOMBI job, the job's status will be changed to EXIT.

With MultiCluster, when a job running on a remote execution cluster becomes a ZOMBI job, the execution cluster will treat the job the same way as local ZOMBI jobs. In addition, it notifies the submission cluster that the job is in ZOMBI state and the submission cluster requeues the job.

RUNTIME

Estimated run time for the job, specified by bsub -We or bmod -We.

RESOURCE USAGE

For the MultiCluster job forwarding model, this information is not shown if MultiCluster resource usage updating is disabled.

The values for the current usage of a job include:

CPU time

Cumulative total CPU time in seconds of all processes in a job.

IDLE FACTOR

Job idle information (CPU time/runtime) if JOB_IDLE is configured in the queue, and the job has triggered an idle exception.

MEM

Total resident memory usage of all processes in a job. By default, memory usage is shown in MB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

SWAP

Total virtual memory usage of all processes in a job. By default, swap space is shown in MB. Use LSF_UNIT_FOR_LIMITS in 1sf. conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

NTHREAD

Number of currently active threads of a job.

PGID

Currently active process group ID in a job.

PIDs

Currently active processes in a job.

RESOURCE LIMITS

The hard resource usage limits that are imposed on the jobs in the queue (see getrlimit(2) and lsb.queues(5)). These limits are imposed on a per-job and a per-process basis.

The possible per-job resource usage limits are:

- **CPULIMIT**
- **PROCLIMIT**
- **MEMLIMIT**
- **SWAPLIMIT**
- **PROCESSLIMIT**
- THREADLIMIT
- **OPENFILELIMIT**

The possible UNIX per-process resource usage limits are:

- **RUNLIMIT**
- **FILELIMIT**
- **DATALIMIT**
- **STACKLIMIT**
- **CORELIMIT**

If a job submitted to the queue has any of these limits specified (see bsub(1)), then the lower of the corresponding job limits and queue limits are used for the job.

If no resource limit is specified, the resource is assumed to be unlimited. User shell

limits that are unlimited are not displayed.

EXCEPTION STATUS Possible values for the exception status of a job include:

idle

The job is consuming less CPU time than expected. The job idle factor (CPU time/runtime) is less than the configured JOB_IDLE threshold for the queue and a job exception has been triggered.

overrun

The job is running longer than the number of minutes specified by the JOB_OVERRUN threshold for the queue and a job exception has been triggered.

underrun

The job finished sooner than the number of minutes specified by the JOB_UNDERRUN threshold for the queue and a job exception has been triggered.

Job Array Summary Information

If you use -A, displays summary information about job arrays. The following fields

are displayed:

JOBID Job ID of the job array.

ARRAY_SPEC Array specification in the format of *name[index]*. The array specification may be

truncated, use -w option together with -A to show the full array specification.

OWNER Owner of the job array.

NJOBS Number of jobs in the job array.

PEND Number of pending jobs of the job array.

RUN Number of running jobs of the job array.

DONE Number of successfully completed jobs of the job array.

EXIT Number of unsuccessfully completed jobs of the job array.

SSUSP Number of LSF system suspended jobs of the job array.

USUSP Number of user suspended jobs of the job array.

PSUSP Number of held jobs of the job array.

Examples

bjobs -pl

Displays detailed information about all pending jobs of the invoker.

bjobs -ps

Display only pending and suspended jobs.

bjobs -u all -a

Displays all jobs of all users.

bjobs -d -q short -m hostA -u user1

Displays all the recently finished jobs submitted by user1 to the queue short, and executed on the host hostA.

bjobs 101 102 203 509

Display jobs with job_ID 101, 102, 203, and 509.

bjobs -X 101 102 203 509

Display jobs with job ID 101, 102, 203, and 509 as uncondensed output even if these jobs belong to hosts in condensed host groups.

bjobs -sla Uclulet

Displays all jobs belonging to the service class Uclulet.

bjobs -app fluent

Displays all jobs belonging to the application profile fluent.

bkill

sends signals to kill, suspend, or resume unfinished jobs

Synopsis

```
bkill [-1] [-app application_profile_name] [-g job_group_name]
   [-sla service_class_name] [-J job_name] [-m host_name |
   -m host_group] [-q queue_name] [-r |
   -s signal_value | signal_name] [-u user_name
   -u user_group | -u all] [job_ID ... | 0 | "job_ID[index]" ...]
bkill [-1] [-b] [-app application_profile_name] [-g job_group_name]
   [-sla service_class_name] [-J job_name] [-m host_name |
   -m host_group] [-q queue_name] [-u user_name
   -u user_group | -u all] [job_ID ... | 0 | "job_ID[index]" ...]
bkill [-h | -V]
```

Description

By default, sends a set of signals to kill the specified jobs. On UNIX, SIGINT and SIGTERM are sent to give the job a chance to clean up before termination, then SIGKILL is sent to kill the job. The time interval between sending each signal is defined by the JOB_TERMINATE_INTERVAL parameter in 1sb.params(5).

By default, kills the last job submitted by the user running the command. You must specify a job ID or -app, -g, -J, -m, -u, or -q. If you specify -app, -g, -J, -m, -u, or -q without a job ID, bkill kills the last job submitted by the user running the command. Specify job ID 0 (zero) to kill multiple jobs.

On Windows, job control messages replace the SIGINT and SIGTERM signals (but only customized applications can process them) and the TerminateProcess() system call is sent to kill the job.

Exit code 130 is returned when a dispatched job is killed with bkill.

Users can only operate on their own jobs. Only root and LSF administrators can operate on jobs submitted by other users.

If a signal request fails to reach the job execution host, LSF tries the operation later when the host becomes reachable. LSF retries the most recent signal request.

If a job is running in a queue with CHUNK_JOB_SIZE set, bkill has the following results depending on job state:

PEND

Job is removed from chunk (NJOBS -1, PEND -1)

RUN

All jobs in the chunk are suspended (NRUN -1, NSUSP +1)

USUSP

Job finishes, next job in the chunk starts if one exists (NJOBS -1, PEND -1, SUSP -1, RUN +1)

WAIT

Job finishes (NJOBS-1, PEND -1)

If the job cannot be killed, use bkill -r to remove the job from the LSF system without waiting for the job to terminate, and free the resources of the job.

Options

- Kills all the jobs that satisfy other options (-app. -g, -m, -q, -u, and -J).
- -b Kills large numbers of jobs as soon as possible. Local pending jobs are killed immediately and cleaned up as soon as possible, ignoring the time interval specified by CLEAN_PERIOD in 1sb.params. Jobs killed in this manner are not logged to 1sb.acct.

Other jobs, such as running jobs, are killed as soon as possible and cleaned up normally.

If the -b option is used with the 0 subcommand, bkill kills all applicable jobs and silently skips the jobs that cannot be killed.

```
bkill -b 0
Operation is in progress
```

The -b option is ignored if used with the -r or -s options.

- -I Displays the signal names supported by bkill. This is a subset of signals supported by /bin/kill and is platform-dependent.
- -r Removes a job from the LSF system without waiting for the job to terminate in the operating system.

Sends the same series of signals as bkill without -r, except that the job is removed from the system immediately, the job is marked as EXIT, and the job resources that LSF monitors are released as soon as LSF receives the first signal.

Also operates on jobs for which a bkill command has been issued but which cannot be reached to be acted on by shatchd (jobs in ZOMBI state). If shatchd recovers before the jobs are completely removed, LSF ignores the zombi jobs killed with bkill -r.

Use bkill -r only on jobs that cannot be killed in the operating system, or on jobs that cannot be otherwise removed using bkill.

The -r option cannot be used with the -s option.

-app application_profile_name

Operates only on jobs associated with the specified application profile. You must specify an existing application profile. If job_ID or 0 is not specified, only the most recently submitted qualifying job is operated on.

-g job_group_name

Operates only on jobs in the job group specified by *job_group_name*.

Use -g with -sla to kill jobs in job groups attached to a service class.

bkill does not kill jobs in lower level job groups in the path. For example, jobs are attached to job groups /risk_group and /risk_group/consolidate:

```
bsub -g /risk_group myjob
Job <115> is submitted to default queue <normal>.
```

```
bsub -g /risk_group/consolidate myjob2
Job <116> is submitted to default queue <normal>.
```

The following bkill command only kills jobs in /risk_group, not the subgroup /risk_group/consolidate:

```
bkill -g /risk_group 0
Job <115> is being terminated
bkill -g /risk_group/consolidate 0
Job <116> is being terminated
```

-J job_name Operates only on jobs with the specified job name. The -J option is ignored if a job ID other than 0 is specified in the *job_ID* option.

-m host_name | -m host_group

Operates only on jobs dispatched to the specified host or host group.

If job ID is not specified, only the most recently submitted qualifying job is operated on. The -m option is ignored if a job ID other than 0 is specified in the job ID option. See bhosts(1) and bmgroup(1) for more information about hosts and host groups.

-q queue_name Operates only on jobs in the specified queue.

If *job_ID* is not specified, only the most recently submitted qualifying job is operated on.

The -q option is ignored if a job ID other than 0 is specified in the job_ID option. See bgueues(1) for more information about queues.

-s signal_value | signal_name

Sends the specified signal to specified jobs. You can specify either a name, stripped of the SIG prefix (such as KILL), or a number (such as 9).

Eligible UNIX signal names are listed by bkill -1.

The -s option cannot be used with the -r option.

Use bkill -s to suspend and resume jobs by using the appropriate signal instead of using bstop or bresume. Sending the SIGCONT signal is the same as using bresume.

Sending the SIGSTOP signal to sequential jobs or the SIGTSTP to parallel jobs is the same as using bstop.

You cannot suspend a job that is already suspended, or resume a job that is not suspended. Using SIGSTOP or SIGTSTP on a job that is in the USUSP state has no effect and using SIGCONT on a job that is not in either the PSUSP or the USUSP state has no effect. See bjobs(1) for more information about job states.

-sla service class name

Operates on jobs belonging to the specified service class.

If *job_ID* is not specified, only the most recently submitted job is operated on.

Use -sla with -g to kill jobs in job groups attached to a service class.

The -sla option is ignored if a job ID other than 0 is specified in the *job_ID* option.

Use bsla to display the configuration properties of service classes configured in 1sb.serviceclasses, the default SLA configured with

ENABLE_DEFAULT_EGO_SLA in 1sb.params, and dynamic information about the state of each service class.

-u user_name | -u user_group | -u all

Operates only on jobs submitted by the specified user or user group, or by all users if the reserved user name all is specified. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\user_name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

If job_ID is not specified, only the most recently submitted qualifying job is operated on. The -u option is ignored if a job ID other than 0 is specified in the job ID option.

job_ID ... | 0 | "job_ID[index]" ...

Operates only on jobs that are specified by job_ID or "job_ID[index]", where "job ID[index]" specifies selected job array elements (see bjobs (1)). For job arrays, quotation marks must enclose the job ID and index, and index must be enclosed in square brackets.

Jobs submitted by any user can be specified here without using the -u option. If you use the reserved job ID 0, all the jobs that satisfy other options (that is, -m, -q, -u and -J) are operated on; all other job IDs are ignored.

The options -u, -q, -m and -J have no effect if a job ID other than 0 is specified. Job IDs are returned at job submission time (see bsub(1)) and may be obtained with the bjobs command (see bjobs (1)).

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

```
bkill -s 17 -g night
```

Sends signal 17 to the last job that was submitted by the invoker to queue night.

```
bkill -q short -u all 0
```

Kills all the jobs that are in the queue short.

```
bkill -r 1045
```

Forces the removal of unkillable job 1045.

```
bkill -sla Tofino 0
```

Kill all jobs belonging to the service class named Tofino.

```
bkill -g /risk_group 0
```

Kills all jobs in the job group /risk_group.

```
bkill -app fluent
```

Kills the most recently submitted job associated with the application profile fluent for the current user.

```
bkill -app fluent 0
```

Kills all jobs associated with the application profile fluent for the current user.

bladmin

reconfigures the Platform LSF License Scheduler daemon (bld)

Synopsis

```
bladmin subcommand
bladmin [-h | -V]
```

Description

Use this command to reconfigure the License Scheduler daemon (bld). You must be a License Scheduler administrator to use this command.

Subcommand List

```
ckconfig [-v]
reconfig [host_name ... | all]
shutdown [host_name ... | all]
blddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o]
blcdebug [-1 debug_level] [-f logfile_name] [-o] collector_name ...
- h
- V
```

Options

ckconfig [-v] Checks LSF License Scheduler configuration in

LSF_ENVDIR/lsf.licensescheduler and lsf.conf.

By default, bladmin ckconfig displays only the result of the configuration file check. If warning errors are found, bladmin prompts you to use the -v option to display detailed messages.

-v

Verbose mode. Displays detailed messages about configuration file checking to stderr.

reconfig [host_name ... | all]

Reconfigures License Scheduler.

shutdown [host name ... | all]

Shuts down License Scheduler.

blddebug [-c class_name ...] [-l debug_level] [-f logfile_name] [-o]

Sets the message log level for bld to include additional information in log files. You must be root or the LSF administrator to use this command.

If the bladmin blddebug is used without any options, the following default values are used:

- class_name=0 (no additional classes are logged)
- debug_level=0 (LOG_DEBUG level in parameter LS_LOG_MASK)
- logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name

-c class name ...

Specifies software classes for which debug messages are to be logged.

Format of *class_name* is the name of a class, or a list of class names separated by spaces and enclosed in quotation marks. Classes are also listed in 1sf.h.

Valid log classes:

- LC_AUTH Log authentication messages
- LC_COMM Log communication messages
- LC_FLEX Log everything related to FLEX_STAT or FLEX_EXEC Macrovision APIs
- LC_LICENCE Log license management messages
- LC_PREEMPT Log preemption policy messages
- LC_TRACE Log significant program walk steps
- LC_XDR Log everything transferred by XDR

Default: 0 (no additional classes are logged)

-I debug level

Specifies level of detail in debug messages. The higher the number, the more detail that is logged. Higher levels include all lower levels.

Possible values:

O LOG_DEBUG level in parameter LS_LOG_MASK in lsf.conf.

1 LOG_DEBUG1 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2 LOG_DEBUG1, and LOG DEBUG levels.

2 LOG_DEBUG2 level for extended logging. A higher level includes lower logging levels. For example, LOG DEBUG3 includes LOG DEBUG2 LOG DEBUG1, and LOG DEBUG levels.

3 LOG_DEBUG3 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2, LOG_DEBUG1, and LOG DEBUG levels.

Default: 0 (LOG_DEBUG level in parameter LS_LOG_MASK)

-f logfile_name

Specifies the name of the file where debugging messages are logged. The file name can be a full path. If a file name without a path is specified, the file is saved in the LSF system log directory.

The name of the file has the following format:

*logfile_name.daemon_name.*log.host_name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, if the specified path is not valid, no log file is created.

Default: current LSF system log file in the LSF system log file directory.

Turns off temporary debug settings and resets them to the daemon starting state. The message log level is reset back to the value of LS_LOG_MASK and classes are reset to the value of LSB_DEBUG_BLD. The log file is also reset back to the default log file.

blcdebug [-l debug_level] [-f logfile_name] [-o] collector_name | all

Sets the message log level for blcollect to include additional information in log files. You must be root or the LSF administrator to use this command.

If the bladmin blcdebug is used without any options, the following default values are used:

- debug_level=0 (LOG_DEBUG level in parameter LS_LOG_MASK)
- logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name
- collector_name=default

-l debug_level

Specifies level of detail in debug messages. The higher the number, the more detail that is logged. Higher levels include all lower levels.

Possible values:

0 LOG_DEBUG level in parameter LS_LOG_MASK in 1sf.conf.

1 LOG_DEBUG1 level for extended logging. A higher level includes lower logging levels. For example, LOG DEBUG3 includes LOG DEBUG2 LOG DEBUG1, and LOG_DEBUG levels.

- 2 LOG_DEBUG2 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2 LOG_DEBUG1, and LOG DEBUG levels.
- 3 LOG_DEBUG3 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2, LOG_DEBUG1, and LOG DEBUG levels.

Default: 0 (LOG_DEBUG level in parameter LS_LOG_MASK)

-f logfile name

Specifies the name of the file where debugging messages are logged. The file name can be a full path. If a file name without a path is specified, the file is saved in the LSF system log directory.

The name of the file has the following format:

*logfile_name.daemon_name.*log.host_name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, if the specified path is not valid, no log file is created.

Default: current LSF system log file in the LSF system log file directory.

-0

Turns off temporary debug settings and resets them to the daemon starting state. The message log level is reset back to the value of LS_LOG_MASK and classes are reset to the value of LSB DEBUG BLD. The log file is also reset back to the default log file.

If a collector name is not specified, default value is to restore the original log mask and log file directory for the default collector.

collector name ... | all

Specifies the collector names separated by blanks. all means all the collectors.

- -h Prints command usage to stderr and exits.
- -V Prints release version to stderr and exits.

blaunch

launches parallel tasks on a set of hosts

Synopsis

```
blaunch [-n] [-u host_file | -z host_name ... | host_name]
   command [argument ...]
blaunch [-h | -V]
```

Description

IMPORTANT: You cannot run blaunch directly from the command line.

Most MPI implementations and many distributed applications use rsh and ssh as their task launching mechanism. The blaunch command provides a drop-in replacement for rsh and ssh as a transparent method for launching parallel applications within LSF.

blaunch supports the following core command line options as rsh and ssh:

- rsh host name command
- ssh host name command

All other rsh and ssh options are silently ignored.

blaunch transparently connects directly to the RES/SBD on the remote host, and subsequently creates and tracks the remote tasks, and provides the connection back to LSF. You do not need to insert pam, taskstarter or any other wrapper.

blaunch only works under LSF. It can only be used to launch tasks on remote hosts that are part of a job allocation. It *cannot* be used as a standalone command. blaunch is not supported on Windows.

When no host names are specified, LSF allocates all hosts listed in the environment variable LSB_MCPU_HOSTS.

Options

-n Standard input is taken from /dev/null.

-u *host_file* Executes the task on all hosts listed in the *host_file*.

Specify the path to a file that contains a list of host names. Each host name must listed on a separater line in the host list file.

This option is exclusive of the -z option.

The name of the host where remote tasks are to be launched. host name

-z host_name ... Executes the task on all specified hosts.

Whereas the host name value for rsh and ssh is a single host name, you can use the - z option to specify a space-delimited list of hosts where tasks are started in parallel.

Specify a list of hosts on which to execute the task. If multiple host names are specified, the host names must be enclosed by quotation marks (" or ') and separated by white space.

This option is exclusive of the -u option.

command [argument ...]

Specify the command to execute. This must be the last argument on the command

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Diagnostics

Exit status is 0 if all commands are executed correctly.

blcollect

license information collection daemon

Synopsis

```
blcollect [-c collector_name ] [-m host_name ...] [-p
   license_scheduler_port]
blcollect [-i lmstat_interval | -D lmstat_path]
blcollect [-h | -V]
```

Description

Periodically collects license usage information from Macrovision FLEXnet. It queries FLEXnet for license usage information from the FLEXnet lmstat command, and passes the information to the License Scheduler daemon (bld). The blcollect daemon improves performance by allowing you to distribute license information queries on multiple hosts.

By default, license information is collected from FLEXnet on one host. Use blcollect to distribute the license collection on multiple hosts.

For each service domain configuration in lsf.licensescheduler, specify one name for bloollect to use. You can only specify one collector per service domain, but you can specify one collector to serve multiple service domains. You can choose any collector name you want, but must use that exact name when you run blcollect.

Options

- -c Required. Specify the collector name you set in lsf.licensescheduler. You must use the collector name (LIC_COLLECT) you define in the ServiceDomain section of the configuration file.
- **-m** Required. Specifies a space-separated list of hosts to which license information is sent. The hosts do not need to be running License Scheduler or a FLEXnet. Use fully qualified host names.
- -p Required. Corresponds to the License Scheduler listening port, which is set in 1sf.licensescheduler. The default value is 9581.

-i *Imstat_interval* Optional. The frequency in seconds of the calls that License Scheduler makes to Imstat to collect license usage information from FLEXnet.

The default interval is 60 seconds.

-D *Imstat_path* Optional. Location of the FLEXnet command lmstat.

- **-h** Prints command usage to stderr and exits.
- -V Prints release version to stderr and exits.

lsf.licensescheduler

blhosts

displays the names of all the hosts running the License Scheduler daemon (bld)

Synopsis

blhosts [-h | -V]

Description

Displays a list of hosts running the License Scheduler daemon. This includes the License Scheduler master host and all the candidate License Scheduler hosts running bld.

Options

- -h Prints command usage to stderr and exits.
- Prints release version to stderr and exits.

Output

Prints out the names of all the hosts running the License Scheduler daemon (bld). For example, the following sample output shows the License Scheduler master host and two candidate License Scheduler hosts running bld:

```
bld is running on:
master: host1.domain1.com
slave: host2.domain1 host3.domain1
```

blimits

displays information about resource allocation limits of running jobs

Synopsis

```
blimits [-w] [-n limit_name ...]
   [-m host_name | -m host_group | -m cluster_name ...]
   [-P project_name ...] [-q queue_name ...]
   [-u user_name | -u user_group ...]
blimits -c
blimits -h | -V
```

Description

Displays current usage of resource allocation limits configured in Limit sections in 1sb.resources:

- Configured limit policy name
- Users (-u option)
- Queues (-q option)
- Hosts (-m option)
- Project names (-P option)
- Limits (SLOTS, MEM, TMP, SWP, JOBS)
- Limit configuration (-c option). This is the same as bresources with no options.

Resources that have no configured limits or no limit usage are indicated by a dash (-). Limits are displayed in a USED/LIMIT format. For example, if a limit of 10 slots is configured and 3 slots are in use, then blimits displays the limit for SLOTS as 3/10.

Note that if there are no jobs running against resource allocation limits, LSF indicates that there is no information to be displayed:

```
No resource usage found.
```

If limits MEM, SWP, or TMP are configured as percentages, both the limit and the amount used are displayed in MB. For example, 1 shosts displays maxmem of 249 MB, and MEM is limited to 10% of available memory. If 10 MB out of 25 MB are used, blimits displays the limit for MEM as 10/25 (10 MB USED from a 25 MB LIMIT).

Limits are displayed for both the vertical tabular format and the horizontal format for Limit sections. If a vertical format Limit section has no name, blimits displays NONAME*nnn* under the NAME column for these limits, where the unnamed limits are numbered in the order the vertical-format Limit sections appear in the 1sb.resources file.

If a resource consumer is configured as all, the limit usage for that consumer is indicated by a dash (-)

PER_HOST slot limits are not displayed. The bhosts commands displays these as MXJ limits.

In MultiCluster, blimits returns the information about all limits in the local

Limit names and policies are set up by the LSF administrator. See 1sb.resources(5) for more information.

Options

- -c Displays all resource configurations in 1sb. resources. This is the same as bresources with no options.
- -w Displays resource allocation limits information in a wide format. Fields are displayed without truncation.
- -n limit name... Displays resource allocation limits the specified named Limit sections. If a list of limit sections is specified, Limit section names must be separated by spaces and enclosed in quotation marks (") or (').

-m host_name | -m host_group | -m cluster_name ...

Displays resource allocation limits for the specified hosts. Do not use quotes when specifying multiple hosts.

To see the available hosts, use bhosts.

For host groups:

- If the limits are configured with HOSTS, the name of the host group is displayed.
- If the limits are configured with PER_HOST, the names of the hosts belonging to the group are displayed instead of the name of the host group.

TIP: PER_HOST slot limits are not displayed. The bhosts command displays these as MXJ limits.

For a list of host groups see bmgroup(1).

In MultiCluster, if a cluster name is specified, displays resource allocation limits in the specified cluster.

-P project_name ... Displays resource allocation limits for the specified projects.

> If a list of projects is specified, project names must be separated by spaces and enclosed in quotation marks (") or (').

Displays resource allocation limits for the specified queues. -q queue_name ...

> The command bqueues returns a list of queues configured in the system, and information about the configurations of these queues.

In MultiCluster, you cannot specify remote queues.

-u user_name | -u user_group ...

Displays resource allocation limits for the specified users.

If a list of users is specified, user names must be separated by spaces and enclosed in quotation marks (") or ('). You can specify both user names and user IDs in the list of users.

If a user group is specified, displays the resource allocation limits that include that group in their configuration. For a list of user groups see bugroup(1)).

- **-h** Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

Configured limits and resource usage for builtin resources (slots, mem, tmp, and swp load indices, and running and suspended job limits) are displayed as INTERNAL RESOURCE LIMITS separately from custom external resources, which are shown as EXTERNAL RESOURCE LIMITS.

Resource Consumers

blimits displays the following fields for resource consumers:

NAME The name of the limit policy as specified by the Limit section NAME parameter.

USERS List of user names or user groups on which the displayed limits are enforced, as specified by the Limit section parameters USERS or PER_USER.

User group names have a slash (/) added at the end of the group name. See

bugroup(1).

QUEUES The name of the queue to which the limits apply, as specified by the Limit section

parameters QUEUES or PER_QUEUES.

If the queue has been removed from the configuration, the queue name is displayed as lost_and_found. Use bhist to get the original queue name. Jobs in the lost_and_found queue remain pending until they are switched with the bswitch command into another queue.

In a MultiCluster resource leasing environment, jobs scheduled by the consumer cluster display the remote queue name in the format queue_name@cluster_name. By default, this field truncates at 10 characters, so you might not see the cluster name unless you use -w or -1.

HOSTS List of hosts and host groups on which the displayed limits are enforced, as specified

by the Limit section parameters HOSTS or PER_HOSTS.

Host group names have a slash (/) added at the end of the group name. See bmgroup(1).

TIP: PER_HOST slot limits are not displayed. The bhosts command displays these as MXJ limits.

PROJECTS List of project names on which limits are enforced., as specified by the Limit section

parameters PROJECTS or PER_PROJECT.

Resource Limits

blimits displays resource allocation limits for the following resources:

SLOTS Number of slots currently used and maximum number of slots configured for the

limit policy, as specified by the Limit section SLOTS parameter.

MEM Amount of memory currently used and maximum configured for the limit policy,

as specified by the Limit section MEM parameter.

TMP Amount of tmp space currently used and maximum amount of tmp space

configured for the limit policy, as specified by the Limit section TMP parameter.

SWP Amount of swap space currently used and maximum amount of swap space

configured for the limit policy, as specified by the Limit section SWP parameter.

JOBS Number of currently running and suspended jobs and the maximum number of

jobs configured for the limit policy, as specified by the Limit section JOBS

parameter.

Example

The following command displays limit configuration and dynamic usage information for project proj1:

blimits -P proj1 INTERNAL RESOURCE LIMITS:

NAME USERS QUEUES HOSTS PROJECTS SLOTS MEM
limit1 user1 - hostA proj1 2/6 NONAMEO22 - hostB proj1 proj2 1/3 -J0BS

EXTERNAL RESOURCE LIMITS:

QUEUES HOSTS PROJECTS
- hostA proj1 1/1 NAME USERS limit1 user1 NAME USERS tmp1

blinfo

displays static License Scheduler configuration information

Synopsis

```
blinfo [-a [-t token_name | "token_name ..."] |
    -A [-t token_name | "token_name ..."] |
-C [-t token_name | "token_name ..."] | -Lp | -p | -D | -G |
    [-t token_name | "token_name ..."]
blinfo [ -h | -V ]
```

Description

Displays different license configuration information, depending on the option selected.

By default, displays information about the distribution of licenses managed by License Scheduler.

Options

-A When LOCAL_TO is configured for a feature in lsf.licensescheduler, shows the feature allocation by cluster locality.

You can optionally provide license token names.

-a Shows all information, including information about non-shared licenses (NON_SHARED_DISTRIBUTION) and workload distribution (WORKLOAD_DISTRIBUTION).

You can optionally provide license token names.

blinfo -a does not display NON_SHARED information for hierarchical project group scheduling policies. Use blinfo -G to see hierarchical group configuration.

-C When LOCAL_TO is configured for a feature in lsf.licensescheduler, shows the cluster locality information for the features.

You can optionally provide license token name.s

- -D Lists the License Scheduler service domains and the corresponding FLEXnet license server hosts.
- **-G** Lists the hierarchical configuration information.

If PRIORITY is defined in the ProjectGroup Section of 1sf.licensescheduler, this option also shows the priorities of each project.

-Lp Lists the active projects managed by License Scheduler.

- Lp only displays projects associated with configured features.

If PRIORITY is defined in the Projects Section of 1sf.licensescheduler, this option also lists the priorities of each project.

-t token_name | "token_name ..."

Only shows information about specified license tokens. Use spaces to separate multiple names, and enclose them in quotation marks.

- -p Displays values of 1sf.licensescheduler configuration parameters and 1sf.conf parameters related to License Scheduler. This is useful for troubleshooting.
- -h Prints command usage to stderr and exits.
- **-V** Prints the License Scheduler release version to stderr and exits.

Output

Default output

Displays the following fields:

FEATURE The license name. This becomes the license token name.

When LOCAL TO is configured for a feature in lsf.licensescheduler, blinfo

shows the cluster locality information for the license features.

SERVICE DOMAIN The name of the service domain that provided the license.

TOTAL The total number of licenses managed by FLEXnet. This number comes from

FLEXnet.

DISTRIBUTION The distribution of the licenses among license projects in the format [project_name,

> percentage[/number licenses owned]]. This determines how many licenses a project is entitled to use when there is competition for licenses. The percentage is

calculated from the share specified in the configuration file.

Allocation output (-A)

FEATURE The license name. This becomes the license token name.

When LOCAL_TO is configured for a feature in lsf.licensescheduler, blinfo

shows the cluster locality information for the license features.

PROJECT The License Scheduler project name.

ALLOCATION

The percentage of shares assigned to each cluster for a feature and a project.

All output (-a)

Same as Default Output with NON_SHARED_DISTRIBUTION.

NON-SHARED_DISTRIBUTION

This column is displayed directly under DISTRIBUTION with the -a option. If there are non-shared licenses, then the non-shared license information is output in the following format: [project_name, number_licenses_non_shared]

If there are no non-shared licenses, then the following license information is output

- (dash)

Cluster locality output (-C)

NAME The license feature token name.

When LOCAL_TO is configured for a feature in 1sf.licensescheduler, blinfo

shows the cluster locality information for the license features.

FLEX NAME The actual FLEXnet feature name—the name used by FLEXnet to identify the type

of license. May be different from the the License Scheduler token name if a different

FLEX_NAME is specified in lsf.licensescheduler.

CLUSTER_NAME The name of the cluster the feature is assigned to.

FEATURE The license feature name. This becomes the license token name.

When LOCAL_TO is configured for a feature in lsf.licensescheduler, blinfo

shows the cluster locality information for the license features.

SERVICE DOMAIN The service domain name.

Service Domain Output (-D)

SERVICE_DOMAIN The service domain name.

LIC_SERVERS Names of FLEXnet license server hosts that belong the to service domain. Each host

name is enclosed in parentheses, as shown:

(port number@host name)

Redundant hosts (that share the same FLEXnet license file) are grouped together as

(port_number@host_name port_number@host_name port_number@host_name)

Hierarchical Output (-G)

The following fields describe the values of their corresponding configuration fields

in the ProjectGroup Section of 1sf.licensecheduler.

GROUP The project names in the hierarchical grouping and its relationships. Each entry

specifies the name of the hierarchical group and its members. The entry is enclosed

in parentheses as shown:

(group (member ...))

SHARES The shares assigned to the hierarchical group member projects.

OWNERSHIP The number of licenses that each project owns.

LIMITS The maximum number of licenses that the hierarchical group member project can

use at any one time.

NON SHARED The number of licenses that the hierarchical group member projects use exclusively.

PRIORITY The priority of the project if it is different from the default behaviour. A larger

number indicates a higher priority.

Project Output (-Lp)

List of active License Scheduler projects.

- Lp only displays projects associated with configured features.

PROJECT

The project name.

PRIORITY

The priority of the project if it is different from the default behaviour. A larger number indicates a higher priority.

Parameters Output (-p)

ADMIN

The License Scheduler administrator. Defined in lsf.licensescheduler.

DISTRIBUTION_POLICY_VIOLATION_ACTION

This parameter includes

- The interval (a multiple of LM STAT INVERVAL periods) at which License Scheduler checks for distribution policy violations, and
- The directory path and command that License Scheduler runs when reporting a violation

Defined in 1sf.licensescheduler.

EXT_FILTER_PORT

TCP listening port used by all external plugins to communicate with License Scheduler hosts. Defined in 1sf.licensescheduler.

FLX_LICENSE_FILE

Path to the file that contains the license keys FLEXnet.Ext.Filter and FLEXnet.Usage.Snapshot to enable the FLEXnet APIs. Defined in lsf.licensescheduler.

HOSTS

License Scheduler candidate hosts. Defined in 1sf.licensescheduler.

LM REMOVE INTERVAL

Minimum time a job must have a license checked out before Imremove can remove the license. Defined in lsf.licensescheduler.

LM_STAT_INTERVAL Time interval between calls that License Scheduler makes to collect license usage information from FLEXnet license management. Defined in lsf.licensescheduler.

LS_MAX_TASKMAN_SESSIONS

Maximum number of taskman jobs that run simultaneously. Defined in lsf.licensescheduler.

LSF LIC SCHED HOSTS

List of hosts that are candidate LSF License Scheduler hosts. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_REQUEUE

Specifies whether to requeue or suspend a job whose license is preempted by LSF License Scheduler. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_SLOT_RELEASE

Specifies whether to release the slot of a job that is suspended when its license is preempted by LSF License Scheduler. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_STOP

Specifies whether to use job controls to stop a job that is preempted. Defined in 1sf.conf.

LSF LICENSE FILE

Location of the LSF license file, which includes License Scheduler keys. Defined in

1sf.conf.

PORT

TCP listening port used by License Scheduler. Defined in lsf.licensescheduler.

Examples

blinfo -a displays both NON_SHARED_DISTRIBUTION and WORKLOAD_DISTRIBUTION information:

blinfo -a FEATURE g1

SERVICE_DOMAIN TOTAL DISTRIBUTION LS 3 [p1, 50.0%] [p2, 50.0% / 2] NON_SHARED_DISTRIBUTION [p2, 2] WORKLOAD_DISTRIBUTION

NON_SHARED_DISTRIBUTION is not defined:

[LSF 66.7%, NON_LSF 33.3%] blinfo -a does not display NON_SHARED_DISTRIBUTION, if the

blinfo -a

SERVICE_DOMAIN TOTAL DISTRIBUTION FEATURE [p1, 50.0%] [p2, 50.0%] LS WORKLOAD_DISTRIBUTION [LSF 66.7%, NON_LSF 33.3%] LS 0 [p1, 50.0%] [p2, 50.0%] g2 WS g33 0 [p1, 50.0%] [p2, 50.0%]

> blinfo -a does not display WORKLOAD_DISTRIBUTION, if the WORKLOAD_DISTRIBUTION is not defined:

blinfo -a

FEATURE SERVICE_DOMAIN TOTAL DISTRIBUTION g1 LS 3 [p1, 50.0%] [p2, 50.0% / 2] NON_SHARED_DISTRIBUTION [p2, 2]

blstat, blusers

blkill

terminates an interactive License Scheduler task

Synopsis

```
blkill [-t seconds] task_ID
blkill [-h | -V]
```

Description

Terminates a running or waiting interactive task in License Scheduler.

Users can kill their own tasks. You must be a License Scheduler administrator to terminate another user's task.

By default, blkill notifies the user and waits 30 seconds before killing the task.

Options

task_ID Task ID of the task you want to kill.

-t seconds Specify how many seconds to delay before killing the task. A value of 0 means to kill the task immediately (do not give the user any time to save work).

- -h Prints command usage to stderr and exits.
- -V Prints License Scheduler release version to stderr and exits.

blparams

displays information about configurable License Scheduler parameters defined in the files lsf.licensescheduler and lsf.conf

Synopsis

blparams [-h | -V]

Description

Displays the following parameter values:

ADMIN

The License Scheduler administrator. Defined in 1sf.licensescheduler.

DISTRIBUTION_POLICY_VIOLATION_ACTION

This parameter includes

- The interval (a multiple of LM_STAT_INVERVAL periods) at which License Scheduler checks for distribution policy violations, and
- The directory path and command that License Scheduler runs when reporting a violation

Defined in 1sf.licensescheduler.

EXT_FILTER_PORT

TCP listening port used by all external plugins to communicate with License Scheduler hosts. Defined in 1sf.licensescheduler.

FLX LICENSE FILE

Path to the file that contains the license keys FLEXnet.Ext.Filter and FLEXnet.Usage.Snapshot to enable the FLEXnet APIs. Defined in lsf.licensescheduler.

HOSTS

License Scheduler candidate hosts. Defined in 1sf.licensescheduler.

LM_REMOVE_INTERVAL

Minimum time a job must have a license checked out before Imremove can remove the license. Defined in 1sf.licensescheduler.

LM_STAT_INTERVAL

Time interval between calls that License Scheduler makes to collect license usage information from FLEXnet license management. Defined in lsf.licensescheduler.

LS_MAX_TASKMAN_SESSIONS

Maximum number of taskman jobs that run simultaneously. Defined in lsf.licensescheduler.

LSF_LIC_SCHED_HOSTS

List of hosts that are candidate LSF License Scheduler hosts. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_REQUEUE

Specifies whether to requeue or suspend a job whose license is preempted by LSF License Scheduler. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_SLOT_RELEASE

Specifies whether to release the slot of a job that is suspended when its license is preempted by LSF License Scheduler. Defined in 1sf.conf.

