"Once upon a time there was a Good Software Engineer whose Customers knew exactly what they wanted.

The Good Software Engineer worked very hard to design the Perfect System that would solve all the Customers' problems now and for decades.

When the Perfect System was designed, implemented and finally deployed, the Customers were very happy indeed.

The Maintainer of the System had very little to do to keep the Perfect System up and running, and the Customers and the Maintainer lived happily every after."

We are all aware that this is a fairy tale...

Could it be because there are no Good Software Engineers?
Could it be because the Users don't really know what they want?
Or is it because the Perfect System doesn't exist?

Lehman laws

M. M. Lehman,

Programs, Life Cycles, and Laws of Software Evolution,

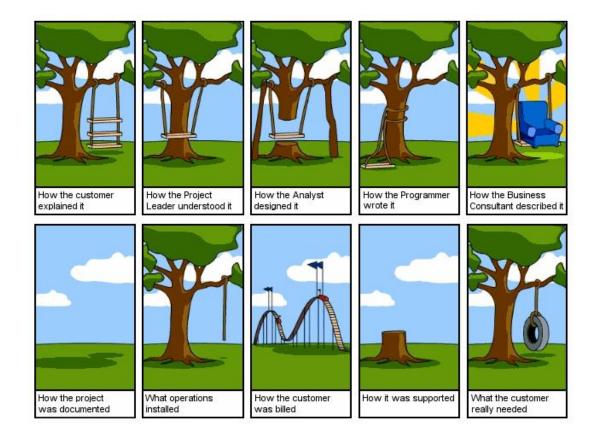

Proc. IEEE, vol. 68, no. 9, Sep. 1980

1. Continuing Change

A program that is used and that as an implementation of its specification reflects some other reality, undergoes continual change or becomes progressively less useful. The change or decay process continues until it is judged more cost effective to replace the system with a recreated version.

2. Increasing Complexity

- As an evolving program is continually changed, **its complexity**, *reflecting deteriorating structure*, **increases** unless work is done to maintain or reduce it.

Refactoring

...is a disciplined technique for improving the design of an existing code

In the ideal world there would be hardly any need for refactoring

In the real world of HEP (and related fields) most software needs to be refactored

By learning refactoring you also learn writing code that minimizes the need to be refactored

"If it ain't broken, don't fix it"

conventional wisdom

A piece of software can be broken in many ways

Functional

it no longer delivers the function it is designed to perform

Maintenance

it can no longer be maintained

- Obsolete or no documentation
- Missing tests
- Original developers or users have left
- Inside knowledge about the system has disappeared
- Limited understanding of the entire system
- Too long to turn things over to production
- Too much time to make simple changes
- Need for constant bug fixes
- Big build times
- Difficulties separating products
- Duplicated code
- Code smells

Warnings you are heading into trouble

usually do not occur isolated

Geant4 photoelectric cross section

Is it consistent with experimental measurements?