LSF_LIC_SCHED_PREEMPT_STOP

Specifies whether to use job controls to stop a job that is preempted. Defined in 1sf.conf.

LSF_LICENSE_FILE

Location of the LSF license file, which includes License Scheduler keys. Defined in lsf.licensescheduler.

PORT

TCP listening port used by License Scheduler. Defined in lsf.licensescheduler.

Options

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

See Also

lsf.licensescheduler, lsf.conf

blplugins

displays plugin activity and the check-in, check-out, and deny counters as seen by the License Scheduler for each feature and service domain

Synopsis

blplugins [-h | -V]

Description

Displays the License Scheduler Vendor Plugin Status.

Options

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

IΡ

The IP address for each external filter server plugin.

checkins

The total number of licenses checked in to the license server from the last time the external filter server was to bld.

checkouts

The total number of licenses checked out from the license server from the last time the external filter server was to bld.

denies

The total number of checkouts denied by the license server from the last time the external filter server was to bld.

See Also

blparams

blstat

displays dynamic license information

Synopsis

```
blstat [-G] [-S] [-D service_domain_name |
   "service_domain_name ..."] [-Lp ls_project_name |
   "ls_project_name ..."] [-t token_name | "token_name ..."]
blstat [ -h | -V]
```

Description

Displays license usage statistics.

By default, shows information about all licenses and all clusters.

Options

-G Displays dynamic hierarchical license information.

blstat -G also works with the -t option to only display hierarchical information for the specified feature names.

- **-S** Displays information on the license server associated with license features.
- -s Displays license usage of the LSF and non-LSF workloads. Workload distributions are defined by WORKLOAD_DISTRIBUTION in lsf.licensescheduler. If there are any distribution policy violations, blstat marks these with an asterisk (*) at the beginning of the line.

-D service_domain_name | "service_domain_name ..."

Only shows information about specified service domains. Use spaces to separate multiple names, and enclose them in quotation marks.

-Lp ls_project_name | "ls_project_name ..."

Only shows license information for specified projects. Use spaces to separate multiple names, and enclose them in quotation marks.

-t token_name | "token_name ..."

Only shows information about specified licenses. Use spaces to separate multiple names, and enclose them in quotation marks.

- -h Prints command usage to stderr and exits.
- **-V** Prints the release version to stderr and exits.

Output

Information is organized first by license feature, then by service domain. For each combination of license and service domain, License Scheduler displays a line of summary information followed by rows of license project information (one row for each license project configured to use the license).

In each group of statistics, numbers and percentages refer only to licenses of the specified license feature that can be checked out from FLEXnet license server hosts in the specified service domain.

Summary output

FEATURE The license name. (This appears only once for each feature.)

SERVICE_DOMAIN The name of the service domain that provided the license.

TOTAL_INUSE The number of licenses in use by License Scheduler projects. (Licenses in use have

been checked out from the FLEXnet license manager.)

TOTAL RESERVE The number of licenses reserved for License Scheduler projects. (Licenses that are

reserved and have not been checked out from the FLEXnet license manager.)

TOTAL FREE The number of free licenses that are available to License Scheduler projects.

(Licenses that are not reserved or in use.)

OTHERS The number of licenses checked out by users who are not submitting their jobs to

License Scheduler projects.

By default, these licenses are not being managed by License Scheduler policies. To enforce license distribution policies for these license features, configure ENABLE DYNAMIC RUSAGE=Y in the feature section for those features in

lsf.licensescheduler.

Workload output

LSF USE The total number of licenses in use by License Scheduler projects in the LSF

workload.

LSF DESERVE The total number of licenses assigned to License Scheduler projects in the LSF

workload..

LSF FREE The total number of free licenses available to License Scheduler projects in the LSF

workload.

NON LSF USE The total number of licenses in use by projects in the non-LSF workload.

NON LSF DESERVE The total number of licenses assigned to projects in the non-LSF workload.

NON_LSF_FREE The total number of free licenses available to projects in the non-LSF workload.

Project output

For each project that is configured to use the license, blstat displays the following

information.

PROJECT The License Scheduler project name. SHARE The percentage of licenses assigned to the license project by the License Scheduler

administrator. This determines how many licenses the project is entitled to when

there is competition for licenses. This information is static.

The percentage is calculated to one decimal place using the share assignment in

lsf.licensescheduler.

INUSE The number of licenses in use by the license project. (Licenses in use have been

checked out from the FLEXnet license manager.)

RESERVE The number of licenses reserved for the license project. (The corresponding job has

started to run, but has not yet checked out its license from the FLEXnet license

manager.)

FREE The number of licenses the license project has free. (The license tokens have been

> allocated to the license project by License Scheduler, but the licenses are not reserved and have not yet been checked out from the FLEXnet license manager.)

DEMAND

n indicates that this license project's license requirements are satisfied.

y indicates that this license project needs more license tokens. (It has pending jobs

waiting for this license feature.)

NON_SHARED The number of non-shared licenses belonging to the license project. (The license

tokens allocated to non-shared distribution are scheduled before the tokens

allocated to shared distribution.)

Hierarchical output

SHARE INFO FOR The root member and name of the hierarchical group. The project information

displayed after this title shows the information specific to this particular

hierarchical group. If this root member is itself a member of another hierarchical

group, the relationship is displayed as follows:

/root_name/member_name/...

PROJECT/GROUP The members of the hierarchical group, listed by its group or project name.

Viewing license feature locality

When LOCAL_TO is configured for a feature in lsf.licensescheduler, blstat shows the cluster locality information for the license features. For example, with a group distribution configuration blatat shows the locality of the hapice feature configured for various sites:

blstat

bltasks

displays License Scheduler interactive task information

Synopsis

```
bltasks [-1] [task_ID]
bltasks [-1] [-p | -r | -w] [-Lp "/s_project_name..."]
[-m "host_name..."] [-t "terminal_name..."] [-u "user_name..."]
bltasks [-h | -V]
```

Description

Displays current information about interactive tasks managed by License Scheduler (submitted using taskman).

By default, displays information about all tasks.

Options

task_ID Only displays information about the specified task.

- -I Long format. Displays detailed information for each task in a multi-line format.
- -p Only displays information about tasks with PREEMPTED status.

Cannot be used with -r or -w.

-r Only displays information about tasks with RUN status.

Cannot be used with -p or -w.

-w Only displays information about tasks with WAIT status.

Cannot be used with -p or -r.

-Lp "ls_project_name..."

Only displays information about tasks associated with the specified projects.

-m "host name..."

Only displays information about tasks submitted from the specified hosts.

-t "terminal_name..."

Only displays information about tasks submitted from the specified terminals.

-u "user_name..."

Only displays information about tasks submitted by the specified users.

- -h Prints command usage to stderr and exits.
- -V Prints License Scheduler release version to stderr and exits.

Output

Default Output

Displays the short format with the following information:

Output

TID Task ID that License Scheduler assigned to the task.

USER The user who submitted the task.

STAT The current status of the task.

RUN: Task is running.

WAIT: Task has not yet started.

PREEMPT: Task has been preempted and currently has no license token.

HOST The name of host from which the task was submitted.

PROJECT The name of the project to which the task belongs.

FEATURES Name of the License Scheduler token.

CONNECT TIME The submission time of the task.

Output for -I Option

Displays detailed information for each task in multi-line format. If the task is in WAIT status, bltasks displays "The application manager is waiting for a token to start" and the resource requirement. Otherwise, the current resource usage of task is displayed as follows:

TERMINAL The terminal the task is using.

PGID UNIX process group ID.

CPU The total accumulated CPU time of all processes in a task, in seconds.

MEM Total resident memory usage of all processes in a task, in KB.

SWAP Total virtual memory usage of all processes in a task, in KB.

Keyboard idle since Time at which the task became idle.

RES_REQ The resource requirement of the task.

Command line The command the License Scheduler task manager is executing.

blusers

displays license usage information

Synopsis

```
blusers [-J | -l | -P -j job_ID -u user_name -m host_name | -P
   -c cluster_name -j job_ID -u user_name -m host_name]
blusers [-h | -V]
```

Description

By default, displays summarized information about usage of licenses.

Options

- -J Displays detailed license usage information about each job.
- -I Long format. Displays additional license usage information. See Output on page 109 for a description of information that is displayed.

-P -j job_ID -u user_name -m host_name

-P -c cluster_name -j job_ID -u user_name -m host_name

This string of options is designed to be used in a customized preemption script. To identify a job, specify the LSF job ID, the user name, and the name of the host where the job is running.

(If the job is an interactive task submitted using taskman, do not specify -c *cluster_name.*)

You see the display terminal used by the job, the licenses it has checked out, and the license servers that provided the licenses. There is one line of output for each license feature from each FLEXnet license server, in the format:

port_number@host_name token_name user_name host_name display

- -h Prints command usage to stderr and exits.
- -V Prints License Scheduler release version to stderr and exits.

Output

Default Output

FEATURE The license name. This becomes the license token name.

SERVICE DOMAIN The name of the service domain that provided the license.

USER The name of the user who submitted the jobs.

HOST The name of the host where jobs have started.

NLICS The number of licenses checked out from FLEXnet.

NTASKS The number of running tasks using these licenses. -J Output

Displays the following summary information for each job:

JOBID The job ID assigned by LSF.

USER The name of the user who submitted the job.

HOST The name of the host where the job has been started.

PROJECT The name of the license project that the job is associated with.

CLUSTER The name of the LSF cluster that the job is associated with. Displays "-" for an

interactive job.

START_TIME The job start time.

Displays the following information for each license in use by the job:

RESOURCE The name of the license requested by the job.

RUSAGE The number of licenses requested by the job.

SERVICE DOMAIN The name of the service domain that provided the license.

The keyword UNKNOWN means the job requested a license from License

Scheduler but has not checked out the license from FLEXnet.

Long Output (-I)

Displays the default output and the following additional information for each job:

OTHERS License usage for non-managed or non-LSF workload.

DISPLAYS Terminall display associated with the license feature.

PIDS Process ID of the process that checked out the license feature.

The Macrovision FLEXnet plugin for LSF License Scheduler must be enabled to

display the process ID.

Viewing license feature locality

When LOCAL_TO is configured for a feature in 1sf.licensescheduler, blusers shows the cluster locality information for the license features. For example:

blusers

| FEATURE | SERVICE_DOMAIN | USER | HOST | NLICS | NTASKS |
|-----------------|----------------|-------|-------|-------|--------|
| hspice@clusterA | SD1 | user1 | host1 | 1 | 1 |
| hspice@siteB | SD2 | user2 | host2 | 1 | 1 |

Examples

blusers -1

NIICS NTASKS OTHERS DISPLAYS PIDS FEATURE SERVICE_DOMAIN USER HOST LanServer user1 hostA 1 feat.1 1 0 (/dev/tty) (16326) blusers -J PROJECT JOBID USER HOST 553 user1 hostA START_TIME CLUSTER Oct 5 15:47:14 cluster1 SERVICE_DOMAIN RESOURCE RUSAGE p1_f1 app_1

bmgroup

displays information about host groups

Synopsis

```
bmgroup [-r] [-1] [-w] [host_group ...]
bmgroup [-h | -V]
```

Description

Displays host groups and host names for each group.

By default, displays information about all host groups including host groups created for EGO-enabled SLA scheduling. A host partition is also considered a host group.

Host groups for EGO-enabled SLA

When hosts are allocated to an EGO-enabled SLA, they are dynamically added to a host group created by the SLA. The name of the host group is _sla_sla_name, where *sla_name* is the name of the EGO-enabled SLA defined in lsb.serviceclasses or in ENABLE DEFAULT EGO SLA in lsb.params. One of the hosts in the host group will have the name _virtual.

When the host is released to EGO, the entry is removed from the host group. bmgroup displays the hosts allocated by EGO to the host group created by the SLA.

Options

- -I Displays static and dynamic host group members. A '+' sign before the host name indicates that the host is dynamic and is currently a member of the host group. A '-' sign before the host name indicates that the host is currently not an LSF host but is a member of the dynamic host group.
 - Also identifies condensed host groups. These host groups are defined by CONDENSE in the HostGroup section of 1sb.hosts.
- -r Expands host groups recursively. The expanded list contains only host names; it does not contain the names of subgroups. Duplicate names are listed only once.
- Wide format. Displays host and host group names without truncating fields.

host group ...

- Only displays information about the specified host groups. Do not use quotes when specifying multiple host groups.
- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

In the list of hosts, a name followed by a slash (/) indicates a subgroup.

Files

Host groups and host partitions are defined in the configuration file 1sb. hosts(5).

bmig

migrates checkpointable or rerunnable jobs

Synopsis

```
bmig [-f] [job_ID | "job_ID[index_list]"] ...
bmig [-f] [-J job_name] [-m "host_name ..." | -m "host_group ..."]
   [-u user_name | -u user_group | -u all] [0]
bmig [-h | -V]
```

Description

Migrates one or more of your checkpointable or rerunnable jobs to a different host. You can migrate only running or suspended jobs; you cannot migrate pending jobs. Members of a chunk job in the WAIT state can be migrated; LSF removes waiting jobs from the job chunk and changes their original dispatch sequence.

By default, migrates the most recently submitted job, or the most recently submitted job that also satisfies other specified options (-u and -J). Specify 0 (zero) to migrate multiple jobs. Only LSF administrators and root can migrate jobs submitted by other users. Both the original and the new hosts must:

- Be binary compatible
- Run the same dot version of the operating system for predictable results
- Have network connectivity and read/execute permissions to the checkpoint and restart executables (in LSF_SERVERDIR by default)
- Have network connectivity and read/write permissions to the checkpoint directory and the checkpoint file
- Have access to all files open during job execution so that LSF can locate them using an absolute path name

When you migrate a checkpointable job, LSF checkpoints and kills the job and then restarts the job on the next available host. If checkpoint fails, the job continues to run on the original host. If you issue the bmig command while a job is being checkpointed—for example, with periodic checkpointing enabled—LSF ignores the migration request.

When you migrate a rerunnable job, LSF kills the job and then restarts it from the beginning on the next available host. LSF sets the environment variable LSB_RESTART to Y when a migrating job restarts or reruns.

NOTE: The user does not receive notification when LSF kills a checkpointable or rerunnable job as part of job migration.

In a MultiCluster environment, you must use brun rather than bmig to move a job to another host.

When absolute job priority scheduling (APS) is configured in the queue, LSF always schedules migrated jobs before pending jobs. For migrated jobs, LSF keeps the existing job priority. If LSB_REQUEUE_TO_BOTTOM and LSB_MIG2PEND are

configured in 1sf.conf, the migrated jobs keep their APS information, and the migrated jobs compete with other pending jobs based on the APS value. If you want to reset the APS value, you must use brequeue instead of bmig.

Options

-f Forces a checkpointable job to be checkpointed and migrated, even if non-checkpointable conditions exist within the operating system environment.

job_ID | "job_ID[index_list]" | 0

Migrates jobs with the specified job IDs. LSF ignores the -J and -u options.

If you specify a job ID of 0 (zero), LSF ignores all other job IDs and migrates all jobs that satisfy the -J and -u options.

If you do not specify a job ID, LSF migrates the most recently submitted job that satisfies the -J and -u options.

-J job name Migrates the job with the specified name. Ignored if a job ID other than 0 (zero) is specified.

-m "host_name ..." | -m "host_group ..."

Migrates jobs to the specified hosts.

This option cannot be used on a MultiCluster job; bmig can only restart or rerun the job on the original host.

-u "user_name" | -u "user_group" | -u all

Migrates only those jobs submitted by the specified users. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (*DOMAIN_NAME\user_name*) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

If you specify the reserved user name all, LSF migrates jobs submitted by all users. Ignored if a job ID other than 0 (zero) is specified.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

[job_ID | "job_ID[index]"]
```

Description

Modifies the options of a previously submitted job. See bsub for complete descriptions of job submission options you can modify with bmod.

Only the owner of the job, or LSF administrators, can modify the options of a job.

All options specified at submission time may be changed. The value for each option may be overridden with a new value by specifying the option as in bsub. To reset an option to its default value, use the option string followed by 'n'. Do not specify an option value when resetting an option.

The -i, -in, and -Z options have counterparts that support spooling of input and job command files (-is, -isn, -Zs, and -Zsn).

Options related to file names and job spooling directories support paths that contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows.

Options related to command names and job names names can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows.

You can modify all options of a pending job, even if the corresponding bsub option was not specified.

Modifying a job that is pending in a chunk job queue (CHUNK_JOB_SIZE) removes the job from the chunk to be scheduled later.

Like bsub, bmod calls the master esub (mesub), which invokes any mandatory esub executables configured by an LSF administrator, and any executable named esub (without .application) if it exists in LSF_SERVERDIR. Only esub executables invoked by bsub can change the job environment on the submission host. An esub invoked by bmod cannot change the job environment.

- cwdn sets the current working directory for the job to the directory where bmod is running.
- Epn cancels the setting of job-level post-execution commands. The job-level post-execution commands will not run. Application-level post-execution commands will run if it exists.
- -rn resets the rerunnable job setting specified by bsub -rn or bsub -r. The application profile and queue level rerunnable job setting if any is used. bmod -rn does not disable or override job rerun if the job was submitted to a rerunnable queue or application profile with job rerun configured. bmod -rn is different from bsub -rn, which does override the application profile and queue level rerunnable job setting.
- -uln sets the user shell limits for pending jobs to to their default values. -uln is not supported on Windows.
- -Wen cancels the estimated job runtime. The runtime estimate will not take effect for the job.

Modifying running jobs

By default, you can modify resource requirements for running jobs (-R "res_req"). To modify additional job options for running jobs, define LSB_MOD_ALL_JOBS=Y in 1sf.conf.

When LSB_MOD_ALL_JOBS=Y is set, the following are the only bmod options that are valid for running jobs. You cannot make any other modifications after a job has been dispatched.

- CPU limit (-c [hour:]minute[/host_name | /host_model])
- Memory limit (-M mem_limit)
- Rerunnable jobs (-r | -rn)
- Resource reservation (-R "res_req")
- Run limit (-W run_limit[/host_name | /host_model])
- Standard output (stdout) file name up to 4094 characters for UNIX and Linux or 255 characters for Windows (-o output_file)

- Standard error (stderr) file name up to 4094 characters for UNIX and Linux or 255 characters for Windows (-e error file)
- Overwrite standard output (stdout) file name up to 4094 characters for UNIX and Linux or 255 characters for Windows (-oo output file)
- Overwrite standard error (stderr) file name up to 4094 characters for UNIX and Linux or 255 characters for Windows (-eo error_file)

Modified resource usage limits cannot exceed limits defined in the queue.

To modify the CPU limit or the memory limit of running jobs, the parameters LSB_JOB_CPULIMIT=Y and LSB_JOB_MEMLIMIT=Y must be defined in 1sf.conf.

If you want to specify array dependency by array name, set JOB_DEP_LAST_SUB in 1sb. params. If you do not have this parameter set, the job will be rejected if one of your previous arrays has the same name but a different index.

By default, options for the following resource usage limits are specified in KB:

- Core limit (-C)
- Memory limit (-M)
- Stack limit (-S)
- Swap limit (-v)

Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a different unit for the limit (MB, GB, TB, PB, or EB).

Modifying resource requirements

The -R option of bmod completely replaces any previous resource requirement specification. It does not add the modification to the existing specification. For example, if you submit a job with

```
bsub -R "rusage[res1=1]"
```

then modify it with

bmod -R "rusage[res2=1]"

the new resource usage requirement for the job is [res2=1], not [res1=1; res2=1].

bmod does not support the OR (||) operator on the -R option.

To remove all of the string input specified using the bsub command, use the -Rn option.

Modifying advance reservations

If advance reservations are enabled, administrators can use the -U option of bmod to change a job to another reservation ID. For example:

bmod -U user1#0 1234

To cancel the reservation, use the -Un option of bmod. For example:

bmod -Un 1234

Closed reservations LSF administrators can prevent running jobs from being killed when the reservation expires by changing the termination time of the job using the reservation (bmod -t) before the reservation window closes.

For example:

```
bmod -t 15:0 1234
```

You can only modify the termination time of an advance reservation job while the reservation is active. When the reservation expires or is deleted, the job is killed and you can no longer make any modifications.

CAUTION: bmod -t will not change the termination time of a pending job.

Open reservations

LSF users can modify the termination time of their open advance reservations without interfering with current job scheduling policies. For example, you specify two open advance reservations as follows:

```
brsvadd -o -n 1 -m hostA -u user1 -b 15:10 -e 15:30
Reservation user1#17 is created
brsvadd -o -n 1 -m hostA -u user1 -b 15:35 -e 15:50
Reservation user1#18 is created
```

At 15:15, while job 122 in user1#17 is running, you modify its termination time as follows:

```
bmod -t 15:40 122
```

This termination time overlaps the reservation window of user1#18, in which job 245 started at 15:35. After modifying the termination time of job 122, the following events occur:

At 15:50, both Job 122 in reservation user#17 and Job 245 in reservation user#18 are suspended. At this point, the existing scheduling policies determine which job runs; in this example, Job 122 in reservation user#17 runs.

| At this time | These events occur | | | |
|--------------|---|--|--|--|
| 15:35 | Job 122 in reservation user1#17 suspends | | | |
| | Job 245 in reservation user1#18 starts | | | |
| 15:40 | Job 122 in reservation user#17 is still suspended | | | |
| | Job 245 in reservation user#18 continues to run | | | |
| 15:50 | Job 122 in reservation user1#17 suspends | | | |
| | Job 245 in reservation user1#18 suspends | | | |
| 15:51 | Job 122 in reservation user1#17 runs | | | |
| | Job 245 in reservation user1#18 suspends | | | |

Modifying job groups

Use the -g option of bmod and specify a job group path to move a job or a job array from one job group to another. For example:

```
bmod -g /risk_group/portfolio2/monthly 105
```

moves job 105 to job group /risk_group/portfolio2/monthly.

Like bsub -g, if the job group does not exist, LSF creates it.

bmod -g cannot be combined with other bmod options. It can only operate on pending jobs. It cannot operate on running or finished jobs.

You can modify your own job groups and job groups that other users create under your job groups. LSF administrators can modify job groups of all users.

You cannot move job array elements from one job group to another, only entire job arrays. If any job array elements in a job array are running, you cannot move the job array to another group. A job array can only belong to one job group at a time.

You cannot modify the job group of a job attached to a service class.

Modifying jobs in service classes

The -sla option modifies a job by attaching it to the specified service class. The -slan option detaches the specified job from a service class. If the service class does not exist, the job is not modified. For example:

bmod -sla Kyuquot 2307

attaches job 2307 to the service class Kyuquot.

bmod -slan 2307

detaches job 2307 from the service class Kyuquot. If a default SLA is configured in 1sb.params, the job is moved to the default service class.

You cannot

- Use -sla with other bmod options
- Move job array elements from one service class to another, only entire job arrays
- Modify the service class of job already attached to a job group. Use bsla to display the configuration properties of service classes configured in 1sb.serviceclasses, the default SLA configured in 1sb.params, and dynamic information about the state of each service class.

If a default SLA is configured in 1sb.params, bmod -slan moves the job to the default SLA. If the job is already attached to the default SLA, bmod -slan has no effect on that job.

Modifying jobs associated with application profiles

The -app option modifies a job by associating it to the specified application profile. The -appn option dissociates the specified job from its application profile. If the application profile does not exist, the job is not modified.

You can only modify the application profile for pending jobs. For example:

bmod -app fluent 2308

associates job 2308 with the application profile fluent.

bmod -appn 2308

dissociates job 2308 from the service class fluent.

Use bapp to display the properties of application profiles configured in LSB_CONFDIR/cluster_name/configdir/lsb.applications.

Modifying absolute priority scheduling options

Administrators can use bmod -aps to adjust the APS value for pending jobs. bmod -apsn cancels previous bmod -aps settings. You cannot combing bmod -aps with other bmod options.

Options

bmod -aps "system=value" job_ID

Set a static non-zero APS value of a pending job. Setting a system APS value overrides any calculated APS value for the job. The system APS value cannot be applied to running jobs.

bmod -aps "admin=value" iob ID

Set a non-zero ADMIN factor value for a pending job. The ADMIN factor adjusts the calculated APS value higher or lower. A negative admin value is lowers the calculated APS value, and a positive value raises the calculated APS value relative to other pending jobs in the APS queue.

You cannot configure APS weight, limit, or grace period for the ADMIN factor. The ADMIN factor takes effect as soon as it is set.

bmod -apsn

Run bmod -apsn to cancel previous bmod -aps settings. You cannot apply bmod - apsn on running jobs in an APS queue. An error is issued if the job has no system APS priority or ADMIN factor set.

Options

job_ID | "job_ID[index]"

Modifies jobs with the specified job ID. Modifies job array elements specified by "job_ID[index]".

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Limitations

Modifying remote running jobs in a MultiCluster environment is not supported.

If you do not specify -e or -eo before the job is dispatched, you cannot modify the name of job error file for a running job. Modifying the job output options of remote running jobs is not supported.

bsub

bparams

displays information about configurable system parameters in lsb.params

Synopsis

```
bparams [-a] [-1]
bparams [-h | -V]
```

Description

Displays the following parameter values:

- **Default Queues**
- Job Dispatch Interval
- Job Checking Interval
- Job Accepting Interval

Options

- All format. Displays all the configurable parameters set in 1sb.params.
- -I Long format. Displays detailed information about all the configurable parameters in lsb.params.
- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

1sb.params

bpeek

displays the stdout and stderr output of an unfinished job

Synopsis

```
bpeek [-f] [-q queue_name | -m host_name | -J job_name |
   job_ID | "job_ID[index_list]"]
bpeek [-h | -V]
```

Description

Displays the standard output and standard error output that have been produced by one of your unfinished jobs, up to the time that this command is invoked.

By default, displays the output using the command cat.

This command is useful for monitoring the progress of a job and identifying errors. If errors are observed, valuable user time and system resources can be saved by terminating an erroneous job.

Options

-f Displays the output of the job using the command tail -f.

Operates on your most recently submitted job in the specified queue. -q queue_name

-m host_name Operates on your most recently submitted job that has been dispatched to the specified host.

-J job_name Operates on your most recently submitted job that has the specified job name.

The job name can be up to 4094 characters long for UNIX and Linux or up to 255 characters for Windows.

job_ID | "job_ID[index_list]"

Operates on the specified job.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

cat, tail, bsub, bjobs, bhist, bhosts, bqueues

bpost

sends external status messages and attaches data files to a job

Synopsis

```
bpost [-i message_index] [-d "description"] [-a data_file]
   job_ID | "job_ID[index]" | -J job_name
bpost [-h | -V]
```

Description

Provides external status information or sends data to a job in the system. Done or exited jobs cannot accept messages.

By default, operates on the message index 0. By default, posts the message "no description".

If a you specify a job ID:

- You can only send messages and data to your own jobs.
- You cannot send messages and data to jobs submitted by other users.
- Only root and LSF administrators can send messages to jobs submitted by other users.
- Root and LSF administrators cannot attach data files to jobs submitted by other

Job names are not unique; if you specify -J job_name:

- You can only send messages and data to your own jobs.
- You cannot send messages and data to jobs submitted by other users.
- Root and the LSF administrators can only send messages and data to their own jobs.

A job can accept messages until it is cleaned from the system. If your application requires transfer of data from one job to another, use the -a option of bpost(1) to attach a data file to the job, then use the bread(1) command to copy the attachment to another file.

You can associate several messages and attached data files with the same job. As the job is processed, use bread(1) or bstatus(1) to retrieve the messages posted to the job. Use bread(1) to copy message attachments to external files.

For example, your application may require additional job status descriptions besides the ones that LSF provides internally (PEND, RUN, SUSP, etc.) Use the -d option to place your own status or job description text as a message to the job.

You can also use bstatus -d to update the external job status. The command:

```
bstatus -d "description" myjob
```

is equivalent to:

```
bpost -i 0 -d "description" myjob
```

With MultiCluster, both clusters must run LSF Version 7 or later. You cannot post a message to a MultiCluster job if the clusters are disconnected. You cannot attach files to MultiCluster jobs.

Options

-a data_file Attaches the specified data file to the job external storage. This option is ignored for MultiCluster jobs; you can only attach a file if the job executes in the local cluster.

> Use the JOB_ATTA_DIR parameter in 1sb.params(5) to specify the directory where attachment data files are saved. The directory must have at least 1 MB of free space. mbatchd checks for available space in the job attachment directory before transferring the file.

> Use the MAX_JOB_ATTA_SIZE parameter in lsb.params to set a maximum size for job message attachments.

-d "description"

Places your own status text as a message to the job. The message description has a maximum length of 512 characters.

For example, your application may require additional job status descriptions besides the ones that LSF provides internally (PEND, RUN, SUSP, etc.)

Default: "no description"

-i message_index

Operates on the specified message index.

Default: 0

Use the MAX_JOB_MSG_NUM parameter in 1sb.params to set a maximum number of messages for a job. With MultiCluster, to avoid conflicts, MAX_JOB_MSG_NUM should be the same in all clusters.

job ID | "job ID[index]" | -J job name

Required. Operates on the specified job. With MultiCluster job forwarding model, you must always use the local job ID.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Example

```
bpost -i 1 -d "step 1" -a step1.out 2500
```

Puts the message text step 1 into message index 1, and attaches the file step1.out to job 2500.

See Also

bread(1), bstatus(1), MAX_JOB_ATTA_SIZE, MAX_JOB_MSG_NUM

bqueues

displays information about queues

Synopsis