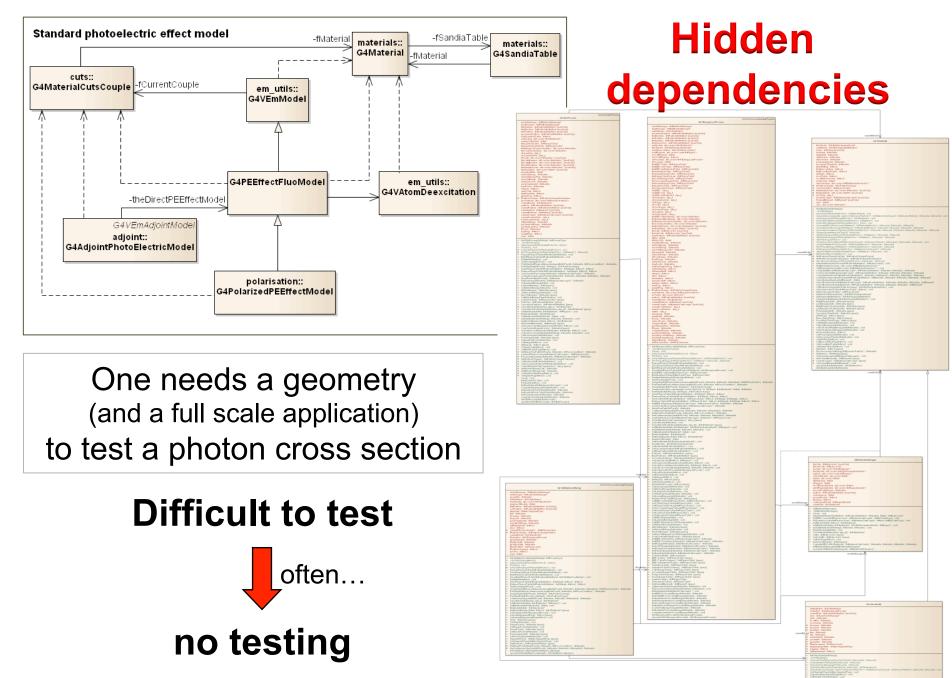

A simple test:

- instantiate a G4PEEffectFluoModel
- invoke
 - ComputeCrossSectionPerAtom in predefined configurations of photon energy and target element
- compare calculated cross sections with experimental data in the same E, Z, A configurations

Peculiarities of refactoring physics software

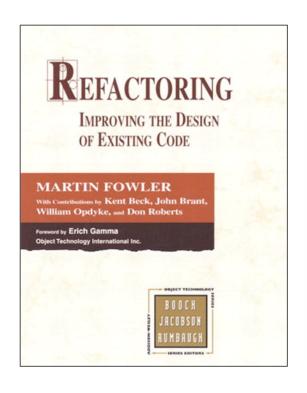

Hands-on practice

Common problems of legacy code

- Insufficient documentation
 - non-existent or out-of-date
- Improper layering
 - too few or too many layers
- Lack of modularity
 - strong coupling
- Duplicated code
 - copy & paste code
- Duplicated functionality
 - similar functionality by separate teams

- Misuse of inheritance
 - code reuse vs. polymorphism
- Missing inheritance
 - duplication, case-statements
- Misplaced operations
 - operations outside classes
- Violation of encapsulation
 - type-casting; C++ "friends"
- Class abuse
 - classes as namespaces

Refactoring

"Refactoring is the process of changing a software system in such a way that it does not alter the external behavior of the code yet improves its internal structure."

"When you refactor you are improving the design of the code after it has been written."

Reengineering

Reengineering "seeks to transform a legacy system into the system you would have built if you had the luxury of hindsight and could have known all the new requirements that you know today."

"Reengineering [...] is the examination and alteration of a subject system to reconstitute it in a new form and the subsequent implementation of the new form."

- "Reverse Engineering is the process of analyzing a subject system
- to identify the system's components and their interrelationships and
- create representations of the system in another form or at a higher level of abstraction."

"Forward Engineering is the traditional process of moving from highlevel abstractions and logical, implementation-independent designs to the physical implementation of a system."

Basic concepts

Refactoring

Reengineering

- What they are
- Why to refactor (reengineer)
- When to refactor
- What NOT to refactor
- When NOT to refactor

Interplay with other processes: testing

Do not refactor what does not pass the tests Do not refactor immediately before a critical deadline

Why?

To make software easier to understand and modify

When?

- Refactor when you want to add functionality
 - before adding it
- Refactor when you have to fix a bug
- Refactor while doing a code review (!)
- Refactor when you want to gain understanding of some legacy code
- **4**

Refactoring embedded in an iterative-incremental life-cycle

Set priorities while refactoring

Risks

The new code may be more "elegant" but it has bugs / is slower
Instead of just fixing a bug, you refactor the core code and screw up
everything

Testing

When replacing old code that has been working fine for a long time, one risks reintroducing old problems that were fixed by some of the "ugly" (undocumented) code

Nobody remembers all of the requirements, but break a single one by refactoring, and you can be in deep trouble

Reengineering

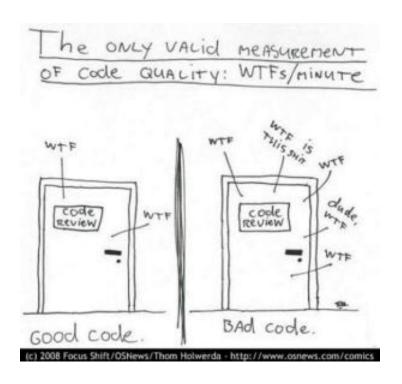

Refactoring increases the amount of verification testing that has to be done: when you refactor a class, you need to retest everything that deals with it (and side effects too)

Planning

Refactoring is an excuse for lazy programmers

Refactor your own code Refactor your colleague's code

What to refactor

How does one identify code that needs to be refactored?

Identifying code to be refactored

Code Smells

If it stinks, change it.

Grandma Beck, discussing child-rearing philosophy

M. Fowler, K. Beck et al.,

Refactoring: Improving the Design of Existing Code

A code smell is a surface indication that usually corresponds to a deeper problem in the system

Smells are heuristics that help in deciding:

- When to refactor
- What to refactor
- How to refactor

Quick to spot

Don't always indicate a problem

Maria Grazia Pia, INFN Genova

Code smells

- Duplicated code
- Long method
- Large class
- Long parameter list
- Divergent change
- Shotgun surgery
- Feature envy
- Data clumps
- Switch statement
- Parallel inheritance hierarchies
- Lazy class

- Speculative generality
- Temporary field
- Comments
- Refused bequest
- Primitive obsession
- Message chains
- Middle man
- Inappropriate intimacy
- Alternative classes with different interfaces
- Incomplete library class
- Data class

M. Fowler, K. Beck et al.,

Refactoring: Improving the Design of Existing Code

Common code smells

Duplicated Code

- if you modify one instance of duplicated code but not the others, you may introduce a bug!

Large class

- tries to do too much

Long Method

- difficult to understand and maintain
- Martin's Rule of Performance: Assume costs of lots of short functions are negligible and wait to be proven wrong!

Long Parameter List

- hard to understand, can become inconsistent

Code smells: dispensable

Data Class

- A data holder: a class that has attributes, getting and setting methods for the fields, and nothing else
- Objects should be about data **and** behavior

Speculative Generality

- "I may need the ability to do this kind of thing someday"

Lazy Class

- A class that no longer "pays its way" e.g. a class that was downsized by refactoring, or represented planned functionality that did not materialize

Dead Code

Code that is not used

Code smells: OO abusers

Refused Bequest

 A subclass ignores most of the functionality provided by its superclass

Switch Statements

- Can be replaced by use of polymorphism

Temporary Field

- An attribute of an object is only set in certain circumstances
 - but an object should need all of its attributes
- or fields used to hold intermediate results

Alternative Classes with Different Interfaces

- Two or more methods do the same thing but have different signature for what they do

Code smells: coupling

Middle Man

- A class delegates most of its responsibilities to another class
- Does it really have a reason to exist?

Message Chains

- A client asks an object for another object, then asks that object for another object etc.

Feature Envy

- A method requires lots of information from some other object

Inappropriate Intimacy

- Classes that know too much about each other's private details

Code smells: hindering change

Divergent Change

 Lack of cohesion: one type of change requires changing one subset of methods; another type of change requires changing another subset

Shotgun Surgery

 A change requires lots of little changes in a lot of different objects

Parallel Inheritance Hierarchies

- Similar to Shotgun Surgery; each time I add a subclass to one hierarchy, I need to do it for all related hierarchies

...and more

Data Clumps

 Attributes that are used together, but are not part of the same object

Primitive Obsession

- A reluctance to use classes instead of primitive data types

Magic Number

- A literal value that appears in a program

Combinatorial Explosion

Lots of code that does almost the same thing

How to refactor

Methods Techniques

Reverse engineering

Not limited to deriving a UML class diagram form the code... Motivation: understanding other people's code

Testing

Refactoring is not meant to alter the behaviour of the code

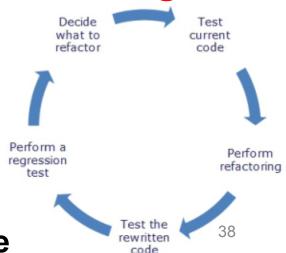

To be tested!