```
bqueues [-w | -1 | -r]
    [-m\ \textit{host\_name}\ |\ -m\ \textit{host\_group}\ |\ -m\ \textit{cluster\_name}\ |\ -m\ \textit{all}]
    [-u user_name | -u user_group | -u all] [queue_name ...]
bqueues [-h | -V]
```

Description

Displays information about queues.

By default, returns the following information about all queues: queue name, queue priority, queue status, job slot statistics, and job state statistics.

In MultiCluster, returns the information about all queues in the local cluster.

Batch queue names and characteristics are set up by the LSF administrator (see 1sb.queues(5) and mbatchd(8)).

CPU time is normalized.

Options

-I Displays queue information in a long multiline format. The -1 option displays the following additional information: queue description, queue characteristics and statistics, scheduling parameters, resource usage limits, scheduling policies, users, hosts, associated commands, dispatch and run windows, and job controls.

Also displays user shares.

If you specified an administrator comment with the -C option of the queue control commands qclose, qopen, qact, and qinact, qhist displays the comment text.

Displays absolute priority scheduling (APS) information for queues configured with APS_PRIORITY.

- -r Displays the same information as the -1 option. In addition, if fairshare is defined for the queue, displays recursively the share account tree of the fairshare queue.
- -w Displays queue information in a wide format. Fields are displayed without truncation.

-m host_name | -m host_group | -m cluster_name | -m all

Displays the queues that can run jobs on the specified host. If the keyword all is specified, displays the queues that can run jobs on all hosts.

If a host group is specified, displays the queues that include that group in their configuration. For a list of host groups see bmgroup(1).

In MultiCluster, if the all keyword is specified, displays the queues that can run jobs on all hosts in the local cluster. If a cluster name is specified, displays all queues in the specified cluster.

-u user_name | -u user_group | -u all

Displays the queues that can accept jobs from the specified user. If the keyword all is specified, displays the queues that can accept jobs from all users.

If a user group is specified, displays the queues that include that group in their configuration. For a list of user groups see bugroup(1)).

queue_name ... Displays information about the specified queues.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

Default Output

Displays the following fields:

QUEUE_NAME

The name of the queue. Queues are named to correspond to the type of jobs usually submitted to them, or to the type of services they provide.

lost_and_found

If the LSF administrator removes queues from the system, LSF creates a queue called lost_and_found and places the jobs from the removed queues into the lost_and_found queue. Jobs in the lost_and_found queue will not be started unless they are switched to other queues (see bswitch).

PRIO

The priority of the queue. The larger the value, the higher the priority. If job priority is not configured, determines the queue search order at job dispatch, suspension and resumption time. Jobs from higher priority queues are dispatched first (this is contrary to UNIX process priority ordering), and jobs from lower priority queues are suspended first when hosts are overloaded.

STATUS

The current status of the queue. The possible values are:

Open

The queue is able to accept jobs.

Closed

The queue is not able to accept jobs.

Jobs in the queue may be started.

Inactive

Jobs in the queue cannot be started for the time being.

At any moment, each queue is either Open or Closed, and is either Active or Inactive. The queue can be opened, closed, inactivated and re-activated by the LSF administrator using badmin (see badmin(8)).

Jobs submitted to a queue that is later closed are still dispatched as long as the queue is active. The queue can also become inactive when either its dispatch window is closed or its run window is closed (see DISPATCH_WINDOWS in the "Output for the -l Option" section). In this case, the queue cannot be activated using badmin.

The queue is re-activated by LSF when one of its dispatch windows and one of its run windows are open again. The initial state of a queue at LSF boot time is set to open, and either active or inactive depending on its windows.

MAX The maximum number of job slots that can be used by the jobs from the queue.

These job slots are used by dispatched jobs which have not yet finished, and by

pending jobs which have slots reserved for them.

A sequential job will use one job slot when it is dispatched to a host, while a parallel job will use as many job slots as is required by bsub -n when it is dispatched. See

bsub(1) for details. If '-' is displayed, there is no limit.

JL/U The maximum number of job slots each user can use for jobs in the queue. These

job slots are used by your dispatched jobs which have not yet finished, and by pending jobs which have slots reserved for them. If '-' is displayed, there is no limit.

JL/P The maximum number of job slots a processor can process from the queue. This

> includes job slots of dispatched jobs that have not yet finished, and job slots reserved for some pending jobs. The job slot limit per processor (JL/P) controls the number of jobs sent to each host. This limit is configured per processor so that multiprocessor hosts are automatically allowed to run more jobs. If '-' is displayed,

there is no limit.

JL/H The maximum number of job slots a host can allocate from this queue. This

> includes the job slots of dispatched jobs that have not yet finished, and those reserved for some pending jobs. The job slot limit per host (JL/H) controls the number of jobs sent to each host, regardless of whether a host is a uniprocessor host

or a multiprocessor host. If '-' is displayed, there is no limit.

NJOBS The total number of job slots held currently by jobs in the queue. This includes

> pending, running, suspended and reserved job slots. A parallel job that is running on n processors is counted as n job slots, since it takes n job slots in the queue. See

bjobs(1) for an explanation of batch job states.

PEND The number of job slots used by pending jobs in the queue.

RUN The number of job slots used by running jobs in the queue.

SUSP The number of job slots used by suspended jobs in the queue.

Long Output (-I)

In addition to the above fields, the -1 option displays the following:

Description A description of the typical use of the queue.

Default queue indication

Indicates that this is the default queue.

PARAMETERS/ STATISTICS

NICE

The nice value at which jobs in the queue will be run. This is the UNIX nice value for reducing the process priority (see nice(1)).

STATUS

Inactive

The long format for the -1 option gives the possible reasons for a queue to be inactive:

Inact Win

The queue is out of its dispatch window or its run window.

The queue has been inactivated by the LSF administrator.

The number of job slots in the queue allocated to jobs that are suspended by LSF because of load levels or run windows.

USUSP

The number of job slots in the queue allocated to jobs that are suspended by the job submitter or by the LSF administrator.

RSV

The number of job slots in the queue that are reserved by LSF for pending jobs.

Migration threshold

The length of time in seconds that a job dispatched from the queue will remain suspended by the system before LSF attempts to migrate the job to another host. See the MIG parameter in 1sb. queues and 1sb. hosts.

Schedule delay for a new job

The delay time in seconds for scheduling after a new job is submitted. If the schedule delay time is zero, a new scheduling session is started as soon as the job is submitted to the queue. See the NEW_JOB_SCHED_DELAY parameter in 1sb.queues.

Interval for a host to accept two jobs

The length of time in seconds to wait after dispatching a job to a host before dispatching a second job to the same host. If the job accept interval is zero, a host may accept more than one job in each dispatching interval. See the JOB_ACCEPT_INTERVAL parameter in 1sb.queues and 1sb.params.

RESOURCE LIMITS

The hard resource usage limits that are imposed on the jobs in the queue (see getrlimit(2) and lsb.queues(5)). These limits are imposed on a per-job and a per-process basis.

The possible per-job limits are:

CPULIMIT

The maximum CPU time a job can use, in minutes, relative to the CPU factor of the named host. CPULIMIT is scaled by the CPU factor of the execution host so that jobs are allowed more time on slower hosts.

When the job-level CPULIMIT is reached, a SIGXCPU signal is sent to all processes belonging to the job. If the job has no signal handler for SIGXCPU, the job is killed immediately. If the SIGXCPU signal is handled, blocked, or ignored by the application, then after the grace period expires, LSF sends SIGINT, SIGTERM, and SIGKILL to the job to kill it.

PROCLIMIT

The maximum number of processors allocated to a job. Jobs that request fewer slots than the minimum PROCLIMIT or more slots than the maximum PROCLIMIT are rejected. If the job requests minimum and maximum job slots, the maximum slots requested cannot be less than the minimum PROCLIMIT, and the minimum slots requested cannot be more than the maximum PROCLIMIT.

MEMLIMIT

The maximum running set size (RSS) of a process. If a process uses more memory than the limit allows, its priority is reduced so that other processes are more likely to be paged in to available memory. This limit is enforced by the <code>setrlimit</code> system call if it supports the RLIMIT_RSS option.

By default, the limit is shown in KB. Use LSF UNIT FOR LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

SWAPLIMIT

The swap space limit that a job may use. If SWAPLIMIT is reached, the system sends the following signals in sequence to all processes in the job: SIGINT, SIGTERM, and SIGKILL.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

PROCESSLIMIT

The maximum number of concurrent processes allocated to a job. If PROCESSLIMIT is reached, the system sends the following signals in sequence to all processes belonging to the job: SIGINT, SIGTERM, and SIGKILL.

THREADLIMIT

The maximum number of concurrent threads allocated to a job. If THREADLIMIT is reached, the system sends the following signals in sequence to all processes belonging to the job: SIGINT, SIGTERM, and SIGKILL.

The possible UNIX per-process resource limits are:

RUNLIMIT

The maximum wall clock time a process can use, in minutes. RUNLIMIT is scaled by the CPU factor of the execution host. When a job has been in the RUN state for a total of RUNLIMIT minutes, LSF sends a SIGUSR2 signal to the job. If the job does not exit within 5 minutes, LSF sends a SIGKILL signal to kill the job.

FILELIMIT

The maximum file size a process can create, in KB. This limit is enforced by the UNIX setrlimit system call if it supports the RLIMIT_FSIZE option, or the ulimit system call if it supports the UL_SETFSIZE option.

DATALIMIT

The maximum size of the data segment of a process, in KB. This restricts the amount of memory a process can allocate. DATALIMIT is enforced by the setrlimit system call if it supports the RLIMIT_DATA option, and unsupported otherwise.

STACKLIMIT

The maximum size of the stack segment of a process. This limit restricts the amount of memory a process can use for local variables or recursive function calls. STACKLIMIT is enforced by the setrlimit system call if it supports the RLIMIT_STACK option.

By default, the limit is shown in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

CORELIMIT

The maximum size of a core file. This limit is enforced by the setrlimit system call if it supports the RLIMIT_CORE option.

If a job submitted to the queue has any of these limits specified (see bsub(1)), then the lower of the corresponding job limits and queue limits are used for the job.

If no resource limit is specified, the resource is assumed to be unlimited.

By default, the limit is shown in KB. Use LSF UNIT FOR LIMITS in 1sf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

SCHEDULING PARAMETERS

The scheduling and suspending thresholds for the queue.

The scheduling threshold loadSched and the suspending threshold loadStop are used to control batch job dispatch, suspension, and resumption. The queue thresholds are used in combination with the thresholds defined for hosts (see bhosts(1) and 1sb.hosts(5)). If both queue level and host level thresholds are configured, the most restrictive thresholds are applied.

The loadSched and loadStop thresholds have the following fields:

r15s

The 15-second exponentially averaged effective CPU run queue length.

r1m

The 1-minute exponentially averaged effective CPU run queue length.

r15m

The 15-minute exponentially averaged effective CPU run queue length.

ut

The CPU utilization exponentially averaged over the last minute, expressed as a percentage between 0 and 1.

pg

The memory paging rate exponentially averaged over the last minute, in pages per second.

io

The disk I/O rate exponentially averaged over the last minute, in KB per second.

The number of current login users.

On UNIX, the idle time of the host (keyboard not touched on all logged in sessions), in minutes.

On Windows, the it index is based on the time a screen saver has been active on a particular host.

tmp

The amount of free space in /tmp, in MB.

The amount of currently available swap space. By default, swap space is shown in MB. Use LSF_UNIT_FOR_LIMITS in lsf.conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

The amount of currently available memory. By default, memory is shown in MB. Use LSF_UNIT_FOR_LIMITS in 1sf. conf to specify a larger unit for display (MB, GB, TB, PB, or EB).

cpuspeed

The speed of each individual cpu, in megahertz (MHz).

bandwidth

The maximum bandwidth requirement, in megabits per second (Mbps).

In addition to these internal indices, external indices are also displayed if they are defined in 1sb. queues (see 1sb. queues(5)).

The loadSched threshold values specify the job dispatching thresholds for the corresponding load indices. If '-' is displayed as the value, it means the threshold is not applicable. Jobs in the queue may be dispatched to a host if the values of all the load indices of the host are within (below or above, depending on the meaning of the load index) the corresponding thresholds of the queue and the host. The same conditions are used to resume jobs dispatched from the queue that have been suspended on this host.

Similarly, the loadStop threshold values specify the thresholds for job suspension. If any of the load index values on a host go beyond the corresponding threshold of the queue, jobs in the queue will be suspended.

JOB EXCEPTION PARAMETERS

Configured job exception thresholds and number of jobs in each exception state for the queue.

Threshold and NumOfJobs have the following fields:

overrun

Configured threshold in minutes for overrun jobs, and the number of jobs in the queue that have triggered an overrun job exception by running longer than the overrun threshold

underrun

Configured threshold in minutes for underrun jobs, and the number of jobs in the queue that have triggered an underrun job exception by finishing sooner than the underrun threshold

alhi

Configured threshold (CPU time/runtime) for idle jobs, and the number of jobs in the queue that have triggered an overrun job exception by having a job idle factor less than the threshold

SCHEDULING POLICIES

Scheduling policies of the queue. Optionally, one or more of the following policies may be configured:

APS PRIORITY

Absolute Priority Scheduling is enabled. Pending jobs in the queue are ordered according to the calculated APS value.

FAIRSHARE

Queue-level fairshare scheduling is enabled. Jobs in this queue are scheduled based on a fairshare policy instead of the first-come, first-serve (FCFS) policy.

BACKFILL

A job in a backfill queue can use the slots reserved by other jobs if the job can run to completion before the slot-reserving jobs start.

Backfilling does not occur on queue limits and user limit but only on host based limits. That is, backfilling is only supported when MXJ, JL/U, JL/P, PJOB_LIMIT, and HJOB_LIMIT are reached. Backfilling is not supported when MAX_JOBS, QJOB LIMIT, and UJOB LIMIT are reached.

IGNORE DEADLINE

If IGNORE_DEADLINE is set to Y, starts all jobs regardless of the run limit.

EXCLUSIVE

Jobs dispatched from an exclusive queue can run exclusively on a host if the user so specifies at job submission time (see bsub(1)). Exclusive execution means that the job is sent to a host with no other batch job running there, and no further job, batch or interactive, will be dispatched to that host while the job is running. The default is not to allow exclusive jobs.

NO INTERACTIVE

This queue does not accept batch interactive jobs. (see the - I, - Is, and - Ip options of bsub(1)). The default is to accept both interactive and non-interactive jobs.

ONLY INTERACTIVE

This queue only accepts batch interactive jobs. Jobs must be submitted using the - I, - Is, and - Ip options of bsub(1). The default is to accept both interactive and non-interactive jobs.

FAIRSHARE_QUEUES

Lists queues participating in cross-queue fairshare. The first queue listed is the master queue—the queue in which fairshare is configured; all other queues listed inherit the fairshare policy from the master queue. Fairshare information applies to all the jobs running in all the queues in the master-slave set.

QUEUE_GROUP

Lists queues participating in an absolute priority scheduling (APS) queue group. If both FAIRSHARE and APS PRIORITY are enabled in the same queue, the FAIRSHARE_QUEUES are not displayed. These queues are instead displayed as QUEUE_GROUP.

DISPATCH ORDER

DISPATCH_ORDER=QUEUE is set in the master queue. Jobs from this queue are dispatched according to the order of queue priorities first, then user fairshare priority. Within the queue, dispatch order is based on user share quota. This avoids having users with higher fairshare priority getting jobs dispatched from low-priority queues.

USER SHARES

A list of [user name, share] pairs. user name is either a user name or a user group name. *share* is the number of shares of resources assigned to the user or user group. A party will get a portion of the resources proportional to that party's share divided by the sum of the shares of all parties specified in this queue.

DEFAULT HOST SPECIFICATION

The default host or host model that will be used to normalize the CPU time limit of all jobs.

If you want to view a list of the CPU factors defined for the hosts in your cluster, see lsinfo(1). The CPU factors are configured in lsf.shared(5).

The appropriate CPU scaling factor of the host or host model is used to adjust the actual CPU time limit at the execution host (see CPULIMIT in 1sb.queues(5)). The DEFAULT_HOST_SPEC parameter in lsb. queues overrides the system DEFAULT_HOST_SPEC parameter in lsb.params (see lsb.params(5)). If a user explicitly gives a host specification when submitting a job using bsub -c cpu_limit[/host_name | /host_model], the user specification overrides the values defined in both 1sb.params and 1sb.queues.

RUN WINDOWS

The time windows in a week during which jobs in the queue may run.

When a queue is out of its window or windows, no job in this queue will be dispatched. In addition, when the end of a run window is reached, any running jobs from this queue are suspended until the beginning of the next run window, when they are resumed. The default is no restriction, or always open.

DISPATCH WINDOWS

Dispatch windows are the time windows in a week during which jobs in the queue may be dispatched.

When a queue is out of its dispatch window or windows, no job in this queue will be dispatched. Jobs already dispatched are not affected by the dispatch windows. The default is no restriction, or always open (that is, twenty-four hours a day, seven days a week). Note that such windows are only applicable to batch jobs. Interactive jobs scheduled by LIM are controlled by another set of dispatch windows (see 1shosts(1)). Similar dispatch windows may be configured for individual hosts (see bhosts(1)).

A window is displayed in the format begin time-end time. Time is specified in the format [day:]hour[:minute], where all fields are numbers in their respective legal ranges: 0(Sunday)-6 for day, 0-23 for hour, and 0-59 for minute. The default value for *minute* is 0 (on the hour). The default value for *day* is every day of the week. The begin_time and end_time of a window are separated by '-', with no blank characters (SPACE and TAB) in between. Both begin_time and end_time must be present for a window. Windows are separated by blank characters.

USERS

A list of users allowed to submit jobs to this queue. LSF administrators can submit jobs to the queue even if they are not listed here.

User group names have a slash (/) added at the end of the group name. See bugroup(1).

If the fairshare scheduling policy is enabled, users cannot submit jobs to the queue unless they also have a share assignment. This also applies to LSF administrators.

HOSTS

A list of hosts where jobs in the queue can be dispatched.

Host group names have a slash (/) added at the end of the group name. See bmgroup(1).

NQS DESTINATION QUEUES

A list of NQS destination queues to which this queue can dispatch jobs.

When you submit a job using bsub -q queue_name, and the specified queue is configured to forward jobs to the NQS system, LSF routes your job to one of the NQS destination queues. The job runs on an NQS batch server host, which is not a member of the LSF cluster. Although running on an NQS system outside the LSF cluster, the job is still managed by LSF in almost the same way as jobs running inside the LSF cluster. Thus, you may have your batch jobs transparently sent to an NQS system to run and then get the results of your jobs back. You may use any supported user interface, including LSF commands and NQS commands (see 1 snqs(1)) to submit, monitor, signal and delete your batch jobs that are running in an NQS system. See 1sb.queues(5) and bsub(1) for more information.

ADMINISTRATORS

A list of queue administrators. The users whose names are specified here are allowed to operate on the jobs in the queue and on the queue itself. See 1sb.gueues(5) for more information.

PRE_EXEC The PRE_EXEC command runs on the execution host before the job associated with

the queue is dispatched to the execution host (or to the first host selected for a

parallel batch job).

POST EXEC The post-execution command for the queue. The POST_EXEC command runs on the

execution host after the job finishes.

REQUEUE EXIT VALUES

Jobs that exit with these values are automatically requeued. See 1sb. queues (5) for

more information.

RES_REQ Resource requirements of the queue. Only the hosts that satisfy these resource

requirements can be used by the queue.

Maximum slot reservation time

The maximum time in seconds a slot is reserved for a pending job in the queue. See the SLOT_RESERVE=MAX_RESERVE_TIME[n] parameter in lsb.queues.

RESUME COND The conditions that must be satisfied to resume a suspended job on a host. See

1sb.gueues(5) for more information.

STOP COND The conditions which determine whether a job running on a host should be

suspended. See 1sb.queues(5) for more information.

JOB STARTER An executable file that runs immediately prior to the batch job, taking the batch job

file as an input argument. All jobs submitted to the queue are run via the job starter,

which is generally used to create a specific execution environment before processing the jobs themselves. See 1sb.queues(5) for more information.

CHUNK_JOB_SIZE Chunk jobs only. Specifies the maximum number of jobs allowed to be dispatched

> together in a chunk job. All of the jobs in the chunk are scheduled and dispatched as a unit rather than individually. The ideal candidates for job chunking are jobs

that typically takes 1 to 2 minutes to run.

SEND JOBS TO MultiCluster. List of remote queue names to which the queue forwards jobs.

RECEIVE JOBS FROM

MultiCluster. List of remote cluster names from which the queue receives jobs.

PREEMPTION PREEMPTIVE

The queue is preemptive. Jobs in this queue may preempt running jobs from lower-priority queues, even if the lower-priority queues are not specified as preemptive.

PREEMPTABLE

The queue is preemptable. Running jobs in this queue may be preempted by jobs in higher-priority queues, even if the higher-priority queues are not specified as preemptive.

RERUNNABLE

If the RERUNNABLE field displays yes, jobs in the queue are rerunnable. That is, jobs in the queue are automatically restarted or rerun if the execution host becomes unavailable. However, a job in the queue will not be restarted if the you have removed the rerunnable option from the job. See 1sb.queues(5) for more information.

CHECKPOINT

If the CHKPNTDIR field is displayed, jobs in the queue are checkpointable. Jobs will use the default checkpoint directory and period unless you specify other values. Note that a job in the queue will not be checkpointed if you have removed the checkpoint option from the job. See 1sb.queues(5) for more information.

CHKPNTDIR

Specifies the checkpoint directory using an absolute or relative path name.

CHKPNTPERIOD

Specifies the checkpoint period in seconds.

Although the output of bqueues reports the checkpoint period in seconds, the checkpoint period is defined in minutes (the checkpoint period is defined through the bsub -k "checkpoint_dir []" option, or in 1sb.queues).

JOB CONTROLS

The configured actions for job control. See JOB_CONTROLS parameter in 1sb.aueues.

The configured actions are displayed in the format [action_type, command] where action_type is either SUSPEND, RESUME, or TERMINATE.

ADMIN ACTION COMMENT

If the LSF administrator specified an administrator comment with the -C option of the queue control commands qclose, qopen, qact, and qinact, qhist the comment text is displayed.

SLOT SHARE

Share of job slots for queue-based fairshare. Represents the percentage of running jobs (job slots) in use from the queue. SLOT_SHARE must be greater than zero. The sum of SLOT_SHARE for all queues in the pool does not need to be 100%. It can be more or less, depending on your needs.

SLOT POOL

Name of the pool of job slots the queue belongs to for queue-based fairshare. A queue can only belong to one pool. All queues in the pool must share the same set of hosts.

Recursive Share Tree Output (-r)

In addition to the fields displayed for the -1 option, the -r option displays the following:

SCHEDULING POLICIES

FAIRSHARE

The -r option causes bqueues to recursively display the entire share information tree associated with the queue.

bread

reads messages and attached data files from a job

Synopsis

```
bread [-i message_index] [-a file_name]
   job_ID | "job_ID[index]" | -J job_name
bread [-h | -V]
```

Description

Reads messages and data posted to an unfinished job with bpost.

By default, displays the message description text of the job. By default, operates on the message with index 0.

You can read messages and data from a job until it is cleaned from the system. You cannot read messages and data from done or exited jobs.

If a you specify a job ID:

- You can get read messages of jobs submitted by other users, but you cannot read data files attached to jobs submitted by other users.
- You can only read data files attached to your own jobs.
- Root and LSF administrators can read messages of jobs submitted by other
- Root and LSF administrators cannot read data files attached to jobs submitted by other users.

Job names are not unique; if you specify -J job_name:

- You only can read messages and data from your own jobs.
- You cannot read messages and data from jobs submitted by other users.
- Root and the LSF administrators can only read messages and data from their own jobs.

The command:

bstatus

is equivalent to:

bread -i 0

Options

Gets the text message and copies the data file attached to the specified message index of the job to the file specified by *file_name*. Data files cannot be attached to MultiCluster jobs.

If you do not specify a message index, copies the attachment of message index 0 to the file. The job must have an attachment, and you must specify a name for the file you are copying the attachment to. If the file already exists, -a overwrites it with the new file.

By default, -a gets the attachment file from the directory specified by the JOB_ATTA_DIR parameter. If JOB_ATTA_DIR is not specified, job message attachments are saved in LSB_SHAREDIR/info/.

-i *message_index* Specifies the message index to be retrieved.

Default: 0

job_ID | "job_ID[index]" | -J job_name

Required. Specify the job to operate on.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Example

```
bpost -i 1 -d "step 1" -a step1.out 2500
bread -i 1 -a step2.in 2500
                          POST_TIME
JOBID
      MSG_ID FROM
                                        DESCRIPTION
2500
                         May 19 13:59
                user1
                                       step 1
```

Displays the message description text step 1 for message index 1 of job 2500 and copies the data in the file step1.out attached to message 1 to the file step2.in.

See Also

bpost(1), bstatus(1), bsub(1), JOB_ATTA_DIR

brequeue

kills and requeues a job

Synopsis

```
brequeue [-J job_name | -J "job_name[index_list]"] [ -u user_name |
   -u all ] [ job_ID | "job_ID[index_list]"] [-d] [-e] [-r] [-a]
   [-H]
brequeue [-h | -V]
```

Description

You can only use brequeue on a job you own, unless you are root or the LSF administrator.

Kills a running (RUN), user-suspended (USUSP), or system-suspended (SSUSP) job and returns it to the queue. A job that is killed and requeued retains its submit time but is dispatched according to its requeue time. When the job is requeued, it is assigned the PEND status or PSUSP if the -H option is used. Once dispatched, the job starts over from the beginning. The requeued job keeps the same job ID.

When JOB_INCLUDE_POSTPROC=Y is set in lsb.params or in an application profile in 1sb.applications, job requeue will happen only after post-execution processing, not when the job finishes.

Use brequeue to requeue job arrays or job array elements.

By default, kills and requeues your most recently submitted job when no job ID is specified.

With MultiCluster, you can only use brequeue on jobs in local queues. A job that is killed and requeued is assigned a new job ID on the cluster in which it is executed, but it retains the same job ID on the cluster from which it was submitted. For example, a job from cluster A that is killed and requeued and then run on cluster B will be assigned a new job ID on cluster B. However, when the bjobs command is used from cluster A, the submitting cluster, the job will be displayed with the original job ID. When the bjobs command is used from cluster B, the execution cluster, the job will be displayed with the new job ID.

When absolute job priority scheduling (APS) is configured in the queue, all requeued jobs are treated as newly submitted jobs for APS calculation. The job priority, system, and ADMIN APS factors are reset on requeue.

Options

- -a Requeues all jobs including running jobs, suspending jobs, and jobs with EXIT or DONE status.
- Requeues jobs that have finished running with DONE job status.
- Requeues jobs that have terminated abnormally with EXIT job status.
- Requeues jobs to PSUSP job status.
- **-r** Requeues jobs that are running.

-J job_name | -J "job_name[index_list]"

Operates on the specified job.

Since job names are not unique, multiple job arrays may have the same name with a different or same set of indices.

-u user_name | -u all Operates on the specified user's jobs or all jobs. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\user_name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

Only root and LSF administrators can requeue jobs submitted by other users.

job_ID |"job_ID[index_list]"

Operates on the specified job or job array elements.

The value of 0 for *job_ID* is ignored.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Limitations

brequeue cannot be used on interactive batch jobs; brequeue only kills interactive batch jobs, it does not restart them.

bresources

displays information about resource reservation and resource limits configuration

Synopsis

```
bresources [-s] [resource_name ...]
bresources [-h | -V]
```

Description

By default, bresources displays all resource configurations in 1sb.resources. This is the same as blimits -c.

Options

-s Displays per-resource reservation configurations from the ReservationUsage section of 1sb.resources. For example:

```
Begin ReservationUsage
RESOURCE
                   METHOD
licenseX
                  PER_JOB
```

licenseY PER_HOST licenseZ PER_SLOT

End ReservationUsage

bresources -s

resource_name ... Only displays information about the specified resource. For example:

```
bresources -s licenseZ
RESOURCE
                     METHOD
                     PER_SLOT
licenseZ
```

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

brestart

restarts checkpointed jobs

Synopsis

```
brestart [bsub_options] [-f] checkpoint_dir
   [job_ID | "job_ID[index]"]
brestart [-h | -V]
```

Option List

```
- B
-f
- N
- X
-b begin_time
-C core_limit
-c [hour:]minute[/host_name|/host_model]
-D data_limit
-E "pre_exec_command [argument ...]"
-F file_limit
-m "host_name[+[pref_level]] | host_group[+[pref_level]] ..."
-G user_group
-M mem_limit
-q "queue_name ..."
-S stack_limit
-t term time
-w 'dependency_expression'
-W run_limit[/host_name|/host_model]
checkpoint_dir [job_ID | "job_ID[index]"]
```

Description

Restarts a checkpointed job using the checkpoint files saved in checkpoint_dir/last_job_ID/. Only jobs that have been successfully checkpointed can be restarted.

Jobs are re-submitted and assigned a new job ID. The checkpoint directory is renamed using the new job ID, *checkpoint_dir/new_job_ID/*.

By default, jobs are restarted with the same output file and file transfer specifications, job name, window signal value, checkpoint directory and period, and rerun options as the original job.

To restart a job on another host, both hosts must be binary compatible, run the same OS version, have access to the executable, have access to all open files (LSF must locate them with an absolute path name), and have access to the checkpoint directory.

The environment variable LSB_RESTART is set to Y when a job is restarted.

LSF invokes the erestart (8) executable found in LSF_SERVERDIR to perform the restart.

Only the bsub options listed here can be used with brestart.

Like bsub, brestart calls the master esub (mesub), which invokes any mandatory esub executables configured by an LSF administrator, and any executable named esub (without .application) if it exists in LSF_SERVERDIR. Only esub executables invoked by bsub can change the job environment on the submission host. An esub invoked by brestart cannot change the job environment.

Options

The following option applies only to brestart.

-f Forces the job to be restarted even if non-restartable conditions exist (these conditions are operating system specific).

See bsub(1) for a description of all other options.

Limitations

In kernel-level checkpointing, you cannot change the value of core limit, CPU limit, stack limit or memory limit with brestart.

bsub(1), bjobs(1), bmod(1), bqueues(1), bhosts(1), bchkpnt(1), lsbqueues(5), echkpnt(8), erestart(8), mbatchd(8)

bresume

resumes one or more suspended jobs

Synopsis

```
bresume [-app application_profile_name] [-g job_group_name]
   [-J job_name] [-m host_name] [-q queue_name]
   [-sla service_class_name] [-u user_name | -u user_group |
   -u all] [0]
bresume [job_ID | "job_ID[index_list]"] ...
bresume [-h | -V]
```

Description

Sends the SIGCONT signal to resume one or more of your suspended jobs.

Only root and LSF administrators can operate on jobs submitted by other users. You cannot resume a job that is not suspended. Using bresume on a job that is not in either the PSUSP or the USUSP state has no effect.

You must specify a job ID or -g, -J, -m, -u, or -q. You cannot resume a job that is not suspended. Specify -0 (zero) to resume multiple jobs.

You can also use bkill -s CONT to send the resume signal to a job.

If a signal request fails to reach the job execution host, LSF will retry the operation later when the host becomes reachable. LSF retries the most recent signal request.

Jobs that are suspended by the administrator can only be resumed by the administrator or root; users do not have permission to resume a job suspended by another user or the administrator. Administrators or root can resume jobs suspended by users or administrators.

ENABLE_USER_RESUME parameter (lsb.params)

If ENABLE_USER_RESUME=Y in 1sb.params, users can resume their own jobs that have been suspended by the administrator.

Options

0 Resumes all the jobs that satisfy other options (-g, -m, -q, -u, and -J).

-app application_profile_name

Resumes only jobs associated with the specified application profile. You must specify an existing application profile.

-g job_group_name Resumes only jobs in the spedified job group.

-J job_name Resumes only jobs with the specified name.

-m host_name Resumes only jobs dispatched to the specified host.

-q queue name Resumes only jobs in the specified queue.

-sla service_class_name

Resume jobs belonging to the specified service class.

Use bsla to display the properties of service classes configured in LSB_CONFDIR/cluster name/configdir/lsb.serviceclasses (see 1sb.serviceclasses(5)) and dynamic information about the state of each configured service class.

-u user_name | -u user_group | -u all

Resumes only jobs owned by the specified user or group, or all users if the reserved user name all is specified. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\ user_name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

job_ID ... | "job_ID[index_list]" ...

Resumes only the specified jobs. Jobs submitted by any user can be specified here without using the -u option.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

bresume -q night 0

Resumes all of the user's suspended jobs that are in the night queue. If the user is the LSF administrator, resumes all suspended jobs in the night queue.

bresume -g /risk_group 0

Resumes all suspended jobs in the job group /risk_group.

See Also

bsub(1), bjobs(1), bqueues(1), bhosts(1), bstop(1), bkill(1), bgadd(1), bgdel(1), bjgroup(1), bparams(1), bapp(1), mbatchd(8), kill(1), signal(2) lsb.params(5), lsb.applications(5)

brlainfo

displays host topology information

Synopsis

```
brlainfo [-1] [host_name ...]
brlainfo [-h | -V]
```

Description

brlainfo contacts the Platform LSF HPC topology adapter (RLA) on the specified host and presents topology information to the user. By default, displays information about all hosts running RLA.

Options

-I Long format. Displays additional host topology information. See Output on page 149 for a description of information that is displayed.

host_name ... Only displays information about the specified host.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

Default output

Displays the following fields:

HOSTNAME Name of the host running RLA

CPUSET_OS RLA host operating system

NCPUS Total number of CPUs

FREECPUS Number of free CPUS

NNODES Number of nodes allocated

NCPU/NODE Number of CPUs per node

NSTATIC_CPUSETS Number of static cpusets allocated

Long output (-I)

The -1 option displays a long format listing with the following additional fields:

FREE CPU LIST List of free CPUs in the cpuset

For example:

0 - 2

NFREECPUS ON EACH NODE

Number of free CPUs on each node

For example:

2/0,1/1

STATIC CPUSETS

List of static cpuset names

For example:

NO STATIC CPUSETS

CPU_RADIUS

Available CPUs with a given radius. CPU radius is determined by the processor topology of the system and is expressed in terms of the number of router hops between CPUs. The CPU radius is displayed as a comma-separated list of the number of free CPUs available with radius 0, radius 1, radius 2, and so on:

For example:

2,3,3,3,3,3,3,3

- 2 CPUs are available within radius 0
- 3 CPUs are available within radius 1, 2, 3, 4, 5, 6, and 7.

CPUs grouped within a smaller radius can be thought of as being closer together and therefore have better communications performance.

Examples

brlainfo hostA hostB hostC

| HOSTNAME | CPUSET_OS | NCPUS | NFREECPUS | NNODES | NCPU/NODE | NSTATIC_CPUSETS |
|----------|-----------|-------|-----------|--------|-----------|-----------------|
| hostA | SGI_IRIX | 2 | 2 | 1 | 2 | 0 |
| hostB | PROPACK_4 | 4 | 4 | 2 | 2 | 0 |
| hostC | PROPACK_4 | 4 | 3 | 2 | 2 | 0 |

brlainfo -1 HOST: hostC

CPUSET_OS NCPUS NFREECPUS NNODES NCPU/NODE NSTATIC_CPUSETS

PROPACK_4 4 3

FREE CPU LIST: 0-2

NFREECPUS ON EACH NODE: 2/0,1/1 STATIC CPUSETS: NO STATIC CPUSETS CPU_RADIUS: 2,3,3,3,3,3,3,3

brsvadd

adds an advance reservation

Synopsis

```
brsvadd [-o] -n processors | -s [-n processors]
   -m "host_name | host_group ..." [-R "res_req"]
   [-u user_name | -g group_name] -b begin_time -e end_time
brsvadd [-o] -n processors | -s [-n processors]
   -m "host_name | host_group ..." [-R "res_reg"]
   [-u user_name | -g group_name ] -t time_window
brsvadd [-o] -n processors | -s [-n processors] -R "res_req"
   [-u user_name | -g group_name] -b begin_time -e end_time
brsvadd [-o] -n processors | -s [-n processors] -R "res_req"
   [-u user_name | -g group_name] -t time_window
brsvadd [-h | -V]
```

Description

CAUTION: By default, this command can only be used by LSF administrators or root.

Reserves processors in advance for a specified period of time for a user or user group, or for system maintenance purposes. Use -b and -e for one-time reservations, and -t for recurring reservations.

To allow users to create their own advance reservations without administrator intervention, configure advance reservation policies in the ResourceReservation section of 1sb.resources.

Only administrators, root, or the users listed in the ResourceReservation section can add reservations for themselves or any other user or user group.

Options

-o Creates an open advance reservation. A job with an open advance reservation will only have the advance reservation property during the reservation window, after which the job becomes a normal job, not subject to termination when the reservation window closes.

This prevents jobs from being killed if the reservation window is too small. Instead, the job is suspended and normal scheduling policies apply after the reservation window.

-s Creates a reservation for system use. LSF does not dispatch jobs to the specified hosts while the reservation is active.

When specifying a system reservation with -s, you do not need to specify the number of processors to reserve with the -n option.

-b begin_time Begin time for a one-time reservation. The begin time is in the form

```
[[[year:]month:]day:]hour:minute
```

with the following ranges:

- year: any year after 1900 (YYYY)
- month: 1-12 (MM)
- day of the month: 1-31 (dd)
- hour: 0-23 (hh)
- *minute*: 0-59 (mm)

You must specify at least hour:minute. Year, month, and day are optional. Three fields are assumed to be day:hour:minute, four fields are assumed to be month:day:hour:minute, and five fields are year:month:day:hour:minute.

If you do not specify a day, LSF assumes the current day. If you do not specify a month, LSF assumes the current month. If you specify a year, you must specify a month.

The time value for -b must use the same syntax as the time value for -e. It must be earlier than the time value for -e, and cannot be earlier than the current time.

-e end time End time for a one-time reservation. The end time is in the form

[[[year:]month:]day:]hour:minute

with the following ranges:

- year: any year after 1900 (YYYY)
- month: 1-12 (MM)
- day of the month: 1-31 (dd)
- hour: 0-23 (hh)
- *minute*: 0-59 (mm)

You must specify at least hour:minute. Year, month, and day are optional. Three fields are assumed to be day:hour:minute, four fields are assumed to be month:day:hour:minute, and five fields are year:month:day:hour:minute.

If you do not specify a day, LSF assumes the current day. If you do not specify a month, LSF assumes the current month. If you specify a year, you must specify a

The time value for -e must use the same syntax as the time value for -b. It must be later than the time value for -b.

-g group_name

Creates a reservation for a user group.

The -g group_name option does not support the @cluster notation for advance reservations on remote clusters.

-m "host_name | host_group ..."

List of hosts for which processors specified with -n are reserved. At job submission, LSF considers the hosts in the specified order.

If you also specify a resource requirement string with the -R option, -m is optional. The hosts can be local to the cluster or hosts leased from remote clusters.

-n processors Number of processors to reserve. *processors* must be less than or equal to the actual number of CPUs for the hosts selected by -m or -R for the reservation.

If you also specify the reservation for system use with the -s option, -n is optional.

-R "res reg" Selects hosts for the reservation according to the specified resource requirements. Only hosts that satisfy the resource requirement expression are reserved. - R accepts any valid resource requirement string, but only the select string takes effect.

If you also specify a host list with the -m option, -R is optional.

For more information about resource requirements, see lsfintro(1).

The size of the resource requirement string is limited to 512 bytes.

-t time window

Time window for a recurring reservation.

To specify a time window, specify two time values separated by a hyphen (-), with no space in between:

```
time_window = begin_time-end_time
```

Times are specified in the format:

```
[day:]hour[:minute]
```

where all fields are numbers with the following ranges:

- day of the week: 0-6 (0 is Sunday)
- hour: 0-23
- minute: 0-59

Specify a time window one of the following ways:

- hour-hour
- hour:minute-hour:minute
- day:hour:minute-day:hour:minute

The default value for minute is 0 (on the hour); the default value for day is every day of the week.

You must specify at least the hour. Day of the week and minute are optional. Both the start time and end time values must use the same syntax. If you do not specify a minute, LSF assumes the first minute of the hour (:00). If you do not specify a day, LSF assumes every day of the week. If you do specify the day, you must also specify the minute.

You can specify multiple time windows, but they cannot overlap. For example:

```
timeWindow(8:00-14:00 18:00-22:00)
```

is correct, but

```
timeWindow(8:00-14:00 11:00-15:00)
```

is not valid.

LSF administrators can prevent running jobs from being killed when the reservation expires by changing the termination time of the job using the reservation (bmod -t) before the reservation window closes.

When the job starts running, the run limit of the reservation is set to the minimum of the job run limit (if specified), the queue run limit (if specified), or the duration of the time window.

-u user name

Creates a reservation for an individual user.

The -u user_name option does not support the @cluster notation for advance reservations on remote clusters.

- **-h** Prints command usage and exits.
- **-V** Prints LSF release version and exits.

Examples

The following command creates a one-time advance reservation for 1024 processors on host hostA for user user1 between 6:00 a.m. and 8:00 a.m. today:

```
brsvadd -n 1024 -m hostA -u user1 -b 6:0 -e 8:0
Reservation "user1#0" is created
```

The hosts specified by -m can be local to the cluster or hosts leased from remote clusters.

The following command creates an advance reservation for 1024 processors on two hosts hostA and hostB for user group groupA every Wednesday from 12:00 midnight to 3:00 a.m.:

```
brsvadd -n 2048 -m "hostA hostB" -g groupA -t "3:0:0-3:3:0"
Reservation "groupA#0" is created
```

The following command creates an open advance reservation for 1024 processors on host hostA for user user1 between 6:00 a.m. and 8:00 a.m. today.