Refactoring begins by designing a solid set of tests for the portion of code under analysis

Usually unit tests

Refactoring occurs as a series of small changes

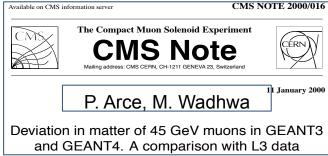

Test original code Apply one action at a time **Test**

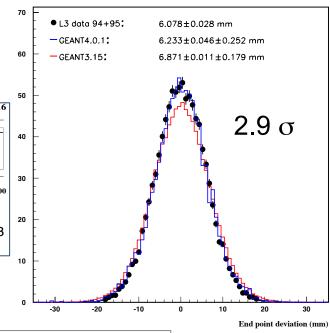

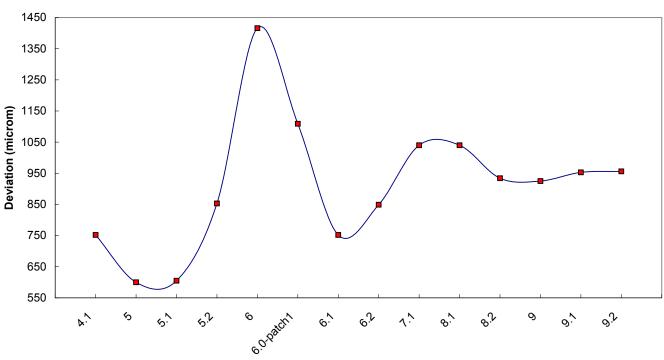

What may happen...

...if the software is changed ("improved") without testing

Risk mitigation

Do not mix!

One of the motivations for refactoring may be the need to introduce new features in the code

Refactoring

Does not modify the code behaviour

Adding new features

Modifying the code behaviour

- Test
- Refactor
- Test
- Add new feature
- Test
- Add new feature

hands-on exercise

Basic actions for common smells

Method invocation

- Consolidate recurring code into a single method
- OK when the recurring code doesn't span methods and all methods containing code belong to the same class

```
commonCode() {
...
}
```

Inheritance

- Common code in two different classes
- New superclass introduced

```
class Child : public Super {
...
};
```

Extract commonality

Abstract interfaces are classes with no implementation
Abstract classes represent mixed design and implementation

Introduce abstract class

a class with no or partial implementation

```
class Common {
  void commonCode(...) {...}
  virtual void contextSpecificCode () = 0;
  ...
};
```

Add delegation

 Delegate the recurring code segments to a helper class

```
class Extension : public Common {
  void method1(...) {
    ...
  helper.SomeMoreCommonCode();
  }
...
};
```

...sounds like common sense?

Many refactoring techniques are just good practices of code hygiene

Apply them when writing new code!

The "legacy code" you may have to refactor in a few months/years may **be your own...**A colleague collaborating at your project may have to refactor your "legacy code"...

in the stink parade

- Same expression in two methods of the same class
 - Use Extract Method refactoring
- Same expression in two methods of sibling classes
 - Use Extract Method and Pull Up Method
- If code is similar, but not same
 - Consider Form Template Method
- Duplicated code in unrelated classes
 - May need to Extract Class
 - Or eliminate one of the versions

Beware:

Sometimes automated tools don't catch code duplication effectively **Code reviews!**

Long method

 The longer a method is, the more difficult it is to understand

- Decomposing methods
- Most of the time: just Extract Method
 - What to extract?
 - Understand what the code does
 - Comments in the code may help

Large class

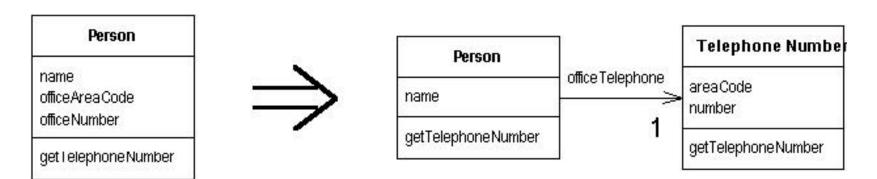

- A class that tries to do too much
- Often has too many instance variables
- Prone to duplicated code
- Extract Class
- Extract SubClass
- Extract Interface

Extract class

One class does work that should be done by two

Create a new class and move the relevant fields and methods from the old class into the new class

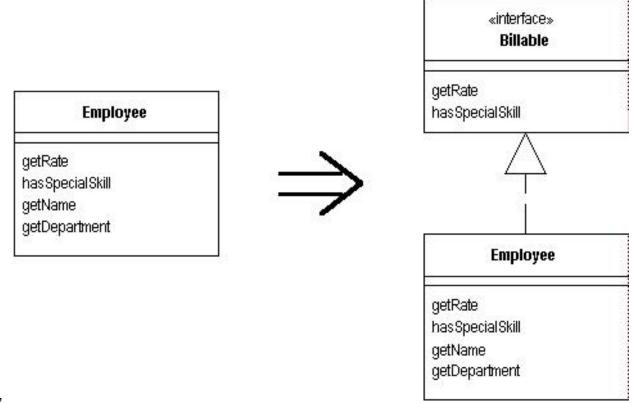

Extract interface

Several clients use the same subset of a class's interface, or two classes have part of their interfaces in common

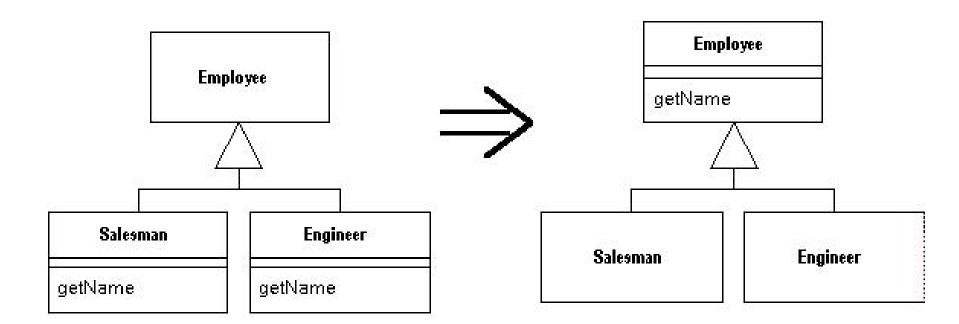

Extract the subset into an abstract interface

Pull up method

Methods with identical results on subclasses

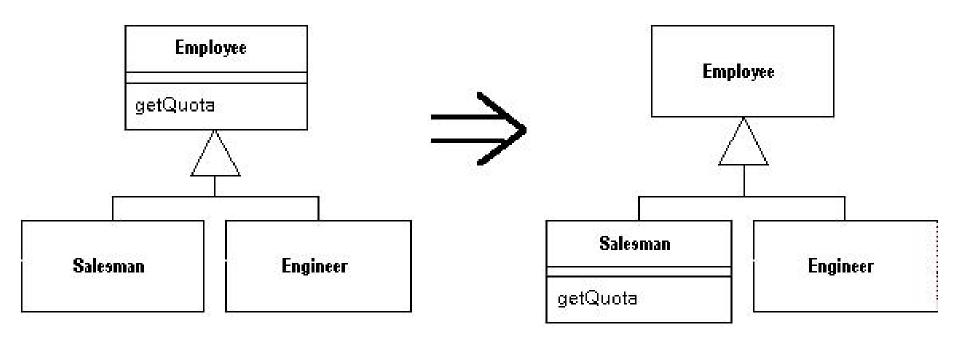

Move them to the superclass

Push down method

Behavior in a superclass is relevant only for some of its subclasses

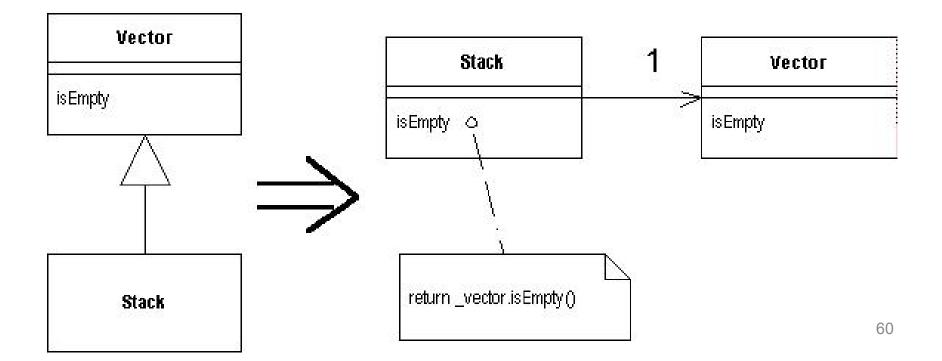

Move it to those subclasses

Replace inheritance with delegation

A subclass uses only part of a superclass interface or does not want to inherit data