```
brsvadd -o -n 1024 -m hostA -u user1 -b 6:0 -e 8:0
Reservation "user1#0" is created
```

See Also

brsvs, brsvdel, 1sb. resources

brsvdel

deletes an advance reservation

Synopsis

```
brsvdel reservation_ID ...
brsvdel [-h | -V]
```

Description

CAUTION: By default, this command can only be used by LSF administrators or root.

Deletes advance reservations for the specified reservation IDs.

For example, if the following command was used to create the reservation user 1#0,

```
brsvadd -n 1024 -m hostA -u user1 -b 13:0 -e 18:0
Reservation "user1#0" is created
```

the following command deletes the reservation:

```
brsvdel user1#0
Reservation user1#0 is being deleted
```

You can delete multiple reservations at a time.

To allow users to delete their own advance reservations without administrator intervention, configure advance reservation policies in the ResourceReservation section of 1sb.resources.

Administrators and root can delete any reservations. Users listed in the ResourceReservation section can only delete reservations they created themselves.

Options

- **-h** Prints command usage and exits.
- **-V** Prints LSF release version and exits.

See Also

brsvadd, brsvs, 1sb. resources

brsvs

displays advance reservations

Synopsis

```
brsvs [-1] [-p all | "host_name ..."] [-w]
brsvs [-1] [-c all | "policy_name"] [-w]
brsvs [-h | -V]
```

Description

By default, displays the current advance reservations for all hosts, users, and groups. For advance reservations across clusters:

- -p all shows local and all remote reservations
- The default all includes both local and remote
- host_name does NOT take host_name@cluster_name

By default, brsvs truncates the reservation ID (RSVID) at 11 characters. Use -w to see the full reservation ID.

Options

- -I Displays advance reservations in a long multiline format. In addition to the standard output, the -1 option displays the reservation type (open or closed) and the job IDs of any jobs associated with the specified advance reservation, sorted by status.
- Wide format. Displays reservation information without truncating fields.

-c all | "policy_name ..."

Shows advance reservation policies defined in 1sb. resources. By default, displays all policy names.

The all keyword shows detailed information for all policies.

-p all | "host_name ..."

Shows a weekly planner for specified hosts using advance reservations.

The all keyword shows a weekly planner for all hosts with reservations.

- **-h** Prints command usage and exits.
- **-V** Prints LSF release version and exits.

Example

```
brsvs -c reservation1
Policy Name: reservation1
Users: ugroup1 ~user1
Hosts: hostA hostB
Time Window: 8:00-13:00
```

See Also

brsvadd, brsvdel, 1sb. resources

brun

forces a job to run immediately

Synopsis

```
brun [-b] [-c] [-f] -m "host_name[#num_cpus] ... " job_ID
brun [-b] [-c] [-f] -m "host_name[#num_cpus] ... "
   "job_ID[index_list]"
brun [-h | -V]
```

Description

CAUTION: This command can only be used by LSF administrators.

Forces a pending job to run immediately on specified hosts.

A job which has been forced to run is counted as a running job, this may violate the user, queue, or host job limits, and fairshare priorities. The forced job can run on hosts with an exclusive resource definition.

A job which has been forced to run cannot be preempted by other jobs even if it is submitted to a preemptable queue and other jobs are submitted to a preemptive

By default, after the job is started, it is still subject to run windows and suspending conditions.

LSF administrators can use brun to force jobs with an advance reservation to run before the reservation is active, but the job must finish running before the time window of the reservation expires.

For example, if the administrator forces a job with a reservation to run one hour before the reservation is active, and the reservation period is 3 hours, a 4 hour run limit takes effect.

OPTIONS

- -b Causes a checkpointable job to start over from the beginning, as if it had never been checkpointed.
- -c Distribute job slots for a multihost parallel job according to free CPUs.

By default, if a parallel job spans for more than one host, LSF distributes the slots based on the static CPU counts of each host listed in the -m option. Use -c to distribute the slots based on the free CPUs of each host instead of the static CPUs.

The -c option can be only applied to hosts whose total slot counts equal to their total CPU counts. MXJ in 1sb. hosts must be less than or equal to the number of CPUs and PJOB_LIMIT=1 must be specified in the queue (1sb.queues).

For example, a 6-CPU job is submitted to hostA and hostB with 4 CPUs each. Without -c, LSF would let the job take 4 slots from host A first and then take 2 slots from hostB regardless to the status or the slots usage on hostA and hostB. If any

slots on hostA are used, the job will remain pending. With -c, LSF takes into consideration that hostA has 2 slots in use and hostB is completely free, so LSF is able to dispatch the job using the 2 free slots on hostA and all 4 slots on hostB.

-f Allows the job to run without being suspended due to run windows or suspending conditions.

-m "host_name[#num_cpus] ... "

Required. Specify one or more hosts on which to run the job.

You can optionally specify the number of CPUs required per host for multihost parallel jobs. The #num_cpus option distributes job slots according the number of CPUs on the host. If #num_cpus is not defined, or if #num_cpus is greater than the number of static CPUs on the host (or the number of free CPUs if -c is specified), LSF distributes job slots according to the number of static CPUs on the host, or the number of free CPUs on the host if -c is specified. The number sign (#) is required as a prefix to the number of CPUs. The square brackets ([])indicate that #num cpus is optional. Do not include them in the command.

For example, the following command forces job 123 to run and specifies 1 CPU on hostA and 1 CPU on hostB:

brun -m "hostA#1 hostB#1" 123

job_ID | "job_ID[index_list]"

Required. Specify the job to run, or specify one element of a job array.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Limitations

You cannot force a job in SSUSP or USUSP state.

brun does not guarantee a job will run; it just forces LSF to dispatch the job.

In the MultiCluster job forwarding model, you can only force a job by running the command in the execution cluster.

bsla

displays information about service class configuration for goal-oriented service-level agreement (SLA) scheduling

Synopsis

```
bsla [service_class_name]
bsla [-h | -V]
```

Description

bsla displays the properties of service classes configured in lsb.serviceclasses and dynamic information about the state of each configured service class.

If a default system service class is configured with ENABLE_DEFAULT_EGO_SLA in 1sb. params but no other service classes are explicity configured in 1sb.serviceclasses, bsla only displays information for the default SLA.

Options

service_class_name The name of a service class configured in lsb.serviceclasses.

- Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

A list of job groups is displayed with the following fields:

SERVICE CLASS NAME

The name of the service class, followed by its description, if any.

PRIORITY

The service class priority. A higher value indicates a higher priority, relative to other service classes. Similar to queue priority, service classes access the cluster resources in priority order.

CONSUMER

For EGO-enabled SLA service classes, the name of the EGO consumer from which hosts are allocated to the SLA.

EGO_RES_REQ

For EGO-enabled SLA service classes, the EGO resource requirement defined in the SLA.

MAX_HOST_IDLE_TIME

For EGO-enabled SLA service classes, how long the SLA will hold its idle hosts before LSF releases them to EGO.

NUM_RECALLED_HOSTS

For EGO-enabled SLA service classes, the number of hosts allocated to the SLA that EGO has reclaimed.

RECALLED_HOSTS_TIMEOUT

For EGO-enabled SLA service classes, the amount of time EGO gives to LSF to clean up its workload before EGO reclaims the host.

USER GROUP

User names or user groups who can submit jobs to the service class.

GOAL

The type of service class goal and its configured value:

- **THROUGHPUT**
- VELOCITY
- **DEADLINE**

ACTIVE WINDOW

The configured time window when the service class goal is active. If a throughput or velocity goal has no time window configured, ACTIVE WINDOW is Always Open.

STATUS

Current status of the service class goal:

- Active:On time—the goal is active and meeting its target.
- Active:Delayed—the goal is active but is missing its target.
- Inactive—the goal is not active; its time window is closed. Jobs are scheduled as if no service class is defined. LSF does not enforce any service-level goal for an inactive SLA.

THROUGHPUT

For throughput goals, the configured job throughput (finished jobs per hour) for the service class.

SLA THROUGHPUT

The current throughput for the SLA finished jobs per clean period.

ESTIMATED FINISH TIME

For goals with a time window, estimated finish time of the SLA. If the service class status is on time, the finish time will be before the configured deadline. If the service class status is delayed, the service class is missing its goal and bsla shows a finish time later than the deadline.

OPTIMUM NUMBER OF RUNNING JOBS

For goals with a time window, the optimum number of jobs that should be running in the service class for the SLA to meet its goal.

NJOBS

The current number of job slots used by jobs in the specified service class. A parallel job is counted as 1 job, regardless of the number of job slots it will use.

PEND

The number of pending job slots used by jobs in the specified service class.

RUN

The number of job slots used by running jobs in the specified service class.

SSUSP

The number of job slots used by the system-suspended jobs in the service class.

USUSP

The number of job slots used by user-suspended jobs in the specified service class.

FINISH

The number of jobs in the specified service class in EXITED or DONE state.

Example

The following service class named Kyuquot is configured in lsb.serviceclasses:

```
Begin ServiceClass
NAME = Kyuquot
CONSUMER = Kyuquot
PRIORITY = 23
USER\_GROUP = user1 user2
GOALS = [VELOCITY 8 timeWindow (9:00-17:30)] \
        [DEADLINE timeWindow (17:30-9:00)]
DESCRIPTION = Daytime/Nighttime SLA
End ServiceClass
```

bsla shows the following properties and current status:

```
bsla Kyuquot
```

```
SERVICE CLASS NAME: Kyuquot
-- Daytime/Nighttime SLA
PRIORITY: 23
CONSUMER: Kyuquot
EGO_RES_REQ: any host
MAX_HOST_IDLE_TIME: 120
USER_GROUP: user1 user2
GOAL: VELOCITY 8
ACTIVE WINDOW: (9:00-17:30)
STATUS: Active:On time
SLA THROUGHPUT: 0.00 JOBS/CLEAN_PERIOD
GOAL: DEADLINE
ACTIVE WINDOW: (17:30-9:00)
STATUS: Inactive
SLA THROUGHPUT: 0.00 JOBS/CLEAN_PERIOD
  NJOBS
        PEND RUN
                        SSUSP USUSP FINISH
     0
         0 0
                        0
                               0
                                        0
```

bslots

displays slots available and backfill windows available for backfill jobs

Synopsis

```
bslots [-1] [-n slots] [-R "res_req"] [-W [hour:]minutes]
bslots [-h | -V]
```

Description

The available slots displayed by bslots are not currently used for running jobs and can be used for backfill jobs. bslots displays a snapshot of the slots currently not in use by parallel jobs or advance reservations. They are not guaranteed to be available at job submission.

By default, displays all available slots, and the available run times (backfil windows) for those slots. When no slots are available for backfill, bslots displays

```
No backfill window exists at this time
```

bslots calculates the backfill window based on the estimated start time of potential backfill jobs. Estimated start time is only relatively accurate according to current running job information. If running jobs finish earlier or later, estimated start time may be moved to earlier or later time. There may be a small delay of a few minutes between the job finish time on which the estimate was based and the actual start time of the allocated job.

If the available backfill window has no run time limit, its length is displayed as UNLIMITED.

Options

-I Displays backfill windows in a long multi-line format. The -1 option displays host names and the number of slots on each host available for backfill.

-n slots Specifies required slots (processors). Backfill windows whose widths are equal or larger than specified value will be returned.

When no slots are available for backfill, bslots -n displays

No backfill window meets these requirements at this time

-R "res_req"

Selects hosts for calculating the backfill windows according to the specified resource requirement. By default, selects hosts of any type. The -R option only supports the select resource requirement string. Other resource requirement section are not supported.

When no slots are available for backfill, bslots -R displays

No backfill window meets these requirements at this time

-W [hour:]minutes Specifies expected runtime limit. Backfill windows whose lengths are equal or larger than specified value will be returned.

When no slots are available for backfill, bslots - W displays

No backfill window meets these requirements at this time

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

bstatus

gets current external job status or sets new job status

Synopsis

```
bstatus [-d "description"] job_ID | "job_ID[index]" | -J job_name
bstatus [-h | -V]
```

Description

Gets and displays the message description text of a job, or changes the contents of the message description text with the -d option. Always operates on the message with index 0.

You can set the external status of a job until it completes. You cannot change the status of done or exited jobs. You can display the status of a job until it is cleaned from the system.

If a you specify a job ID:

- You can get the external job status of jobs submitted by other users, but you cannot set job status of jobs submitted by other users.
- You can only set external status on your own jobs.
- Only root and LSF administrators can set external job status on jobs submitted by other users.

Job names are not unique; if you specify -J job_name:

- You can only get or set the external status on your own jobs.
- You cannot get or set external job status on jobs submitted by other users.
- Root and the LSF administrators can only get or set the external status on their own jobs.

Options

-d "description" Updates the job status with specified message description text.

```
job_ID | "job_ID[index]" | -J job_name
```

Required. Operates on the specified job.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

```
bstatus 2500
JOBID
        FROM
                UPDATE_TIME
                              STATUS
2500
        user1
                Sep 14 16:54 step 1
```

Displays the message description text of message index 0 of job 2500.

```
bstatus -d "step 2" 2500
```

Changes the message description text of message index 0 of job 2500 to step 2.

bpost(1), bread(1)

bstop

suspends unfinished jobs

Synopsis

```
bstop [-a] [-d] [-app application_profile_name] [-g job_group_name]
   [-sla service_class_name] [-J job_name] [-m host_name | -m
   host_group] [-q queue_name] [-u user_name |
   -u user_group | -u all] [0] [job_ID ... | "job_ID[index]"] ...
bstop [-h | -V]
```

Description

Suspends unfinished jobs.

Sends the SIGSTOP signal to sequential jobs and the SIGTSTP signal to parallel jobs to suspend them.

You must specify a job ID or -g, -J, -m, -u, or -q. You cannot suspend a job that is already suspended. Specify job ID 0 (zero) to stop multiple jobs.

Only root and LSF administrators can operate on jobs submitted by other users.

Use bresume to resume suspended jobs.

Using bstop on a job that is in the USUSP state has no effect.

You can also use bkill -s STOP to send the suspend signal to a job or use bkill -s TSTP to suspend one or more parallel jobs. Use bkill -s CONT to send a resume signal to a job.

If a signal request fails to reach the job execution host, LSF will retry the operation later when the host becomes reachable. LSF retries the most recent signal request.

Options

- **O** Suspends all the jobs that satisfy other options (-g, -m, -q, -u, and -J).
- -a Suspends all jobs.

-app application profile name

Suspends only jobs associated with the specified application profile. You must specify an existing application profile.

-g *job_group_name* Suspends only jobs in the specified job group.

-J *job_name* Suspends only jobs with the specified name.

-m host_name | -m host_group

Suspends only jobs dispatched to the specified host or host group.

-q queue_name Suspends only jobs in the specified queue.

-sla service class name

Suspends jobs belonging to the specified service class.

Use bsla to display the properties of service classes configured in LSB_CONFDIR/cluster name/configdir/lsb.serviceclasses (see 1sb.serviceclasses(5)) and dynamic information about the state of each configured service class.

-u user_name | -u user_group | -u all

Suspends only jobs owned by the specified user or user group, or all users if the keyword all is specified. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\ user_name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

job_ID ... | "job_ID[index]" ...

Suspends only the specified jobs. Jobs submitted by any user can be specified here without using the -u option.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

bstop 314

Suspends job number 314.

bstop -m hostA

Suspends the invoker's last job that was dispatched to host host A.

bstop -u jsmith 0

Suspends all the jobs submitted by user jsmith.

bstop -u all

Suspends the last submitted job in the LSF system.

bstop -u all 0

Suspends all jobs for all users in the LSF system.

bstop -g /risk_group/consolidate 0

Suspends all jobs in the job group /risk_group/consolidate.

bstop -app fluent 0

Suspends all jobs associated with the application profile fluent.

```

Description

Submits a job for batch execution and assigns it a unique numerical job ID.

Runs the job on a host that satisfies all requirements of the job, when all conditions on the job, host, queue, application profile, and cluster are satisfied. If LSF cannot run all jobs immediately, LSF scheduling policies determine the order of dispatch. Jobs are started and suspended according to the current system load.

Sets the user's execution environment for the job, including the current working directory, file creation mask, and all environment variables, and sets LSF environment variables before starting the job.

When a job is run, the command line and stdout/stderr buffers are stored in the directory home_directory/.lsbatch on the execution host. If this directory is not accessible, /tmp/.lsbtmp user_ID is used as the job's home directory. If the current working directory is under the home directory on the submission host, then the current working directory is also set to be the same relative directory under the home directory on the execution host.

By default, if the current working directory is not accessible on the execution host, the job will run in /tmp. If the environment variable

LSB EXIT IF CWD NOTEXIST is set to Y and the current working directory is not accessible on the execution host, the job exits with the exit code 2.

If no command is supplied, bsub prompts for the command from the standard input. On UNIX, the input is terminated by entering CTRL-D on a new line. On Windows, the input is terminated by entering CTRL-Z on a new line.

To kill a batch job submitted with bsub, use bkill.

Use bmod to modify jobs submitted with bsub. bmod takes similar options to bsub. Jobs submitted to a chunk job queue with the following options are not chunked; they are dispatched individually:

- I (interactive jobs)
- -c (jobs with CPU limit greater than 30)
- -W (jobs with run limit greater than 30 minutes)

To submit jobs from UNIX to display GUIs through Microsoft Terminal Services on Windows, submit the job with bsub and define the environment variables LSF_LOGON_DESKTOP=1 and LSB_TSJOB=1 on the UNIX host. Use tssub to submit a Terminal Services job from Windows hosts. See *Using Platform LSF on* Windows for more details.

If the parameter LSB_STDOUT_DIRECT in 1sf.conf is set to Y or y, and you use the -o or -oo option, the standard output of a job is written to the file you specify as the job runs. If LSB_STDOUT_DIRECT is not set, and you use -o or -oo, the standard output of a job is written to a temporary file and copied to the specified file after the job finishes. LSB_STDOUT_DIRECT is not supported on Windows.

Default Behavior

LSF assumes that uniform user names and user ID spaces exist among all the hosts in the cluster. That is, a job submitted by a given user will run under the same user's account on the execution host. For situations where nonuniform user names and user ID spaces exist, account mapping must be used to determine the account used to run a job.

bsub uses the command name as the job name. Quotation marks are significant.

Options related to file names and job spooling directories support paths that contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows.

Options related to command names and job names names can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows.

Options for the following resource usage limits are specified in KB:

- Core limit (-C)
- Memory limit (-M)
- Stack limit (-S)

◆ Swap limit (-v)

Use LSF_UNIT_FOR_LIMITS in 1sf. conf to specify a larger unit for the limit (MB, GB, TB, PB, or EB).

If fairshare is defined and you belong to multiple user groups, the job will be scheduled under the user group that allows the quickest dispatch.

The job is not checkpointable.

bsub automatically selects an appropriate queue. If you defined a default queue list by setting LSB_DEFAULTQUEUE environment variable, the queue is selected from your list. If LSB_DEFAULTQUEUE is not defined, the queue is selected from the system default queue list specified by the LSF administrator with the **DEFAULT_QUEUE** parameter in 1sb.params.

LSF tries to obtain resource requirement information for the job from the remote task list that is maintained by the load sharing library (see <code>lsfintro(1)</code>). If the job is not listed in the remote task list, the default resource requirement is to run the job on a host or hosts that are of the same host type (see | shosts(1)) as the submission host.

bsub assumes only one processor is requested.

bsub does not start a login shell but runs the job file under the execution environment from which the job was submitted.

The input file for the batch job is /dev/null (no input).

bsub sends mail to you when the job is done. The default destination is defined by LSB_MAILTO in 1sf.conf. The mail message includes the job report, the job output (if any), and the error message (if any).

bsub charges the job to the default project. The default project is the project you define by setting the environment variable LSB_DEFAULTPROJECT. If you do not set LSB_DEFAULTPROJECT, the default project is the project specified by the LSF administrator with DEFAULT_PROJECT parameter in 1sb.params. If DEFAULT_PROJECT is not defined, then LSF uses default as the default project name.

Options

- **-B** Sends mail to you when the job is dispatched and begins execution.
- -H Holds the job in the PSUSP state when the job is submitted. The job will not be scheduled until you tell the system to resume the job (see bresume(1)).
- -I | -Ip | -Is Submits a batch interactive job. A new job cannot be submitted until the interactive job is completed or terminated.

Sends the job's standard output (or standard error) to the terminal. Does not send mail to you when the job is done unless you specify the -N option.

Terminal support is available for a batch interactive job.

When you specify the -Ip option, submits a batch interactive job and creates a pseudo-terminal when the job starts. Some applications (for example, vi) require a pseudo-terminal in order to run correctly.

When you specify the -Is option, submits a batch interactive job and creates a pseudo-terminal with shell mode support when the job starts. This option should be specified for submitting interactive shells, or applications which redefine the CTRL-C and CTRL-Z keys (for example, jove).

If the -i input_file option is specified, you cannot interact with the job's standard input via the terminal.

If the -0 out_file option is specified, sends the job's standard output to the specified output file. If the -e err_file option is specified, sends the job's standard error to the specified error file.

You cannot use - I, - Ip, or - Is with the - K option.

Interactive jobs cannot be checkpointed.

Interactive jobs cannot be rerunnable (bsub -r).

The options that create a pseudo-terminal (-Ip and -Is) are not supported on Windows.

-K Submits a batch job and waits for the job to complete. Sends the message "Waiting for dispatch" to the terminal when you submit the job. Sends the message "Job is finished" to the terminal when the job is done.

You will not be able to submit another job until the job is completed. This is useful when completion of the job is required in order to proceed, such as a job script. If the job needs to be rerun due to transient failures, bsub returns after the job finishes successfully. bsub will exit with the same exit code as the job so that job scripts can take appropriate actions based on the exit codes. bsub exits with value 126 if the job was terminated while pending.

You cannot use the -K option with the -I, -Ip, or -Is options.

Sends the job report to you by mail when the job finishes. When used without any other options, behaves the same as the default.

Use only with -0, -00, -I, -Ip, and -Is options, which do not send mail, to force LSF to send you a mail message when the job is done.

-r | -rn If the execution host becomes unavailable while a job is running, specifies that the job will rerun on another host. LSF requeues the job in the same job queue with the same job ID. When an available execution host is found, reruns the job as if it were submitted new, even if the job has been checkpointed. You receive a mail message informing you of the host failure and requeuing of the job.

If the system goes down while a job is running, specifies that the job will be requeued when the system restarts.

Reruns a job if the execution host or the system fails; it does not rerun a job if the job itself fails.

-rn specifies that the job is never rerunnable. bsub -rn disables job rerun if the job was submitted to a rerunnable queue or application profile with job rerun configured. The command level job rerunnable setting overrides the application profile and and queue level setting. bsub -rn is different from bmod -rn, which cannot override the application profile and queue level rerunnable job setting.

Members of a chunk job can be rerunnable. If the execution host becomes unavailable, rerunnable chunk job members are removed from the queue and dispatched to a different execution host.

Interactive jobs (bsub - I) cannot be rerunnable.

-ul Passes the current operating system user shell limits for the job submission user to the execution host. User limits cannot override queue hard limits. If user limits exceed queue hard limits, the job will be rejected.

RESTRICTION: UNIX and Linux only. - ull is not supported on Windows.

The following bsub options for job-level runtime limits override the value of the user shell limits:

- Per-process (soft) core file size limit (-C)
- CPU limit (-c)
- Per-process (soft) data segment size limit (-D)
- File limit (-F)
- Per-process (soft) memory limit (-M)
- Process limit (-p)
- Per-process (soft) stack segment size limit (-S)
- Limit of the number of concurrent threads (-⊺)
- Total process virtual memory (swap space) limit (-v)
- Runtime limit (-W)

LSF collects the user limit settings from the user's running environment that are supported by the operating system, and sets the value to submission options if the value is no unlimited. If the operating system has other kinds of shell limits, LSF will not collect them. LSF collects the following operating system user limits:

- CPU time in milliseconds
- Maximum file size
- Data size
- Stack size
- Core file size
- Resident set size
- Open files
- Virtual (swap) memory
- Process limit
- Thread limit
- -x Puts the host running your job into exclusive execution mode.

In exclusive execution mode, your job runs by itself on a host. It is dispatched only to a host with no other jobs running, and LSF does not send any other jobs to the host until the job completes.

To submit a job in exclusive execution mode, the queue must be configured to allow exclusive jobs.

When the job is dispatched, bhosts(1) reports the host status as closed Excl, and 1sload(1) reports the host status as lockU.

Until your job is complete, the host is not selected by LIM in response to placement requests made by lsplace(1), lsrun(1) or lsgrun(1) or any other load sharing applications.

You can force other batch jobs to run on the host by using the -m *host_name* option of brun(1) to explicitly specify the locked host.

You can force LIM to run other interactive jobs on the host by using the -m host_name option of lsrun(1) or lsgrun(1) to explicitly specify the locked host.

-a esub_application

Specifies one or more application-specific esub executables that you want LSF to associate with the job.

The value of -a must correspond to the application name of an actual esub file. For example, to use bsub -a fluent, the file esub. fluent must exist in LSF_SERVERDIR.

For example, to submit a job that invokes two application-specific esub executables named esub.license and esub.fluent, enter:

bsub -a license fluent my_job

mesub uses the method name license to invoke the esub named LSF_SERVERDIR/esub.license, and the method name fluent to invoke the esub named LSF_SERVERDIR/esub.fluent.

The name of an application-specific esub program is passed to the master esub. The master esub program (LSF_SERVERDIR/mesub) handles job submission requirements of the application. Application-specific esub programs can specify their own job submission requirements. The value of -a is set in the LSB_SUB_ADDITIONAL option in the LSB_SUB_PARM file used by esub.

If an LSF administrator specifies one or more mandatory esub executables using the parameter LSB_ESUB_METHOD, LSF invokes the mandatory executables first, followed by the executable named esub (without .esub_application in the file name) if it exists in LSF_SERVERDIR, and then any application-specific esub executables (with .esub_application in the file name) specified by -a.esub_application.

The name of the esub program must be a valid file name. It can contain only alphanumeric characters, underscore (_) and hyphen (-).

RESTRICTION: After LSF version 5.1, the value of -a and LSB_ESUB_METHOD must correspond to an actual esub file in LSF_SERVERDIR. For example, to use bsub -a fluent, the file esub.fluent must exist in LSF_SERVERDIR.

-app application_profile_name

Submits the job to the specified application profile. You must specify an existing application profile. If the application profile does not exist in lsb.applications, the job is rejected.

-b [[month:]day:]hour:minute

Dispatches the job for execution on or after the specified date and time. The date and time are in the form of [[month:]day:]hour:minute where the number ranges are as follows: month 1-12, day 1-31, hour 0-23, minute 0-59.

At least two fields must be specified. These fields are assumed to be hour:minute. If three fields are given, they are assumed to be day:hour:minute, and four fields are assumed to be month: day: hour: minute.

-C core limit Sets a per-process (soft) core file size limit for all the processes that belong to this batch job (see getrlimit(2)).

> By default, the limit is specified in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for the limit (MB, GB, TB, PB, or EB).

> The behavior of this option depends on platform-specific UNIX or Linux systems.

In some cases, the process is sent a SIGXFSZ signal if the job attempts to create a core file larger than the specified limit. The SIGXFSZ signal normally terminates the process.

In other cases, the writing of the core file terminates at the specified limit.

-c [hour:]minute[/host_name | /host_model]

Limits the total CPU time the job can use. This option is useful for preventing runaway jobs or jobs that use up too many resources. When the total CPU time for the whole job has reached the limit, a SIGXCPU signal is first sent to the job, then SIGINT, SIGTERM, and SIGKILL.

If LSB_JOB_CPULIMIT in 1sf.conf is set to n, LSF-enforced CPU limit is disabled and LSF passes the limit to the operating system. When one process in the job exceeds the CPU limit, the limit is enforced by the operating system.

The CPU limit is in the form of [hour:] minute. The minutes can be specified as a number greater than 59. For example, three and a half hours can either be specified as 3:30, or 210.

The CPU time you specify is the *normalized* CPU time. This is done so that the job does approximately the same amount of processing for a given CPU limit, even if it is sent to host with a faster or slower CPU. Whenever a normalized CPU time is given, the actual time on the execution host is the specified time multiplied by the CPU factor of the normalization host then divided by the CPU factor of the execution host.

Optionally, you can supply a host name or a host model name defined in LSF. You must insert a slash (/) between the CPU limit and the host name or model name. (See 1 sinfo(1) to get host model information.) If a host name or model name is not given, LSF uses the default CPU time normalization host defined at the queue level (DEFAULT_HOST_SPEC in 1sb. queues) if it has been configured, otherwise uses the default CPU time normalization host defined at the cluster level (DEFAULT_HOST_SPEC in 1sb.params) if it has been configured, otherwise uses the submission host.

Jobs submitted to a chunk job queue are not chunked if the CPU limit is greater than 30 minutes.

-cwd "current_working_directory"

Specifies the current working directory for the job.

By default, if the current working directory is not accessible on the execution host, the job will run in /tmp. If the environment variable

LSB_EXIT_IF_CWD_NOTEXIST is set to Y and the current working directory is not accessible on the execution host, the job exits with the exit code 2.

-D data limit Sets a per-process (soft) data segment size limit for each of the processes that belong to the batch job (see getrlimit(2)). The limit is specified in KB.

> This option affects calls to sbrk() and brk(). An sbrk() or malloc() call to extend the data segment beyond the data limit returns an error.

NOTE: Linux does not use sbrk() and brk() within its calloc() and malloc(). Instead, it uses (mmap()) to create memory. DATALIMIT cannot be enforced on Linux applications that call sbrk() and malloc().

-E "pre exec command [arguments ...]"

Runs the specified pre-execution command on the execution host before actually running the job. For a parallel job, the pre-execution command runs on the first host selected for the parallel job. If you want the pre-execution command to run on a specific first execution host, specify one or more first execution host candidates at the job level using -m, at the queue level with PRE_EXEC in 1sb.queues, or at the application level with PRE_EXEC in 1sb.applications.

If the pre-execution command returns a zero (0) exit code, LSF runs the job on the selected host. Otherwise, the job and its associated pre-execution command goes back to PEND status and is rescheduled. LSF keeps trying to run pre-execution commands and pending jobs. After the pre-execution command runs successfully, LSF runs the job. You must ensure that the pre-execution command can run multiple times without causing side effects, such as reserving the same resource more than once.

The standard input and output for the pre-execution command are directed to the same files as the job. The pre-execution command runs under the same user ID, environment, home, and working directory as the job. If the pre-execution command is not in the user's usual execution path (the \$PATH variable), the full path name of the command must be specified.

-Ep "post_exec_command [arguments ...]"

Runs the specified post-execution command on the execution host after the job finishes.

If both application-level (POST_EXEC in 1sb.applications) and job-level post-execution commands are specified, job level post-execution overrides application-level post-execution commands. Queue-level post-execution commands (POST_EXEC in 1sb. queues) run after application-level post-execution and job-level post-execution commands.

-e error_file

Specify a file path. Appends the standard error output of the job to the specified file.

If the parameter LSB STDOUT DIRECT in 1sf.conf is set to Y or y, the standard error output of a job is written to the file you specify as the job runs. If LSB_STDOUT_DIRECT is not set, it is written to a temporary file and copied to the specified file after the job finishes. LSB_STDOUT_DIRECT is not supported on Windows.

If you use the special character %J in the name of the error file, then %J is replaced by the job ID of the job. If you use the special character % I in the name of the error file, then %I is replaced by the index of the job in the if the job is a member of an array. Otherwise, % I is replaced by 0 (zero).

If the current working directory is not accessible on the execution host after the job starts, LSF writes the standard error output file to /tmp/.

NOTE: The file path can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows, including the directory, file name, and expanded values for %J (job_ID) and %I (index_ID).

-eo error_file

Specify a file path. Overwrites the standard error output of the job to the specified

If the parameter LSB_STDOUT_DIRECT in 1sf. conf is set to Y or y, the standard error output of a job is written to the file you specify as the job runs, which will occur every time the job is submitted with the overwrite option, even if it is requeued manually or by the system. If LSB_STDOUT_DIRECT is not set, it is written to a temporary file and copied to the specified file after the job finishes. LSB STDOUT DIRECT is not supported on Windows.

If you use the special character %J in the name of the error file, then %J is replaced by the job ID of the job. If you use the special character % I in the name of the error file, then % I is replaced by the index of the job in the array if the job is a member of an array. Otherwise, % I is replaced by 0 (zero).

If the current working directory is not accessible on the execution host after the job starts, LSF writes the standard error output file to /tmp/.

NOTE: The file path can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows, including the directory, file name, and expanded values for %J (job_ID) and %I (index ID).

-ext[sched] "external scheduler options"

Application-specific external scheduling options for the job.

To enable jobs to accept external scheduler options, set LSF_ENABLE_EXTSCHEDULER=y in 1sf.conf.

You can abbreviate the -extsched option to -ext.

You can specify only one type of external scheduler option in a single -extsched string.

For example, SGI IRIX hosts and AlphaServer SC hosts running RMS can exist in the same cluster, but they accept different external scheduler options. Use external scheduler options to define job requirements for either IRIX cpusets OR RMS, but not both. Your job will run either on IRIX or RMS. If external scheduler options are not defined, the job may run on IRIX but it will not run on an RMS host.

The options set by -extsched can be combined with the queue-level MANDATORY_EXTSCHED or DEFAULT_EXTSCHED parameters. If -extsched and MANDATORY_EXTSCHED set the same option, the MANDATORY_EXTSCHED setting is used. If -extsched and DEFAULT_EXTSCHED set the same options, the -extsched setting is used. Use DEFAULT_EXTSCHED in 1sb.queues to set default external scheduler options for a queue.

To make certain external scheduler options mandatory for all jobs submitted to a queue, specify MANDATORY_EXTSCHED in 1sb.queues with the external scheduler options you need or your jobs.

See *Using Platform LSF HPC* for information about specific external scheduler options.

-F file_limit Sets a per-process (soft) file size limit for each of the processes that belong to the batch job (see getrlimit(2)). The limit is specified in KB.

> If a job process attempts to write to a file that exceeds the file size limit, then that process is sent a SIGXFSZ signal. The SIGXFSZ signal normally terminates the process.

-f "local file operator [remote file]" ...

Copies a file between the local (submission) host and the remote (execution) host. Specify absolute or relative paths, including the file names. You should specify the remote file as a file name with no path when running in non-shared systems.

If the remote file is not specified, it defaults to the local file, which must be given. Use multiple - f options to specify multiple files.

operator

An operator that specifies whether the file is copied to the remote host, or whether it is copied back from the remote host. The operator must be surrounded by white space.

The following describes the operators:

- > Copies the local file to the remote file before the job starts. Overwrites the remote file if it exists.
- < Copies the remote file to the local file after the job completes. Overwrites the local file if it exists.
- << Appends the remote file to the local file after the job completes. The local file must exist.
- >< Copies the local file to the remote file before the job starts. Overwrites the remote file if it exists. Then copies the remote file to the local file after the job completes. Overwrites the local file.
- <> Copies the local file to the remote file before the job starts. Overwrites the remote file if it exists. Then copies the remote file to the local file after the job completes. Overwrites the local file.

If you use the -i *input_file* option, then you do not have to use the -f option to copy the specified input file to the execution host. LSF does this for you, and removes the input file from the execution host after the job completes.

If you use the -o *out_file*, -e *err_file*, -oo *out_file*, or the -eo *err_file* option, and you want the specified file to be copied back to the submission host when the job completes, then you must use the -f option.

If the submission and execution hosts have different directory structures, you must make sure that the directory where the remote file and local file will be placed exists. If the local and remote hosts have different file name spaces, you must always specify relative path names. If the local and remote hosts do not share the same file system, you must make sure that the directory containing the remote file exists. It is recommended that only the file name be given for the remote file when running in heterogeneous file systems. This places the file in the job's current working directory. If the file is shared between the submission and execution hosts, then no file copy is performed.

LSF uses 1srcp to transfer files (see 1srcp(1) command). 1srcp contacts RES on the remote host to perform the file transfer. If RES is not available, rcp is used (see rcp(1)). The user must make sure that the rcp binary is in the user's \$PATH on the execution host.

Jobs that are submitted from LSF client hosts should specify the -f option only if rcp is allowed. Similarly, rcp must be allowed if account mapping is used.

-G user group

Only useful with fairshare scheduling.

Associates the job with the specified group. Specify any group that you belong to that does not contain any subgroups. You must be a direct member of the specified user group.

-g job_group_name

Submits jobs in the job group specified by *job_group_name* The job group does not have to exist before submitting the job. For example:

bsub -g /risk_group/portfolio1/current myjob Job <105> is submitted to default queue.

Submits myjob to the job group /risk_group/portfolio1/current.

If group /risk_group/portfoliol/current exists, job 105 is attached to the job group.

Job group names can be up to 512 characters long.

If group /risk_group/portfoliol/current does not exist, LSF checks its parent recursively, and if no groups in the hierarchy exist, all three job groups are created with the specified hierarchy and the job is attached to group.

You can use -q with -sla. All jobs in a job group attached to a service class are scheduled as SLA jobs. It is not possible to have some jobs in a job group not part of the service class. Multiple job groups can be created under the same SLA. You can submit additional jobs to the job group without specifying the service class name again.

For example, the following attaches the job to the service class named opera, and the group /risk_group/portfolio1/current:

bsub -sla opera -g /risk_group/portfolio1/current my.job

To submit another job to the same job group, you can omit the SLA name:

bsub -g /risk_group/portfolio1/current myjob2

-i input_file | -is input_file

Gets the standard input for the job from specified file. Specify an absolute or relative path. The input file can be any type of file, though it is typically a shell script text file. Unless you use -is, you can use the special characters %J and %I in the name of the input file. %J is replaced by the job ID. %I is replaced by the index of the job in the array, if the job is a member of an array, otherwise by 0 (zero). The special characters %J and %I are not valid with the -is option.

NOTE: The file path can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows, including the directory, file name, and expanded values for %J (job_ID) and %I (index_ID).

If the file exists on the execution host, LSF uses it. Otherwise, LSF attempts to copy the file from the submission host to the execution host. For the file copy to be successful, you must allow remote copy (rcp) access, or you must submit the job from a server host where RES is running. The file is copied from the submission host to a temporary file in the directory specified by the JOB_SPOOL_DIR parameter in 1sb.params, or your \$HOME/.1sbatch directory on the execution host. LSF removes this file when the job completes.

By default, the input file is spooled to LSB_SHAREDIR/cluster_name/lsf_indir. If the lsf_indir directory does not exist, LSF creates it before spooling the file. LSF removes the spooled file when the job completes. Use the -is option if you need to modify or remove the input file before the job completes. Removing or modifying the original input file does not affect the submitted job.

If JOB_SPOOL_DIR is specified, the -is option spools the input file to the specified directory and uses the spooled file as the input file for the job.

JOB SPOOL DIR can be any valid path up to a maximum length up to 4094 characters on UNIX and Linux or up to 255 characters for Windows.

JOB_SPOOL_DIR must be readable and writable by the job submission user, and it must be shared by the master host and the submission host. If the specified directory is not accessible or does not exist, bsub -is cannot write to the default directory LSB_SHAREDIR/cluster_name/1sf_indir and the job will fail.

-J job_name | -J "job_name[index_list]%job_slot_limit"

Assigns the specified name to the job, and, for job arrays, specifies the indices of the job array and optionally the maximum number of jobs that can run at any given time.

The job name does not need to be unique.

Job names can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows.

To specify a job array, enclose the index list in square brackets, as shown, and enclose the entire job array specification in quotation marks, as shown. The index list is a comma-separated list whose elements have the syntax start[-end[:step]] where start, end and step are positive integers. If the step is omitted, a step of one is assumed. The job array index starts at one.

By default, the maximum number of jobs in a job array is 1000, which means the maximum size of a job array (that is, the maximum job array index) can never exceed 1000 jobs.

To change the maximum job array value, set MAX JOB ARRAY SIZE in 1sb.params to any positive integer between 1 and 2147483646. The maximum number of jobs in a job array cannot exceed the value set by MAX JOB ARRAY SIZE.

You may also use a positive integer to specify the system-wide job slot limit (the maximum number of jobs that can run at any given time) for this job array.

All jobs in the array share the same job ID and parameters. Each element of the array is distinguished by its array index.

After a job is submitted, you use the job name to identify the job. Specify "job ID[index]" to work with elements of a particular array. Specify "job_name[index]" to work with elements of all arrays with the same name. Since job names are not unique, multiple job arrays may have the same name with a different or same set of indices.

-jsdl file_name | -jsdl_strict file_name

Submits a job using a JSDL file to specify job submission options.

LSF provides an extension to the JSDL specification so that you can submit jobs using LSF features not defined in the JSDL standard schema. The JSDL schema (jsdl.xsd), the POSIX extension (jsdl-posix.xsd), and the LSF extension (jsdl-lsf.xsd) are located in the LSF_LIBDIR directory.