Create a field for the superclass, adjust methods to delegate to the superclass, and remove the subclassing

Refactoring mechanics

Catalog of refactoring techniques

Reference material in Fowler's book and web site

Not meant to be learned by heart, but to be exercised when a pertinent "smell" is identified

Composing Methods

- Extract Method turns a code fragment into a function
- Inline Method is the opposite of Extract Method
- Inline Temp gets rid of a temporary variable by moving the expression to where the temp is used
- Replace Temp with Query removes a temporary variable and instead uses a function call where the temp was used
- Introduce Explaining Variable replaces comments and complex expressions with a temp variable that is well named
- Split Temporary Variable splits a temp that is used for two different things into two different variables
- Remove Assignments to Parameters removes assignments to function parameters within the function
- Replace Method with Method Object moves a complex function to its own class
- Substitute Algorithm

Moving Features Between Objects

- Move Method moves a method from one class to a more appropriate class
- Move Field moves a field (member object) from one class to another class
- Extract Class pulls a set of methods and fields from one class into a new class
- Inline Class opposite of Extract Class
- Hide Delegate: a class that provides access to an object of another class instead provides the methods of that class by delegation
- Remove Middle Man opposite of Hide Delegate
- Introduce Foreign Method adds a method to an untouchable class by passing an instance of the untouchable class into the method
- Introduce Local Extension adds methods to an untouchable class by deriving from it or by wrapping it

Organizing Data

- Self Encapsulate Field creates accessors for private member objects
- Replace Data Value with Object turns a member object into a fullfledged class
- Change Value to Reference
- Change Reference to Value
- Replace Array with Object converts an array which has various fields in each entry into an object
- Duplicate Observed Data introduces a Document/View architecture into an interactive application
- Change Unidirectional Association to Bidirectional introduces a back pointer
- Change Bidirectional Association to Unidirectional is the opposite
- Replace Magic Number with Symbolic Constant

Organizing Data

- Encapsulate Field adds getters and setters
- Encapsulate Collection hides a collection within a class
- Replace Record with Data Class makes a dumb data class to represent a record structure
- Replace Type Code with Class replaces an enumeration type with a class that has a set of global instances of itself, one for each possible value
- Replace Type Code with Subclasses introduces a polymorphic hierarchy to replace an enumeration
- Replace Type Code with State/Strategy allows change at runtime
- Replace Subclass with Fields is used when the subclasses no longer serve any real purpose

Simplifying Conditional Expressions

- Decompose Conditional extracts the condition, the "then" part, and the "else" part into functions
- Consolidate Conditional Expression combines a series of "if" into one
- Consolidate Duplicate Conditional Fragments factors out code that is common to a "then" part and an "else" part
- Remove Control Flag replaces flags that trigger exits with return, continue, and break
- Replace Nested Conditional with Guard Clauses replaces nested "if" with returns
- Replace Conditional with Polymorphism replaces case statements with polymorphism
- Introduce Null Object replaces checks for null values with an object
- Introduce Assertion uses assertions to describe a function's preconditions

Making Method Calls Simpler

- Rename Method
- Add Parameter to a function
- Remove Parameter from a function
- Separate Query from Modifier avoid side-effects
- Parametrize Method reduces a set of similar functions to a single function with a parameter to differentiate amongst the functions
- Replace Parameter with Explicit Methods
- Preserve Whole Object passes an object to a method instead of selected fields
- Replace Parameter with Method reduces a parameter list by using a value that is already available within the class
- Introduce Parameter Object groups parameters into a single object
- Remove Setting Method makes an attribute read-only
- Hide Method makes a method private
- Replace Constructor with Factory Method supports polymorphism
 Encapsulate Downcast hides a downcast within a method
- Replace Error Code with Exception separates error-handling from normal paths
- Replace Exception with Test provides a method for caller to avoid an exception

Dealing with Generalization

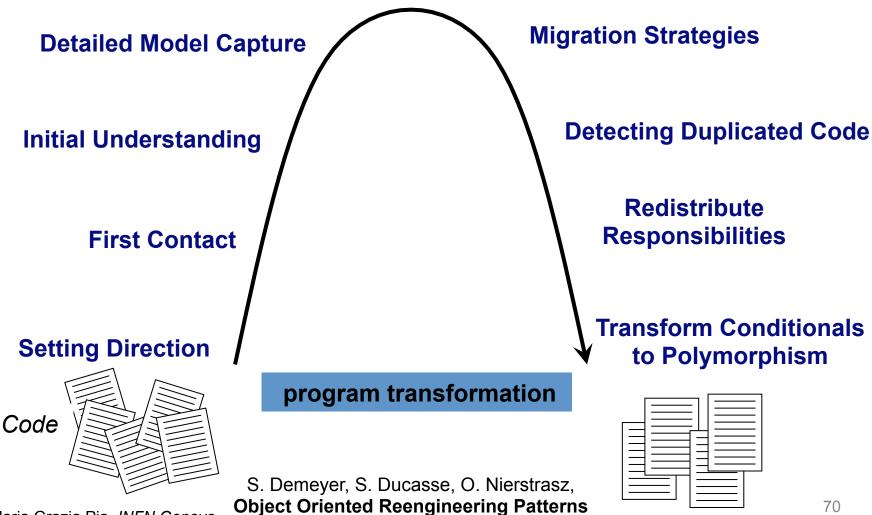

- Pull Up Field factors a common field into a superclass
- Pull Up Method factors a common method into a superclass
- Push Down Method moves a unique method down into a subclass
- Push Down Field moves a unique field down into a subclass
- Extract Subclass creates a subclass and moves features into it
- Extract Superclass factors common code into a superclass
- Extract Interface promotes decoupling and partitioning of a class's responsibilities by extracting an interface class
- Collapse Hierarchy combines a subclass and a superclass into one
- Form Template Method factors out common behavior into a superclass
- Replace Inheritance with Delegation Replace Delegation with Inheritance

Big Refactorings

- Tease Apart Inheritance deals with a messy inheritance hierarchy
- Convert Procedural Design to Objects
- Separate Domain from Presentation moves domain logic out of the UI classes
- Extract Hierarchy introduces polymorphism to replace complex conditional code

Computational performance

Popular belief

Physics model X is intrinsically slow

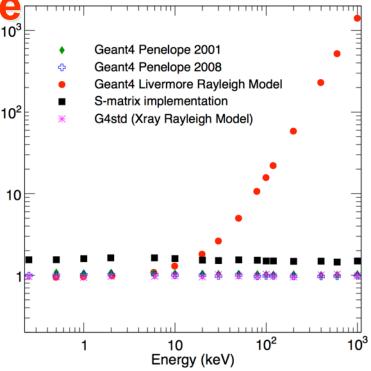

Baroque methods to combine it with "faster" lower precision models and limit its use to cases where one is willing to pay for higher precision

This design introduces an additional computational burden due to the effects of inheritance and the combination algorithms themselves

Truth

Physics model X is intrinsically fast

But its computationally fast physics functionality is spoiled by an inefficient sampling algorithm

- No code smell
- Spotted through in-depth code review in the course of software validation

Dealing with legacy code

Legacy code often lacks tests

Techniques to make existing code testable

The legacy code dilemma

It works
It doesn't hurt... so long as you don't want to change it

When we change code, we should have tests in place

To put tests in place, we often need to change code

Lack of tests

distinguishes legacy code from non-legacy code

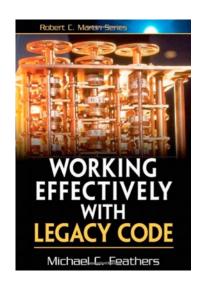

Most of the fear involved in making changes to large software systems is **fear of introducing bugs**

With tests, you can change (and improve) your code

Without tests, you just don't know whether things are getting better or worse

Legacy management strategy

- 1. Identify change points
- 2. Find an inflection point
- 3. Cover the inflection point
 - a. Break external dependencies
 - b. Break internal dependencies
 - c. Write tests
- 4. Make changes
- 5. Refactor the covered code

Test Covering

A set of tests used to introduce an invariant on a code base

- Usually cover a set of classes
- Provide some "invariant" that let us know when we have changed the behaviour of our system
 - get that invariant before refactoring or adding new behavior
- Correctness is defined by original behaviour of the code base
 - ...but was the code base ever verified?