- To submit a job that uses the LSF extension, use the -jsdl option.
- To submit a job that uses only standard JSDL elements and POSIX extensions, use the -jsdl_strict option. You can use the -jsdl_strict option to verify that your file contains only valid JSDL elements and POSIX extensions. Error messages indicate invalid elements, including:
 - Elements that are not part of the JSDL specification
 - Valid JSDL elements that are not supported in this version of LSF
 - Extension elements that are not part of the JSDL standard and POSIX extension schemas

NOTE: For a detailed mapping of JSDL elements to LSF submission options, and for a complete list of supported and unsupported elements, see the chapter "Submitting Jobs Using JSDL" in Administering Platform LSF.

If you specify duplicate or conflicting job submission parameters, LSF resolves the conflict by applying the following rules:

- The parameters specified in the command line override all other parameters.
- A job script or user input for an interactive job overrides parameters specified in the JSDL file.

-k "checkpoint dir [checkpoint period][method=method name]"

Makes a job checkpointable and specifies the checkpoint directory. If you omit the checkpoint period, the quotes are not required. Specify a relative or absolute path name.

When a job is checkpointed, the checkpoint information is stored in checkpoint dir/job ID/file name. Multiple jobs can checkpoint into the same directory. The system can create multiple files.

The checkpoint directory is used for restarting the job (see brestart(1)). The checkpoint directory can be any valid path.

Optionally, specifies a checkpoint period in minutes. Specify a positive integer. The running job is checkpointed automatically every checkpoint period. The checkpoint period can be changed using bchkpnt(1). Because checkpointing is a heavyweight operation, you should choose a checkpoint period greater than half an hour.

Optionally, specifies a custom checkpoint and restart method to use with the job. Use method=default to indicate to use the default LSF checkpoint and restart programs for the job, echkpnt.default and erestart.default.

The echkpnt.method_name and erestart.method_name programs must be in LSF_SERVERDIR or in the directory specified by LSB_ECHKPNT_METHOD_DIR (environment variable or set in lsf.conf).

If a custom checkpoint and restart method is already specified with LSB_ECHKPNT_METHOD (environment variable or in lsf.conf), the method you specify with bsub -k overrides this.

Process checkpointing is not available on all host types, and may require linking programs with a special libraries (see libckpt.a(3)). LSF invokes echkpnt (see echkpnt(8)) found in LSF_SERVERDIR to checkpoint the job. You can override the default echkpnt for the job by defining as environment variables or in 1sf.conf LSB_ECHKPNT_METHOD and LSB_ECHKPNT_METHOD_DIR to point to your own echkpnt. This allows you to use other checkpointing facilities, including application-level checkpointing.

The checkpoint method directory should be accessible by all users who need to run the custom echkpnt and erestart programs.

Only running members of a chunk job can be checkpointed.

-Llogin shell

Initializes the execution environment using the specified login shell. The specified login shell must be an absolute path. This is not necessarily the shell under which the job will be executed.

Login shell is not supported on Windows.

-Lp ls_project_name

Assigns the job to the specified License Scheduler project.

-M mem_limit

Sets a per-process (soft) memory limit for all the processes that belong to this batch job (see getrlimit(2)).

By default, the limit is specified in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for the limit (MB, GB, TB, PB, or EB).

If LSB_MEMLIMIT_ENFORCE or LSB_JOB_MEMLIMIT are set to y in 1sf.conf, LSF kills the job when it exceeds the memory limit. Otherwise, LSF passes the memory limit to the operating system. UNIX operating systems that support RUSAGE_RSS for setrlimit() can apply the memory limit to each process.

The following operating systems do not support the memory limit at the OS level:

- Windows
- Sun Solaris 2.x

-m "host_name[@cluster_name][[!] | +[pref_level]] | host_group[[!] |+[pref_level]] ..."

Runs the job on one of the specified hosts.

By default, if multiple hosts are candidates, runs the job on the least-loaded host.

To change the order of preference, put a plus (+) after the names of hosts or host groups that you would prefer to use, optionally followed by a preference level. For preference level, specify a positive integer, with higher numbers indicating greater preferences for those hosts. For example, -m "hostA groupB+2 hostC+1" indicates that groupB is the most preferred and hostA is the least preferred.

The keyword others can be specified with or without a preference level to refer to other hosts not otherwise listed. The keyword others must be specified with at least one host name or host group, it cannot be specified by itself. For example, -m "hostA+ others" means that hostA is preferred over all other hosts.

If you also use -q, the specified queue must be configured to include all the hosts in the your host list. Otherwise, the job is not submitted. To find out what hosts are configured for the queue, use bqueues -1.

If the host group contains the keyword all, LSF will dispatch the job to any available host, even if the host is not defined for the specified queue.

To display configured host groups, use bmgroup.

For the MultiCluster job forwarding model, you cannot specify a remote host by name.

For parallel jobs, specify first execution host candidates when you want to ensure that a host has the required resources or runtime environment to handle processes that run on the first execution host.

To specify one or more hosts or host groups as first execution host candidates, add the (!) symbol after the host name, as shown in the following example:

bsub -n 2 -m "host1 host2! hostgroupA! host3 host4" my_parallel_job LSF runs my_parallel_job according to the following steps:

LSF selects either host2 or a host defined in hostgroup A as the first execution host for the parallel job.

NOTE: First execution host candidates specified at the job-level (command line) override candidates defined at the queue level (in 1sb.queues).

- If any of the first execution host candidates have enough processors to run the job, the entire job will run on the first execution host, and not on any other hosts.
 - In the example, if host2 or a member of hostgroup A has two or more processors, the entire job will run on the first execution host.
- If the first execution host does not have enough processors to run the entire job, LSF selects additional hosts that are not defined as first execution host candidates.

Follow these guidelines when you specify first execution host candidates:

- If you specify a host group, you must first define the host group in the file 1sb.hosts.
- Do not specify a dynamic host group as a first execution host.

- Do not specify all, all remote, or others, or a host partition as a first execution host.
- ❖ Do not specify a preference (+) for a host identified by (!) as a first execution host candidate.
- For each parallel job, specify enough regular hosts to satisfy the processor requirement for the job. Once LSF selects a first execution host for the current job, the other first execution host candidates become unavailable to the current job, but remain available to other jobs as either regular or first execution hosts.
- You cannot specify first execution host candidates when you use the brun command.

In a MultiCluster environment, insert the (!) symbol after the cluster name, as shown in the following example:

bsub -n 2 -m "host2@cluster2! host3@cluster2" my_parallel_job

-n min_proc[,max_proc]

Submits a parallel job and specifies the number of processors required to run the job (some of the processors may be on the same multiprocessor host).

You can specify a minimum and maximum number of processors to use. The job can start if at least the minimum number of processors is available. If you do not specify a maximum, the number you specify represents the exact number of processors to use.

If PARALLEL_SCHED_BY_SLOT=Y in 1sb.params, this option specifies the number of slots required to run the job, not the number of processors.

Jobs that request fewer slots than the minimum PROCLIMIT defined for the queue or application profile to which the job is submitted, or more slots than the maximum PROCLIMIT are rejected. If the job requests minimum and maximum job slots, the maximum slots requested cannot be less than the minimum PROCLIMIT, and the minimum slots requested cannot be more than the maximum PROCLIMIT.

For example, if the queue defines PROCLIMIT=4 8:

- bsub -n 6 is accepted because it requests slots within the range of PROCLIMIT
- bsub -n 9 is rejected because it requests more slots than the PROCLIMIT allows
- bsub -n 1 is rejected because it requests fewer slots than the PROCLIMIT allows
- bsub -n 6,10 is accepted because the minimum value 6 is within the range of the PROCLIMIT setting
- bsub -n 1,6 is accepted because the maximum value 6 is within the range of the PROCLIMIT setting
- bsub -n 10,16 is rejected because its range is outside the range of **PROCLIMIT**
- bsub -n 1,3 is rejected because its range is outside the range of PROCLIMIT See the PROCLIMIT parameter in lsb.queues(5) and lsb.applications(5) for

more information.

In a MultiCluster environment, if a queue exports jobs to remote clusters (see the SNDJOBS TO parameter in 1sb. queues (5)), then the process limit is not imposed on jobs submitted to this queue.

Once at the required number of processors is available, the job is dispatched to the first host selected. The list of selected host names for the job are specified in the environment variables LSB HOSTS and LSB MCPU HOSTS. The job itself is expected to start parallel components on these hosts and establish communication among them, optionally using RES.

Specify first execution host candidates using the -m option when you want to ensure that a host has the required resources or runtime environment to handle processes that run on the first execution host.

If you specify one or more first execution host candidates, LSF looks for a first execution host that satisfies the resource requirements. If the first execution host does not have enough processors or job slots to run the entire job, LSF looks for additional hosts.

-o output file

Specify a file path. Appends the standard output of the job to the specified file. Sends the output by mail if the file does not exist, or the system has trouble writing

If only a file name is specified, LSF writes the output file to the current working directory. If the current working directory is not accessible on the execution host after the job starts, LSF writes the standard output file to /tmp/.

If you use the special character %J in the name of the output file, then %J is replaced by the job ID of the job. If you use the special character % I in the name of the output file, then % I is replaced by the index of the job in the array, if the job is a member of an array. Otherwise, % I is replaced by 0 (zero).

NOTE: The file path can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows, including the directory, file name, and expanded values for %J (job_ID) and %I (index_ID).

If the parameter LSB_STDOUT_DIRECT in 1sf. conf is set to Y or y, the standard output of a job is written to the file you specify as the job runs. If LSB STDOUT DIRECT is not set, it is written to a temporary file and copied to the specified file after the job finishes. LSB_STDOUT_DIRECT is not supported on Windows.

If you use -o without -e or -eo, the standard error of the job is stored in the output file.

If you use -0 without -N, the job report is stored in the output file as the file header.

If you use both -0 and -N, the output is stored in the output file and the job report is sent by mail. The job report itself does not contain the output, but the report will advise you where to find your output.

-oo output file

Specify a file path. Overwrites the standard output of the job to the specified file if it exists, or sends the output to a new file if it does not exist. Sends the output by mail if the system has trouble writing to the file.

If only a file name is specified, LSF writes the output file to the current working directory. If the current working directory is not accessible on the execution host after the job starts, LSF writes the standard output file to /tmp/.

If you use the special character %J in the name of the output file, then %J is replaced by the job ID of the job. If you use the special character % I in the name of the output file, then % I is replaced by the index of the job in the array, if the job is a member of an array. Otherwise, % I is replaced by 0 (zero).

NOTE: The file path can contain up to 4094 characters for UNIX and Linux, or up to 255 characters for Windows, including the directory, file name, and expanded values for %J (job_ID) and %I (index_ID).

If the parameter LSB_STDOUT_DIRECT in 1sf.conf is set to Y or y, the standard output of a job overwrites the output file you specify as the job runs, which will occur every time the job is submitted with the overwrite option, even if it is requeued manually or by the system. If LSB STDOUT DIRECT is not set, the output is written to a temporary file that overwrites the specified file after the job finishes. LSB_STDOUT_DIRECT is not supported on Windows.

If you use - oo without -e or -eo, the standard error of the job is stored in the output file.

If you use -00 without -N, the job report is stored in the output file as the file header.

If you use both -00 and -N, the output is stored in the output file and the job report is sent by mail. The job report itself does not contain the output, but the report will advise you where to find your output.

-P project_name

Assigns the job to the specified project.

On IRIX 6, you must be a member of the project as listed in /etc/project(4). If you are a member of the project, then /etc/projid(4) maps the project name to a numeric project ID. Before the submitted job executes, a new array session (newarraysess(2)) is created and the project ID is assigned to it using setprid(2).

-p process_limit Sets the limit of the number of processes to process_limit for the whole job. The default is no limit. Exceeding the limit causes the job to terminate.

-q "queue_name ..."

Submits the job to one of the specified queues. Quotes are optional for a single queue. The specified queues must be defined for the local cluster. For a list of available queues in your local cluster, use bqueues.

When a list of queue names is specified, LSF selects the most appropriate queue in the list for your job based on the job's resource limits, and other restrictions, such as the requested hosts, your accessibility to a queue, queue status (closed or open), etc. The order in which the queues are considered is the same order in which these queues are listed. The queue listed first is considered first.

-R "res reg" [-R "res_req" ...] Runs the job on a host that meets the specified resource requirements. A resource requirement string describes the resources a job needs. LSF uses resource requirements to select hosts for job execution.

The size of the resource requirement string cannot exceed 512 characters. If you need to include a hyphen (-) within the string, enclose the text in single quotation marks, for example, bsub -R "select[hname!='host06-x12']".

A resource requirement string is divided into the following sections. Each section has a different syntax.

- A selection section (select). The selection section specifies the criteria for selecting execution hosts from the system.
- An ordering section (order). The ordering section indicates how the hosts that meet the selection criteria should be sorted.
- A resource usage section (rusage). The resource usage section specifies the expected resource consumption of the task.
- A job spanning section (span). The job spanning section indicates if a parallel batch job should span across multiple hosts.
- A same resource section (same). The same section indicates that all processes of a parallel job must run on the same type of host.

The resource requirement string sections have the following syntax:

```
select[selection string] order[order string] rusage[usage string
[, usage_string][|| usage_string] ...] span[span_string]
same[same_string]
```

The square brackets must be typed as shown for each section.

If no section name is given, then the entire string is treated as a selection string (selection_string]). The select keyword may be omitted if the selection string is the first string in the resource requirement.

Any resource for run queue length, such as r15s, r1m or r15m, specified in the resource requirements refers to the normalized run queue length.

By default, memory (mem) and swap (swp) limits in select[] and rusage[] sections are specified in MB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for the these limits (MB, GB, TB, PB, or EB).

For example, to submit a job which will run on Solaris 7 or Solaris 8:

```
bsub -R "sol7 || sol8" myjob
```

The following command runs the job called my job on an HP-UX host that is lightly loaded (CPU utilization) and has at least 15 MB of swap memory available.

```
bsub -R "swp > 15 && hpux order[ut]" myjob
```

bsub also accepts multiple - R options for the order, same, rusage, and select sections. You can specify multiple strings instead of using the && operator:

```
bsub -R "select[swp > 15]" -R "select[hpux] order[r15m]" -R
rusage[mem=100]" -R "order[ut]" -R "same[type]" -R
rusage[tmp=50:duration=60]" -R "same[model]" myjob
```

LSF merges the multiple - R options into one string and selects a host that meets all of the resource requirements. The number of -R option sections is unlimited, up to a maximum of 512 characters for the entire string.

REMEMBER: Use multiple -R options only with the order, same, rusage, and select sections of the resource requirements string and with the bsub and bmod commands.

You defined a resource called bigmem in lsf.shared and defined it as an exclusive resource for hostE in 1sf.cluster.mycluster. Use the following command to **submit a job that will run on** hostE:

```
bsub -R "bigmem" myjob
or
bsub -R "defined(bigmem)" myjob
```

You configured a static shared resource for licenses for the Verilog application as a resource called verilog_lic. To submit a job that will run on a host when there is a license available:

bsub -R "select[defined(verilog_lic)] rusage[verilog_lic=1]" myjob

The following job requests 20 MB memory for the duration of the job, and 1 license for 2 minutes:

```
bsub -R "rusage[mem=20, license=1:duration=2]" myjob
```

The following job requests 20 MB of memory and 50 MB of swap space for 1 hour, and 1 license for 2 minutes:

bsub -R "rusage[mem=20:swp=50:duration=1h, license=1:duration=2]" myjob

The following job requests 20 MB of memory for the duration of the job, 50 MB of swap space for 1 hour, and 1 license for 2 minutes.

bsub -R "rusage[mem=20,swp=50:duration=1h, license=1:duration=2]" myjob

The following job requests 50 MB of swap space, linearly decreasing the amount reserved over a duration of 2 hours, and requests 1 license for 2 minutes:

bsub -R "rusage[swp=50:duration=2h:decay=1, license=1:duration=2]" myjob

The following job requests two resources with same duration but different decay:

bsub -R "rusage[mem=20:duration=30:decay=1, lic=1:duration=30]" myjob

You are running an application version 1.5 as a resource called app_lic_v15 and the same application version 2.0.1 as a resource called app_lic_v201. The license key for version 2.0.1 is backward compatible with version 1.5, but the license key for version 1.5 will not work with 2.0.1.

Job-level resource requirement specifications that use the || operator take precedence over any queue-level resource requirement specifications.

• If you can only run your job using one version of the application, submit the job without specifying an alternative resource. To submit a job that will only use app_lic_v201:

```
bsub -R "rusage[app_lic_v201=1]" myjob
```

If you can run your job using either version of the application, try to reserve version 2.0.1 of the application. If it is not available, you can use version 1.5. To submit a job that will try app_lic_v201 before trying app_lic_v15:

```
bsub -R "rusage[app_lic_v201=1||app_lic_v15=1]" myjob
```

 If different versions of an application require different system resources, you can specify other resources in your rusage strings. To submit a job that will use 20 MB of memory for app_lic_v201 or 20 MB of memory and 50 MB of swap space for app_lic_v15:

```
bsub -R "rusage[mem=20:app_lic_v15=1||mem=20:swp=50:app_lic_v201=1]" myjob
```

-S stack_limit Sets a per-process (soft) stack segment size limit for each of the processes that belong to the batch job (see getrlimit(2)).

> By default, the limit is specified in KB. Use LSF UNIT FOR LIMITS in 1sf.conf to specify a larger unit for the limit (MB, GB, TB, PB, or EB).

-s signal Send the specified signal when a queue-level run window closes.

By default, when the window closes, LSF suspends jobs running in the queue (job state becomes SSUSP) and stops dispatching jobs from the queue.

Use - s to specify a signal number; when the run window closes, the job is signalled by this signal instead of being suspended.

-sla service_class_name

Specifies the service class where the job is to run.

If the SLA does not exist or the user is not a member of the service class, the job is rejected.

If EGO-enabled SLA scheduling is configured with

ENABLE_DEFAULT_EGO_SLA in lsb.params, jobs submitted without -sla are attached to the configured default SLA.

You can use -g with -sla. All jobs in a job group attached to a service class are scheduled as SLA jobs. It is not possible to have some jobs in a job group not part of the service class. Multiple job groups can be created under the same SLA. You can submit additional jobs to the job group without specifying the service class name again.

TIP: You should submit your jobs with a runtime limit (- W option) or you should specify a run time limit in a queue or application profile (RUNLIMIT in the queue definition in 1sb.queues or RUNLIMIT in the application profile definition in 1sb.applications). If you do not specify a run time limit, LSF automatically adjusts the optimum number of running jobs according to the observed run time of finished jobs.

Use bs la to display the properties of service classes configured in LSB_CONFDIR/cluster_name/configdir/lsb.serviceclasses (see 1sb.serviceclasses(5)) and dynamic information about the state of each service class.

-sp priority

Specifies user-assigned job priority which allow users to order their jobs in a queue. Valid values for priority are any integers between 1 and MAX_USER_PRIORITY (configured in 1sb.params, displayed by bparams -1). Job priorities that are not valid are rejected. LSF and queue administrators can specify priorities beyond MAX_USER_PRIORITY.

The job owner can change the priority of their own jobs. LSF and queue administrators can change the priority of all jobs in a queue.

Job order is the first consideration to determine job eligibility for dispatch. Jobs are still subject to all scheduling policies regardless of job priority. Jobs with the same priority are ordered first come first served.

User-assigned job priority can be configured with automatic job priority escalation to automatically increase the priority of jobs that have been pending for a specified period of time (JOB PRIORITY OVER TIME in 1sb.params).

When absolute priority scheduling is configured in the submission queue (APS PRIORITY in 1sb. queues), the user-assigned job priority is used for the JPRIORITY factor in the APS calculation.

-T thread_limit Sets the limit of the number of concurrent threads to *thread_limit* for the whole job. The default is no limit.

> Exceeding the limit causes the job to terminate. The system sends the following signals in sequence to all processes belongs to the job: SIGINT, SIGTERM, and SIGKILL.

-t [[month:]day:]hour:minute

Specifies the job termination deadline.

If a UNIX or Linux job is still running at the termination time, the job is sent a SIGUSR2 signal, and is killed if it does not terminate within ten minutes.

If a Windows job is still running at the termination time, it is killed immediately. (For a detailed description of how these jobs are killed, see bkill.)

In the queue definition, a TERMINATE action can be configured to override the bkill default action (see the JOB_CONTROLS parameter in 1sb.queues(5)).

In an application profile definition, a TERMINATE_CONTROL action can be configured to override the bkill default action (see the TERMINATE_CONTROL parameter in 1sb.applications(5)).

The format for the termination time is [[month:]day:]hour:minute where the number ranges are as follows: month 1-12, day 1-31, hour 0-23, minute 0-59.

At least two fields must be specified. These fields are assumed to be hour: minute. If three fields are given, they are assumed to be day: hour: minute, and four fields are assumed to be *month:day:hour:minute*.

-U reservation ID

If an advance reservation has been created with the brsvadd command, the -U option makes use of the reservation.

For example, if the following command was used to create the reservation user 1#0,

```
brsvadd -n 1024 -m hostA -u user1 -b 13:0 -e 18:0
Reservation "user1#0" is created
```

The following command uses the reservation:

```
bsub -U user1#0 myjob
```

The job can only use hosts reserved by the reservation user1#0. LSF only selects hosts in the reservation. You can use the -m option to specify particular hosts within the list of hosts reserved by the reservation, but you cannot specify other hosts not included in the original reservation.

If you do not specify hosts (bsub -m) or resource requirements (bsub -R), the default resource requirement is to select hosts that are of any host type (LSF assumes "type==any" instead of "type==local" as the default select string).

If you later delete the advance reservation while it is still active, any pending jobs still keep the "type==any" attribute.

A job can only use one reservation. There is no restriction on the number of jobs that can be submitted to a reservation; however, the number of slots available on the hosts in the reservation may run out. For example, reservation user2#0 reserves

128 slots on hostA. When all 128 slots on hostA are used by jobs referencing user2#0, hostA is no longer available to other jobs using reservation user2#0. Any single user or user group can have a maximum of 100 reservation IDs

Jobs referencing the reservation are killed when the reservation expires. LSF administrators can prevent running jobs from being killed when the reservation expires by changing the termination time of the job using the reservation (bmod -t) before the reservation window closes.

To use an advance reservation on a remote host, submit the job and specify the remote advance reservation ID. For example:

bsub -U user1#01@cluster1

In this example, we assume the default queue is configured to forward jobs to the remote cluster.

-u mail user

Sends mail to the specified email destination. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN NAME\user name) in a Windows command line or a double backslash (DOMAIN_NAME\\user_name) in a UNIX command line.

-v swap_limit Set the total process virtual memory limit to swap_limit for the whole job. The default is no limit. Exceeding the limit causes the job to terminate.

> By default, the limit is specified in KB. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for the the limit (MB, GB, TB, PB, or EB).

-W [hour:]minute[/host name | /host model]

Sets the runtime limit of the batch job. If a UNIX or Linux job runs longer than the specified run limit, the job is sent a SIGUSR2 signal, and is killed if it does not terminate within ten minutes. If a Windows job runs longer than the specified run limit, it is killed immediately. (For a detailed description of how these jobs are killed, see bkill.)

In the queue definition, a TERMINATE action can be configured to override the bkill default action (see the JOB_CONTROLS parameter in lsb.queues(5)).

In an application profile definition, a TERMINATE CONTROL action can be configured to override the bkill default action (see the TERMINATE_CONTROL parameter in lsb.applications(5)).

If you want to provide LSF with an estimated run time without killing jobs that exceed this value, submit the job with -We, or define the RUNTIME parameter in 1sb.applications and submit the job to that application profile. LSF uses the estimated runtime value for scheduling purposes only..

The run limit is in the form of [hour:] minute. The minutes can be specified as a number greater than 59. For example, three and a half hours can either be specified as 3:30, or 210.

The run limit you specify is the normalized run time. This is done so that the job does approximately the same amount of processing, even if it is sent to host with a faster or slower CPU. Whenever a normalized run time is given, the actual time on the execution host is the specified time multiplied by the CPU factor of the normalization host then divided by the CPU factor of the execution host.

If ABS RUNLIMIT=Y is defined in 1sb.params, the runtime limit and the runtime estimate are not normalized by the host CPU factor. Absolute wall-clock run time is used for all jobs submitted with a runtime limit or runtime estimate.

Optionally, you can supply a host name or a host model name defined in LSF. You must insert '/' between the run limit and the host name or model name. (See lsinfo(1) to get host model information.)

If no host or host model is given, LSF uses the default runtime normalization host defined at the queue level (DEFAULT_HOST_SPEC in 1sb. queues) if it has been configured; otherwise, LSF uses the default CPU time normalization host defined at the cluster level (DEFAULT_HOST_SPEC in 1sb.params) if it has been configured; otherwise, LSF uses the submission host.

For MultiCluster jobs, if no other CPU time normalization host is defined and information about the submission host is not available, LSF uses the host with the largest CPU factor (the fastest host in the cluster).

If the job also has termination time specified through the bsub -t option, LSF determines whether the job can actually run for the specified length of time allowed by the run limit before the termination time. If not, then the job will be aborted.

If the IGNORE_DEADLINE parameter is set in 1sb.queues(5), this behavior is overridden and the run limit is ignored.

Jobs submitted to a chunk job queue are not chunked if the run limit is greater than 30 minutes.

-We [hour:]minute[/host_name | /host_model]

Specifies an estimated run time for the job. LSF uses the estimated value for job scheduling purposes only, and does not kill jobs that exceed this value unless the jobs also exceed a defined runtime limit. The format of runtime estimate is same as run limit set by the -W option.

Use JOB_RUNLIMIT_RATIO in 1sb.params to limit the runtime estimate users can set. If JOB_RUNLIMIT_RATIO is set to 0 no restriction is applied to the runtime estimate.

The job-level runtime estimate setting overrides the RUNTIME setting in an application profile in 1sb.applications.

-w 'dependency_expression'

LSF will not place your job unless the dependency expression evaluates to TRUE. If you specify a dependency on a job that LSF cannot find (such as a job that has not yet been submitted), your job submission fails.

The dependency expression is a logical expression composed of one or more dependency conditions. To make dependency expression of multiple conditions, use the following logical operators:

&& (AND) \parallel (OR) ! (NOT)

Use parentheses to indicate the order of operations, if necessary.

Enclose the dependency expression in single quotes (') to prevent the shell from interpreting special characters (space, any logic operator, or parentheses). If you use single quotes for the dependency expression, use double quotes for quoted items within it, such as job names.

In dependency conditions, job names specify only your own jobs, unless you are the LSF administrator. By default, if you use the job name to specify a dependency condition, and more than one of your jobs has the same name, all of your jobs that have that name must satisfy the test. If JOB_DEP_LAST_SUB in 1sb.params is set to 1, the test is done on the job submitted most recently. Use double quotes (") around job names that begin with a number. In the job name, specify the wildcard character asterisk (*) at the end of a string, to indicate all jobs whose name begins with the string. For example, if you use jobA* as the job name, it specifies jobs named jobA, jobA1, jobA_test, jobA.log, etc.

Use the * with dependency conditions to define one-to-one dependency among job array elements such that each element of one array depends on the corresponding element of another array. The job array size must be identical.

For example:

```
bsub -w "done(myarrayA[*])" -J "myArrayB[1-10]" myJob2
```

indicates that before element 1 of myArrayB can start, element 1 of myArrayA must be completed, and so on.

You can also use the * to establish one-to-one array element dependencies with bmod after an array has been submitted.

If you want to specify array dependency by array name, set JOB_DEP_LAST_SUB in 1sb. params. If you do not have this parameter set, the job will be rejected if one of your previous arrays has the same name but a different index.

In dependency conditions, the variable *op* represents one of the following relational operators:

> >= < <= == !=

Use the following conditions to form the dependency expression.

done(job_ID |"job_name" ...)

The job state is DONE.

LSF refers to the oldest job of *job_name* in memory.

ended(job ID | "job name")

The job state is EXIT or DONE.

exit(job_ID | "job_name" [,[operator] exit_code])

The job state is EXIT, and the job's exit code satisfies the comparison test.

If you specify an exit code with no operator, the test is for equality (== is assumed).

If you specify only the job, any exit code satisfies the test.

external(job_ID | "job_name", "status_text")

The job has the specified job status.

If you specify the first word of the message description (no spaces), the text of the job's status begins with the specified word. Only the first word is evaluated.

job_ID | "job_name"

If you specify a job without a dependency condition, the test is for the DONE state (LSF assumes the "done" dependency condition by default).

numdone(job_ID, operator number | *)

For a job array, the number of jobs in the DONE state satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numended(job ID, operator number | *)

For a job array, the number of jobs in the DONE or EXIT states satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numexit(job ID, operator number | *)

For a job array, the number of jobs in the EXIT state satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numhold(job_ID, operator number | *)

For a job array, the number of jobs in the PSUSP state satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numpend(job_ID, operator number | *)

For a job array, the number of jobs in the PEND state satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numrun(job_ID, operator number | *)

For a job array, the number of jobs in the RUN state satisfies the test. Use * (with no operator) to specify all the jobs in the array.

numstart(job_ID, operator number | *)

For a job array, the number of jobs in the RUN, USUSP, or SSUSP states satisfies the test. Use * (with no operator) to specify all the jobs in the array.

post_done(job_ID | "job_name")

The job state is POST_DONE (post-execution processing of the specified job has completed without errors).

post_err(job_ID | "job_name")

The job state is POST_ERR (post-execution processing of the specified job has completed with errors).

started(job_ID | "job_name")

The job state is:

- RUN, DONE, or EXIT
- PEND or PSUSP, and the job has a pre-execution command (bsub -E) that is running.

-wa '[signal | command | CHKPNT]'

Specifies the job action to be taken before a job control action occurs.

A job warning action must be specified with a job action warning time in order for job warning to take effect.

If -wa is specified, LSF sends the warning action to the job before the actual control action is taken. This allows the job time to save its result before being terminated by the job control action.

You can specify actions similar to the JOB_CONTROLS queue level parameter: send a signal, invoke a command, or checkpoint the job.

The warning action specified by -wa option overrides JOB_WARNING_ACTION in the queue. JOB_WARNING_ACTION is used as the default when no command line option is specified.

For example the following specifies that 2 minutes before the job reaches its runtime limit, an URG signal is sent to the job:

bsub -W 60 -wt '2' -wa 'URG' myjob

-wt '[hour:]minute'

Specifies the amount of time before a job control action occurs that a job warning action is to be taken. Job action warning time is not normalized.

A job action warning time must be specified with a job warning action in order for job warning to take effect.

The warning time specified by the bsub -wt option overrides

JOB_ACTION_WARNING_TIME in the queue.

JOB ACTION WARNING TIME is used as the default when no command line option is specified.

For example the following specifies that 2 minutes before the job reaches its runtime limit, an URG signal is sent to the job:

bsub -W 60 -wt '2' -wa 'URG' myjob

-Zs Spools a job command file to the directory specified by the JOB_SPOOL_DIR parameter in 1sb.params, and uses the spooled file as the command file for the job.

By default, the command file is spooled to

LSB_SHAREDIR/cluster_name/lsf_cmddir. If the lsf_cmddir directory does not exist, LSF creates it before spooling the file. LSF removes the spooled file when the job completes.

If JOB_SPOOL_DIR is specified, the -Zs option spools the command file to the specified directory and uses the spooled file as the input file for the job.

JOB_SPOOL_DIR can be any valid path up to a maximum length up to 4094 characters on UNIX and Linux or up to 255 characters for Windows.

JOB_SPOOL_DIR must be readable and writable by the job submission user, and it must be shared by the master host and the submission host. If the specified directory is not accessible or does not exist, bsub -Zs cannot write to the default directory LSB_SHAREDIR/cluster_name/1sf_cmddir and the job will fail.

The -Zs option is not supported for embedded job commands because LSF is unable to determine the first command to be spooled in an embedded job command.

-h Prints command usage to stderr and exits.

Prints LSF release version to stderr and exits.

command [argument]

The job can be specified by a command line argument command, or through the standard input if the command is not present on the command line. The *command* can be anything that is provided to a UNIX Bourne shell (see sh(1)). command is assumed to begin with the first word that is not part of a bsub option. All arguments that follow *command* are provided as the arguments to the *command*.

The job command can be up to 4094 characters long for UNIX and Linux or up to 255 characters for Windows. If no job name is specified with -J, bjobs, bhist and bacct displays the command as the job name.

If the batch job is not given on the command line, bsub reads the job commands from standard input. If the standard input is a controlling terminal, the user is prompted with bsub> for the commands of the job. The input is terminated by entering CTRL-D on a new line. You can submit multiple commands through standard input.

The commands are executed in the order in which they are given. bsub options can also be specified in the standard input if the line begins with #BSUB; e.g., #BSUB -x. If an option is given on both the bsub command line, and in the standard input, the command line option overrides the option in the standard input. The user can specify the shell to run the commands by specifying the shell path name in the first line of the standard input, such as #!/bin/csh. If the shell is not given in the first line, the Bourne shell is used. The standard input facility can be used to spool a user's job script; such as bsub < script.

See Examples for examples of specifying commands through standard input.

Output

If the job is successfully submitted, displays the job ID and the queue to which the job has been submitted.

Examples

bsub sleep 100

Submit the UNIX command sleep together with its argument 100 as a batch job.

bsub -q short -o my_output_file "pwd; ls"

Submit the UNIX command pwd and 1s as a batch job to the queue named short and store the job output in my_output file.

bsub -m "host1 host3 host8 host9" my_program

Submit my_program to run on one of the candidate hosts: host1, host3, host8 and host9.

bsub -q "queue1 queue2 queue3" -c 5 my_program

Submit my_program to one of the candidate queues: queue1, queue2, and queue3 which are selected according to the CPU time limit specified by -c 5.

bsub -I ls

Submit a batch interactive job which displays the output of 1s at the user's terminal.

bsub - Ip vi myfile

Submit a batch interactive job to edit myfile.

```
bsub -Is csh
```

Submit a batch interactive job that starts csh as an interactive shell.

```
bsub -b 20:00 -J my_job_name my_program
```

Submit my_program to run after 8 p.m. and assign it the job name my_job_name.

```
bsub my_script
```

Submit my_script as a batch job. Since my script is specified as a command line argument, the my_script file is not spooled. Later changes to the my_script file before the job completes may affect this job.

```
bsub < default_shell_script</pre>
```

where default_shell_script contains:

```
sim1.exe
sim2.exe
```

The file default_shell_script is spooled, and the commands will be run under the Bourne shell since a shell specification is not given in the first line of the script.

```
bsub < csh_script
```

where csh_script contains:

```
#!/bin/csh
sim1.exe
sim2.exe
```

csh_script is spooled and the commands will be run under /bin/csh.

```
bsub -q night < my_script
```

where my_script contains:

```
#!/bin/sh
#BSUB -q test
#BSUB -o outfile -e errfile # my default stdout, stderr files
#BSUB -m "host1 host2" # my default candidate hosts
#BSUB -f "input > tmp" -f "output << tmp"
#BSUB -D 200 -c 10/host1
#BSUB -t 13:00
#BSUB -k "dir 5"
sim1.exe
sim2.exe
```

The job is submitted to the night queue instead of test, because the command line overrides the script.

```
bsub -b 20:00 -J my_job_name
bsub> sleep 1800
bsub> my_program
bsub> CTRL-D
```

The job commands are entered interactively.

```
bsub -T 4 myjob
```

Submits myjob with a maximum number of concurrent threads of 4.

```
bsub -W 15 -sla Kyuquot sleep 100
```

Submit the UNIX command sleep together with its argument 100 as a batch job to the service class named Kyuquot.

Limitations

When using account mapping the command bpeck(1) will not work. File transfer via the -f option to bsub(1) requires rcp(1) to be working between the submission and execution hosts. Use the -N option to request mail, and/or the -o and -e options to specify an output file and error file, respectively.

bswitch

switches unfinished jobs from one queue to another

Synopsis

```
bswitch [-J job_name] [-m host_name | -m host_group] [-q queue_name]
   [-u user_name | -u user_group | -u all] destination_queue [0]
bswitch destination_queue [job_ID | "job_ID[index_list]"] ...
bswitch [-h | -V]
```

Description

Switches one or more of your unfinished jobs to the specified queue. LSF administrators and root can switch jobs submitted by other users.

By default, switches one job, the most recently submitted job, or the most recently submitted job that also satisfies other specified options (-m, -q, -u, or -J). Specify -0 (zero) to switch multiple jobs.

The switch operation can be done only if a specified job is acceptable to the new queue as if it were submitted to it, and, in case the job has been dispatched to a host, if the host can be used by the new queue. If the switch operation is unsuccessful, the job stays where it is.

If a switched job has not been dispatched, then its behavior will be as if it were submitted to the new queue in the first place.

If a switched job has been dispatched, then it will be controlled by the loadSched and loadStop vectors and other configuration parameters of the new queue, but its nice value and resource limits will remain the same.

Also, if a switched job has been dispatched, it will be controlled by the PRIORITY and RUN_WINDOW configuration parameters of the new queue.

Members of a chunk job can be switched to another queue. Running chunk job members are removed from the chunk and switched; all other WAIT jobs are requeued to PEND. For chunk jobs in WAIT state, only the WAIT job is removed from the chunk and switched, and requeued to PEND.

The bswitch command is useful to change a job's attributes inherited from the queue.

Options

0 (Zero). Switches multiple jobs. Switches all the jobs that satisfy other specified options (-m, -q, -u and -J).

-J job_name Only switches jobs that have the specified job name.

-m host_name | -m host_group

Only switches jobs dispatched to the specified host or host group.