Identify change point

can't get this class in a test harness

Inflection Point

A narrow interface to a set of classes

If anyone changes any of the classes behind an inflection point, the change is either detectable at the inflection point, or inconsequential in the application

Cover an inflection point

Write tests for it

Hard point: make it compile in a test harness

Usually requires breaking dependencies

External dependencies

objects which we have to provide to setup the object we are creating (e.g. in a constructor)

Internal dependencies

the class we want to cover creates its own objects internally

Techniques for breaking dependencies

Write tests
Make changes
Refactor

Pia, *INFN Genova*

I can't get this class in a test harness

- Objects of the class can't be created easily
- The test harness won't easily build with the class in it
- The constructor we need to use has bad side effects
- Significant work happens in the constructor, and we need to sense it

"Tricks" to make the class testable

Irritating parameter

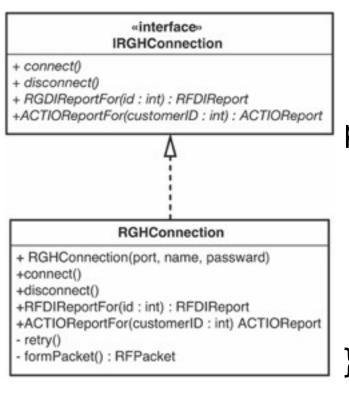

Maria Grazia Pia, INFN Genova

How am I going to construct these parameters for the test?

```
public class CreditValidator {
public CreditValidator(RGHConnection connection,
                      CreditMaster master,
                      String validatorID) {
                                           Setting up network
                                            connection is not
                                                possible
Certificate validateCustomer(Customer customer)
   throws InvalidCredit {
```

Solution to irritating parameter

Extract interface + create FakeConnection class

```
public class FakeConnection
    implements IRGHConnection {
    public RFDIReport report;
    public void connect() {}
    public void disconnect() {}
```

Solutions for irritating parameter

Pass null

- If an object requires a parameter that is hard to construct
- If the parameter is used during your test execution an exception will be thrown
- You can then still reconsider to construct a real object

Variant solution: "null object"

- A sibling to the original class with no real functionality
- Returns default values

Hidden dependency

```
mailing_list_dispatcher::mailing_list_dispatcher()
    : service(new mail_service), status(MAIL_OKAY)
{
    const int client_type = 12;
    service->connect();
    status = MAIL_OFFLINE;
    mail_service

    mail_service
```

We don't want to initialize the mail_service, because then we connect to the network and start sending actual mails...

Solution to hidden dependency

Parameterize constructor

```
mailing_list_dispatcher::mailing_list_dispatcher (mail_service* service) : status(MAIL_OKAY)
```

Big improvement

Allows for introducing a fake mail service

- Extract interface for mail_service
- Introduce fake class that senses the things we do

Hidden method

• How do we write a test for a private method?

Two obvious solutions:

• Make the method public

Change the private method to protected and

then subclass it

... and more No time to go into details

Tip on software development

 Most of these problems can be easily solved if we simply write tests as we develop our code

If a test is hard to write, that means that we have to find a different design which is testable

It is always possible

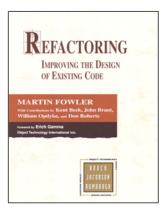

Provocative thought...

Need to refactor legacy code due to:

- Requirements change
- Computing environment changes (compilers, language standards...)
- New technology becomes available

Need to refactor legacy code due to:

- Laziness to adopt a sound software development process
- Sloppiness
- Refuse to invest in learning technology
- Contempt for good practices
- Lack of design and code reviews
- Lack of adequate mentoring
- ...