-q queue_name Only switches jobs in the specified queue.

-u user_name | -u user_group | -u all

Only switches jobs submitted by the specified user, or all users if you specify the keyword all. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\user_name) in a Windows command line or a double backslash (*DOMAIN_NAME\\user_name*) in a UNIX command line.

If you specify a user group, switches jobs submitted by all users in the group.

destination_queue Required. Specify the queue to which the job is to be moved.

job_ID ... |"job_ID[index_list]" ...

Switches only the specified jobs.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Limitations

You cannot switch a MultiCluster job.

bqueues(1), bhosts(1), bugroup(1), bsub(1), bjobs(1)

btop

moves a pending job relative to the first job in the queue

Synopsis

```
btop job_ID | "job_ID[index_list]" [position]
btop [-h | -V]
```

Description

Changes the queue position of a pending job or a pending job array element, to affect the order in which jobs are considered for dispatch.

By default, LSF dispatches jobs in a queue in the order of their arrival (that is, first-come-first-served), subject to availability of suitable server hosts.

The btop command allows users and the LSF administrator to manually change the order in which jobs are considered for dispatch. Users can only operate on their own jobs, whereas the LSF administrator can operate on any user's jobs. Users can only change the relative position of their own jobs.

If invoked by the LSF administrator, btop moves the selected job before the first job with the same priority submitted to the queue. The positions of all users' jobs in the queue can be changed by the LSF administrator.

If invoked by a regular user, btop moves the selected job before the first job with the same priority submitted by the user to the queue. Pending jobs are displayed by bjobs in the order in which they will be considered for dispatch.

A user may use btop to change the dispatch order of his/her jobs scheduled using a fairshare policy. However, if a job scheduled using a fairshare policy is moved by the LSF administrator using btop, the job will not be subject to further fairshare scheduling unless the same job is subsequently moved by the LSF administrator using bbot; in this case the job will be scheduled again using the same fairshare policy (see the FAIRSHARE keyword in 1sb.queues(5) and HostPartition keyword in 1sb.hosts (5)).

To prevent users from changing the queue position of a pending job with btop, configure JOB_POSITION_CONTROL_BY_ADMIN=Y in lsb.params.

You cannot run btop on jobs pending in an absolute priority scheduling (APS) queue.

Options

job_ID | "job_ID[index_list]"

Required. Job ID of the job or of the job array on which to operate.

For a job array, the index list, the square brackets, and the quotation marks are required. An index list is used to operate on a job array. The index list is a comma separated list whose elements have the syntax start_index[-end_index[:step]] where start_index, end_index and step are positive integers. If the step is omitted, a step of one is assumed. The job array index starts at one. The maximum job array index is 1000. All jobs in the array share the same job_ID and parameters. Each element of the array is distinguished by its array index.

position Optional. The *position* argument can be specified to indicate where in the queue the job is to be placed. position is a positive number that indicates the target position of the job from the beginning of the queue. The positions are relative to only the applicable jobs in the queue, depending on whether the invoker is a regular user or the LSF administrator. The default value of 1 means the position is before all the other jobs in the queue that have the same priority.

- -h Prints command usage to stderr and exits
- -V Prints LSF release version to stderr and exits

bugroup

displays information about user groups

Synopsis

```
bugroup [-1] [-r] [-w] [user_group ...]
bugroup [-h | -V]
```

Description

Displays user groups and user names for each group.

The default is to display information about all user groups.

Options

- -I Displays information in a long multi-line format. Also displays share distribution if shares are configured.
- **-r** Expands the user groups recursively. The expanded list contains only user names; it does not contain the names of subgroups. Duplicate user names are listed only once.
- -w Wide format. Displays user and user group names without truncating fields.

user group ...

Only displays information about the specified user groups. Do not use quotes when specifying multiple user groups.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

In the list of users, a name followed by a slash (/) indicates a subgroup.

Files

User groups and user shares are defined in the configuration file 1sb.users(5).

See Also

lsb.users(5), bmgroup(1), busers(1)

busers

displays information about users and user groups

Synopsis

```
busers [-w] [user_name ... | user_group ... | all]
busers [-h | -V]
```

Description

Displays information about users and user groups.

By default, displays information about the user who runs the command.

Options

user_name ... | user_group ... | all

Displays information about the specified users or user groups, or about all users if you specify a 11. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN_NAME\user_name) in a Windows command line or a double backslash (DOMAIN NAME\\user name) in a UNIX command line.

- **-h** Prints command usage to stderr and exits.
- Prints LSF release version to stderr and exits.
- Prints user and user group pending job thresholds and exits.

Output

A listing of the users and user groups is displayed with the following fields:

USER/GROUP

The name of the user or user group.

JL/P

The maximum number of job slots that can be processed simultaneously for the specified users on each processor. For non-preemptive scheduling, these job slots are used by running and suspended jobs or by pending jobs which have jobs slots reserved for them. For preemptive scheduling, these job slots are used by running jobs or by pending jobs which have slots reserved for them. (see the description of PREEMPTION in 1sb. queues(5)). This job limit is configured per processor so that multiprocessor hosts have more job slots. If the dash character (-) is displayed, there is no limit. JL/P is defined in the LSF configuration file lsb.users(5).

MAX

The maximum number of job slots that can be processed concurrently for the specified users' jobs. For non-preemptive scheduling, these job slots are used by running and suspended jobs or by pending jobs which have job slots reserved for them. For preemptive scheduling, these job slots are used by running jobs or by

pending jobs which have job slots reserved for them. (see the description of PREEMPTIVE in 1sb.queues(5)). If the character '-' is displayed, there is no limit. MAX is defined by the MAX_JOBS parameter in the configuration file 1sb.users(5).

NJOBS

The current number of job slots used by specified users' jobs. A parallel job that is pending is counted as n job slots for it will use n job slots in the queue when it is dispatched.

PEND

The number of pending job slots used by jobs of the specified users.

RUN

The number of job slots used by running jobs of the specified users.

SSUSP

The number of job slots used by the system-suspended jobs of the specified users.

USUSP

The number of job slots used by user-suspended jobs of the specified users.

RSV

The number of job slots used by pending jobs of the specified users which have job slots reserved for them.

MPEND

The pending job threshold for the specified users or user groups. MPEND is defined by the MAX_PEND_JOBS parameter in the configuration file 1sb.users(5).

ch

changes the host on which subsequent commands are to be executed

Synopsis

```
ch [-S] [-t] [host_name]
ch [-h | -V]
```

Description

Changes the host on which subsequent commands are to be executed.

By default, if no arguments are specified, changes the current host to the home host, the host from which the ch command was issued.

By default, executes commands on the home host.

By default, shell mode support is not enabled.

By default, does not display execution time of tasks.

The ch command allows you to quickly change to a designated host with the same execution environment. A simple shell is started that delivers all subsequent commands (except built-in commands) to the designated host for execution.

When the simple shell starts, it is in the current working directory and has the same command execution environment as that of the parent shell. Every remotely dispatched command is executed with the same environment as that on the home host. The syntax of the ch command is similar to that of the Bourne shell. However, there are some important differences.

The ampersand (&) following a command line (representing a background job in the Bourne shell) is ignored by ch. You can submit background jobs in ch with the built-in post command and bring them into the foreground with the built-in contact command (see below for details).

ch recognizes a ~ (tilde) as a special path name. If a ~ (tilde) is followed by a space, tab, new line or / (slash) character, then the ~ character is translated into the user's home directory. Otherwise, the ~ is translated as the home directory of the user name given by the string following the ~ character. Pipelines, lists of commands and redirection of standard input/output are all handled by invoking /bin/sh.

The following sequence of commands illustrates the behavior of the ch command. For example, the user is currently on hostA:

```
ch hostB
hostB> ch hostC
hostC> ch
hostA> ... ...
```

Options

-S Starts remote tasks with shell mode support. Shell mode support is required for running interactive shells or applications which redefine the CTRL-C and CTRL-Z keys (for example, jove).

-t Turns on the timing option. The amount of time each subsequent command takes to execute is displayed.

host_name Executes subsequent commands on the specified host.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Usage

The ch command interprets the following built-in commands:

cd [directory name]

Changes the current working directory to the specified directory. If a directory is not specified, changes to the user's home directory by default.

ch[*host_name*] Changes the current working host to the specified host. If a host is not specified, changes to the home host by default.

post [command [argument ...]]

Posts the specified command for execution in the background on the current working host. ch assigns a unique task ID to this command and displays this ID, then continues to interact with the user. However, the output of background jobs may disturb the screen. You can post multiple commands on one host or on different hosts. When a previously posted command is completed, ch reports its status to the standard error. If a command is not specified, ch displays all currently running background commands.

contact task ID

Brings a previously posted background command into the foreground, task ID is the ID returned by the post command. Standard input is now passed to this foreground command. You cannot put an active foreground job into the background. A command that has been brought into the foreground with the contact command cannot be put back into the background.

exit Exits ch if there are no posted commands running. Typing an EOF character (usually CTRL-D but may be set otherwise, see stty(1)) forces ch to exit; uncompleted posted commands are killed.

Limitations

Currently, the ch command does not support script, history, nor alias.

The ch prompt is always the current working host:current working directory followed by a > (right angle bracket) character. If the ch session is invoked by a shell that supports job control (such as tcsh or ksh), CTRL-Z suspends the whole ch session. The exit status of a command line is printed to stderr if the status is non-zero.

Isacct

displays accounting statistics on finished RES tasks in the LSF system

Synopsis

```
lsacct [-1] [-C time0, time1] [-S time0, time1] [-f logfile_name]
   [-m host_name] [-u user_name ... | -u all] [pid ...]
1sacct [-h | -V]
```

Description

Displays statistics on finished tasks run through RES. When a remote task completes, RES logs task statistics in the task log file.

By default, displays accounting statistics for only tasks owned by the user who invoked the leacet command.

By default, displays accounting statistics for tasks executed on all hosts in the LSF system.

By default, displays statistics for tasks logged in the task log file currently used by RES: LSF_RES_ACCTDIR/lsf.acct.host_name or /tmp/lsf.acct.host_name (see lsf.acct(5)).

If -1 is not specified, the default is to display the fields in SUMMARY only (see OUTPUT).

The RES on each host writes its own accounting log file. These files can be merged using the lsacctmrg command to generate statistics for the entire LSF cluster.

All times are reported in seconds. All sizes are reported in kilobytes.

Options

- -I Per-task statistics. Displays statistics about each task. See OUTPUT for a description of information that is displayed.
- -C time0,time1 Displays accounting statistics for only tasks that completed or exited during the specified time interval.

The time format is the same as in bhist(1).

Searches the specified task log file for accounting statistics. Specify either an -f logfile_name absolute or a relative path.

> Useful for analyzing old task log files or files merged with the lsacctmrg command.

- Displays accounting statistics for only tasks executed on the specified hosts. -m host_name ...
 - If a list of hosts is specified, host names must be separated by spaces and enclosed in quotation marks (") or (').
 - -S time0,time1 Displays accounting statistics for only tasks that began executing during the specified time interval.

The time format is the same as in bhist(1).

-u user_name ... | -u all Displays accounting statistics for only tasks owned by the specified users, or by all

users if the keyword all is specified.

If a list of users is specified, user names must be separated by spaces and enclosed in quotation marks (") or ('). You can specify both user names and user IDs in the list of users. To specify a Windows user account, include the domain name in uppercase letters and use a single backslash (DOMAIN NAME\user name) in a Windows command line or a double backslash (*DOMAIN_NAME*\\user_name) in a UNIX command line.

pid ... Displays accounting statistics for only tasks with the specified pid. This option overrides all other options except for -1, -f, -h, -V.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Output

SUMMARY (default format)

Overall statistics for tasks.

The total, average, maximum and minimum resource usage statistics apply to all specified tasks.

The following fields are displayed:

Total number of tasks

Total number of tasks including tasks completed successfully and total number of exited tasks.

Time range of started tasks

Start time of the first and last task selected.

Time range of ended tasks

Completion or exit time of the first and last task selected.

Resource usage of tasks selected

See getrusage (2).

CPU time Total CPU time consumed by the task.

Page faults Number of page faults.

Swaps Number of times the process was swapped out.

Blocks in Number of input blocks.

Blocks out Number of output blocks.

Messages sent Number of System VIPC messages sent.

Messages rcvd Number of IPC messages received. Files

Voluntary cont sw Number of voluntary context switches.

Involuntary con sw Number of involuntary context switches.

Turnaround Elapsed time from task execution to task completion.

Per Task Statistics (-I)

In addition to the fields displayed by default in SUMMARY, displays the following

fields for each task:

Starting time Time the task started.

User and host name User who submitted the task, host from which the task was submitted, in the format

user_name@host.

PID UNIX process ID of the task.

Execution host Host on which the command was run.

Command line Complete command line that was executed.

CWD Current working directory of the task.

Completion time Time at which the task completed.

Exit status UNIX exit status of the task.

Files

Reads 1sf.acct.host_name

Isacctmrg

merges task log files

Synopsis

```
lsacctmrg [-f] logfile_name ... target_logfile_name
lsacctmrg [-h | -V]
```

Description

Merges specified task log files into the specified target file in chronological order according to completion time.

All files must be in the format specified in 1sf.acct (see 1sf.acct(5)).

Options

-f Overwrites the target file without prompting for confirmation.

logfile_name ... Specify log files to be merged into the target file, separated by spaces. Specify either an absolute or a relative path.

target_logfile_name Specify the file into which all log files are to be merged. Specify either an absolute or a relative path. The target file cannot be part of the files to be merged.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

lsf.acct(5), res(8)

Isadmin

administrative tool for LSF

Synopsis

```
lsadmin subcommand
lsadmin [-h | -V]
```

Description

CAUTION: This command can only be used by LSF administrators.

Isadmin is a tool that executes privileged commands to control LIM and RES operations in the LSF cluster.

If no subcommands are supplied for lsadmin, lsadmin prompts for subcommands from the standard input.

For subcommands for which multiple host names or host groups can be specified, do not enclose the multiple names in quotation marks.

Subcommand List

```
ckconfig[-v]
reconfig [-f] [-v]
limstartup[-f][host_name...|all]
limshutdown [-f] [host_name ... | all]
limrestart [-v] [-f] [host_name ... | all]
limlock [-1 time_seconds]
limunlock
resstartup [-f] [host_name ... | all]
resshutdown [-f] [host_name ... | all]
resrestart [-f] [host_name ... | all]
reslogon [-c cpu_time] [host_name ... | all]
reslogoff [host_name ... | all]
limdebug [-c "class_name ..."] [-1 debug_level] [-f logfile_name] [-0]
["host_name ..."]
resdebug [-c "class_name"] [-1 debug_level] [-f logfile_name] [-0]
["host_name ..."]
limtime [-1 timing_level] [-f logfile_name] [-o] ["host_name ..."]
restime [-1 timing_level] [-f logfile_name] [-o] ["host_name ..."]
showconf lim [ host_name ... | all ]
help [subcommand ...] | ? [subcommand ...]
quit
```

- h

- V

Options

subcommand Executes the specified subcommand. See Usage section.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Usage

ckconfig [-v] Checks LSF configuration files.

Displays detailed messages about configuration file checking.

reconfig [-f] [-v] Restarts LIMs on all hosts in the cluster. You should use reconfig after changing configuration files. The configuration files are checked before all LIMs in the cluster are restarted. If the configuration files are not correct, reconfiguration will not be initiated.

> If LSF_MASTER_LIST is specified in 1sf.conf, you are prompted to confirm the reconfiguration for only the master candidate hosts.

Disables user interaction and forces LIM to restart on all hosts in the cluster if no fatal errors are found. This option is useful in batch mode.

Displays detailed messages about configuration file checking.

limstartup [-f] [host_name ... |all]

Starts LIM on the local host if no arguments are specified.

Starts LIMs on the specified hosts or on all hosts in the cluster if the word all is the only argument provided. You are promted to confirm LIM startup.

Only root and users listed in the parameter LSF_STARTUP_USERS in 1sf.sudoers(5) can use the all and -f options to start LIM as root.

These users must also be able to use rsh or ssh on all LSF hosts without having to type in passwords. If permission to start up LIMs as root is not configured, limstartup will start up LIMs as yourself after your confirmation.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

-f

Disables interaction and does not ask for confirmation for starting LIMs.

limshutdown [-f] [host name ... | all]

Shuts down LIM on the local host if no arguments are supplied.

Shuts down LIMs on the specified hosts or on all hosts in the cluster if the word all is specified. You are promted to confirm LIM shutdown.

-f

Disables interaction and does not ask for confirmation for shutting down LIMs.

limrestart [-v] [-f] [host_name ... | all]

Restarts LIM on the local host if no arguments are supplied.

Restarts LIMs on the specified hosts or on all hosts in the cluster if the word all is specified. You are prompted to confirm LIM restart.

limrestart should be used with care. Do not make any modifications until all the LIMs have completed the startup process. If you execute limrestart host name... to restart some of the LIMs after changing the configuration files, but other LIMs are still running the old configuration, confusion will arise among these LIMs. To avoid this situation, use reconfig instead of limrestart.

Displays detailed messages about configuration file checking.

-f

Disables user interaction and forces LIM to restart if no fatal errors are found. This option is useful in batch mode. limrestart -fall is the same as reconfig -f.

limlock [-l time seconds]

Locks LIM on the local host until it is explicitly unlocked if no time is specified. When a host is locked, LIM's load status becomes lockU. No job will be sent to a locked host by LSF.

-I time seconds

The host is locked for the specified time in seconds.

LSF suspends all non-exclusive jobs running on the host. This is useful if a machine is running an exclusive job requiring all the available CPU time and/or memory. If LSB_DISABLE_LIMLOCK_EXCL=y (to enable preemption of exclusive jobs, for example) LSF suspends all jobs, including exclusive jobs.

limunlock Unlocks LIM on the local host.

resstartup [-f] [host_name ... | all]

Starts RES on the local host if no arguments are specified.

Starts RESs on the specified hosts or on all hosts in the cluster if the word all is specified. You are prompted to confirm RES startup.

Only root and users defined by the LSF_STARTUP_USERS parameter in 1sf.sudoers(5) can use the all and -f options to start RES as root.

These users must be able to use rsh or ssh on all LSF hosts without having to type in passwords. For root installation to work properly, Isadmin must be installed as a setuid to root program.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

-f

Disables interaction and does not ask for confirmation for starting RESs.

resshutdown [-f] [host_name ... | all]

Shuts down RES on the local host if no arguments are specified.

Shuts down RESs on the specified hosts or on all hosts in the cluster if the word all is specified. You are prompted to confirm RES shutdown.

If RES is running, it will keep running until all remote tasks exit.

-f

Disables interaction and does not ask for confirmation for shutting down RESs.

resrestart [-f] [host_name ... | all]

Restarts RES on the local host if no arguments are specified.

Restarts RESs on the specified hosts or on all hosts in the cluster if the word all is specified. You are prompted to confirm RES restart.

If RES is running, it will keep running until all remote tasks exit. While waiting for remote tasks to exit, another RES is restarted to serve the new queries.

-f

Disables interaction and does not ask for confirmation for restarting RESs.

reslogon [-c cpu_time] [host_name ... | all]

Logs all tasks executed by RES on the local host if no arguments are specified.

Logs tasks executed by RESs on the specified hosts or on all hosts in the cluster if all is specified.

RES will write the task's resource usage information into the log file 1sf.acct.host_name. The location of the log file is determined by LSF_RES_ACCTDIR defined in lsf.conf. If LSF_RES_ACCTDIR is not defined, or RES cannot access it, the log file will be created in /tmp instead.

-c cpu time

Logs only tasks that use more than the specified amount of CPU time. The amount of CPU time is specified by cpu_time in milliseconds.

reslogoff [host_name ... | all]

Turns off RES task logging on the specified hosts or on all hosts in the cluster if all is specified.

If no arguments are specified, turns off RES task logging on the local host.

limdebug [-c "class_name ..."] [-l debug_level] [-f logfile_name] [-o] ["host_name ..."]

Sets the message log level for LIM to include additional information in log files. You must be root or the LSF administrator to use this command.

If the command is used without any options, the following default values are used: class_name=0 (no additional classes are logged)

debug_level=0 (LOG_DEBUG level in parameter LSF_LOG_MASK)

logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon name. log.host name

host name= local host (host from which command was submitted)

In MultiCluster, debug levels can only be set for hosts within the same cluster. For example, you could not set debug or timing levels from a host in clusterA for a host in clusterB. You need to be on a host in clusterB to set up debug or timing levels for clusterB hosts.

-c "class name ..."

Specify software classes for which debug messages are to be logged. If a list of classes is specified, they must be enclosed in quotation marks and separated by spaces.

Possible classes:

LC AFS - Log AFS messages

LC_AUTH - Log authentication messages

LC_CHKPNT - log checkpointing messages

LC_COMM - Log communication messages

LC_CONF - Print out all parameters in 1sf.conf (and ego.conf

LC_DCE - Log messages pertaining to DCE support

LC_EXEC - Log significant steps for job execution

LC_FILE - Log file transfer messages

LC_HANG - Mark where a program might hang

LC_LICENCE - Log license management messages

LC_MULTI - Log messages pertaining to MultiCluster

LC_PIM - Log PIM messages

LC_SIGNAL - Log messages pertaining to signals

LC_TRACE - Log significant program walk steps

LC_XDR - Log everything transferred by XDR

Default: 0 (no additional classes are logged)-f

NOTE: Classes are also listed in 1 s f . h.

-I debug level

Specify level of detail in debug messages. The higher the number, the more detail that is logged. Higher levels include all lower levels.

Possible values:

- 0 LOG_DEBUG level in parameter LSF_LOG_MASK in lsf.conf.
- 1 LOG_DEBUG1 level for extended logging. A higher level includes lower logging levels. For example, LOG DEBUG3 includes LOG DEBUG2 LOG DEBUG1, and LOG DEBUG levels.
- 2 LOG_DEBUG2 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2 LOG_DEBUG1, and LOG DEBUG levels.
- 3 LOG_DEBUG3 level for extended logging. A higher level includes lower logging levels. For example, LOG_DEBUG3 includes LOG_DEBUG2, LOG_DEBUG1, and LOG DEBUG levels.

Default: 0 (LOG_DEBUG level in parameter LSF_LOG_MASK)

-f logfile_name

Specify the name of the file into which debugging messages are to be logged. A file name with or without a full path may be specified.

If a file name without a path is specified, the file will be saved in the LSF system log file directory.

The name of the file created has the following format:

logfile_name.daemon_name.log.host_name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, no log file is created.

Default: current LSF system log file in the LSF system log file directory, in the format daemon name. log.host name.

-o

Turns off temporary debug settings and reset them to the daemon starting state. The message log level is reset back to the value of LSF_LOG_MASK and classes are reset to the value of LSF_DEBUG_RES, LSF_DEBUG_LIM.

Log file is reset back to the default log file.

"host name ..."

Sets debug settings on the specified host or hosts.

Default: local host (host from which command was submitted)

resdebug [-c "class name"] [-l debug level] [-f logfile name] [-o] ["host name ..."]

Sets the message log level for RES to include additional information in log files. You must be the LSF administrator to use this command, not root.

See description of limdebug for an explanation of options.

limtime [-l timing_level] [-f logfile_name] [-o] ["host_name ..."]

Sets timing level for LIM to include additional timing information in log files. You must be root or the LSF administrator to use this command.

If the command is used without any options, the following default values are used: timing_level=no timing information is recorded

logfile_name=current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name

host name=local host (host from which command was submitted)

In MultiCluster, timing levels can only be set for hosts within the same cluster. For example, you could not set debug or timing levels from a host in clusterA for a host in clusterB. You need to be on a host in clusterB to set up debug or timing levels for clusterB hosts.

-I timing level

Specifies detail of timing information that is included in log files. Timing messages indicate the execution time of functions in the software and are logged in milliseconds.

Valid values: 1 | 2 | 3 | 4 | 5

The higher the number, the more functions in the software that are timed and whose execution time is logged. The lower numbers include more common software functions. Higher levels include all lower levels.

Default: undefined (no timing information is logged)

-f logfile_name

Specify the name of the file into which timing messages are to be logged. A file name with or without a full path may be specified.

If a file name without a path is specified, the file will be saved in the LSF system log file directory.

The name of the file created has the following format:

logfile_name.daemon_name.log.host_name

On UNIX, if the specified path is not valid, the log file is created in the /tmp directory.

On Windows, no log file is created.

NOTE: Both timing and debug messages are logged in the same files.

Default: current LSF system log file in the LSF system log file directory, in the format daemon_name.log.host_name.

-0

Turns off temporary timing settings and resets them to the daemon starting state. The timing level is reset back to the value of the parameter for the corresponding daemon (LSF_TIME_LIM, LSF_TIME_RES).

Log file is reset back to the default log file.

"host name ..."

Sets the timing level on the specified host or hosts.

Default: local host (host from which command was submitted)

restime [-l timing_level] [-f logfile_name] [-o] ["host_name ..."]

Sets timing level for RES to include additional timing information in log files. You must be the LSF administrator can use this command, not root.

See description of limtime for an explanation of options.

showconf lim [host name ... | all]

Display all configured parameters and their values set in lsf.conf or ego.conf that affect 1 im.

Use Isadmin showconf lim to display the parameters configured in Isf.conf and ego.conf that apply to root LIM. By default, Isadmin displays the local LIM parameters. You can optionally specify the host to display the LIM parameters.

In a MultiCluster environment, 1 sadmin showconf only displays the parameters of daemons on the local cluster.

Running Isadmin showconf from a master candidate host will reach all server hosts in the cluster. Running Isadmin showconf from a slave-only host may not be able to reach other slave-only hosts.

You cannot run lsadmin showconf lim from client hosts. lsadmin shows only server host configuration, not client host configuration.

Isadmin showconf only displays the values used by LSF.

LIM reads EGO_MASTER_LIST from wherever it is defined. You can define either LSF MASTER LIST in 1sf.conf or EGO MASTER LIST in ego.conf.LIM reads 1sf.conf first, and ego.conf if EGO is enabled in the LSF cluster. LIM only takes the value of LSF_MASTER_LIST if EGO_MASTER_LIST is not defined at all in ego.conf.

For example, if EGO is enabled in the LSF cluster, and you define LSF_MASTER_LIST in lsf.conf, and EGO_MASTER_LIST in ego.conf, lsadmin showconf displays the value of EGO_MASTER_LIST in ego.conf.

If EGO is disabled, ego.conf not loaded, so whatever is defined in 1sf.conf is displayed.

help [subcommand ...] | ? [subcommand ...]

Displays the syntax and functionality of the specified commands. The commands must be explicit to lsadmin.

From the command prompt, you may use help or?.

quit Exits the lsadmin session.

Isclusters

displays configuration information about LSF clusters

Synopsis

```
lsclusters [-1] [cluster_name ...]
lsclusters [-h | -V]
```

Description

Displays configuration information about LSF clusters.

By default, returns information about the local cluster and all other clusters of which the local cluster is aware (all clusters defined in the RemoteClusters section of 1sf.cluster. cluster name if that section exists, otherwise all clusters defined in 1sf.shared).

Options

-I Long format. Displays additional information.

cluster_name ... Only displays information about the specified clusters.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

Default Output

The information includes: cluster name, cluster master host, primary cluster administrator's login name, total number of hosts in the cluster, and the number of server hosts in the cluster.

A listing of the clusters is displayed with the following fields:

CLUSTER NAME

The name of the cluster.

STATUS

The current status of the cluster. Possible values are:

The cluster is in normal load sharing state, and will exchange load information with the local cluster.

unavail

The cluster is unavailable.

MASTER_HOST

The name of the cluster's master host.

ADMIN

The user account name of the cluster's primary LSF administrator.

HOSTS

Number of LSF static client and server hosts in the cluster. The HOSTS field does

not include floating clients.

SERVERS

Number of LSF server hosts in the cluster.

Long Format (-I)

If this option is specified, the command will also list available resource names, host types, host models and cluster administrator's login names, and whether local cluster accepts or sends interactive jobs to this cluster.

Iseligible

displays whether a task is eligible for remote execution

Synopsis

```
lseligible [-r] [-q] [-s] task
lseligible [-h | -V]
```

Description

Displays whether the specified task is eligible for remote execution.

By default, only tasks in the remote task list are considered eligible for remote execution.

Options

- -q Quiet mode. Displays only the resource requirement string defined for the task. The string ELIGIBLE or NON-ELIGIBLE is omitted.
- -r Remote mode. Considers eligible for remote execution any task not included in the local task list.
- -s Silent mode. No output is produced. The -q and -s options are useful for shell scripts which operate by testing the exit status (see DIAGNOSTICS).

task Specify a command.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Output

If the task is eligible, the string ELIGIBLE followed by the resource requirements associated with the task are printed to stdout. Otherwise, the string NON-ELIGIBLE is printed to stdout.

If lseligible prints ELIGIBLE with no resource requirements, the task has the default requirements of CPU consumption and memory usage.

Diagnostics

Iseligible has the following exit statuses:

- 0 Task is eligible for remote execution
- 1 Command is to be executed locally
- -1 Syntax errors
- -10 A failure is detected in the LSF system

See Also

Isfinstall

runs 1sfinstall, the Platform LSF installation and configuration script

Synopsis

```
lsfinstall -f install.config
lsfinstall -s -f slave.config
lsfinstall -h
```

Description

1sfinstall runs the LSF installation scripts and configuration utilities to install a new Platform LSF cluster or upgrade LSF from a previous release.

To install a fully operational LSF cluster that all users can access, you should install as root.

You can run lsfinstall as a non-root user, with limitations.

Required install.config variables

- ◆ LSF_TOP="/path"
- LSF_ADMINS="user_name [user_name...]"
- LSF_CLUSTER_NAME="cluster_name"

Required slave.config variables

If you use slave.config for dynamic slave host installation, the following parameters are required:

- LSF_TOP="/path"
- LSF_TARDIR="/path"
- ◆ LSF_SERVER_HOSTS="host_name [host_name ...]"

Variables that require an absolute path

- LSF_LICENSE="/path/license_file"
- LSF_TOP="/path"
- LSF_TARDIR="/path"

What Isfinstall does

Before installing and configuring LSF, Isfinstall checks the installation prerequisites, and outputs the results to <code>lsfprechk.rpt.lsfinstall</code> writes any unrecoverable errors to the Install.err file and exits. You must correct these errors before continuing to install and configure LSF.

During installation, 1sfinstall logs installation progress in the Install.log file, calls other utilities to uncompress, extract and copy product files, installs a license, and configures the cluster.

After installation, you should run hostsetup to set up each server host in the cluster. After setting up the server hosts, you should start your cluster and test the installation by running some basic commands.

Where Isfinstall is located

Isfinstall is included in the LSF installation script tar file lsf7Update2_lsfinstall.tar.Zandislocated in the lsf7Update2_lsfinstall directory created when you uncompress and extract installation script tar file.

After installation, 1sfinstall is located in LSF_TOP/7.0/install/.

Before running Isfinstall

- *Plan* your installation by choosing:
 - LSF installation directory on file server (e.g., LSF_TOP="/usr/share/lsf")
 - LSF hosts (master host, server hosts, and client-only hosts; e.g., LSF_ADDSERVERS="hosta hostb hostc")
 - Cluster name (39 characters or less with no white spaces; e.g., LSF_CLUSTER_NAME="cluster1")

IMPORTANT: Do not use the name of any host, user, or user group as the name of your cluster.

- Primary LSF administrator (owns the LSF configuration files and log files; e.g., LSF_ADMINS="lsfadmin")
- LSF server hosts that are candidates to become the master host for the cluster, if you are installing a new host to be dynamically added to the cluster (e.g., LSF_MASTER_LIST="hosta hostb")
- *Prepare* your systems for installation:
 - Make sure the installation file system on the file server host has enough disk space for all hosts types (approximately 300 MB per host type).
 - Make sure the top-level installation directory (LSF_TOP) is accessible with the same path name from all hosts in the cluster (e.g., /usr/share/lsf).
 - Create user accounts for LSF administrators (e.g., 1sfadmin).
 - Read the "Release Notes for Platform LSF" (/distrib/7.0/lsf7Update2_release_notes.html) on the ftp.platform.com FTP site for detailed steps for downloading LSF distribution tar files
 - Get the LSF installation script tar file lsf7Update2_lsfinstall.tar.Z and extract it. For example:

zcat lsf7Update2_lsfinstall.tar.Z | tar xvf -

- Read 1sf7Update2_1sfinstall/README for information about the contents of lsf7Update2_lsfinstall.tar.Z.
- Get the distribution tar files for all host types you need.

Put the distribution files in the same directory as lsf7Update2_lsfinstall.tar.Z

TIP: Do not uncompress and extract the distribution tar files.

Get a valid license key and create a license file (license.dat) in the same directory as the distribution files and <code>lsf7Update2_lsfinstall.tar.Z.</code>

CAUTION: If you do not specify a license file with LSF LICENSE, or lsfinstall cannot find a license file in the default location, <code>lsfinstall</code> exits.

Make sure the installation file system containing LSF TOP is writable by the user account that is running lsfinstall.

Running Isfinstall

- Log on as root to the installation file server.
- 2 Edit lsf7Update2_lsfinstall/install.config or lsf7Update2_lsfinstall/slave.config.

Uncomment the options you want in the template file, and replace the example values with your own settings.

To enable Platform LSF HPC installation, specify ENABLE HPC INST=Y in install.config.

TIP: The sample values in the install.config and slave.config template files are examples only. They are not default installation values.

- Change to lsf7Update2_lsfinstall/.
- Run lsfinstall:
 - ♦ # ./lsfinstall -f install.config OR
 - ♦ # ./lsfinstall -s -f slave.config
- 5 Before using your cluster, read the following:
 - lsf7Update2_lsfinstall/lsf_getting_started.html to find out how to set up your LSF hosts, start LSF and test your new cluster.
 - lsf7Update2_lsfinstall/lsf_quick_admin.html to learn more about your new cluster.

If you install as a non-root user

You can install as a non-root user with some limitations. During installation, Isfinstall detects that you are not root. You must choose to configure either a multi-user cluster or a single-user cluster:

Single-user — Your user account must be primary LSF administrator. You can start LSF daemons, but only your user account can submit jobs to the cluster. Your user account must be able to read the system kernel information, such as /dev/kmem.

Multi-user—By default, only root can start the LSF daemons. Any user can submit jobs to your cluster. To make the cluster available to other users, you must manually change the ownership and setuid bit for lsadmin and badmin to root, and the file permission mode to -rwsr-xr-x (4755) so that the user ID bit for the owner is setuid.

Use the following commands to set the correct owner, user ID bit, and file permission mode for a multi-user cluster:

```
# chown root lsadmin badmin eauth swtbl_api ntbl_api
# chmod 4755 lsadmin badmin eauth swtbl_api ntbl_api
```

After installing Platform LSF

1 Optional. Run host setup to configure host-based resources and set up automatic LSF startup on your server hosts.

TIP: For Platform LSF HPC hosts, running hostsetup is optional on AIX and Linux. You must run hostsetup on SGI IRIX, TRIX, and Altix hosts, and on HP-UX hosts.

- a Log on to each server host as root. Start with the master host. If you are not root, you can continue with host setup, but by default, only root can start the LSF daemons.
- b Run hostsetup on each server host. For example:

```
# cd /usr/share/lsf/7.0/install
# ./hostsetup --top="/usr/share/lsf" --boot="y"
```

TIP: For complete hostsetup usage, enter hostsetup -h.

- 2 Log on to the LSF master host as root, and set your LSF environment:
 - For csh or tcsh:
 - % source LSF_TOP/conf/cshrc.lsf
 - For sh, ksh, or bash:
 - \$. LSF_TOP/conf/profile.lsf
- 3 Run 1sfstartup to start the cluster.

TIP: For large cluster, where cluster management software exists, you should use /etc/init.d lsf start instead of Isftartup.

4 Test your cluster by running some basic commands (e.g., lsid, lshosts, bhosts)

After testing your cluster, be sure all LSF users include LSF_CONFDIR/cshrc.lsf or LSF_CONFDIR/profile.lsf in their .cshrc or .profile.

Follow the steps in 1sf7Update2_lsfinstall/lsf_quick_admin.html for using LSF_CONFDIR/cshrc.lsf and LSF_CONFDIR/profile.lsf to set up the Platform LSF environment for users.

hostsetup example

The following example sets up a host to use the cluster installed in /usr/share/lsf. It also configures the LSF daemons to start automatically (--boot="y"): # hostsetup --top="/usr/share/lsf" --boot="y"

Running host setup remotely (rhostsetup)

Use the rhostsetup script to launch hostsetup on remote hosts.

rhostsetup uses either ssh or rsh. It is included in the installation script tar file lsf7Update2_lsfinstall.tar.Zandislocated in the lsf7Update2_lsfinstall directory created when you uncompress and extract installation script tar file.

After installation, rhostsetup is located in LSF_TOP/7.0/install/.

rhostsetup parameters

Before using rhostsetup, you must configure the following parameters at the top of the script:

- ◆ LSF_RSHCMD—the remote shell command (e.g, rsh or ssh) accessing the remote host
- ◆ LSF_HOSTS—list of hosts to run hostsetup on
- LSF TOPDIR—sets the hostsetup --top option. Specify the full path to the top-level installation directory. rhostsetup tries to detect this from lsf.conf if it is not defined here.
- LSF_BOOT—sets the hostsetup --boot option. Default is no (n).
- ◆ LSF_QUIET—sets the hostsetup --quiet option. Default is no (n).

Example rshostsetup configuration

```
LSF_RSHCMD="ssh -n"
LSF_HOSTS="hostA hostB hostC"
LSF_TOPDIR=/usr/local/ls
LSF BOOT=y
LSF_QUIET=n
```

Options

-f option_file Name of the file containing the installation options. The file can be any name you choose. The name of the default template file for normal installation is install.config. To install slave hosts for dynamic host configuration, use the template file slave.config.

-s Install a dynamic slave host.

Specify installation options in the slave.config file.

Required parameters:

- ◆ LSF_SERVER_HOSTS="host_name [host_name ...]"
- LSF_TOP="/path"
- LSF_TARDIR="/path"

Optional parameters:

LSF_LIM_PORT=port_number

If the master host does not use the default LSF_LIM_PORT, you must specify the same LSF_LIM_PORT defined in 1sf.conf on the master host.

LSF LOCAL RESOURCES="resource ..."

Defines the local resources for a dynamic host.

• For numeric resources, defined name-value pairs:

"[resourcemap value*resource_name]"

• For Boolean resources, the value will be the resource name in the form:

"[resource resource_name]"

For example:

LSF_LOCAL_RESOURCES="[hostname hostA] [server 1] [resourcemap 1*verilog] [resource linux]"

TIP: If LSF_LOCAL_RESOURCES are already defined in a local 1sf.conf on the slave host, lsfinstall does not add resources you define in LSF_LOCAL_RESOURCES in slave.config.

1sfinstall creates a local 1sf.conf for the slave host, which sets the following parameters:

- LSF_CONFDIR="/path"
- LSF_GET_CONF=lim
- LSF_LIM_PORT=port_number
- LSF_LOCAL_RESOURCES="resource ..."
- LSF_SERVER_HOSTS="host_name [host_name ...]"
- LSF_VERSION=7.0
- **-h** Prints command usage and exits.

lsf.conf, install.config, slave.config

Isfmon

installs or uninstalls LSF Monitor

Synopsis

1sfmon -install 1sfmon -remove

Description

Installs or uninstalls LSF Monitor in an existing cluster.

LSF Monitor runs on Microsoft Windows and allows you to use Windows Performance Monitor to chart information about the LSF cluster.

The LSF Monitor service runs under the account of an LSF cluster administrator.

Options

-install Installs LSF Monitor on the host.

-remove Removes LSF Monitor from the host.

Isfrestart

restarts LIM, RES, shatchd and mbatchd on all hosts in the cluster

Synopsis

lsfrestart [-f | -h | -V]

Description

CAUTION: This command can only be used by root or users listed in lsf.sudoers.

Restarts LIM, RES, shatchd and mbatchd, in that order, on all hosts in the local

By default, prompts for confirmation of the next operation if an error is encountered.

In order to be able to control all daemons in the cluster:

- The file /etc/lsf.sudoers has to be set up properly.
- You must be able to run the rsh or ssh command across all LSF hosts without having to enter a password. See your operating system documentation for information about configuring the rsh and ssh commands.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

Options

- **-f** Force mode. Continues to restart daemons even if an error is encountered.
- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

See Also

lsadmin(8), badmin(8), lsfshutdown(8), lsf.sudoers(5)

Isfshutdown

shuts down LIM, RES, shatchd and mbatchd on all hosts in the cluster

Synopsis

lsfshutdown [-f | -h | -V]

Description

CAUTION: This command can only be used by root or users listed in lsf.sudoers.

Shuts down shatchd, RES, LIM, and mbatchd, in that order, on all hosts.

By default, prompts for confirmation of the next operation if an error is encountered.

In order to be able to control all daemons in the cluster:

- The file /etc/lsf.sudoers has to be set up properly.
- You must be able to run the rsh or ssh command across all LSF hosts without having to enter a password. See your operating system documentation for information about configuring the rsh and ssh commands.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

Options

- -f Force mode. Continues to shut down daemons even if an error is encountered.
- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

See Also

lsadmin(8), badmin(8), lsfrestart(8), lsf.sudoers(5)

Isfstartup

starts LIM, RES, shatchd, and mbatchd on all hosts in the cluster

Synopsis

```
lsfstartup [-f ]
lsfstartup [-h | -V]
```

Description

CAUTION: This command can only be used by root or users listed in lsf.sudoers.

Starts LIM, RES, sbatchd, and mbatchd, in that order, on all hosts.

By default, prompts for confirmation of the next operation if an error is encountered.

If LSF daemons are already running, use 1sfrestart instead, or use 1sfshutdown and shut down the running daemons before you use lsfstartup.

In order to be able to control all daemons in the cluster:

- The file /etc/lsf.sudoers has to be set up properly.
- You must be able to run the rsh or ssh command across all LSF hosts without having to enter a password. See your operating system documentation for information about configuring the rsh and ssh commands.

The shell command specified by LSF_RSH in 1sf.conf is used before rsh is tried.

Options

- **-f** Force mode. Continues to start daemons even if an error is encountered.
- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

lsadmin(8), badmin(8), lsfshutdown(8), lsfrestart(8), lsf.sudoers(5)

Isgrun

executes a task on a set of hosts

Synopsis

```
lsgrun [-i] [-p | -P | -S] [-v]
   -f host_file | -m host_name ... | -n num_hosts [-R "res_req"]
   [command [argument ...]]
lsgrun [-h | -V]
```

Description

Executes a task on the specified hosts. Is grun is useful for fast global operations such as starting daemons, replicating files to or from local disks, looking for processes running on all hosts, checking who is logged in on each host, and so on. The hosts can be specified using a host file, a list of host names or by letting the system select the hosts. If LSB_DISABLE_LIMLOCK_EXCL=y (to enable preemption of exclusive jobs, for example), you can use 1 sgrun to start a task on hosts that are currently running exclusive jobs.

By default:

- 1 sgrun is not interactive.
- The specified task will be executed sequentially on hosts with full pseudo tty support.
- 1 sgrun does not create a pseudo-terminal.
- LSF uses as many processors as available to run the specified task.
- The resource requirement for host selection is r15s:pg.
- The prompt Command is displayed to allow users to type in a command (task) terminated by a CTRL-D or EOF. The command is then executed on the specified hosts.

Options

- -i Interactive operation mode. You are asked whether the task will be executed on all hosts. If you answer y, the task is started on all specified hosts; otherwise, you are asked to specify hosts interactively.
- -P Creates a pseudo-terminal on UNIX hosts. This is necessary to run programs requiring a pseudo-terminal (for example, vi).
 - This option is not supported on Windows.
- -p Parallel run mode. Executes the task on all hosts simultaneously and without pseudo tty support.
 - If this option is specified and the -P option is specified, the -P option is ignored. This option is useful for fast start-up of tasks. However, any output from remote tasks will arrive at the terminal in arbitrary order, depending on task execution speeds on individual hosts.

-S Creates a pseudo-terminal with shell mode support on UNIX hosts.

Shell mode support is required for running interactive shells or applications which redefine the CTRL-C and CTRL-Z keys (such as jove).

This option is not supported on Windows.

-v Verbose mode. Displays the name of the host or hosts running the task.

-f host_file Either -f host_file, -m host_name or -n num_processors is required.

Executes the task on all hosts listed in the *host_file*.

Specify a file that contains a list of host names. Host names must be separated by white space characters (for example, SPACE, TAB, and NEWLINE).

This option is exclusive of options -n, -R, and -m.

-m host_name ... Either - f host_file, -m host_name or -n num_processors is required.

Executes the task on all specified hosts.

Specify hosts on which to execute the task. If multiple host names are specified, the host names must be enclosed by " or ' and separated by white space.

This option is exclusive of options -n, -R, and -f.

-n num_hosts Either - f *host_file*, -m *host_name* or -n *num_hosts* is required.

Executes the task in a cluster with the required number of available hosts.

One host may be used to start several tasks if the host is multiprocessor. This option can be used together with option -R to select desired hosts.

This option is exclusive of options -m and -f.

-R "res req" Executes the task on hosts with the required resource requirements.

> Specify the resource requirement expression for host selection. The resource requirement will be used to choose from all hosts with the same host type as the local host, unless a "type == value" exists in res_req to specify otherwise.

This option can be used together with option -n to choose a specified number of processors to run the task.

Exclusive resources need to be explicitly specified within the resource requirement string. For example, you defined a resource called bigmem in 1sf.shared and defined it as an exclusive resource for hostE in lsf.cluster.mycluster. Use the following command to submit a task to run on host E:

```
lsgrun -R "bigmem" myjob
```

lsgrun -R "defined(bigmem)" myjob

If the -m option is specified with a single host name, the -R option is ignored.

command [argument ...]

Specify the command to execute. This must be the last argument on the command

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Diagnostics

Exit status is 0 if all commands are executed correctly.

Otherwise, the exit status is the first non-zero status returned by a remotely executed task. Is grun will execute the task on all hosts even if some have non-zero exit status.

Exit status is -10 if a problem is detected in LSF.

1sfintro, lsrun, lsplace

Ishosts

displays hosts and their static resource information

Synopsis

```
lshosts [-w | -1] [-R "res_req"] [host_name | cluster_name] ...
lshosts -s [shared_resource_name ...]
1shosts [-h | -V]
```

Description

Displays static resource information about hosts.

By default, returns the following information: host name, host type, host model, CPU factor, number of CPUs, total memory, total swap space, whether or not the host is a server host, and static resources. Displays information about all hosts in the cluster. See 1sf.cluster(5).

In MultiCluster job forwarding model, the default behavior is to return the following information: host name, host type, host model, CPU factor, number of CPUs, total memory, total swap space, whether or not the host is a server host, and static resources. Displays information about all hosts in the local cluster and for all hosts in equivalent remote clusters that the local cluster sees. See lsf.cluster(5).

In MultiCluster resource leasing model, returns information about hosts in the

The -s option displays information about the static shared resources and their associated hosts.

Options

- -I Displays host information in a long multi-line format. In addition to the default fields, displays additional information, including maximum /tmp space, the number of local disks, the execution priority for remote jobs, load thresholds, run windows, and the license classes used or needed.
- -w Displays host information in wide format. Fields are displayed without truncation.

-R "res reg"

Only displays information about the hosts that satisfy the resource requirement expression. For more information about resource requirements, see lsfintro(1). The size of the resource requirement string is limited to 512 bytes. LSF supports ordering of resource requirements on all load indices, including external load indices, either static or dynamic.

In MultiCluster, only displays information about the hosts in the local cluster that satisfy the resource requirement expression.

host_name...| cluster_name...

Only displays information about the specified hosts. Do not use quotes when specifying multiple hosts.

For MultiCluster, displays information about hosts in the specified clusters. The names of the hosts belonging to the cluster are displayed instead of the name of the cluster. Do not use quotes when specifying multiple clusters.

-s [shared_resource_name ...]

Displays information about the specified resources. The resources must be static shared resources. If no shared resource is specified, then displays information about all shared resources. Returns the following information: the resource names, the values of the resources, and the resource locations.

- -h Prints command usage to stderr and exits.
- -V Prints the LSF release version to stderr and exits.

Output

cpuf

Host-Based Default

Displays the following fields:

HOST NAME The name of the host. This display field is truncated.

The host type. This display field is truncated. type

> With MultiCluster, if the host type of a remote cluster's host is not defined in the local cluster, the keyword unknown will be displayed.

model The host model. This display field is truncated.

> With MultiCluster, if the host model of a remote cluster's host is not defined in the local cluster, the keyword unknown will be displayed.

The relative CPU performance factor. The CPU factor is used to scale the CPU load value so that differences in CPU speeds are considered. The faster the CPU, the larger the CPU factor.

The CPU factor of a host with an unknown host type is 1.0.

ncpus The number of processors on this host.

> If LSF_ENABLE_DUALCORE=Y in lsf.conf for dual-core CPU hosts, displays the number of cores instead of physical CPUs.

If EGO is enabled in the LSF cluster and EGO DEFINE NCPUS is specified in 1sf.conf or ego.conf, the appropriate value for nopus is displayed, depending on the value of EGO_DEFINE_NCPUS:

- EGO_DEFINE_NCPUS=procs—ncpus=number of processors
- EGO_DEFINE_NCPUS=cores—ncpus=number of processors x number of
- EGO_DEFINE_NCPUS=threads—ncpus=number of processors x number of cores x number of threads

EGO_DEFINE_NCPUS=cores is the same as setting LSF_ENABLE_DUALCORE=Y.

maxmem The maximum amount of physical memory available for user processes.

Platform LSF Command Reference 239

By default, the amount is displayed in KB. The amount may appear in MB depending on the actual system memory. Use LSF UNIT FOR LIMITS in 1sf.conf to specify a larger unit for the limit (GB, TB, PB, or EB).

maxswp The total available swap space.

> By default, the amount is displayed in KB. The amount may appear in MB depending on the actual system swap space. Use LSF_UNIT_FOR_LIMITS in

1sf.conf to specify a larger unit for the limit (GB, TB, PB, or EB).

Indicates whether the host is a server or client host. "Yes" is displayed for LSF server

servers. "No" is displayed for LSF clients. "Dyn" is displayed for dynamic hosts.

RESOURCES The Boolean resources defined for this host, denoted by resource names, and the

values of external numeric and string static resources. See lsf.cluster(5), and

1sf.shared(5) on how to configure external static resources.

Host Based -I Option

In addition to the above fields, the -1 option also displays the following:

ndisks The number of local disk drives directly attached to the host.

The maximum / tmp space in MB configured on a host. maxtmp

rexpri UNIX only. The execution priority of remote jobs run by the RES. rexpri is a

> number between -20 and 20, with -20 representing the highest priority and 20 the lowest. The default rexpri is 0, which corresponds to the default scheduling priority of 0 on BSD-based UNIX systems and 20 on System V-based systems.

nprocs The number of physical processors per CPU configured on a host.

ncores The number of cores per processor configured on a host.

nthreads The number of threads per core configured on a host.

RUN WINDOWS The time windows during which LIM considers the host as available to execute

remote jobs. These run windows have the same function for LSF hosts as dispatch

windows have for LSF hosts. (See 1sf.cluster(5).)

LICENSES ENABLED

The licenses that are enabled for each specified host.

If LSF_ENABLE_DUALCORE=Y in 1sf.conf for dual-core CPU hosts,

1 shosts -1 also displays if dual-core CPU license is enabled for the hosts and the

number of dual-core licenses enabled.

LICENSE CLASS NEEDED

The required banded license class for each specified host.

If LSF_ENABLE_DUALCORE=Y in 1sf.conf for dual-core CPU hosts,

Ishosts -1 also displays if dual-core CPU license is enabled for the hosts and the

number of dual-core licenses needed.

LOAD_THRESHOLDS

The thresholds for scheduling interactive jobs. If a load index exceeds the load threshold (or falls below the load threshold, for decreasing load indices), the host status is changed to "busy." If the threshold is displayed as a dash "-", the value of that load index does not affect the host's status. See lsload(1).

Resource-Based -s Option

Displays the static shared resources. Each line gives the value and the associated hosts for the static shared resource. See 1sf.shared(5), and 1sf.cluster(5) on how to configure static shared resources.

The following fields are displayed:

RESOURCE The name of the resource.

VALUE The value of the static shared resource.

LOCATION The hosts that are associated with the static shared resource.

Files

Reads lsf.cluster.cluster_name.

See Also

lsfintrols_info, ls_policy, ls_gethostinfo, lsf.cluster, lsf.shared

Isid

displays the current LSF version number, the cluster name, and the master host name

Synopsis

1sid [-h | -V]

Description

Displays the current LSF version number, the cluster name, and the master host

The master host is dynamically selected from all hosts in the cluster.

In MultiCluster, the master host is dynamically selected from all hosts in the local cluster.

Options

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Files

The host names and cluster names are defined in lsf.cluster.cluster_name and 1sf.shared, respectively.

See Also

ls_getclustername(3), ls_getmastername(3), lsinfo(1)

Isinfo

displays load sharing configuration information

Synopsis

```
lsinfo [-1] [-m | -M] [-r] [-t] [resource_name ...]
lsinfo [-h | -V]
```

Description

By default, displays all load sharing configuration information including resource names and their meanings, host types and models, and associated CPU factors known to the system.

By default, displays information about all resources. Resource information includes resource name, resource type, description, and the default sort order for the resource.

You can use resource names in task placement requests.

Use this command with options to selectively view configured resources, host types, and host models.

Options

- -I Displays resource information in a long multi-line format. Additional parameters are displayed including whether a resource is built-in or configured, and whether the resource value changes dynamically or is static. If the resource value changes dynamically then the interval indicates how often it is evaluated.
- Displays information about all host models in the file lsf.shared.
- -m Displays only information about host models that exist in the cluster.
- **-r** Displays only information about configured resources.
- -t Displays only information about configured host types. See lsload(1) and 1shosts(1).

- **resource_name ...** Displays only information about the specified resources.
 - **-h** Prints command usage to stderr and exits.
 - -V Prints LSF release version to stderr and exits.

Output

-l option

The -1 option displays all information available about load indices.

TYPE

Indicates whether the resource is numeric, string, or Boolean.

ORDER

Inc—If the numeric value of the load index increases as the load it measures increases, such as CPU utilization(ut).

- Dec—If the numeric value decreases as the load increases.
- N/A—If the resource is not numeric.

INTERVAL

The number of seconds between updates of that index. Load indices are updated every INTERVAL seconds. A value of 0 means the value never changes.

BUILTIN

If BUILTIN is Yes, the resource name is defined internally by LIM. If BUILTIN is No, the resource name is site-specific defined externally by the LSF administrator.

DYNAMIC

If DYNAMIC is Yes the resource is a load index that changes over time. If DYNAMIC is No the resource represents information that is fixed such as the total swap space on a host. Resources are Static or Boolean.

RELEASE

Applies to numeric shared resources only, such as floating licenses. Indicates whether LSF releases the resource when a job using the resource is suspended. When a job using a shared resource is suspended, the resource is held or released by the job depending on the configuration of the RELEASE parameter in 1sf.shared.

No indicates the resource is held. Yes indicates the resource is released.

lsfintro(1), lshosts(1), lsload(1), lsf.shared(5), ls_info(3), ls_policy(3)

Isload

displays load information for hosts

Synopsis

```
lsload [-1] [-N | -E] [-I load_index[:load_index] ...]
   [-n num_hosts] [-R res_req] [host_name ... | cluster_name ...]
lsload -s [resource_name ...]
lsload [-h | -V]
```

Description

Displays load information for hosts. Load information can be displayed on a per-host basis, or on a per-resource basis.

By default, displays load information for all hosts in the local cluster, per host.

With MultiCluster, also displays load information for all hosts in equivalent clusters (see lsf.cluster(5)).

By default, displays raw load indices.

By default, load information for resources is displayed according to CPU and paging load.

Options

-I Long format. Displays load information without truncation along with additional fields for I/O and external load indices.

This option overrides the index names specified with the -I option.

- -N Displays normalized CPU run queue length load indices (see lsfintro(1)).
- -E Displays effective CPU run queue length load indices (see lsfintro(1)). Options - N and - E are mutually exclusive.
- -w Displays load information in wide format. Fields are displayed without truncation.

-I load_index[:load_index] ...

Displays only the specified load indices. Separate multiple index names with colons (for example, r1m:pg:ut).

Specify any built-in load index. Specify external load indices only for host-based resources that are numeric and dynamic (you cannot specify external load indices for shared, string or Boolean resources).

-n num hosts

Displays only load information for the requested number of hosts. Information for up to num_hosts hosts that best satisfy the resource requirements is displayed.

-R res req

Displays only load information for hosts that satisfy the specified resource requirements. See lsinfo(1) for a list of built-in resource names.

Load information for the hosts is sorted according to load on the specified resources.

If res_req contains special resource names, only load information for hosts that provide these resources is displayed (see 1 shosts (1) to find out what resources are available on each host).

If one or more host names are specified, only load information about the hosts that satisfy the resource requirements is displayed.

With MultiCluster, when a cluster name is specified, displays load information of hosts in the specified cluster that satisfy the resource requirements.

host_name ... | cluster_name ...

Displays only load information for the specified hosts.

With MultiCluster, displays only load information for hosts in the specified clusters.

- -s [resource_name ...] Displays information about all dynamic shared resources configured in the cluster, or about the specified resources only. Specify dynamic shared resources.
 - **-h** Prints command usage to stderr and exits.
 - **-V** Prints LSF release version to stderr and exits.

Output

Host-Based Output (default output)

Built-in load indices include r15s, r1m, r15m, ut, pg, io, 1s, it, swp, mem and tmp. External load indices are configured in the file lsf.cluster.cluster_name (see 1sf.cluster(5)). The selection and order sections of res_req control for which hosts are displayed and how the information is ordered (see lsfintro(1)).

The display includes the following fields:

HOST_NAME

Standard host name used by LSF, typically an Internet domain name with two components.

status

Status of the host. A minus sign (-) may precede the status, indicating that RES is not running on the host.

Possible statuses are:

ok

The host is in normal load sharing state and can accept remote jobs. The ok status indicates that the Load Information Manager (LIM) is unlocked and that both LIM and the Remote Execution Server (RES) are running.

Author Comment:

Comment by K. Cann. importance.

I have purposely avoided saying that the status shows ok when a host is running an exclusive job with preemption of exclusive jobs enabled. It seems counterintuitive that the host would show "ok" if it is not actually available to run jobs because an exclusive job is running.

-ok

The (LIM) on the host is running but RES is unreachable.

busy

The host is overloaded because some load indices exceed configured thresholds. Load index values that caused the host to be busy are preceded by an asterisk (*).

lockW

The host is locked by its run window. Run windows for a host are specified in the configuration file (see 1sf.conf(5)) and can be displayed by 1shosts. A locked host will not accept load shared jobs from other hosts.

lockU

The host is locked by the LSF administrator or root.

unavail

The host is down or the LIM on the host is not running.

unlicensed

The host does not have a valid LSF license.

r15s The 15-second exponentially averaged CPU run queue length.

r1m The 1-minute exponentially averaged CPU run queue length.

r15m The 15-minute exponentially averaged CPU run queue length.

ut The CPU utilization exponentially averaged over the last minute, between 0 and 1.

The memory paging rate exponentially averaged over the last minute, in pages per pg

second.

ls The number of current login users.

it On UNIX, the idle time of the host (keyboard not touched on all logged in

sessions), in minutes.

On Windows, the it index is based on the time a screen saver has been active on a

particular host.

The amount of free space in /tmp, in MB. tmp

swp The amount of available swap space.

> By default, the amount is displayed in KB. The amount may appear in MB depending on the actual system swap space. Use LSF_UNIT_FOR_LIMITS in

1sf.conf to specify a larger unit for the limit (GB, TB, PB, or EB).

The amount of available RAM. mem

> By default, the amount is displayed in KB. The amount may appear in MB depending on the actual system memory. Use LSF_UNIT_FOR_LIMITS in 1sf.conf to specify a larger unit for the limit (GB, TB, PB, or EB).

io By default, io is not shown.

If -1 is specified, shows the disk I/O rate exponentially averaged over the last

minute, in KB per second.

external_index

By default, external load indices are not shown.

If -1 is specified, shows indices for all dynamic custom resources available on the host, including shared, string and Boolean resources.

If - I *load_index* is specified, only shows indices for specified non-shared (host-based) dynamic numeric custom resources.

Resource-Based Output (Isload -s)

Displays information about dynamic shared resources. Each line gives the value and the associated hosts for an instance of the resource. See lim(8), and 1sf.cluster(5) for information on configuring dynamic shared resources.

The displayed information consists of the following fields:

RESOURCE

Name of the resource.

VALUE

Value for an instance of the resource.

LOCATION

Hosts associated with the instance of the resource.

Examples

```
lsload -R "select[r1m<=0.5 && swp>=20 && type==ALPHA]"
```

OR, in restricted format:

lsload -R r1m=0.5:swp=20:type=ALPHA

Displays the load of ALPHA hosts with at least 20 MB of swap space, and a 1-minute run queue length less than 0.5.

```
lsload -R "select[(1-swp/maxswp)<0.75] order[pg]"</pre>
```

Displays the load of the hosts whose swap space utilization is less than 75%. The resulting hosts are ordered by paging rate.

```
lsload -I r1m:ut:io:pg
```

Displays the 1-minute CPU raw run queue length, the CPU utilization, the disk I/O and paging rates for all hosts in the cluster.

```
1sload -E
```

Displays the load of all hosts, ordered by r15s:pg, with the CPU run queue lengths being the effective run queue lengths (see lsfintro(1)).

```
lsload -s verilog_license
```

Displays the value and location of all the verilog_license dynamic shared resource instances.

Diagnostics

Exit status is -10 for LSF problems or a bad resource names.

Exit status is -1 if a bad parameter is specified, otherwise lsload returns 0.

ls_load(3)
```

Isloadadj

adjusts load indices on hosts

Synopsis

```
lsloadadj [-R res_req] [host_name[:num_task] ...]
lsloadadj [-h | -V]
```

Description

Adjusts load indices on hosts. This is useful if a task placement decision is made outside LIM by another application.

By default, assumes tasks are CPU-intensive and memory-intensive. This means the CPU and memory load indices are adjusted to a higher number than other load indices.

By default, adjusts load indices on the local host, the host from which the command was submitted.

By default, starts 1 task.

Upon receiving a load adjustment request, LIM temporarily increases the load on hosts according to resource requirements. This helps LIM avoid sending too many jobs to the same host in quick succession. The adjusted load decays over time before the real load produced by the dispatched task is reflected in LIM's load information.

1sloadadj adjusts all indices except for ls (login sessions), it (idle time), r15m (15-minute run queue length) and external load indices. Other load indices can only be adjusted beyond specific maximum values.

- tmp is -0.5
- swp is -1.5
- mem is -1.0
- r1m is 0.4
- ut is 15%

Options

-R res reg

Specify resource requirements for tasks. Only the resource usage section of the resource requirement string is considered (see lsfintro(1)). This is used by LIM to determine by how much individual load indices are to be adjusted.

For example, if a task is swap-space-intensive, load adjustment on the swp load index is higher; other indices are increased only slightly.

host_name[:num_task] ...

Specify a list of hosts for which load is to be adjusted. num_task indicates the number of tasks to be started on the host.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Examples

lsloadadj -R "rusage[swp=20:mem=10]"

Adjusts the load indices swp and mem on the host from which the command was submitted.

Diagnostics

Returns -1 if a bad parameter is specified; otherwise returns 0.

See Also

lsinfo(1), lsplace(1), lsload(1), ls_loadadj(3)

Islogin

remotely logs in to a lightly loaded host

Synopsis

```
lslogin [-v] [-m "host_name ..." | -m "cluster_name ..."]
   [-R "res_req"] [rlogin_options]
lslogin [-h | -V]
```

Description

Remotely logs in to a lightly loaded host.

By default, Islogin selects the least loaded host, with few users logged in, and remotely logs in to that host using the UNIX rlogin command.

In a MultiCluster environment, the default is to select the least loaded host in the local cluster.

Options

-v Displays the name of the host to which Islogin remotely logs you in.

-m "host_name ..." | -m "cluster_name ..."

Remotely logs in to the specified host.

With MultiCluster job forwarding, when a cluster name is specified, remotely logs in to the least loaded host in the specified cluster, if the remote cluster accepts interactive jobs from the local cluster (see lsf.cluster(5)).

-R "res_req"

Remotely logs in to a host that meets the specified resource requirement. The resource requirement expression restricts the set of candidate hosts and determines the host selection policy.

For a complete explanation of resource requirement expressions, see lsfintro(1). To find out what resources are configured in your system, use lsinfo(1) and lshosts(1).

rlogin_options

Specify remote login options passed to the rlogin command.

If remote execution fails, Islogin will log in locally only if the local host also satisfies required resources; otherwise, log in will fail.

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Example

```
lslogin -R "select[it>1 && bsd]"
```

Remotely logs in to a host that has been idle for at least 1 minute, that runs BSD UNIX, and is lightly loaded both in CPU resources and the number of users logged in.

Diagnostics

Because Islogin passes all unrecognized arguments to rlogin, incorrect options usually cause the rlogin usage message to be displayed rather than the lslogin usage message.

See Also

lsfintro(1), ls_placereq(3), rlogin(1)

Isltasks

displays or updates a local task list

Synopsis

```
lsltasks [+ task_name ... | - task_name ...]
lsltasks [-h | -V]
```

Description

Displays or updates a user local task list in \$HOME/.lsftask.

When no options are specified, displays tasks listed in the system task file 1sf.task and the user task file .lsftask.

If there is a conflict between the system task file 1sf.task and the user task file (.lsftask), the user task file overrides the system task file.

Tasks in the local task list are not eligible for remote execution, either because they are trivial tasks or because they need resources on the local host.

Options

+ task_name If + is specified and the specified task names are not already in the user task file (.lsftask), adds the task names to the file with a plus sign (+) preceding them.

> If any of the task names are already in the .lsftask file, the actual action depends on the entry in the file. If the entry starts with a + or nothing, replaces the entry with the specified content; if the entry starts with a minus sign (-), deletes the entry from the .1sftask file.

- task_name If - is specified and specified task names are not already in the user .lsftask file, adds the task names to the file with a – preceding the task name.

> If any of the task names are already in the .lsftask file, the actual action depends on the entry in the file. If the entry starts with a -, no operation is done; if the entry starts with a +, deletes the entry from the .lsftask file.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

```
lsltasks + foo
```

Adds the command foo to the local task list.

Files

Reads the system task file lsf.task, and the user .lsftask file. See lsf.task(5) for more details.

The system and user task files contain two sections, one for the remote task list, the other for the local task list. The local tasks section starts with Begin Local Tasks and ends with End LocalTasks. Each line in the section is an entry consisting of a task name.

A plus sign (+) or a minus sign (-) can optionally precede each entry. If no + or - is specified, then + is assumed.

See Also

lsfintro(1), lseligible(1), ls_task(3), lsrtasks(1), lsf.task(5), ls_eligible(3)

Ismon

displays load information for LSF hosts and periodically updates the display

Synopsis

```
lsmon [-N | -E] [-n num_hosts] [-R res_req] [-I index_list]
   [-i interval] [-L file_name] [host_name ...]
1smon [-h | -V]
```

Description

1 smon is a full-screen LSF monitoring utility that displays and updates load information for hosts in a cluster.

By default, displays load information for all hosts in the cluster, up to the number of lines that will fit on-screen.

By default, displays raw load indices.

By default, load information is sorted according to CPU and paging load.

By default, load information is updated every 10 seconds.

Options

- -N Displays normalized CPU run queue length load indices (see lsfintro(1)).
- -E Displays effective CPU run queue length load indices (see lsfintro(1)). Options - N and - E are mutually exclusive.

-n num_hosts Displays only load information for the requested number of hosts. Information for up to num_hosts hosts that best satisfy resource requirements is displayed.

-R res req Displays only load information for hosts that satisfy the specified resource requirements. See <code>lsinfo(1)</code> for a list of built-in resource names.

> Load information for the hosts is sorted according to load on the specified resources.

If res_req contains special resource names, only load information for hosts that provide these resources is displayed (see 1 shosts (1) to find out what resources are available on each host).

If one or more host names are specified, only load information for the hosts that satisfy the resource requirements is displayed.

-lindex_list Displays only load information for the specified load indices. Load index names must be separated by a colon (for example, r1m:pg:ut).

> If the index list *index_list* is too long to fit in the screen of the user who invoked the command, the output is truncated. For example, if the invoker's screen is 80 characters wide, then up to 10 load indices are displayed.

- **-i interval** Sets how often load information is updated on-screen, in seconds.
- **-L file_name** Saves load information in the specified file while it is displayed on-screen.

If you do not want load information to be displayed on your screen at the same time, use lsmon -L *file name* < /dev/null. The format of the file is described in lim.acct(5).

host_name ... Displays only load information for the specified hosts.

- **-h** Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Usage

You can use the following commands while 1 smon is running: $[^L|i|n|N|E|R|q]$

- **^L** Refreshes the screen.
 - i Prompts you to input a new update interval.
- **n** Prompts you to input a new number of hosts to display.
- **N** Toggles between displaying raw CPU run queue length load indices and normalized CPU run queue length load indices.
- **E** Toggles between displaying raw CPU run queue length load indices and effective CPU run queue length load indices.
- **R** Prompts you to input new resource requirements.
- q Quits 1 smon.

Output

The following fields are displayed by default.

HOST NAME

Name of specified hosts for which load information is displayed, or if resource requirements were specified, name of hosts that satisfied the specified resource requirement and for which load information is displayed.

status

Status of the host. A minus sign (-) may precede the status, indicating that the Remote Execution Server (RES) on the host is not running.

Possible statuses are:

ok

The host is in normal load sharing state and can accept remote jobs.

busy

The host is overloaded because some load indices exceed configured thresholds. Load index values that caused the host to be busy are preceded by an asterisk (*). Built-in load indices include r15s, r1m, r15m, ut, pg, io, ls, it, swp, mem and tmp (see below). External load indices are configured in the file lsf.cluster.cluster_name (see lsf.cluster(5)).

lockW

The host is locked by its run window. Run windows for a host are specified in the configuration file (see 1sf.conf(5)) and can be displayed by 1shosts. A locked host will not accept load shared jobs from other hosts.

lockU

The host is locked by the LSF administrator or root.

unavail

The host is down or the Load Information Manager (LIM) on the host is not running.

unlicensed

The host does not have a valid LSF license.

r15s

The 15-second exponentially averaged CPU run queue length.

r1m

The 1-minute exponentially averaged CPU run queue length.

r15m

The 15-minute exponentially averaged CPU run queue length.

ut

The CPU utilization exponentially averaged over the last minute, between 0 and 1.

pg

The memory paging rate exponentially averaged over the last minute, in pages per second.

ls

The number of current login users.

it

On UNIX, the idle time of the host (keyboard not touched on all logged in sessions), in minutes.

On Windows, the it index is based on the time a screen saver has been active on a particular host.

tmp

The amount of free space in /tmp, in megabytes.

swp

The amount of currently available swap space, in megabytes.

mem

The amount of currently available memory, in megabytes.

Diagnostics

Specifying an incorrect resource requirement string while 1 smon is running (via the R option) causes 1 smon to exit with an appropriate error message.

1 smon exits if it does not receive a reply from LIM within the update interval.

See Also

lsfintro(1), lshosts(1), lsinfo(1), lsload(1), lsload(1), lslockhost(8), lim.acct(5), $ls_load(3)$

Ispasswd

registers user passwords in LSF on Windows

Synopsis

```
lspasswd [-u user_name] [-p password]
lspasswd [-r] [-u user_name]
lspasswd [-c] [-u user_name] [-p password]
lspassword [-h | -V]
```

Description

Registers user passwords in LSF on Windows. Passwords must be longer than 3 characters and 31 characters or less.

By default, if no options are specified, the password applies to the user who issued the command.

Users must update the password maintained by LSF if they change their Windows user account password.

Passwords are Windows user account passwords and are saved in the LSF database. LSF uses the passwords to start jobs on behalf of the user.

1 spasswd communicates with LSF services to store the password. The password is stored in encrypted format and the password database is protected by file access permissions. The password remains encrypted as it travels through the network.

The -p option allows scripts to use lspasswd. You should not use this option directly on the command line because the password is entered in full view on the command line. Only error messages are displayed when using the -p option.

Options

-c -u user_name -p password

Check that the password is valid for the specified user.

-r -u user name

Remove the user entry from the password database.

-u user_name -p password

Specify the user and password for the user whose password you want to register or change. Include the domain name in uppercase letters (DOMAIN_NAME\ user_name).

- -h Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Limitations

You must run 1 spasswd from an LSF Windows host.

Isplace

displays hosts available to execute tasks

Synopsis

```
lsplace [-L] [-n minimum | -n 0] [-R res_req] [-w maximum | -w 0]
   [host_name ...]
lsplace [-h | -V]
```

Description

Displays hosts available for the execution of tasks, and temporarily increases the load on these hosts (to avoid sending too many jobs to the same host in quick succession). The inflated load will decay slowly over time before the real load produced by the dispatched task is reflected in the LIM's load information. Host names may be duplicated for multiprocessor hosts, to indicate that multiple tasks can be placed on a single host.

By default, displays only one host name.

By default, uses LSF default resource requirements.

Options

- -L Attempts to place tasks on as few hosts as possible. This is useful for distributed parallel applications in order to minimize communication costs between tasks.
- -n minimum | -n 0 Displays at least the specified number of hosts. Specify 0 to display as many hosts as possible.

Prints Not enough host(s) currently eligible and exits with status 1 if the required number of hosts holding the required resources cannot be found.

- **-R** res_req Displays only hosts with the specified resource requirements.
- -w maximum | -w 0 Displays no more than the specified number of hosts. Specify 0 to display as many hosts as possible.
 - **host_name ...** Displays only hosts that are among the specified hosts.
 - -h Prints command usage to stderr and exits.
 - -V Prints LSF release version to stderr and exits.

Examples

Isplace is mostly used in backquotes to pick out a host name which is then passed to other commands. The following example issues a command to display a lightly loaded HPPA-RISC host for your program to run on:

```
1srun -m '1splace -R hppa' myprogram
```

In order for a job to land on a host with an exclusive resource, you need to explicitly specify that resource for the resource requirements. The following example issues a command to display the host with the bigmem exclusive resource for your program to run on:

lsrun -m 'lsplace -R "bigmem" 'myprogram

The -w and -n options can be combined to specify the upper and lower bounds in processors to be returned, respectively. For example, the command

1splace -n 3 -v 5

returns at least 3 and not more than 5 host names.

Diagnostics

1 splace returns 1 if insufficient hosts are available. The exit status is -10 if a problem is detected in LSF, -1 for other errors, otherwise 0.

See Also

lsinfo(1), ls_placereq(3), lsload(1), lsrun(1)

Isrcp

remotely copies files using LSF

Synopsis

```
lsrcp [-a] source_file target_file
1srcp [-h | -V]
```

Description

Remotely copies files using LSF.

1srcp is an LSF-enabled remote copy program that transfers a single file between hosts in an LSF cluster. Isrcp uses RES on an LSF host to transfer files. If LSF is not installed on a host or if RES is not running then Isrop uses rop to copy the file.

To use 1srcp, you must have read access to the file being copied.

Both the source and target file must be owned by the user who issues the command.

Isrcp uses rcp to copy a source file to a target file owned by another user. See rcp(1) and LIMITATIONS below for details.

Options

-a Appends source_file to target_file.

source file target file

Specify an existing file on a local or remote host that you want to copy, and a file to which you want to copy the source file.

File format is as follows:

[[user_name@][host_name]:][path/]file_name

user name

Login name to be used for accessing files on the remote host. If user_name is not specified, the name of the user who issued the command is used.

host name

Name of the remote host on which the file resides. If *host_name* is not specified, the local host, the host from which the command was issued, is used.

path

Absolute path name or a path name relative to the login directory of the user. Shell file name expansion is not supported on either the local or remote hosts. Only single files can be copied from one host to another.

Use "\" to transfer files from a Windows host to another Windows host. For example:

c:\share>lsrcp file1 hostA:c:\temp\file2

Use "/" to transfer files from a UNIX host to a UNIX host. For example:

lsrcp file1 hostD:/home/usr2/test/file2

Always use "/" to transfer files from a UNIX host to a Windows host, or from a Windows host to a UNIX host. This is because the operating system interprets "\" and Isrcp will open the wrong files.

For example, to transfer a file from UNIX to a Windows host:

```
lsrcp file1 hostA:c:/temp/file2
```

To transfer a file from Windows to a UNIX host:

c:\share>lsrcp file1 hostD:/home/usr2/test/file2

file name

Name of source file. File name expansion is not supported.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

Examples

lsrcp myfile @hostC:/home/usr/dir1/otherfile

Copies file myfile from the local host to file otherfile on hostC.

lsrcp user1@hostA:/home/myfile user1@hostB:otherfile

Copies the file myfile from hostA to file otherfile on hostB.

lsrcp -a user1@hostD:/home/myfile /dir1/otherfile

Appends the file myfile on hostD to the file otherfile on the local host.

lsrcp /tmp/myfile user1@hostF:~/otherfile

Copies the file myfile from the local host to file otherfile on hostF in user1's home directory.

Diagnostics

lsrcp attempts to copy source_file to target_file using RES. If RES is down or fails to copy the source_file, Isrcp will use either rsh or the shell command specified by LSF_RSH in 1sf.conf when the -a option is specified. When -a is not specified, 1srcp will use rcp.

Limitations

File transfer using 1 srcp is not supported in the following contexts:

- If LSF account mapping is used; 1 srcp fails when running under a different user account
- On LSF client hosts. LSF client hosts do not run RES, so 1 srcp cannot contact RES on the submission host
- Third party copies. Isrcp does not support third party copies, when neither source nor target file are on the local host. In such a case rcp or rsh (or the shell command specified by LSF_RSH in 1sf.conf) will be used. If the target_file exists, 1srcp preserves the modes; otherwise, 1srcp uses the source_file modes modified with the umask (see umask(2)) of the source host.

You can do the following:

- rcp on UNIX. If 1 srcp cannot contact RES on the submission host, it attempts to use rcp to copy the file. You must set up the /etc/hosts.equiv or HOME/.rhosts file in order to use rcp. See the rcp(1), rsh(1), ssh(1) manual pages for more information on using the rcp, rsh, and ssh commands.
- You can replace Isrcp with your own file transfer mechanism as long as it supports the same syntax as Isrcp. This might be done to take advantage of a faster interconnection network, or to overcome limitations with the existing 1srcp. sbatchd looks for the 1srcp executable in the LSF_BINDIR directory.

Isrtasks

displays or updates a remote task list

Synopsis

```
lsrtasks [+ task_name[/res_req] ... | - task_name[/res_req] ...]
lsrtasks [-h | -V]
```

Description

Displays or updates a user's remote task list in \$HOME/.lsftask.

When no options are specified, displays tasks listed in the system task file 1sf.task and the user's task file (.lsftask).

If there is a conflict between the system task file 1sf.task and the user task file, the user task file overrides the system task file.

Tasks in the remote task list are eligible for remote execution. You can associate resource requirements with each task name. Eligibility of tasks not specified in a task list for remote execution depends on the operation mode: local or remote. In local mode, tasks are not eligible for remote execution; in remote mode, tasks are eligible. You can specify the operation mode when deciding the eligibility of a task (see lseligible(1), and ls_eligible(3)).

Options

+ task name[/res req] ...

If plus sign (+) is specified and the specified task names are not already in the user task file (.lsftask), adds the task names to the file with a + sign preceding them.

If any of the task names are already in the .1sftask file, the actual action depends on the entry in the file. If the entry starts with a + or nothing, replaces the entry with the specified content; if the entry starts with a minus sign (-), deletes the entry from the .1sftask file.

Remote tasks can have a resource requirement expression associated with them, **separated by a backslash (/). See** ls_task(3).

- task name[/res req] ...

If – is specified and specified task names are not already in the user task file (.lsftask), adds the task names to the file with a – preceding the task name.

If any of the task names are already in the .lsftask file, the actual action depends on the entry in the file. If the entry starts with a -, no operation is done; if the entry starts with a +, deletes the entry from the .lsftask file.

Remote tasks can have a resource requirement expression associated with them, separated by a backslash /. See ls_task(3).

-h

Prints command usage to stderr and exits.

-V

Prints LSF release version to stderr and exits.

Examples

```
% lsrtasks + task1 task2/"select[cpu && mem]" - task3
or in restricted form:
% lsrtasks + task1 task2/cpu:mem - task3
```

Adds the command task1 to the remote task list with no resource requirements, adds task2 with the resource requirement cpu:mem, and removes task3 from the remote task list.

```
% lsrtasks + myjob/swap>=100 && cpu
```

Adds my job to the remote tasks list with its resource requirements.

Running 1srtasks with no arguments displays the resource requirements of tasks in the remote list, separated from the task name by a slash (/):

% 1srtasks

```
cfd3d/type == SG1 && cpu compressdir/cpu:mem
cc/cpu
                        verilog/cpu && cadence compress/cpu
hspice/cpu && cadence nas/swp > 200 && cpu
epi/hpux11 sparc regression/cpu
f77/cpu
dsim/type == any
compress/-:cpu:mem epi/hpux11 sparc
                                                       regression/cpu
cc/type == local
                        synopsys/swp >150 && cpu
```

Files

Reads the system task file 1sf.task, and the user task file (.1sftask). See 1sf.task(5) for more details.

The system and user task files contain two sections, one for the remote task list, the other for the local task list. The remote tasks section starts with Begin RemoteTasks and ends with End RemoteTasks. Each line in the section is an entry consisting of a task name.

A plus sign + or a minus sign - can optionally precede each entry. If no + or - is specified, then + is assumed.

```

Isrun

runs an interactive task through LSF

Synopsis

```
lsrun [-1] [-L] [-P] [-S] [-v] [-m "host_name
   ..." | -m "cluster_name ..."] [-R "res_req"] command [argument
1srun [-h | -V]
```

Description

Submits a task to LSF for execution.

With MultiCluster job forwarding model, the default is to run the task on a host in the local cluster.

By default, 1 s run first tries to obtain resource requirement information from the remote task list to find an eligible host. (See lseligible(1) and ls_task(3).) Otherwise, Isrun runs the task on a host that is of the same host type (or architecture) as the submission host. If several hosts of the same architecture are available, the host with the lowest CPU and memory load is selected.

By default, if execution fails and the local host satisfies resource requirements, LSF runs the task locally.

By default, Isrun does not create a pseudo-terminal when running the task.

Options

- -I If execution on another host fails, runs the task locally.
- -L Forces Isrun to go through RES to execute a task. By default, Isrun will not use RES if the task is going to run on the current host.
- -P Creates a pseudo-terminal when starting the task on UNIX hosts. This is necessary in order to run programs that require a pseudo-terminal (for example, vi). This option is not supported on Windows.
- -S Creates a pseudo-terminal with shell mode support when starting the task on a UNIX host. Shell mode support is required for running interactive shells or applications which redefine the CTRL-C and CTRL-Z keys (for example, jove). This option is not supported on Windows.
- -v Displays the name of the host running the task.

```
-m "host name ..." | -m "cluster name ..."
```

The execution host must be one of the specified hosts. If a single host is specified, all resource requirements are ignored.

If multiple hosts are specified and you do not use the -R option, the execution host must satisfy the resource requirements in the remote task list (see lsrtasks(1)). If none of the specified hosts satisfy the resource requirements, the task will not run. With MultiCluster job forwarding model, the execution host can be a host in one of the specified clusters, if the remote cluster accepts tasks from the local cluster. (See RemoteClusters section in lsf.cluster(5).)

-R "res reg"

Runs the task on a host that meets the specified resource requirement. The size of the resource requirement string is limited to 512 bytes. For a complete explanation of resource requirement expressions, see lsfintro(1). To find out what resources are configured in your system, use <code>lsinfo(1)</code> and <code>lshosts(1)</code>.

LSF supports ordering of resource requirements on all load indices, including external load indices, either static or dynamic.

Exclusive resources need to be explicitly specified within the resource requirement string. For example, you defined a resource called bigmem in 1sf.shared and defined it as an exclusive resource for hostE in lsf.cluster.mycluster. Use the following command to submit a task to run on host E:

```
lsrun -R "bigmem" myjob
or
lsrun -R "defined(bigmem)" myjob
```

If the -m option is specified with a single host name, the -R option is ignored.

- **-h** Prints command usage to stderr and exits.
- **-V** Prints LSF release version to stderr and exits.

Usage

You can use Isrun together with other utility commands such as Isplace(1), lsload(1), lsloadadj(1), and lseligible(1) to write load sharing applications in the form of UNIX shell scripts.

1 srun supports interactive job control. Suspending 1 srun suspends both the task and Isrun, and continuing Isrun continues the task.

If LSB_DISABLE_LIMLOCK_EXCL=y (to enable preemption of exclusive jobs, for example), you can use 1 s run to start a task on a host that is currently running an exclusive job.

The -n option of rsh(1) can be simulated by redirecting input from /dev/null. For example:

lsrun cat </dev/null &

Diagnostics

1 srun exits with status -10 and prints an error message to stderr if a problem is detected in LSF and the task is not run.

The exit status is -1 and an error message is printed to stderr if a system call fails or incorrect arguments are specified.

Otherwise, the exit status is the exit status of the task.

Istcsh

load sharing tesh for LSF

Synopsis

lstcsh [tcsh_options] [-L] [argument ...]

Description

1stcsh is an enhanced version of tcsh. 1stcsh behaves exactly like tcsh, except that it includes a load sharing capability with transparent remote job execution for

By default, a 1stcsh script is executed as a normal tcsh script with load sharing disabled.

If a command line is considered eligible for remote execution, LSF selects a suitable host—typically a powerful and/or lightly loaded host that can execute the command line correctly—and sends the command line to that host.

You can restrict who can use @ for host redirection in lstcsh with the parameter LSF_SHELL_AT_USERS in 1sf.conf.

Remote Hosts

1stcsh provides a high degree of network transparency. Command lines executed on remote hosts behave the same as they do on the local host. The remote execution environment is designed to mirror the local one as closely as possible by using the same values for environment variables, terminal setup, current working directory, file creation mask, and so on. Each modification to the local set of environment variables is automatically reflected on remote hosts.

Shell variables, nice values, and resource limits are not automatically propagated to remote hosts.

Job Control

Job control in 1stcsh is exactly the same as in tcsh except for remote background jobs. 1stcsh numbers background jobs separately for each of the hosts that are used to execute them. The output of the built-in command job lists background jobs together with their execution hosts.

To bring a remote background job to the foreground, the host name must be specified together with an at sign (@), as in the following example:

```
fg %2 @hostA
```

Similarly, the host name must be specified when killing a remote job. For example:

```
kill %2 @hostA
```

Options

tcsh_options 1 stcsh accepts all the options used by tcsh. See tcsh(1) for the meaning of specific options.

-L Executes a script with load sharing enabled.

There are three ways to run a lstcsh script with load sharing enabled:

- Execute the script with the L option
- Use the built-in command source to execute the script
- Insert "#!/local/bin/lstcsh -L" as the first line of the script (assuming you install lstcsh in /local/bin).

Using @ or 1 smode in a script will not enable load sharing if the script has not been executed using one of these three ways.

Usage

In addition to the built-in commands in tesh, 1stesh provides the following built-in commands:

lsmode [on | off] [local | remote] [@] [v | -v] [e | -e] [t | -t] [connect [host_name ...]] [1srtasks [lsrtasks_options]] [1s1tasks [lsltasks_options]] [jobs]

on off Turns load sharing on or off. When off, you can specify @ to send a command line to a remote host.

local | remote Sets operation mode of 1stcsh.

The default is local.

local

Local operation mode. This is the default mode.

In this mode, a command line is eligible for remote execution only if all the specified tasks are present in the remote task list in the user's tasks file \$HOME/.lsftask, or if@is specified on the command line to force specified tasks to be eligible for remote execution.

Tasks in the local task list must be executed locally.

The local mode of operation is conservative, and can fail to take advantage of the performance benefits and load balancing advantages of LSF.

The way 1stcsh handles tasks that are not present in the remote task list nor in the local task list, depends on the mode of operation of lstcsh (local or remote).

remote

Remote operation mode.

In this mode, a command line is considered eligible for remote execution only if none of the specified tasks are present in the local task list in the user's tasks file \$HOME/.lsftask.

Tasks in the remote list can be executed remotely.

The remote mode of operation is aggressive, and promotes extensive use of LSF.

The way 1stcsh handles tasks that are not present in the remote task list nor in the local task list, depends on the mode of operation of 1stcsh (local or remote).

Specify @ to explicitly specify the eligibility of a command for remote execution.

The @ may be anywhere in the command line except in the first position (which is used to set the value of shell variables).

There are several ways to use @:

@: Specify @ followed by nothing to indicate the command line is eligible for remote execution.

@ host_name: Specify @ followed by a host name to force the command line to be executed on that host.

Host names and the reserved word local following @ can all be abbreviated as long as they do not cause ambiguity.

@ local: Specify @ followed by the reserved word local to force the command line to executed on the local host.

@ /res_req: Specify @ followed by / and a resource requirement string to indicate the command is eligible for remote execution, and that the specified resource requirements must be used instead of those in the remote task list.

When specifying resource requirements following the @ it is necessary to use / only if the first requirement characters specified are also the first characters of a host name.

e | **-e** Turns eligibility verbose mode on (e) or off (-e).

If eligibility verbose mode is on, 1 stcsh shows whether the command is eligible for remote execution, and displays the resource requirement used if the command is eligible.

The default is off.

v | -**v** Turns task placement verbose mode on (v) or off (-v). If verbose mode is on, 1stcsh displays the name of the host on which the command is run if the command is not run on the local host.

The default is on.

t|-t Turns wall clock timing on (t) or off (-t).

If timing is on, the actual response time of the command is displayed. This is the total elapsed time in seconds from the time you submit the command to the time the prompt comes back.

This time includes all remote execution overhead. The csh time built-in does not include the remote execution overhead.

This is an impartial way of comparing the response time of jobs submitted locally or remotely, because all the load sharing overhead is included in the displayed elapsed time.

The default is off.

connect [host_name ...]

Establishes connections with specified remote hosts. If no hosts are specified, lists all the remote hosts to which an 1stcsh connection has been established.

A plus sign (+) with a remote host indicates that a server-shell has also been started on it.

Isrtasks [+ task_name[/res_req ...] | - task_name[/res_req ...]]

Displays or update a user's remote task list in the user's task list \$HOME/.lsftask.

This command has the same function as the external command lartasks, except that the modified remote task list takes effect immediately for the current 1stcsh session.

See lsrtasks(1) for more details.

Isltasks [+ task_name ... | - task_name ...]

Displays or update a user's local task list in the user's task list \$HOME/.lsftask.

This command has the same function as the external command lsltasks, except that the modified local task list takes effect immediately for the current lstcsh session.

See lsltasks(1) for more details.

jobs Lists background jobs together with the execution hosts. This break of transparency is intentional in order to provide you with more control over your background jobs.

Files

There are three optional configuration files for lstcsh:

- .shrc
- .hostrc
- .lsftask

The .shrc and .hostrc files are used by lstcsh alone, whereas .lsftask is used by LSF to determine general task eligibility.

~/.shrc

Use this file when you want an execution environment on remote hosts that is different from that on the local host. This file is sourced automatically on a remote host when a connection is established. For example, if the remote host is of different type, you may need to run a version of the executable for that particular host type, therefore it may be necessary to set a different path on the remote host.

~/.hostrc

Use this file to indicate a list of host names to which the user wants to be connected (asynchronously in the background) at 1stcsh startup time. This saves the time spent in establishing the connections dynamically during execution of shell commands. Once a connection is set up, you can execute further remote commands on those connected hosts with very little overhead.

~/.lsftask

Use this file to specify lists of remote and local tasks that you want to be added to the respective system default lists. Each line of this file is of the form task_name/res_req, where task_name is the name of a task, and res_req is a string specifying the resource requirements of the task. If res_req is not specified, the command is executed on machines of the same type as the local host.

Limitations

Type-ahead for the next command is discarded when a job is executing in the foreground on a remote host.

It is not possible to provide input data to load sharing shell scripts (that is, shell scripts whose content is load shared).

The lstcsh is fully compatible with tcsh 6.03 7-bit mode. Any feature that is not included in tesh 6.03 is not supported.

pam

Parallel Application Manager – job starter for MPI applications

Synopsis

HP-UX vendor MPI syntax

```
bsub pam -mpi mpirun [mpirun_options ] mpi_app [argument ...]
```

SGI vendor MPI syntax

```
bsub pam [-n num_tasks ] -mpi -auto_place mpi_app [argument ...]
```

Generic PJL framework syntax

```
bsub pam [-t] [-v] [-n num_tasks ] -g [num_args]
   pjl_wrapper [pjl_options] mpi_app [argument ...]
pam [-h] [-V]
```

Description

The Parallel Application Manager (PAM) is the point of control for Platform LSF. PAM is fully integrated with Platform LSF to interface the user application with LSF. PAM acts as the supervisor of a parallel LSF job.

MPI jobs started by pam can only be submitted through the LSF Batch system. PAM cannot be used interactively to start parallel jobs. sbatchd starts PAM on the first execution host.

For all parallel application processes (tasks), PAM:

- Uses a vendor MPI library or an MPI Parallel Job Launcher (PJL; for example, mpirun, poe) to start a parallel job on a specified set of hosts in a LSF cluster.
- PAM contacts RES on each execution host allocated to the parallel job.
- PAM queries RES periodically to collect resource usage for each parallel task and passes control signals through RES to all process groups and individual running tasks, and cleans up tasks as needed.
- Passes job-level resource usage and process IDs (PIDs and PGIDs) to shatchd for enforcement
- Collects resource usage information and exit status upon termination

Task startup for vendor MPI jobs

The pam command starts a vendor MPI job on a specified set of hosts in a LSF cluster. Using pam to start an MPI job requires the underlying MPI system to be LSF aware, using a vendor MPI implementation that supports LSF (SGI IRIX vendor MPI or HP-UX vendor MPI).

PAM uses the vendor MPI library to spawn the child processes needed for the parallel tasks that make up your MPI application. It starts these tasks on the systems allocated by LSF. The allocation includes the number of execution hosts needed, and the number of child processes needed on each host.

Task startup for LSF HPC generic PJL jobs

For parallel jobs submitted with bsub:

- PAM invokes the PJL, which in turn invokes the TaskStarter (TS).
- TS starts the tasks on each execution host, reports the process ID to PAM, and waits for the task to finish.

Options

Options for vendor MPI jobs

-auto_place The -auto_place option on the pam command line tells the SGI IRIX mpirun library to launch the MPI application according to the resources allocated by LSF.

-mpi In the SGI environment, the -mpi option on the bsub and pam command line is equivalent to the mpirun command.

On HP-UX, you can have LSF manage the allocation of hosts to achieve better resource utilization by coordinating the start-up phase with mpi run. This is done by preceding the regular HP MPI mpirun command with:

bsub pam -mpi

For HP-UX vendor MPI jobs, the -mpi option must be the first option of the pam command.

For example, to run a single-host job and have LSF select the host, the command:

mpirun -np 14 a.out

is entered as:

bsub pam -mpi mpirun -np 14 a.out

-n num tasks

The number of processors required to run the MPI application, typically the number of parallel tasks in the job. If the host is a multiprocessor, one host can start several tasks.

You can use both bsub -n and pam -n in the same job submission. The number specified in the pam -n option should be less than or equal to the number specified by bsub -n. If the number of tasks specified with pam -n is greater than the number specified by bsub -n, the pam -n is ignored.

For example, on SGI IRIX or SGI Altix, you can specify:

bsub -n 5 pam -n 2 -mpi -auto_place a.out

Here, the job requests 5 processors, but PAM only starts 2 parallel tasks.

mpi_app [argument ...]

The name of the MPI application to be run on the listed hosts. This must be the last argument on the command line.

- -h Prints command usage to stderr and exit.
- -V Prints LSF release version to stderr and exit.

Options for LSF HPC generic PJL jobs

- -t This option tells pam not to print out the MPI job tasks summary report to the standard output. By default, the summary report prints out the task ID, the host on which it was executed, the command that was executed, the exit status, and the termination time.
- -v Verbose mode. Displays the name of the execution host or hosts.

-g [num_args] pjl_wrapper [pjl_options]

The -g option is required to use the LSF generic PJL framework. You must specify all the other pam options before -g.

num args

Specifies how many space-separated arguments in the command line are related to the PJL (after that, the remaining section of the command line is assumed to be related to the binary application that launches the parallel tasks).

pjl_wrapper

The name of the PJL

pjl_options

Optional arguments to the PJL

For example:

◆ A PJL named no_arg_pjl takes no options, so num_args=1. The syntax is:

```
pam [pam_options] -g 1 no_arg_pjl job [job_options]
```

A PJL is named 3_arg_pj1 and takes the options -a, -b, and group_name, so *num args*=4. The syntax is:

```
pam [pam_options] -g 4 3_arg_pjl -a -b group_name job [job_options]
```

-n num_tasks The number of processors required to run the MPI application, typically the number of parallel tasks in the job. If the host is a multiprocessor, one host can start several tasks.

> You can use both bsub -n and pam -n in the same job submission. The number specified in the pam - n option should be less than or equal to the number specified by bsub -n. If the number of tasks specified with pam -n is greater than the number specified by bsub -n, the pam -n is ignored.

mpi_app [argument ...]

The name of the MPI application to be run on the listed hosts. This must be the last argument on the command line.

- -h Prints command usage to stderr and exit.
- **-V** Prints LSF release version to stderr and exit.

Exit Status

pam exits with the exit status of mpirun or the PJL wrapper.

bsub(1)

patchinstall

UNIX only. Manage patches in a licensed Platform cluster.

Synopsis

```
patchinstall [-f env_file] [--silent] package...
patchinstall -c [-f env_file] [--silent] package...
patchinstall -r [-f env_file] [--silent] package
patchinstall -r [-f env_file] [--silent] build_number
patchinstall -h
```

Description

Permission required to run this command depends on the package contents and the original cluster installation account; you should normally log on as root, but you can patch some binaries as cluster administrator (1 s f a d m i n).

By default, the command installs one or more packages in an existing cluster.

The cluster location is normally determined by your environment setting, so ensure your environment is set before you run this command (for example, you sourced cshrc.lsf or profile.lsf).

Specify the packages you want to install.

The installer does some checking first. If it does not find a problem, it prompts you to proceed with installation. If you confirm, it backs up the current binaries to the patch backup directory and then installs the specified packages on the cluster, updating or adding new binaries. It does not modify any existing configuration files. If there is any problem during installation of a package, it automatically rolls back to the cluster's previous state. It records the changes in the patch history directory. This additional checking can take more time than installing with 1sfinstall.

The command can also be used to do the following:

- Check—do the checking for the packages without installing them. For more information, see the -c option.
- Roll back—remove the most recent patch and return the cluster to the previous patch level. If you want to roll back multiple versions, you must roll back one patch level at a time, in the reverse order of installation. For more information, see the -r option.

Options

-c Check. Perform checking as if to install, but do not proceed with installation. Specify each package you want to check. You may specify multiple packages. Checks that the existing cluster is compatible with the patch (the same version of the product is already installed on the same binary types). Fixes and fix packs may also require that a specific enhancement pack be installed.

Checks that your user account has permission to write to the installation directory, backup directory, and history directory.

Lists existing files that will be overwritten by the patch.

Lists files that will be added by the patch.

-f env file This option should only be used if you cannot set your environment (for example, you cannot source cshrc.lsf or profile.lsf).

> Specify the full path and file name of a file (such as your LSF install.config file) that properly defines the parameter LSF_TOP.

> If you use this option, the command gets the cluster location from this file, not from the settings in your environment.

- **-h** Outputs command usage and exits.
- -r Rollback. You must specify the most recently installed patch. The installer checks all binary types and finds all instances where the most recently installed patch has the same build number. These packages are removed and the cluster reverts to the previous patch level.

Specify the build number of the most recent patch or specify full path to the package you used to install the most recent patch, The installer will automatically check the package to determine the build. You cannot specify any other build.

To remove multiple patches and roll back multiple versions, you must run the command multiple times and roll back one patch level at a time.

You cannot roll back if the backup files from the previous patch level are unavailable (if you deleted them from the patch backup directory).

--silent Silent mode. Install or roll back without any interactive prompts for confirmation.

Output

Status information and prompts are displayed in your command console.

Status information is also logged to patch.log (when patching or rolling back the cluster) or precheck.log (when checking a package).

If there are any problems found when checking a package, errors are displayed in your command console and also logged to patch.err.

pversions (Windows)

Windows version of the command: displays the version information for Platform products installed on a Windows host.

Synopsis

```
pversions [product_name]
pversions -h
pversions -V
```

Description

Displays the version and patch level of a Platform product installed on a Windows host, and the list of patches installed.

Options

product_name

Specify the Platform product for which you want version information. Specify one of the following:

- EGO—to see version information for Platform EGO
- Symphony—to see version information for Platform Symphony and Symphony Developer's Edition
- ◆ LSF—to see version information for Platform LSF
- -h Prints command usage to stderr and exits from the software.
- -V Prints product version to stderr and exits.

pversions (UNIX)

UNIX version of the command: displays the version information for Platform products installed on UNIX hosts.

Synopsis

```
pversions [-f env_file] [-p product_name]
pversions [-f env_file] -b build_number
pversions [-f env_file] -q file_name
pversions -c package_name
pversions -h
```

Description

By default, displays the version and patch level of Platform products.

The cluster location is normally determined by your environment setting, so ensure your environment is set before you run this command (for example, you sourced cshrc.lsf or profile.lsf).

For each binary type, displays basic version information (package build date, build number, package installed date) and lists patches installed (package type, build number, date installed, fixes).

Optionally, the command can also be used to do the following:

- Check the contents of a package before installing it
- Show information about a specific Platform product installed
- Show information about installed packages from specific build
- Find current versions of a specific Platform file and see information for each

Options

This option should only be used if you cannot set your environment (for example, you cannot source cshrc.lsf or profile.lsf).

Specify the full path and file name of a file (such as your LSF install.config file) that properly defines the parameter LSF_TOP.

If you use this option, the command gets the cluster location from this file, not from the settings in your environment.

-b build number

Specify the build number of an installed patch (you can specify the most recent full installation or patches installed after the most recent full installation).

Displays information and the contents of the build (binary type and install date, notes, fixes, and files in the package).

-c package_name

Specify the full path and file name of an uninstalled package. For this option, you do not need to set your environment because a cluster is not required.

Displays package contents (notes, fixes, and files in the patch).

-p product name

Specify one Platform product to see information for that product only. Specify LSF to see information about LSF or PMC to see information about the Console package. **-q file_name** Specify the file name of one installed file.

For each binary type, displays basic version information and file location. If the binary has been updated after the most recent full installation, displays additional information about the most recent patch that updated the file (build number, fixes, notes, date installed)

-h Outputs command usage and exits.

Output

Information is displayed in your command console.

Product Version Information (Default and -p)

By default, displays product information for entire cluster. With -p, displays information for specified product only.

For each Platform product, displays product name and version followed by specific information about each binary type.

For each binary type, displays basic version information (package build date, build number, package installed date) and lists any patches installed (package type, build number or fix number, date installed).

binary type Binary type, build number of binary, and build date of the binary for the most

> recent full installation (a full installation is installation of any distribution that contains a complete set of new binaries. A full installation can be a new cluster, a

licensed upgrade, or patching with an enhancement pack).

installed Date the binary was installed for the most recent full installation.

patched For each patch after the most recent full installation, displays fix number, build

number, and date patch was installed. If the patch was a fix pack, multiple fixes are

listed.

File Version With -q, displays information for specified file only.

Information (-q) For each Platform product that contains the specifed file, displays product name

and version followed by specific information about each binary type.

For each binary type that contains the specified file, displays basic version information and file location. If the binary has been updated after the most recent full installation, displays additional information about the most recent patch that

updated the file (build number, fixes, notes, date installed).

binary type

Binary type, build number of binary, and build date of the binary for the most recent full installation (a full installation is any distribution that contains a complete set of new binaries. A full installation can be a new cluster installation, a licensed

version upgrade, or patching with an enhancement pack).

installed

Date the binary was installed for the most recent full installation.

file

Full path to the version of the file being used for this binary type.

last patched

For the last patch to update the file after the most recent full installation, displays build number and date patch was installed.

last patch notes

Optional. Some information provided by Platform for the last patch that updated the file.

last patch fixes

Fixes included in the last patch that updated the file.

Build Version Information (-b)

With -b, displays information for patches with the specified build number only. For each Platform product, if the product is using binaries from the specifed build, displays product name and version followed by specific information about each binary type.

For each binary type, displays the following:

binary type Binary type, build number and build date of the patch.

installed Date the patch was installed.

notes Optional. Some information provided by Platform for the build.

fixes Fixes included in the patch.

files Files included in the patch (not shown for a full distribution such as enhancement

pack). Full path to the file installed by this patch.

Package Version Information (-c)

With -c, displays version information for a specified uninstalled package.

product Displays Platform product name and version.

binary type Binary type, build number and build date of the patch.

notes Optional. Some information provided by Platform for the build.

fixes Fixes included in the patch.

files Files included in the patch (not shown for a full distribution such as enhancement

pack). Relative path to the file.

taskman

checks out a license token and manages interactive UNIX applications

Synopsis

```
taskman -Lp project
   -R "rusage[token=number[:duration=minutes | hoursh]
   [:token=number[:duration=minutes | hoursh]]...] [-N n_retries]
   [-v] command
taskman [-h | -V]
```

Description

Runs the interactive UNIX application on behalf of the user. When it starts, the task manager connects to License Scheduler to request the application license tokens. When all the requested licenses are available, the task manager starts the application. While the application is running, the task manager monitors resource usage, CPU, and memory, and reports the usage to License Scheduler. When the application terminates, the task manager exits.

By default, a license is reserved for the duration of the task, so the application can check out the license at any time. Use the duration keyword if you want unused licenses to be reallocated if the application fails to check out the license before the reservation expires.

Options

Required. The command to start the job that requires the license.

-v Verbose mode. Displays detailed messages about the status of configuration files.

-N *n_retries* Specifies the maximum number of retry attempts taskman will take to connect to the daemon. If this option is not specified, taskman will retry indefinitely.

-Lp project Required. Specifies the interactive license project that is requesting tokens. The client must be known to LSF License Scheduler.

-R "rusage[token=number[:duration=minutes | hoursh][:token=number[:duration=minutes | hoursh]]...]

Required. Specifies the type and number of license tokens to request from GLB. Optionally, specifies a time limit for the license reservation, expressed as an integer (the keyword h following the number indicates hours instead of minutes). You may specify multiple license types, with different duration values. Separate each requirement with a colon (:). Enclose the entire list in one set of square brackets.

- -h Prints command usage to stderr and exits.
- **-V** Prints the License Scheduler release version to stderr and exits.

tspeek

displays the stdout and stderr output of an unfinished Terminal Services job

Synopsis

```
tspeek job_ID
tspeek [-h | -V]
```

Description

Displays the standard output and standard error output that have been produced by one of your unfinished Terminal Services jobs, up to the time that this command is invoked.

This command is useful for monitoring the progress of a job and identifying errors. If errors are observed, valuable user time and system resources can be saved by terminating an erroneous job.

tspeek is supported on Windows and Linux. You cannot use tspeek to monitor job output from UNIX. tspeek on Linux requires rdesktop.

You can use tspeek from any Linux host where rdesktop is installed to view the output of a Terminal Services job. For example, if your job ID is 23245, run:

tspeek 23245

Options

job_ID Operates on the specified Terminal Services job.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

See Also

tssub

tssub

submits a Terminal Services job to LSF

Synopsis

```
tssub [bsub_options] command [arguments]
tssub [-h | -V]
```

Description

Submits a Terminal Services job for batch execution and assigns it a unique numerical job ID.

tssub is a wrapper around the bsub command which only submits jobs to hosts that have Microsoft Terminal Services installed. For bsub options, see the bsub

You submit Terminal Services job with tssub instead of bsub. If the terminal window is closed, the job will remain running. You can reconnect to view the job with tspeek.

tssub is supported on Windows and Linux. You cannot use tssub to submit Terminal Services jobs from UNIX.

If the job is dispatched to a host in which Terminal Services is not installed or properly configured, the job is set to the PEND state and a pending reason is written in sbatchd.log.host_name.

If tssub - I is specified, a terminal display is visible on the submission host after the job has been started.

If the job is not a GUI job, LSF runs a command window and output is displayed in the command window when something is written to stdout.

Pre- and post-execution commands are executed within the terminal session. The job does not complete until post-execution commands complete.

If you use bjobs -1 to monitor the job, you will see a message similar to "External Message 2 was posted from LSF\lsfadmin to message box 2". The body of the message contains the ID of the terminal session that was created.

Use tspeek to view job output.

tssub sets the LSB_TSJOB and LSF_LOGON_DESKTOP environment variables. These variables are then transferred to the execution host:

LSF LOGON DESKTOP

When LSF_LOGON_DESKTOP=1, jobs run in interactive foreground sessions. This allows GUIs to be displayed on the execution host. If this parameter is not defined, jobs run in the background.

LSB TSJOB

When the LSB_TSJOB variable is defined to any value, it indicates to LSF that the job is a Terminal Services job.

Limitations

- You cannot use bmod to modify a job submitted as a Terminal Services job to become a non-Terminal Services job
- The bsub option -o out_file is not supported for tssub
- Only Windows bsub options are supported for tssub. For example, you cannot use the options - Ip, - Is, - L login_shell of bsub with tssub.
- Interactive bsub options (-I, -Ip, -Is) are not supported with tssub on Linux
- If user mapping is defined, the user who invokes tapeak must have the required privileges to access the session
- MultiCluster is not supported

Options

bsub_options

Only Windows bsub options are supported for tssub. For example, you cannot use the options - Ip, - Is, - L login_shell of bsub with tssub.

For bsub options, see the bsub command.

command [argument]

The job can be specified by a command line argument command, or through the standard input if the command is not present on the command line. The *command* is assumed to begin with the first word that is not part of a tssub option. All arguments that follow *command* are provided as the arguments to the *command*.

The job command can be up to 4094 characters long for UNIX and Linux or up to 255 characters for Windows. If no job name is specified with -J, bjobs, bhist and bacct displays the command as the job name.

The commands are executed in the order in which they are given.

- -h Prints command usage to stderr and exits.
- -V Prints LSF release version to stderr and exits.

bsub, tspeek

wgpasswd

changes a user's password for an entire Microsoft Windows workgroup

Synopsis

```
wgpasswd [user_name]
wgpasswd [-h]
```

Description

You must run this command on a host in a Windows workgroup. You must have administrative privileges to change another user's password.

Prompts for old and new passwords, then changes the password on every host in the workgroup.

By default, modifies your own user account.

Options

user_name Specifies the account to modify. You must have administrative privileges to change another user's password.

-h Prints command usage to stderr and exits.

Output

For each host in the workgroup, returns the status of the operation (SUCCESS or FAILED).

Files

Modifies the LSF password file.

wguser

modifies user accounts for an entire Microsoft Windows workgroup

Synopsis

```
wguser [-r] user_name ...
wguser [-h]
```

Description

CAUTION: You must run this command on a host in a Microsoft Windows workgroup. You should have administrative privileges on every host in the workgroup.

Modifies accounts on every host in the workgroup that you have administrative privileges on.

By default, prompts for a default password to use for all of the accounts, and then creates the specified user accounts on each host, if they do not already exist.

Use -r to remove accounts from the workgroup.

Options

-r Removes the specified user accounts from each host, if they exist.

Required. Specifies the accounts to add or remove. user_name ...

-h Prints command usage to stderr and exits.

Output

For each host in the workgroup, returns the result of the operation (SUCCESS or FAILED).
